Some comments expressed concern that LADWP needs to ensure its financial stability and integrity. Many comments presented concerns with rising electricity rates wanting to ensure that the cost and benefits were clearly presented, and recommended a comparison of costs with other regional and out-of-state utilities. One comment suggested that LADWP keep coal for as long as possible explaining that other forms of energy were not mature and too costly. Conversely, other comments suggested that rate increases were acceptable if EE options are made available to help customers reduce their bills. One comment suggested that LADWP rates are too low and the tiers are too generous – resulting in disincentives for EE and renewables.

Maintain Power Reliability

Some comments expressed concern about the state of the LADWP infrastructure, noting that the reliability program continues to be subject to budgets cuts – unlike mandated areas such as renewables. They point to the 2011 windstorm and 2006 heat storm as evidence that the infrastructure is getting older and more costly to maintain, and suggest that paying more now to address this problem will save money later.

AR0070070

LADWP's Should Take a Leadership Role

Regarding renewable resources and other green energy matters, many suggested that LADWP, as a municipal utility, should lead by example, consider unconventional business models, and through its governance, garner the political will to do something different.

For further discussion of the themes and the overall public outreach process, see Appendix O.

5.3 Recommended Strategic Case

As discussed in Section 4.4.4, Case 5 with the addition of 150 MW of EE1 by 2016 has emerged as the Recommended Case for this 2012 IRP. The key attributes of Case 5 includes the following:

- At least 18 percent of Los Angeles' electric needs will be met through new customer energy efficiency measures by 2020.
- At least 500 MW of capacity reduction through Demand Response programs by 2026.
- Generate at least 33 percent of its electricity from renewable resources by 2020 and maintain that level through 2032. Although this IRP incorporates one combination set of renewable resources to achieve a 33% RPS, LADWP will not limit itself to only these types and amounts of resources to achieve its goals and needs flexibility in resource development for the best fit for the electrical system.
- Diversify LADWP's RPS through incorporating 114 MWs of generic renewable resources by 2032. These resources could be technologies such as biomass, ocean tidal power or other emerging technologies.
- Diversify LADWP's energy portfolio through a variety of fuels, technologies and power plant sites throughout the western United States to maintain a high level of reliability.
- Implement advanced reliability improvements thru Smart Grid.
- Emphasize local solar by proposing approximately 340 MW of solar capacity to be locally sited in Los Angeles by 2016. This will be accomplished through programs such as the Customer Solar Incentive Program, a feed-in tariff goal of 150 MW by 2016, and Solar on Los Angeles properties under public/private partnership (a.k.a. UBS).

Benefits of early Navajo divestiture include a better sales price than waiting until 2019, and better availability (less costs) of replacement energy. With Case 5 and the noted addition of EE1 and Navajo divestiture in place, LADWP can begin to focus its attention on early replacement of IPP coal generation, prior to 2027, by working with the other power purchasers and the IPP plant owner.

The Recommended Case for 2012 is summarized in Table 5-1.

AR0070071

Table 5-1. 2012 IRP RECOMMENDED CASE

	2020	SB 1368 Compliance Date		New Renewables Installed (MW) 2012-2020				New Renewables Installed (MW) 2012-2032				
Case ID	RPS Target	Navajo End Date	IPP End Date	Geo/ Biomass	Non-DG Solar	Dist. Solar	Generic	Geo/ Biomass	Wind	Non-DG Solar	Dist. Solar	Generic
Case 5	33%	12/31/2015	6/15/2027	242	842	382	39	283	54	915	496	114

Figure 5-1 illustrates the changing generation resource percentages for 2010, 2020, and 2030 based on the Recommended Case. Because energy efficiency forecasts are forward-looking, the savings of 1,256 GWh or 5.5 percent of sales that was implemented between 2000 and 2010 are embedded into the load forecast and are not included as part of the generation resource mix shown below.

AR0070072

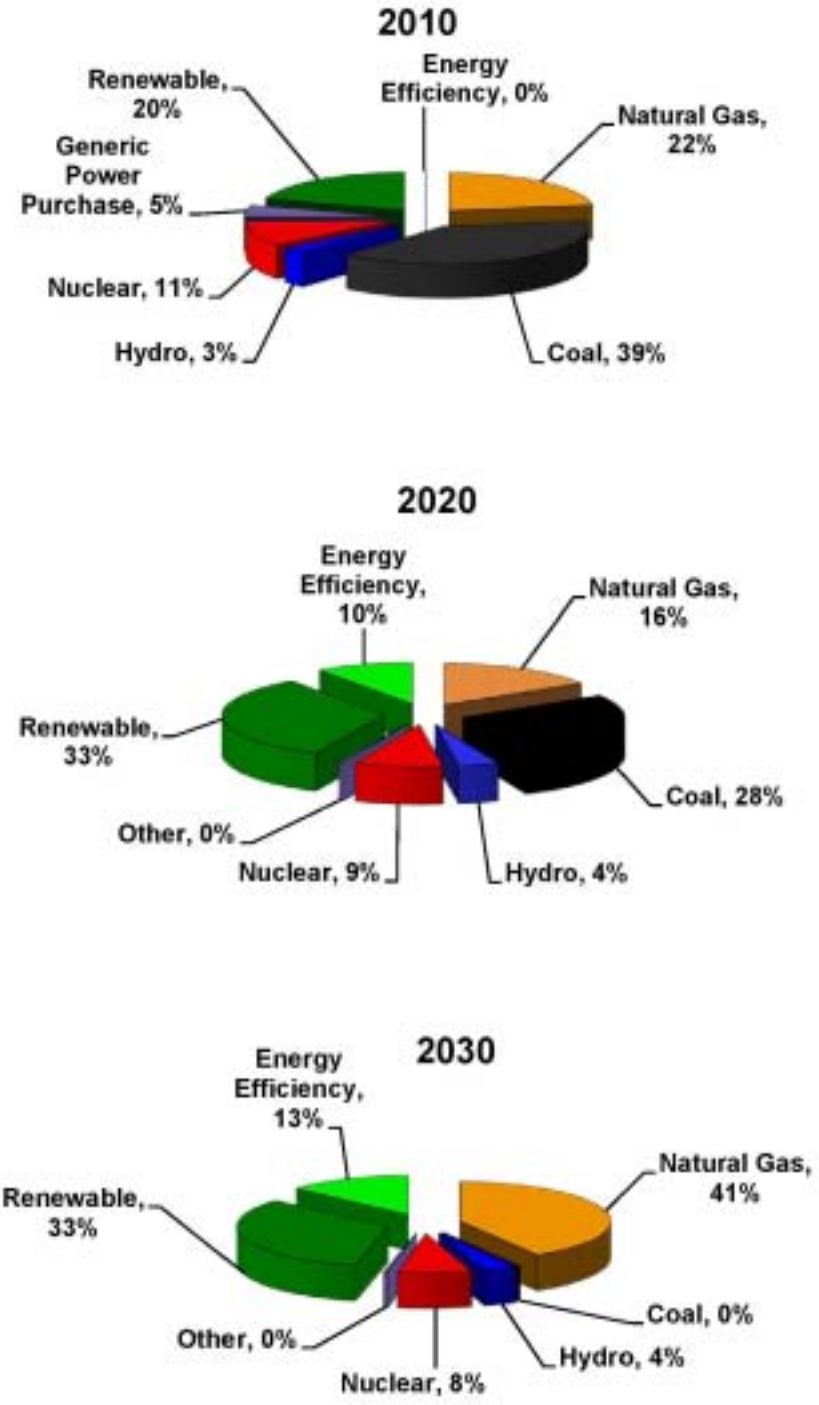

Figure 5-1. Generation resource percentages for 2010, 2020, and 2030.

AR0070073

Figure 5-2 shows the renewable energy resource mix of the Recommended Case. The major change from the 2011 IRP is expanded levels of new solar over the next 20 years and lower amounts of new wind.

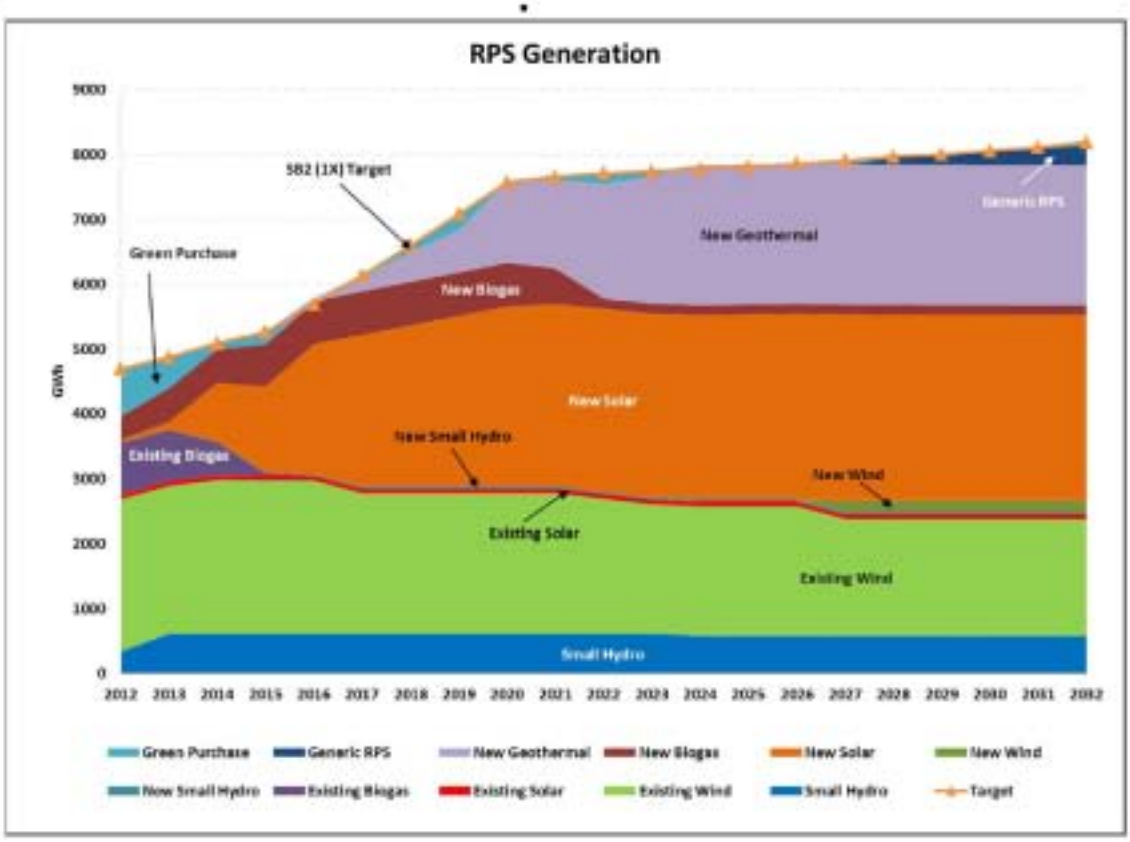

Figure 5-2. Recommended case renewable generation by technology.

The Table 5-2 below illustrates the revenue requirements necessary to supply the recommended resources required to meet future load growth, achieve energy efficiency targets, secure the necessary demand response capabilities, reach and maintain the RPS requirement of 33% by 2020 and thereafter, and ensure that the necessary replacement resources are in-service before divestiture of Navajo in 2015 and replacement of IPP in 2027 can occur.

AR0070074

Table 5-2. Revenue and resources recommended to replace coal and load growth ($ million)

The Recommended Case will meet the LADWP combined objectives of maintaining a reliable Power System, environmental stewardship, and minimizing ratepayer impacts. The Recommended Case provides a roadmap for the LADWP to achieve its long term planning goals, while providing the required reliability and necessary flexibility to adapt to dynamic economic, environmental, and regulatory conditions. The Recommended Case will put upward pressure on retail rates, but will maintain adequate reliability and avoid fines and penalties that may otherwise result from violations in state and federal laws. The Recommended case also successfully reduces the amount of GHG emissions released into the environment and provides for additional job growth and economic benefits thru the increased use of local solar.

AR0070075

5.4 Revenue Requirements

A brief discussion is in order here regarding budget shortfalls over the past few years. These shortfalls have prevented LADWP from fully funding existing and new programs during that timeframe. The delays surrounding resolution of the Power System budget have the potential of impeding LADWP's ability to meet its long term plans and obligations.

Based on the 2010 IRP, a multi year rate increase was recommended beginning fiscal year 2011-12. The rate increase would have supported elements of the 2010 IRP, all of which remain as the foundation for LADWP's short and long term plans. Because the rate increase was not realized in July 2011, many of the programs that required funding were scaled down, delayed or deferred.

Last year's 2011 IRP was prepared concurrent to the rate process that began in early 2011, and recognized that the process would likely conclude in 2012. As of this writing, the rate ordinance has been completed having received City Council and Mayor approval on October 5, 2012.

Although somewhat outside LADWP's control, future *multi-year* funding plans are desirable to provide consistent and sustainable project and program development. Funding that is based on annual budgets are subject to year to year fluctuations which introduces uncertainty for our customers and the inefficient use of staff and financial resources that are necessary to meet LADWP's objectives and compliance requirements.

Properly funded programs will enable LADWP to achieve the following objectives:

- Modernize its coastal generation units to replace aging equipment and to satisfy once-through cooling regulatory requirements
- Implement early coal divestiture and replacement.
- Secure the state-mandated amounts of renewable energy.
- Through the Power Reliability Program, reduce the number of distribution outages and improve system reliability
- Implement necessary transmission improvements to maintain reliability
- Achieve energy efficiency target levels
- Implement Smart Grid initiatives
- Comply with FERC-approved reliability standards

Securing adequate multi-year funding will help to ensure LADWP's ability to stay on track towards meeting its future long term goals and obligations.

AR0070076

5.5 Electric Rates

LADWP currently uses an Excel-based financial model that has been developed and used for over a decade. This financial model has been used to develop forward-looking Power System financials for the Board of Water and Power Commissioners' annual budget approval and for rating agency presentation for debt issuances.

The model is modified to analyze fuel expense, purchased power expense, and additional capital and O&M expenses for any new LADWP-owned resource additions as well as off-balance sheet resource additions. The strategic cases are overlaid on existing capital and O&M expenses for the approved FY12-13 budget data, which contains forward-looking budget data up until FY21-22. For years beyond FY22-23, general capital and O&M expenses are escalated at 2.5 percent per annum.

Effective November 11, 2012 LADWP retail revenue shall be funded from the existing Electric Rate Ordinance and the Incremental Electric Rate Ordinance through the following billing factors:

(1) Base Rate
(2) Energy Cost Adjustment (ECA) and Reliability Cost Adjustment (RCA) factors
(3) Incremental adjustments:
- Variable Energy Adjustment (VEAA),
- Capped Renewable Portfolio Standard Energy Adjustment (CRPSEAA),
- Variable Renewable Portfolio standard Energy Adjustment (VRPSEAA),
- Incremental Reliability Cost Adjustment (IRCA), and
- Incremental Base Rates

These factors are described briefly below.

Effective November 11, 2012, the Base Rate under the existing Electric Rate Ordinance shall be capped and remain fixed at their levels as of November 3, 2010. The Base Rate covers a portion of a rate other than the adjustments and is used to cover expenses from debt service arising from capital projects except RPS projects, operational and maintenance expense except RPS related, public benefit spending, property tax, and pro-rated portion of the city transfer.

The ECA under the existing Electric Rate Ordinance is used to cover fuel, purchased power, RPS and energy efficiency-related expenses. Effective November 11, 2012 under the Incremental Electric Rate Ordinance the ECA factor shall be known as the Capped Energy Cost Adjustment and shall not exceed $0.05603/kWh, which was the level applied as of November 3, 2010.

The RCA under the existing Electric Rate Ordinance is used to cover power reliability related expenses. Effective November 11, 2012 under the Incremental Electric Rate Ordinance the RCA factor applied to residential customers shall be known as the Capped Residential Capped Reliability Cost Adjustment and shall not exceed $0.00304/kWh and the RCA factor applied to general service customers shall be known as the General Service Capped Reliability Cost

AR0070077

Adjustment and shall not exceed $0.06 per kW, which were the levels applied as of November 3, 2010.

The Incremental Electric Rate Ordinance provides incremental charges to provide funding of expenditures outlet by the existing ordinance. These incremental charges are in addition to charges paid in corresponding rates of the existing Electric Rate Ordinance. These incremental charges provide more granularity and transparency for LADWP and our customers and include the following:

- Variable Energy Adjustment (VEA): Recovers costs associated with fuel, non-renewable portfolio standard power purchase agreements, economy purchases, legacy ECAF under-collection, and base rate decoupling from energy efficiency impact.
  Capped Renewable Portfolio Standard Energy Adjustment (CRPSEA): Recovers costs associated with renewable portfolio standard O&M, debt service, and energy efficiency programs.
- Variable Renewable Portfolio standard Energy Adjustment (VRPSEA): Recovers costs associated with renewable portfolio standard market purchases and costs above and beyond any O&M and debt service payments.
- Incremental Reliability Cost Adjustment (IRCA): Recover costs associated with O&M, debt service expense of the Power System Reliability Program (PRP), and RCA under-collection.
  Incremental Base Rates: Recovers costs of providing electric utility service that are not recovered by the above adjustment factors and Base Rate. These costs include labor costs, real estate costs, costs to rebuild and operate local power plants, equipment costs, operation and maintenance costs, expenditures for jointly owned plants and other inflation-sensitive costs.

To sustain LADWP's financial strength while mitigating rate impacts to customers, maintain existing "AA-" credit rating or equivalent bond ratings to minimize financing costs, and obtain funding needed for Power System capital programs, the LADWP has adopted the following financial metric targets: (1) maintain debt service coverage of at least 2.25, (2) unrestricted operating cash target of $300 million and (3) capitalization ratio of less than 68.

Debt service coverage is the amount of cash available from operation divided by the debt service amount. The debt service amount contains only LADWP's direct debt. Capitalization ratio is the ratio of the total direct debt divided by the total asset.

To achieve these various financial coverage parameters, the base rate factor will need to be increased as necessary to meet the objectives of this IRP.

5.5.1 Rates Analysis for Cases

The retail electric rates, including estimated CO_2 emission expenses, for all strategies are discussed in this subsection. Factors driving the increases over the twenty-year period include rising fuel price, increased power reliability program spending, replacement of aging basin

AR0070078

generating units to meet once-through cooling and South Coast Air Quality District emission requirements, replacement of coal generation to lower CO_2 emissions, installation of renewables generation according to legislative mandates and program costs for energy efficiency, demand response, and other programs, and payment for emission allowances due to anticipated CO_2 cap and trade requirements.

The capital cost and the associated O&M expense of any new generation resource is priced at 2012 dollars with 2.5 percent escalation except for certain solar projects, which are priced at levelized 2012 dollars due to anticipated pricing declines.

For each year, the retail rate through either the base rate or the energy cost adjustment factor is raised sufficiently high enough to meet the various financial ratios recommended by financial advisors to maintain LADWP's "AA-" bond rating.

Using Case 5 as an example, which is very similar to the 2011 Recommended Case except for additional energy efficiency of 10% by 2020 and slightly higher amounts of solar DG, customer rates are estimated to increase on average 6 percent to 7 percent per year over the next five years, and 3 percent to 4 percent per year over the next 20 years.

The CO_2 emission allowance price is estimated to range from $15 per Metric Ton in 2013 to $36 per Metric Ton in 2020. The California Air Resources Board established an allocation cap, and emissions exceeding this cap will require purchases of additional allowances or in some cases, emissions below the cap can be used in future compliance periods.

AR0070079

Assumptions used to model rate impacts can change. In order to reflect the variability in model assumptions, a sensitivity analysis was performed to determine a realistic range of rate impact trajectories. Figure 5-3 shows the retail price impact comparison of the 2012 IRP recommended case bounded by a high and low range fuel price. The high range assumes higher natural gas and coal costs while the low range assumes minimal natural gas and coal costs.

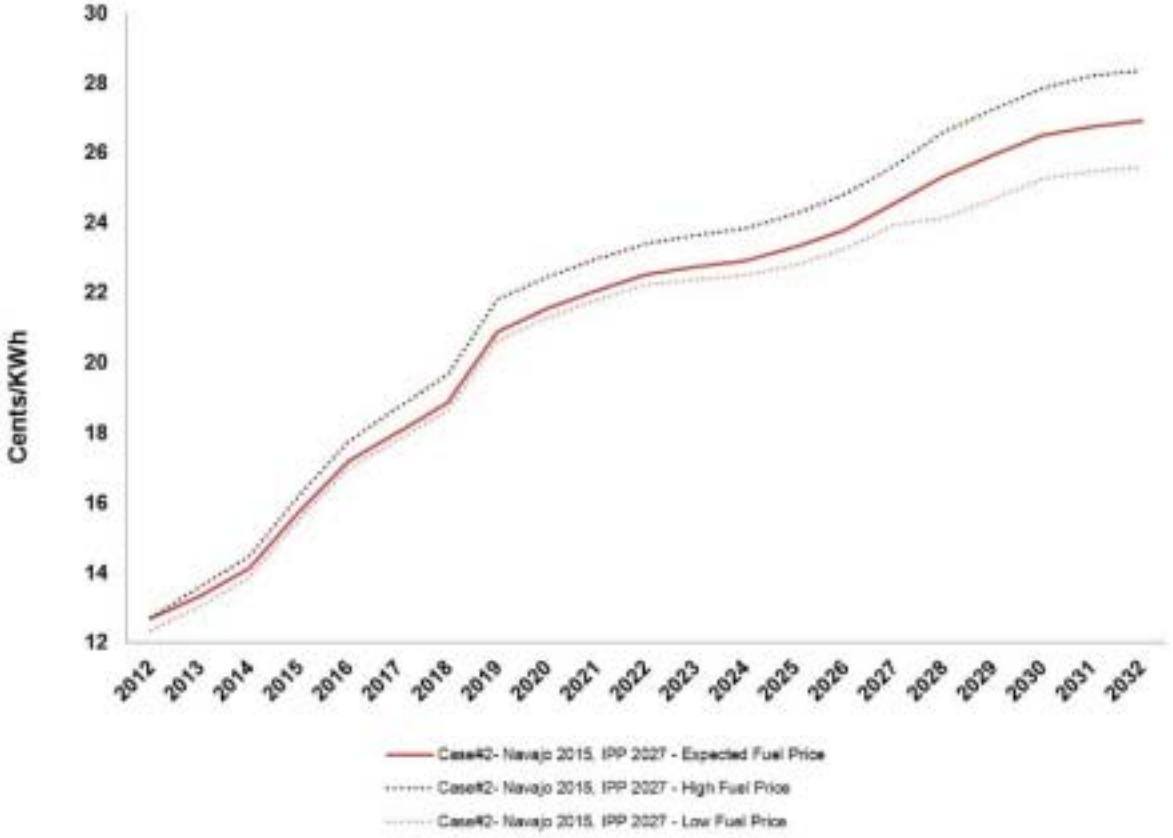

Figure 5-3. Recommended Case - retail price impact bounded by high and low range fuel.

AR0070080

Figure 5-4 presents the fiscal year breakdown for Case 5 comprising rate contributions from reliability, energy efficiency, renewable energy, coal replacement, OTC repowering, other General Transmission and Distribution (GT&D), and fuel costs between 2012 and 2032. These individual contributions represent incremental adders to the rates. For analysis purposes, the Reliability Program has been segmented into the basic program and preferred program. The preferred program contribution shown is incremental to the basic program.

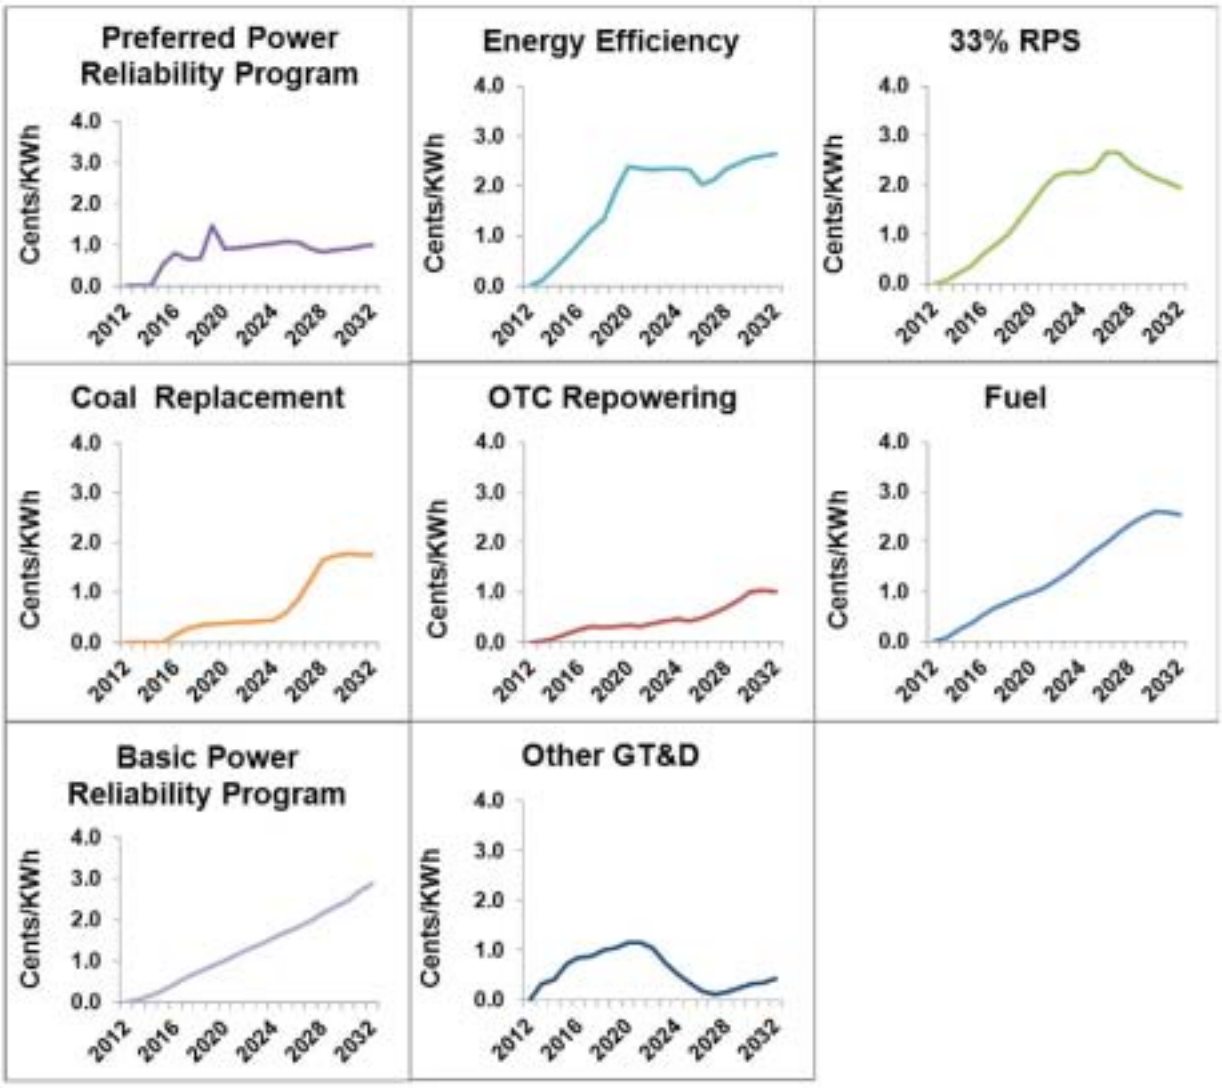

Figure 5-4. Retail electric rate contributions breakdown, based on the 2012-13 budget forecast (Case 5).

Figure 5-5 shows the total retail rate impact after combining all of the program components. One can draw the conclusion that rising fuel costs and complying with various regulatory requirements are the primary drivers of the growth in rates.

AR0070081

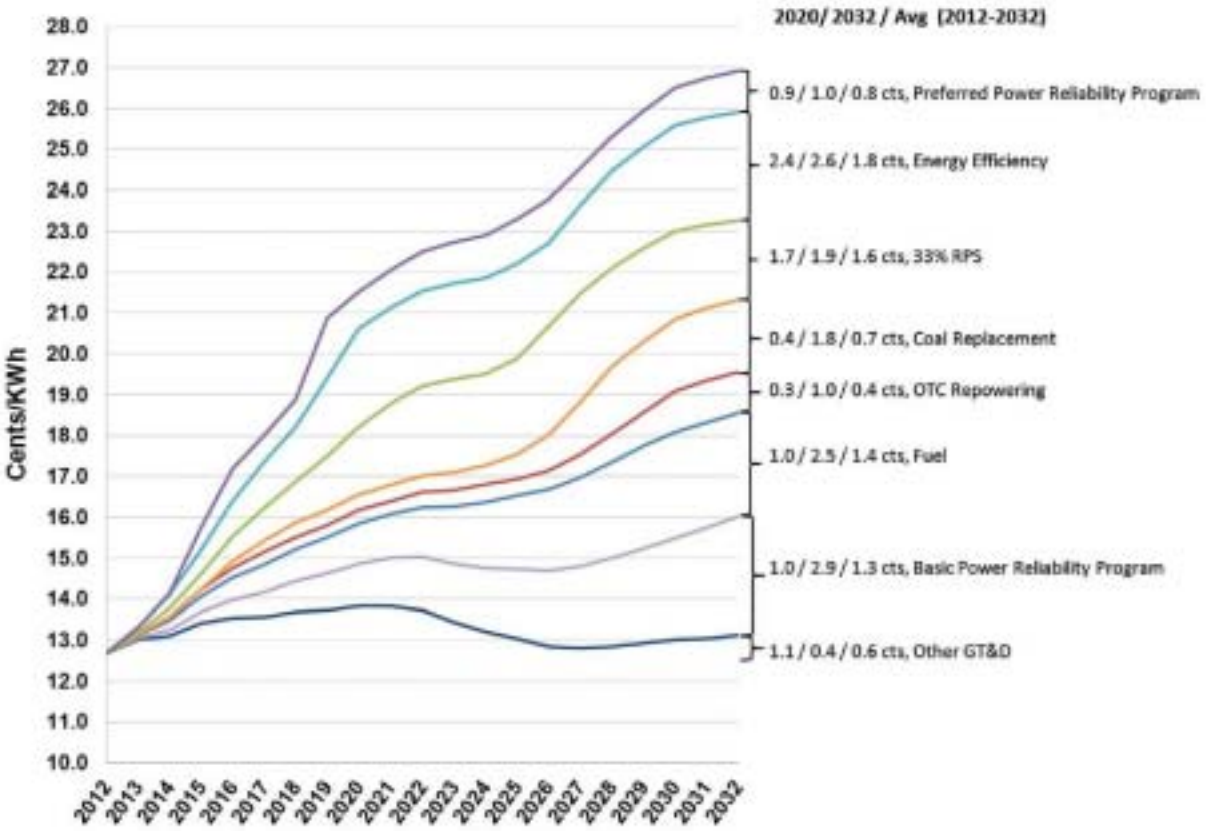

Figure 5-5. Total retail electric rate composite by fiscal year, based on the 2012-13 budget forecast (Case 5).

A few observations from Figures 5-4 and 5-5[10] can be made regarding the RPS and EE programs. Firstly, the influence of the RPS program on rates increases substantially through 2020 after the RPS percentage of sales reaches 33% and the RPS component of rates begins to decline as fuel savings increases over time with escalating fuel prices. In 2027, the RPS component of rates increases as new renewable projects are added to replace expiring PPA agreements and then the RPS component of rates resumes a downward trend due to fuel savings. Secondly, the EE program component of rates increases over time as program incentive payments and net revenue loss attributable to the EE program are recovered. Like RPS, EE has savings beyond 2020 due to fuel savings. Thirdly, general inflation in fuel costs and GT&D costs represents a significant growth in rates.

Preferred levels of funding for the Power Reliability Program (PRP) include capital and O&M expenditures to replace over age distribution and transmission system components that have exceeded their life expectancy, and ensure levels of funding to reduce the backlog of "fix-it"

[10] Figures 5-4 and 5-5 represent forecasted rate increases based on system averages, and do not account for rate structure variations across and within customer classes.

AR0070082

tickets which are temporary repairs that need to be corrected. The spikes in the preferred PRP and EE curve occurs when capital borrowing limits are reached around 2019-20 and cash is needed to fund capital expenses. This quickly subsides as the capacity to borrow resumes shortly thereafter.

The GT&D component of rates rises in the early years because of general inflationary pressure. After 2023 when the IPP debt is fully paid, the GT&D component of rates lowers slightly and goes slightly negative until IPP is replaced with new gas fired generation and then resumes the familiar inflationary path.

The cost contributions from various environmental and reliability programs towards the retail rates are summarized in Table 5-3.

Table 5-3. Cost contributions from various environmental and reliability programs

Program	Retail Rate Impact at FY2020 (cents/kWh)	Retail Rate Impact at FY2032 (cents/kWh)	Average Retail Rate Impact 2012-2032 (cents/kWh)
33% RPS from 20%	1.7	1.9	1.6
Preferred EE (20% by 2020)	2.4	2.6	1.8
Preferred Power Reliability Program	0.9	1.0	0.8
Basic Power Reliability Program	1.0	2.5	1.4
Coal Replacement	0.4	1.8	0.7
OTC Repowering	0.3	1.6	1.0
Total – Recommended Case	**6.7**	**11.5**	**7.2**

Figures 5-6 and 5-7[1] further illustrate the impact to average residential and commercial-industrial customer monthly bills from these environmental and reliability programs. To show the potential effect of energy efficiency on customer bills, the dashed lines on these figures represents what a total monthly bill would amount to after implementing energy efficiency measures that result in a 14% savings. While LADWP's overall energy efficiency program is evolving and much will depend on the new potential study to be conducted in 2013, these figures illustrate what may reasonably be achievable by customers who have not already implemented significant energy efficiency measures to reduce their electricity consumption.

[1] Figures 5-6 and 5-7 are general representations only, and do not account for rate structure variations across and within customer classes, such as the effect of tiered rates, minimum charges, time-of-use, etc. The figures provide an indication of the relative contributions of the individual programs towards a typical monthly bill.

AR0070083

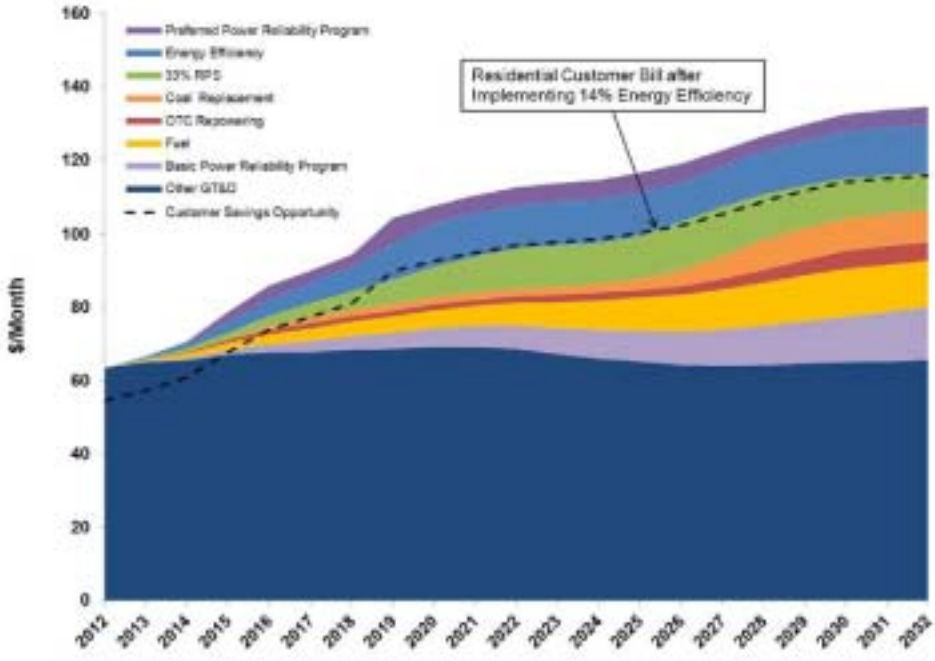

Figure 5-6. Average residential customer bill (500 kWh/month) with environmental and reliability programs by fiscal year based on the 2012-13 budget forecast (Case 5).

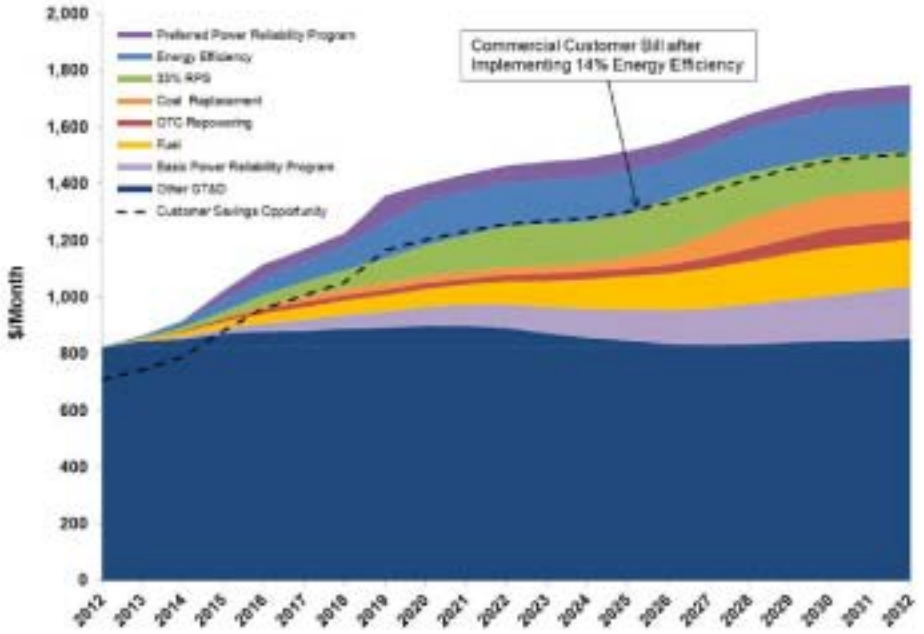

Figure 5-7. Average commercial/industrial customer bill (6,500 kWh/month) with environmental and reliability programs by fiscal year based on the 2012-13 budget forecast (Case 5).

AR0070084

Aside from the environmental and reliability improvement programs, increased fossil fuel expenses also drive the rate increase, for example: (1) coal that feeds IPP's projected to climb by 76 percent from 2012 to 2027, and (2) natural gas at SoCal border is projected to climb from 2013's $3.62/MMBtu to 2032's $9.31/MMBtu. If these fuel increases do not materialize, then the average rate and cost curves shown in Figures 5-3 thru 5-7 will shift downward, however, the cost of environmental and reliability programs will remain substantially unchanged.

Because the analysis and conclusion are heavily dependent on a number of assumptions, LADWP will continually update its long term plan. As expectations change (e.g., due to technology development, commodity price fluctuations, and policy changes), they will be analyzed and incorporated into subsequent IRPs.

AR0070085

5.6 Recommended Near-term Actions

Except for early Navajo divestiture, the actions needed to be taken by LADWP in the next two to four years are very similar no matter what resource procurement strategy is chosen. Base on the strategic requirements presented earlier and projected resource procurement needs, the following actions are recommended to be taken in the near-term:

1. Proceed with re-powering plans for generator units at the Haynes and Scattergood Generating Stations, and pre-development plans for the Harbor Generating Station.
2. Continue to investigate the technical and contractual options for coal-fired generation to be compliant with SB 1368.
3. Divest from the Navajo Coal Plant by 2015.
4. Continue the implementation of existing energy efficiency efforts, in anticipation of an expanded program pending the results of a new energy efficiency potential study to be conducted in 2013.
5. Continue to implement the Power Reliability Program (PRP) to replace aging infrastructure components. Develop electric modeling capability to better define the necessary investments and to prioritize the expenditures.
6. Develop/update a sustainable workforce development plan that addresses staffing needs, skill set identification for new and evolving work areas, training/professional development, application of new technologies, and recruitment strategy.
7. Implement recommendations contained in the Ten-Year Transmission Assessment Plan.
8. Develop a Demand Response Program to initially provide 8 MW of new peak load reduction capability by 2013 which will ramp up incrementally to 200 MW by 2020 and 500 MW by 2026.
9. Implement renewable strategies for geothermal, biogas, solar, and wind resources to ensure increasing levels of renewable procurement in accordance with SB 2 (1X). Sign Power Purchase Agreements for an additional 300-400 MW of cost effective renewable energy projects by 2014.
10. Complete a comprehensive study of issues associated with integrating increasing amounts of variable energy resources such as wind and solar to reflect possible megawatt limits for the LADWP electric Power System.
11. Develop and incorporate strategies to:
    a. Fully utilize existing transmission assets.
    b. Locate renewables as close as practical to the load center to reduce transmission losses.
    c. Preserve existing brown field sites to be repurposed for renewable or natural gas generation.
    d. Incorporate the concept of O&M cluster zones[1] to maximize operational efficiencies.
    e. Assess and develop necessary transmission facilities to deliver electricity generated from new facilities.

[1] Clustering renewable projects in relative proximity will decrease O&M expenditures due to economies of scales and personnel efficiencies. This would need to be balanced with the need for geographic diversity.

AR0070086

12. Develop a renewable energy feed-in tariff program to encourage 150 MW of renewable generation resources to be developed by 2016
13. Encourage the development of an additional 80 MW of customer net-metered solar projects before 2015.
14. Develop up to 30 MW of solar capacity on existing properties under public/private partnership projects before 2015
15. Investigate the use of term physical gas supply arrangements, either with contracts for physical supplies or futures contracts to limit LADWP's exposure to volatile gas prices. Evaluate and potentially implement any recommendations in the Fuel Hedging Plan
16. Investigate and develop energy storage targets by October 1, 2014, per AB 2514
17. Refine and implement a Smart Grid strategy that can assist in the procurement and development of advanced technologies to support areas such as: weather forecasting/ energy scheduling, customer kWh metering, high speed communications and information systems, and energy storage systems. Deployment of these technologies will increase operational efficiency, help reduce system losses, improve outage response times, increase utilization of predictive/proactive maintenance techniques for improved grid reliability, enable better management of the Power System, and lower costs

AR0070087

5.7 Long-Term Planning Considerations

The analysis and conclusions contained in this IRP are heavily dependent on a number of assumptions, such as the projected fuel and purchase power costs, RPS target goals, renewable generation costs, proposed state and federal mandates, and GHG emissions costs. If these assumptions were to change, LADWP's long-term strategies will need to change accordingly.

Integrated resource planning is an on-going process. LADWP will continue to adapt and refine the IRP as the uncertainties are better understood, and policy direction and requirements are solidified. A new IRP process will be undertaken in 2013.

AR0070088

AR0070089

Appendix A. Load Forecasting

A.1 Overview

The 2012 Retail Sales and Demand Forecast (2012 Forecast) is a long-run projection of electrical energy sales, production, and peak demands in the City of Los Angeles (City) and Owens Valley. A flowchart of the forecast process is illustrated on Figure A-1. The sections which follow describe the four key components shown on the flow chart: data collection, sales and Net Energy for Load (NEL) forecast, peak demand forecast, and hourly allocation.

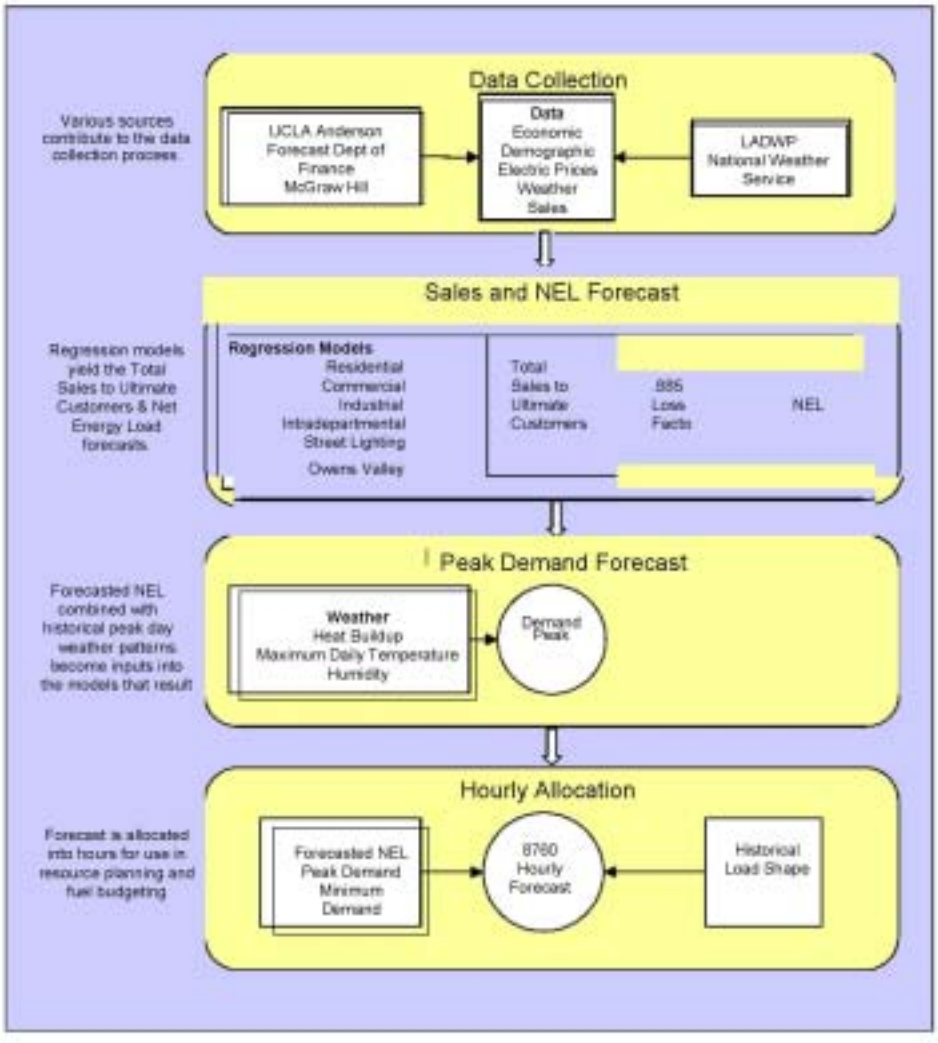

Figure A-1. Overview of the load forecasting process

AR0070090

A.2 Data Collection

Data collection is the first step in the process. LADWP purchases an economic forecast of Los Angeles County from the Los Angeles Modeling Group of the University of California of Los Angeles (UCLA) Anderson Forecast Project. The Los Angeles County Forecast provides time series data for various demographic and economic statistics beginning with year 1991 and continuing through the forecast horizon. For demographic history and projections, LADWP uses the State of California Department of Finance Demographic Research Unit. To gain further insight into development patterns, LADWP purchases a construction forecast from McGraw-Hill Construction service. The construction forecast gives a five-year view of construction projects detailed by building types. Weather also affects energy sales and demand. Weather data is collected from three key stations – Civic Center, Los Angeles Airport, and Woodland Hills. The other key components in the forecast are from LADWP's own internal data. Historical sales, Net Energy for Load (NEL), billing cycles, electric price, and budget data is incorporated into the forecast. The economic, demographic, weather, and electric price data provide the key inputs to the models that forecast retail electric sales.

A.3 Sales and NEL Forecast

The retail sales forecast is divided into seven separate customer classes; residential, commercial, industrial, plug-in electric vehicle (PEV), intradepartmental, streetlight and Owens Valley. The residential, commercial, industrial, and streetlight classes are commonly used sales classes throughout the electric industry because they represent relatively homogeneous loads. Intradepartmental sales are sales to the Water System and are primarily related to water pumping activities.

The California Energy Commission's PEV forecast has been adapted to the LADWP service area. Further, PEV load is forecast as a separate class, which will facilitate financial modeling due to the expected subsidies and production modeling as PEV load has a unique load shape when compared to the residential class.

Owens Valley sales include all of the above sales classes. The Owens Valley service area is separate and discrete from the Los Angeles service area. Because of limited land available to be developed, Owens Valley sales exhibit very slow growth rates, and total sales are relatively small compared to total LADWP system sales. As such, Owens Valley sales are rolled into a single class and forecast separately.

The forecast model consists of six single equations plus the adapted PEV forecast. For the residential, commercial, and industrial sales classes, the equations are estimated using Generalized Least Squares regression techniques. Historical sales for each customer class are the dependent variables. Sales are regressed against a combination of the demographic, economic, weather, and electric price variables. Binary variables are used to account for extraordinary events like earthquakes, civil disturbances, billing problems, and the California Energy Crisis. The equations fit

AR0070091

historical data quite accurately, producing coefficients of determination (R-Squared) statistics greater than 80 percent. For the streetlight, intradepartmental, and the Owens Valley sales classes, time trend models are used. The results of the six equations plus the PEV forecast are summed to forecast Total Sales to Ultimate Customers (Sales).

The Retail Sales Forecast represents sales that will be realized at the meter. The NEL forecast is a function of the Sales forecast. The NEL is forecast by adjusting annual forecasted Sales upward by a historic average loss factor and then allocating a portion of the annual energy to each calendar month based on historical proportions. Loss factor has the potential to change on the way that the System is run. Electricity generated in distant places will have a higher loss factor than electricity generated located locally. The change in loss factor is accounted for in the resource planning models.

The 2012 Forecast includes committed energy efficiency and customer self-generation. Committed energy efficiency includes budgeted utility programs and expected energy efficiency gains from the Huffman Bill lighting standards. Expected Huffman Bill energy efficiency savings were developed by Global Energy for the 2010 LADWP Energy Potential study. Since the 2012 Forecast is created early in the planning process, budgeted utility energy efficiency programs are subject to change. Planners using the 2012 Forecast should be aware of the potential changes and make appropriate adjustments. Forecasting self-generation which currently is almost entirely focused on solar rooftops in the LADWP service area follows a process similar to the energy efficiency. Planners working with energy efficiency and self-generation data should be careful to include only the incremental impacts of the programs on retail sales In the Forecast, energy efficiency and self-generation savings are expected to occur uniformly throughout the year as a simplifying assumption.

A.4 Peak Demand Forecast

The next step is to forecast annual peak demand. The drivers for forecasted peak demand are temperature, load growth, and time of the summer. The temperature variable used in the estimation is the weighted-average of three weather stations. The temperature variable incorporates heat buildup effects and humidity. Temperature is then divided into splines using a unique megawatt- response per degree estimate for different levels of temperature. Ordinary Least Square regression techniques are used to model maximum weekday summer daily hourly demand against the temperature splines and the time of the summer. The constant that is estimated from the regression model is assumed to be the weather-insensitive demand at the peak hour. To forecast the peak demand, it is assumed that the peak will occur in August and that the peak day temperature is equal to the forty-year historical mean peak day temperature. Peak demand then is assumed to grow at the same rate as sales.

The forecast process described above produces the trend (or base case) forecast. LADWP also produces alternative peak demand forecasts. LADWP wants to ensure that it can meet native demand with its own resources. System response to weather is uncertain. Temperature and humidity are the primary influences, but other variables such as cloud cover and wind speed can also influence the load. The problem is further

AR0070092

complicated by the fact that LADWP serves three distinct climate zones including the Los Angeles Basin, the Santa Monica Bay Coast, and the San Fernando Valley. To prepare for these uncertainties, LADWP formulates its alternative cases by examining expected demands at different temperatures. Based on the Central Limit theorem, it is assumed that the normal distribution produces unbiased and efficient estimators of the true distribution of peak day temperatures. The normal distribution is estimated from the 40 year historical sample of peak day temperatures. From the normal distribution, the probability that the peak day temperature will be below a given temperature can be determined. For the one-in-ten case, it is the given temperature where ninety percent of the time the actual peak day temperature is expected to be below it and ten percent of the time the actual temperature will be above it. Similar calculations are performed for the one-in-five and one-in-forty cases. These temperatures are input into the peak demand regression model to provide the alternative peak demand forecasts.

In the Integrated Resource Plan, LADWP uses the One-in-Ten Case Peak Demand forecast rather than the Base Case forecast. LADWP's policy regarding obligation to serve is to be self-sufficient in supplying native load and not rely on external energy markets. The Base Case Peak Demand forecast falls short of this standard since it is expected that fifty percent of the time actual peak demands will exceed the Base Case Peak Demand forecast. The One-in-Ten Case provides LADWP ninety percent confidence that the forecasted peak demand will not be exceeded in any given year.

A.5 Hourly Allocation

The final step of the process is to forecast a monthly peak demand and load for each hour in the year. Monthly peak demands, outside of the August annual peak, are forecast using the load factor formula. The historical average monthly load factor and the forecasted NEL for each month are the known inputs. To forecast load for each hour of the year, the Loadfarm algorithm developed by Global Energy is used. The inputs into Loadfarm are a historical system load shape, monthly forecasted energy, and monthly forecasted peak demand. The system load shape is developed using a ranked-average procedure permuting historical loads so that all peaks occur on the fourth Thursday in August. Table A-1 contains the numerical 2012 Forecast.

AR0070093

Table A-1. TREND CASE ENERGY SALES AND PEAK DEMAND

	SECTOR SALES					Total Sales to Ultimate Customers	Net Energy for Load	Peak Demand
Fiscal Year	Residential (GWh)	Commercial (GWh)	Industrial (GWh)	Miscellaneous* (GWh)	PHEV (GWh)	(GWh)	(GWh)	(MW)

2012 Retail Electric Sales and Demand Forecast

Overview

The 2012 Retail Electric Sales and Demand Forecast (Forecast) supersedes the 2011 Retail Electric Sales and Demand Forecast as the City of Los Angeles Department of Water and Power's (LADWP) official Power System Forecast. The Forecast is the basis for LADWP Power System planning activities including but not limited to Financial Planning, Integrated Resource Planning (IRP), Transmission and Distribution Planning and Wholesale Marketing.

Because the Forecast is a public document, only publically available information is used in its development. (This practice has become a standard among California electric utilities.) LADWP Planners wishing to use their own proprietary data should adjust the Forecast accordingly. The Load Forecast Group (LFG) is available to help Planners make adjustments and produces an Unmitigated and Gross Forecast to facilitate those adjustments.

Data Sources

1. Historical Sales reconciled to the Consumption and Earnings Report prepared by General Accounting
2. Historical NEL, Peak Demand and Losses reconciled to the PowerMaster database maintained by the Power System Planning & Development Group
3. Historical weather data is provided by the National Weather Service and Los Angeles Pierce College.
4. Historical Los Angeles County employment data is provided by the State of California Economic Development Division using the March 2010 Benchmark.
5. Historical population estimates and projections are provided by the State of California Department of Finance.
6. The long-term Los Angeles County economic forecast with quarterly short-run updates is provided by UCLA Anderson Forecast.
7. The construction activity forecast is provided by McGraw-Hill Construction.
8. The Electric Vehicle forecast is based on the California Energy Commission (CEC) statewide forecast. The California Electric Transportation Coalition of which LADWP is a member prepared the CEC forecast.
9. The port electrification forecast is provided by the Port of Los Angeles.
10. The LADWP program energy efficiency forecast is based on the LADWP Energy Efficiency projected budget through Fiscal year 2016-17 dated February 21, 2012. Historical installation rates are provided by the Energy Efficiency group.
11. The forecasted impacts of the Energy Independence Security Act (EISA) and the Huffman Bill on residential lighting rely on the Energy Efficiency Potential Study prepared in 2010 by Global Energy.
12. Historical and projected solar rooftop installations are the draft 2011 Integrated Resources Planning Assumptions document dated October 14, 2011.
13. Electric Price Forecast is developed by Financial Services organization.
14. Historical data is current through December 2011.

AR0070098

Five-Year Sales Forecast

The Retail Sales Forecast represents sales that will be realized at the meter through Fiscal Year End 2017. After FYE 2017, some of the forecasted sales will not be realized at the meter due to the incremental impacts of LADWP-sponsored energy efficiency programs. After FYE 2017, LADWP-sponsored energy efficiency programs will be accounted for in the Integrated Resource Plan.

The historical accumulated Energy Efficiency and Solar Saving are from 1999 forward and only include LADWP installed savings. Since July 1, 2008, LADWP-installed Energy Efficiency savings are 715 GWH for which LADWP recovers lost revenue. In the Forecast, energy efficiency and solar savings are expected to occur uniformly throughout the year as a simplifying assumption. Installation schedules are difficult to prepare because they rely on the customers allowing the installation to occur.

Retail sales decrease of 0.6 percent in Fiscal Year 2013-14 is attributed to the full ramp up of the Huffman Bill and accelerated incremental savings rates in LADWP's energy efficiency programs. Beginning January 2012, the Huffman Bill significantly raises the efficiency standard of light bulbs. The 0.5 increase in FYE 2014-15 is due to the projected completion of port electrification projects and a decline in the LADWP incremental energy efficiency savings rate.

Forecasted Energy Efficiency is based LADWP Board approved AB 2021 goal of saving 2161 GWH from FYE 2011 through FYE 2020 and forecasted Huffman bill savings. The targeted goal for rooftop solar installations is 242 MW by 2020.

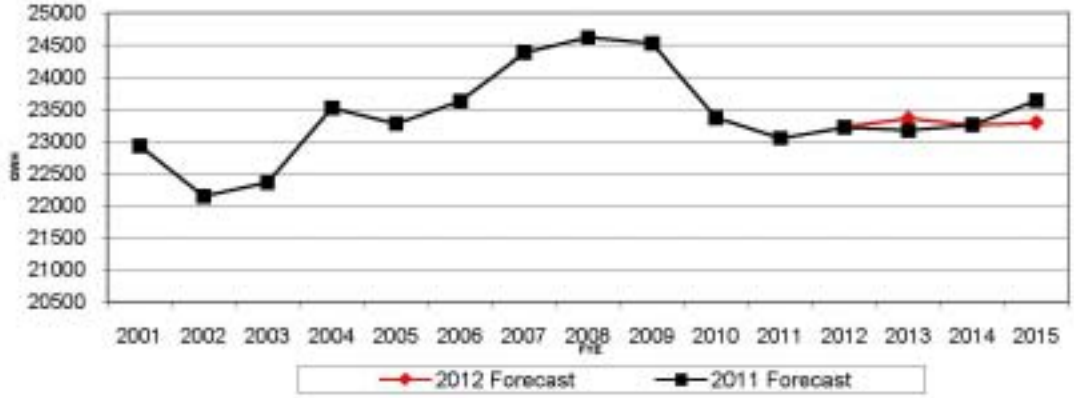
Short-Run Growth

Fiscal Year	Retail Sales		Accumulated EE & Solar Savings	Gross Sales
Ending June 30	(GWH)	YOY Growth Rate	(GWH)	(GWH)
2010-11	23053		1470	24523
Forecast				
2011-12	23232	0.8%	1725	24957
2012-13	23361	0.6%	2102	25426
2013-14	23256	-0.4%	2428	25684
2014-15	23294	0.2%	2772	26066
2015-16	23253	-0.2%	3113	26366
2016-17	23224	-0.1%	3448	26672

* Actual sales through December 2011

AR0070099

Retail Sales Net of Energy Efficiency and Distributed Generation



Peak Demand Forecast

Growth in annual peak demand over the next ten years is 0.3 percent.

Long-Run Growth

Fiscal Year End June 30	Base Case Peak Demand (MW)	Growth Rate Base Year 2011-12	One-in-Ten Peak Demand (MW)
2011-12	5631[1]		6073
Forecast			
2016-17	5590	-0.1%	6026
2021-22	5881	0.4%	6342
2031-32	6441	0.7%	6885
2040-41	6992	0.7%	7546

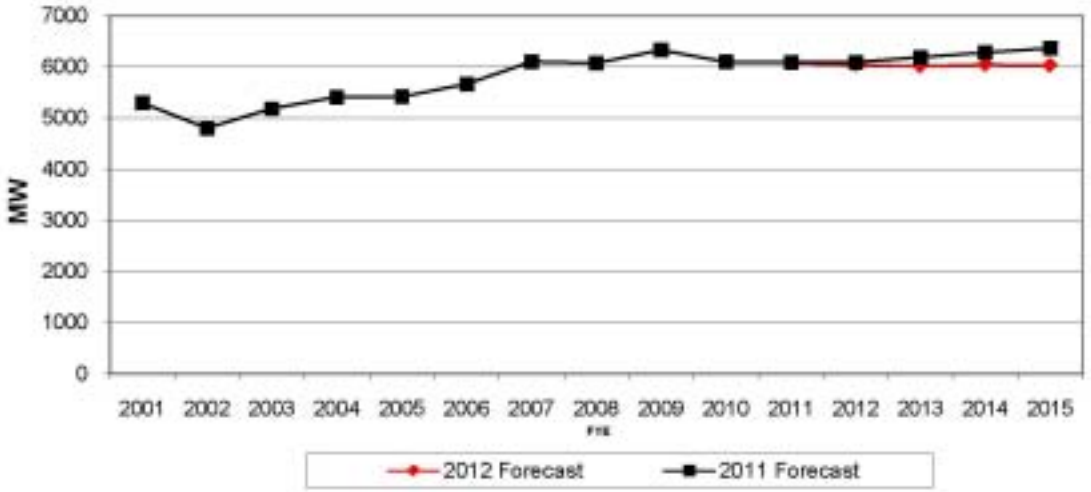
[1]Weather-normalized. Actual peak was 5907 MW.

In 2011, the System set its calendar annual peak at 5907 MW on September 7, 2011 on a day that was a 1-in-2.3 weather event. The weather-adjusted one-in-two peak for 2011 is 5631 MW. The following graph of the One-in-Ten peak demand forecast is used for the Integrated Resource Plan (IRP). In the 1990s through 2005, annual System load factors were trending slowly upward. Since 2006, System load factors are trending down. Three factors are generally thought to be contributing to this effect. Most customers are making greater efforts to conserve energy but during extreme weather events safety and comfort predominate over conservation causing the peak to spike. Much of the historical and forecasted energy efficiency effort is lighting which has a greater impact on consumption rather than peak which lowers the load factor. Solar rooftops peak production is between 1200 and 1300 hours and declines to 40 to 50 percent of capacity at 1600 hours when the

AR0070100

peak occurs. In contrast, the load factor will rise due to significant load growth from the greater use of electric vehicles. The new electric vehicle forecast adopted from the California Electric Transportation Coalition has less impact on the peak than the 2011 Forecast.

One-in-Ten Peak Demand Comparisons



The Peak Demand Forecast is primarily used in the following areas:

1. Integrated Resource Planning
2. Wholesale Energy Marketing
3. Distribution Planning
4. Transmission Planning

In Integrated Resource Planning, LADWP uses the One-in-Ten Case Peak Demand forecast rather than the Base Case forecast. LADWP's policy is to ensure reliability in times of volatility by controlling its own generation capacity. Planning generation resources at the one-in-ten level has proven over the years to be an effective tool in meeting the reliability policy. The one-in-ten case is based on historical peak day weather events and uses a statistical model and the underlying retail sales forecast to forecast an annual peak demand. The peak demand is adjusted for lighting energy efficiency and electric vehicle impacts.

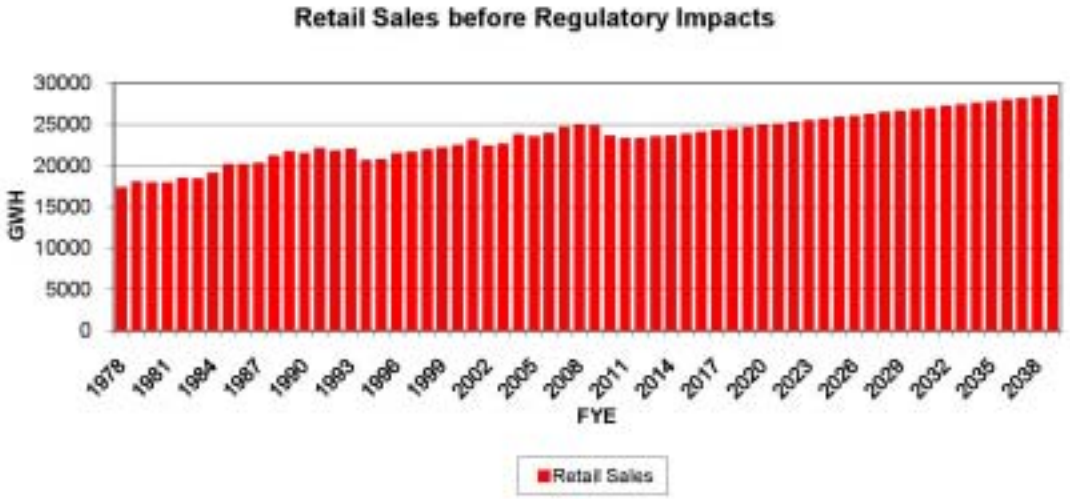
Plausibility

To measure plausibility we compare the current forecast to historical periods. Data is available electronically from 1978 forward. A direct comparison is not appropriate because the forecast period includes programs that reduce all forms of energy consumption due to an aggressive regulatory agenda primary aimed at reducing greenhouse emissions. Instead the unmitigated forecast is compared against history. The unmitigated forecast is the forecast that would occur before the impacts of AB 32 and AB 2021 are considered. It might also be considered a "business-as-usual" case.

AR0070101

The decline in forecasted sales 2008 through 2010 is most directly compared to the decline in sales between 1992 and 1994. The 1992 through 1994 time period was difficult for Los Angeles in many aspects. An economic slump occurred mostly created by the downsizing of the aerospace industry but it also was time of civil unrest and natural disaster. The combination of events caused a major migration of people leaving Los Angeles. Peak-to-Trough sales declined 7 percent in the 1992 through 1994 time period. The following table shows all the peak-to-through declines since 1978. The chart then gives visual evidence of the long-term perspective.

Peak-to-Trough Analysis		
Years	GWH Decline	Percent Decline
2008-2010	1,910	8.3%
1992-1994	1,421	7.0%
2000-2002	572	2.6%
1979-1980	322	1.8%
1981-1982	145	0.8%



Primarily due to the recession that began in December 2007 and ended in June 2009, the historical sales experienced a decline of 8.3 percent in the 2008 through 2010 time period. While the 1992-94 sales decline was specific to Los Angeles and the aerospace industry, in 2008-2010 the decline in Los Angeles mirrored the malaise in the national economy. Going forward, there are conflicting trends in the economic forecast for Los Angeles County going forward. On the positive note, Real Personal Income is increasing. Per capita energy consumption is historically positively correlated with increases in personal income and consumption. The negative trends are population out-migration and fewer jobs in Los Angeles County. Population out-migration means smaller demand for housing infrastructure. Fewer jobs imply that vacant commercial floor space will not be absorbed. Based on economic variables sales will not reach 2008 levels until 2021. The next decade will be much like the 1990s.

Variables in the Forecast

Population The 2010 United States Census reported 3,792,621 residents in the City of Los Angeles. This number was far lower than the previous 4,094,764 estimated by State of California Department of Finance Demographic unit. The State relies on birth-death records and driver license data to estimate population between censuses. The 2000 United States Census reported 3,694,742. The population growth rate was only 0.2 percent per annum in the first decade of the 21st century. This data seems contrary to other data such as new residential accounts for example. New residential accounts increased at a 0.5% rate in the same time period. This Forecast relies less on the population data since it gives us an unexpected result.

SB 375 SB 375 layers statewide guidelines onto local planning decisions. It favors redevelopment, known as brown field development, near transportation centers over new (green field) development. The goal is to reduce vehicle miles traveled thereby reducing emissions. Most development in Los Angeles is brown field development. However, brown field development is more complicated and expensive than green field development so overall development could slow. The City of L.A.'s "Housing that Works" plan fits well into the SB 375 structure. Residential construction activity is forecast to rebound to normal levels within the next three years.

Emission Allowances AB 32 seeks to reduce emissions to 1990 levels using a cap-and-trade scheme. Originally the program was to begin in 2012 but has been delayed. Program is designed to protect utilities and consumers. Climate impacts are unknown.

Electric Vehicles LADWP is making electric vehicles a key strategic initiative. The Forecast uses the 2011 California Energy Commission mid-level forecast for electric load growth. This forecast was developed by the California Plug-in Electric Vehicle Coalition of which LADWP is a member. Demand response strategies are intrinsic to this forecast whereas in the 2011 Forecast Demand Response strategies for electric vehicles were external to the electric vehicle forecast. Alternative forecasts for load growth from electric vehicles vary widely.

Energy Efficiency According to the State of California Strategic Plan, achieving the energy efficiency goals relies on new emerging technologies. The firming of the market availability and the adoption rates for the new technologies is unknown.

Smart Grid It is unknown when LADWP will complete its Smart Grid program. Some believe that developing a Smart Grid system is a necessary precondition towards a successful electric vehicle program. Also Smart Grid is an important component towards achieving energy efficiency goals in the residential sector.

Vacancy Factor in Residential Sector Vacancy rose faster than expected in the recession. Some of the vacancy rate was due to households combining and living in the same structure. Vacancy could rapidly swing lower as the economy begins to expand. The Forecast has vacancy rate returning to five percent which is the long-term average by 2015.

AR0070103

Vacancy Factor in Commercial Sector - High vacancy factor is expected to remain more persistent in the commercial sector as models for delivery of services especially in retail change. The rise of big box retail stores and the Internet have crowded out the small retail shop owner over the past twenty years. There is a smaller need for a physical presence.

Panama Canal Widening - Panama is widening its canal to accommodate the modern larger container ships. It is expected to be completed by 2014. Eastern seaports are also dredging to allow the larger container ships to dock. Currently the larger container ships dock in Los Angeles and Long Beach and the goods are shipped by rail to the East Coast. A decline in this business would hurt the Los Angeles economy. Wholesale Trade and Transportation represent about ten percent of the employment in Los Angeles County.

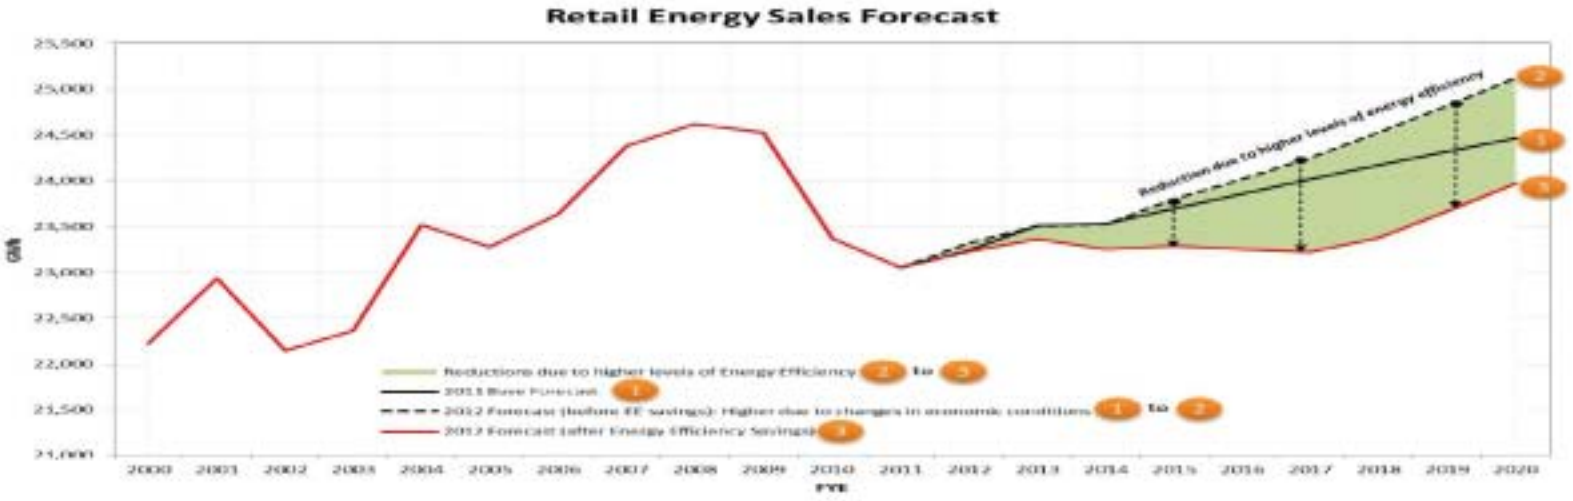
Retail Sales

Key Change Factors from 2011 to 2012 forecast:

- ✓ EE included through FYE 2017
- ✓ EE has contributed to the reduction in the retail sales forecast as part of implementing AB 2021. LADWP has targeted an additional 8.6% reduction by 2020.
- ✓ Construction activity remains at low level for extended period. Construction jobs concentrated on rebuilding infrastructure rather than adding housing units or commercial floor space which would have greater impact on electricity sales.



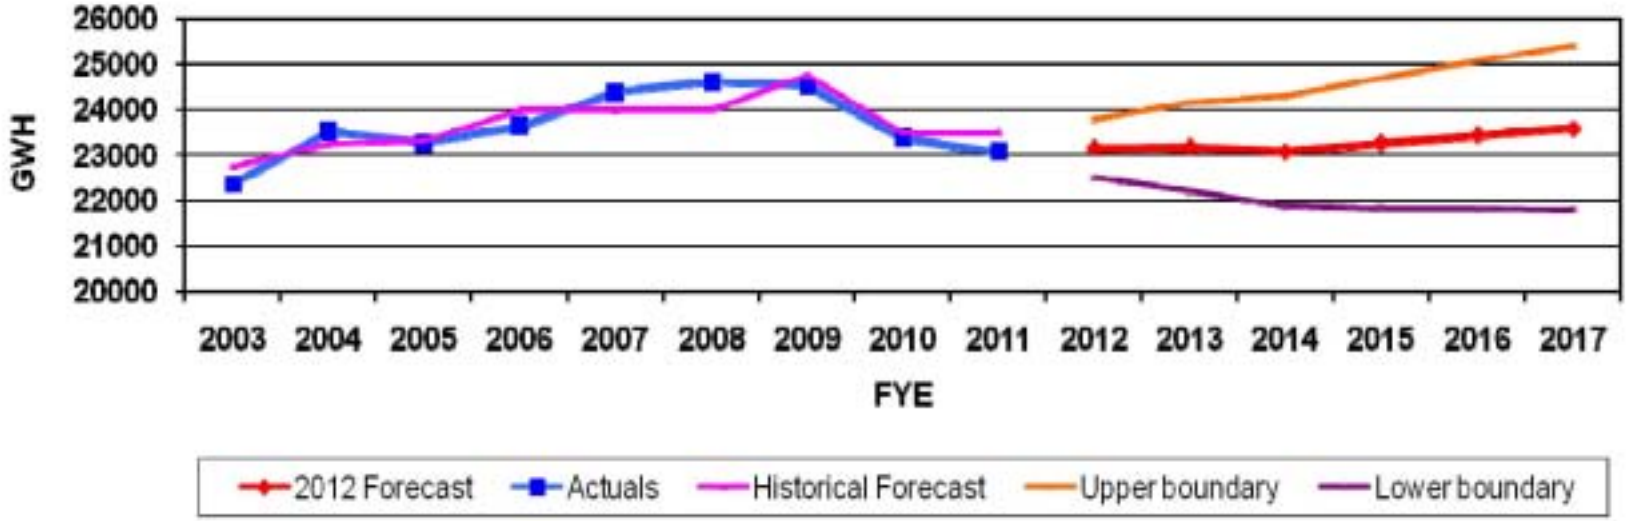
Retail Sales

Accuracy:

✓EE and Solar were not modeled explicitly in Historical Forecasts.

✓Historical accuracy is 0.2% with a 1.6% deviation. However expect larger variation in accuracy due uncertainty of new programs.

✓Forecast variation is a function of weather, economic forecasts, meeting program goals and model specification.



Energy Efficiency and Solar Rooftops

Historical and Forecasted Accumulated Savings

- ✓ EE before 2008 not included in ECAF Lost Revenue calculation.
- ✓ Energy Efficient Light Bulbs savings are the result of a new State appliance standard. (Huffman)

Peak Demand

Cases:

✓The variance around the 1-in-2 forecasted peak has widened based on events since 2006.

✓Based on the climate change finding, it is now expected that the System will approach its potential more frequently so the distance between the 1-in-10 and 1-in-40 forecasts is compressed.

	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020

Peak Demand

✓Annual peak demand is dependent on the severity of the heat storms that are encountered during the year.

✓The cases are built on the probability of a weather event occurring in a given year.

NEL (MW) Fiscal Year Annual Peak Demand				
Fiscal Year	Base Case	1 in 5	1 in 10	1 in 40 Hot
2012-13	5,606	5,894	6,046	6,279
2013-14	5,577	5,863	6,014	6,245
2014-15	5,604	5,891	6,042	6,274
2015-16	5,591	5,878	6,028	6,260
2016-17	5,590	5,876	6,026	6,257
2017-18	5,597	5,884	6,034	6,265
2018-19	5,658	5,947	6,099	6,333
2019-00	5,725	6,018	6,172	6,409
2020-21	5,791	6,088	6,244	6,484
2021-22	5,881	6,184	6,342	6,586
2022-23	5,942	6,248	6,409	6,656
2023-24	5,995	6,305	6,467	6,716
2024-25	6,050	6,363	6,526	6,779
2025-26	6,105	6,421	6,586	6,840
2026-27	6,160	6,478	6,645	6,902
2027-28	6,216	6,537	6,705	6,965
2028-29	6,271	6,595	6,765	7,027
2029-30	6,326	6,653	6,824	7,088
2030-31	6,381	6,712	6,885	7,151

1-in-10 Peak Demand

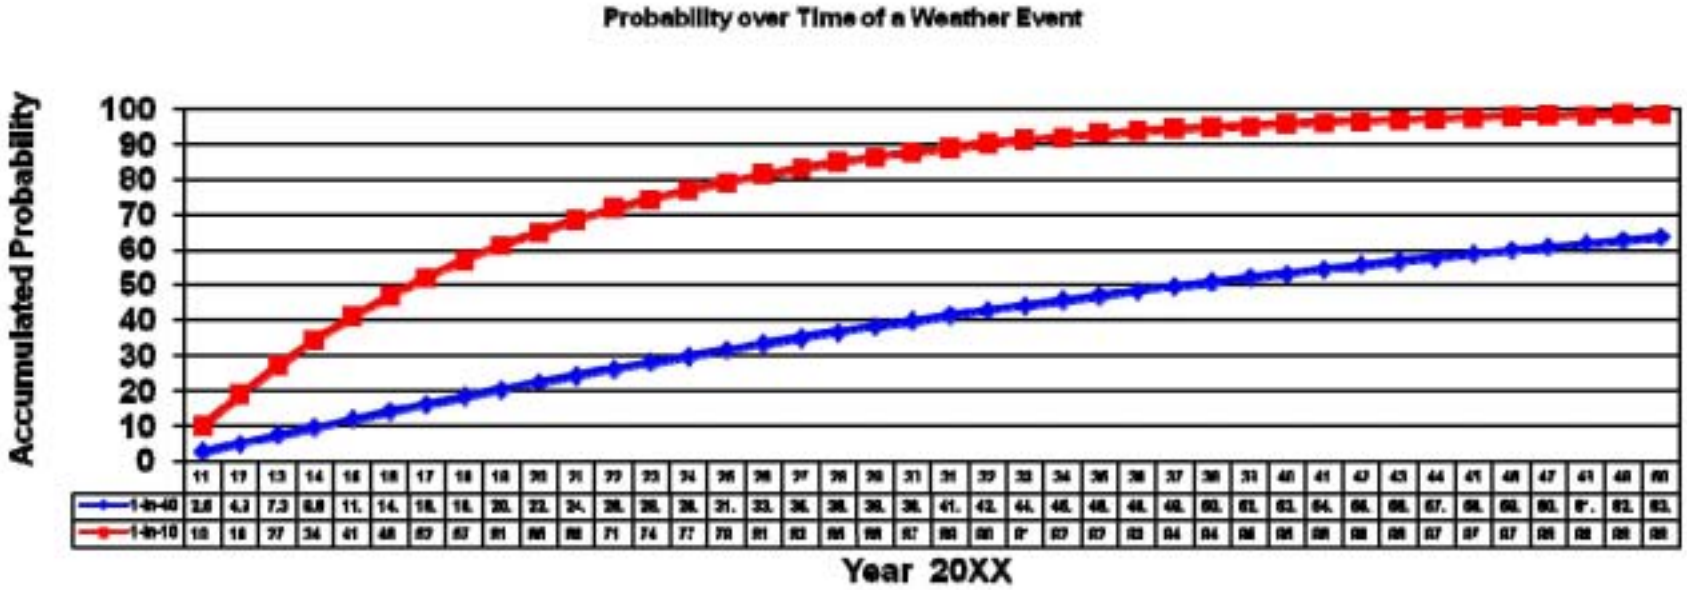
1-in-10 peak used in Integrated Resource Planning process:

- ✓2011 Actual Peak = 5907 MW.
- ✓2011 Weather-Normalized peak = 5631 MW.
- ✓2011 Forecasted Weather-normalized peak = 5589 MW.
- ✓Peaks after 2006 have tended to spike.

1-in-10 Peak Demand

Probability accumulates over time:

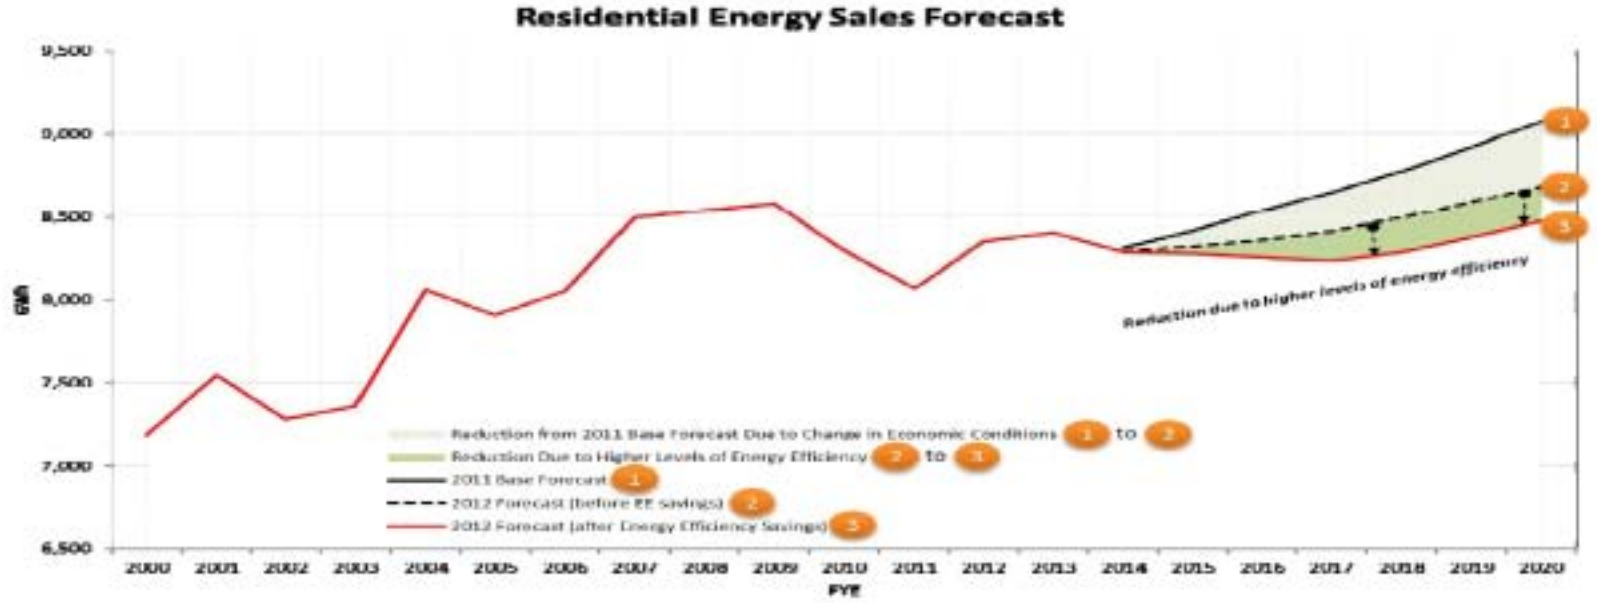
- ✓There is a 65% chance of having a 1-in-10 weather event by 2020.
- ✓There is a 22% chance of having a 1-in-40 weather event by 2020.
- ✓$P_t=1-(1-P_e)^t$



Residential Energy Sales

Components of Change

- ✓ Lowered new-units-built forecast
- ✓ Lower economic forecast

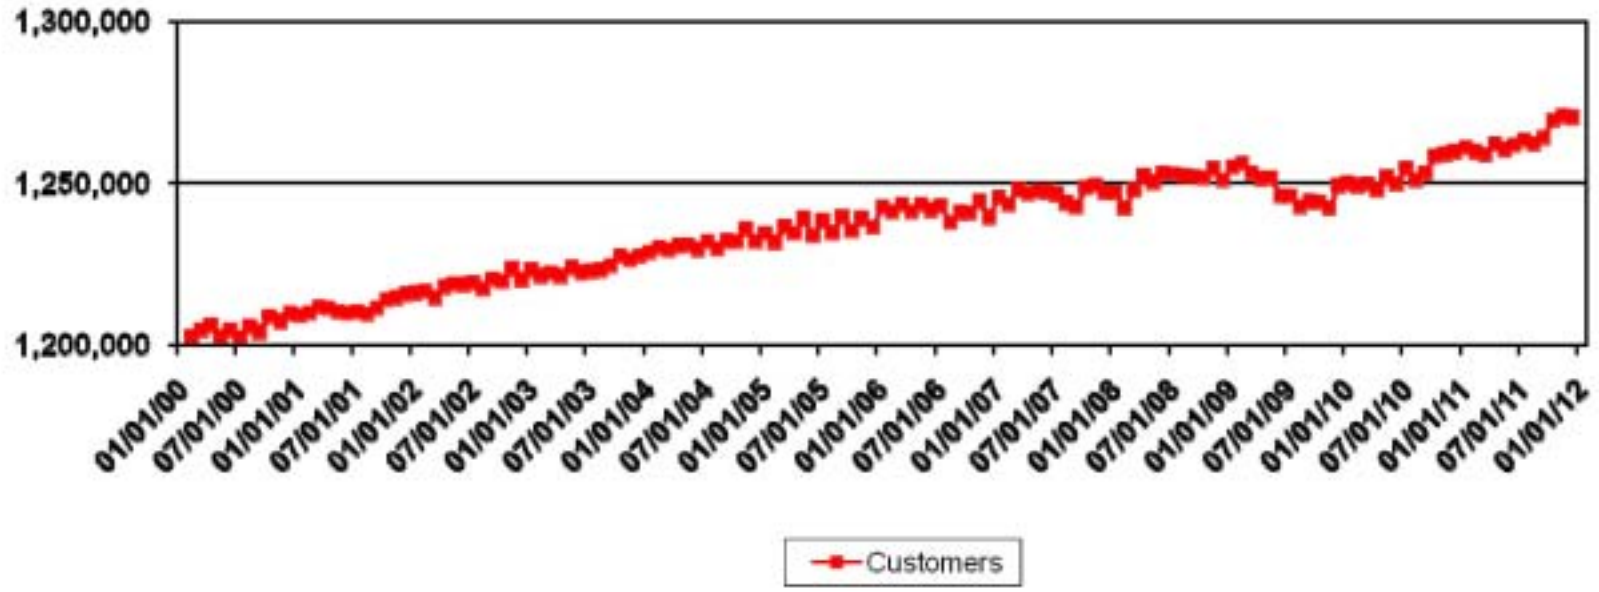


Residential Energy Sales

Number of Residential Customers

Recent Evidence

- ✓ 10,000 active meters added in 2011.
- ✓ Returning to long-term trend quickly.
- ✓ The majority of residential customers are renters and live in multi-family units.
- ✓ The attractiveness of downtown living has increased due to the "Housing that Works" plan.



Residential Energy Sales
Average Sales per Customer

Recent Evidence

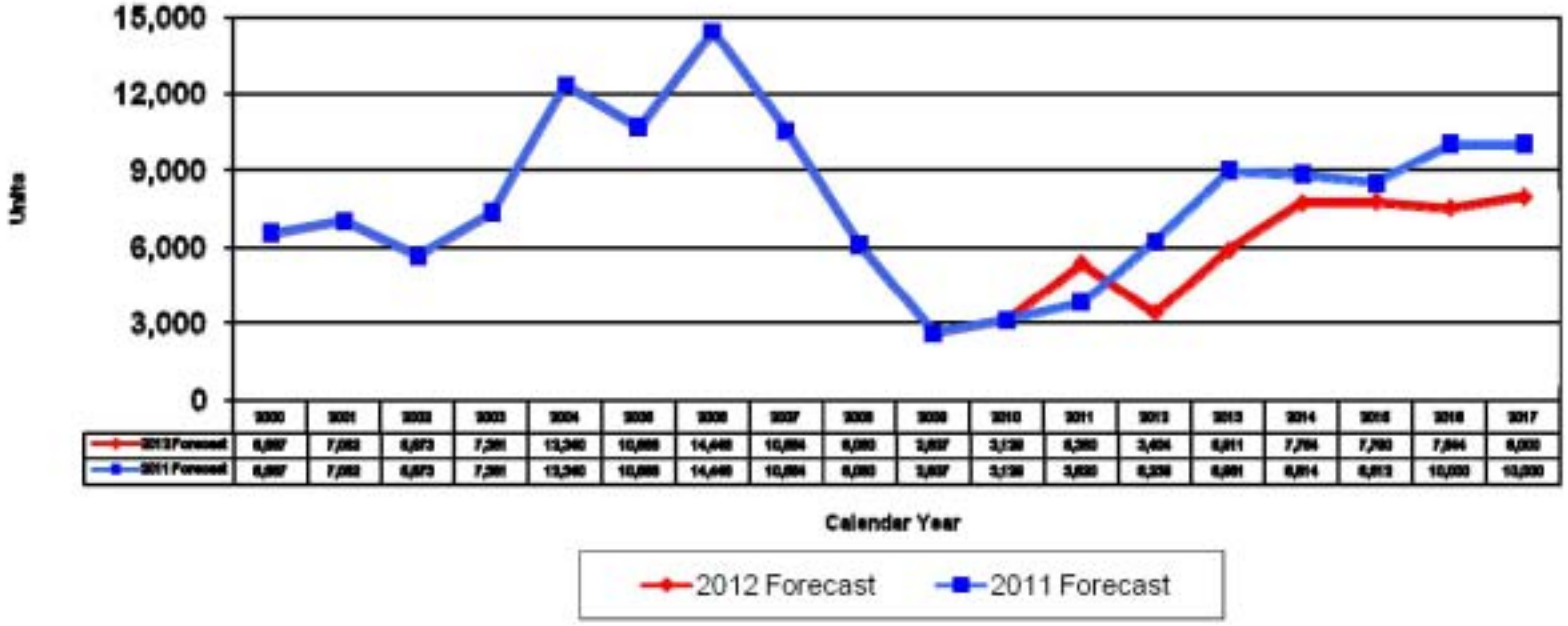
- ✓Sales per residential customer reached an all-time high of 519 KWH per month in December 2008.
- ✓The December 2011 rate is 482 KWH per Month.
- ✓Weather -normalized September 2011 rate is 495 kWh per Month.

Residential Energy Sales

New Residential Building Units

Recent Evidence

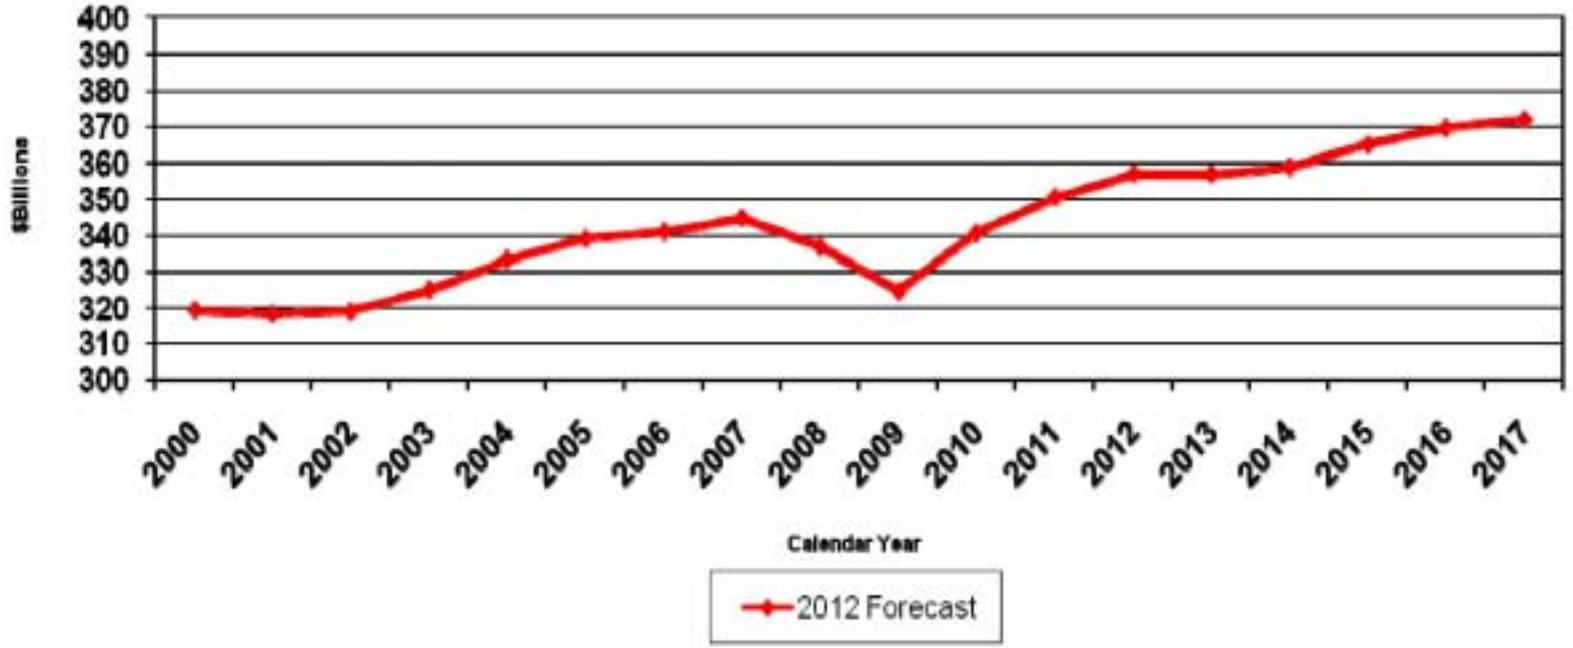
- ✓ New units are 20% Single-Family and 80% Multi-family which lowers future average consumption per household.
- ✓ Recent Housing Starts are at historical lows.



Residential Energy Sales
Recent Economic Impact

Real Personal Consumption

- ✓ Recovery ends and expansion begins in 2012.
- ✓ 1% growth - Below historical mean growth.

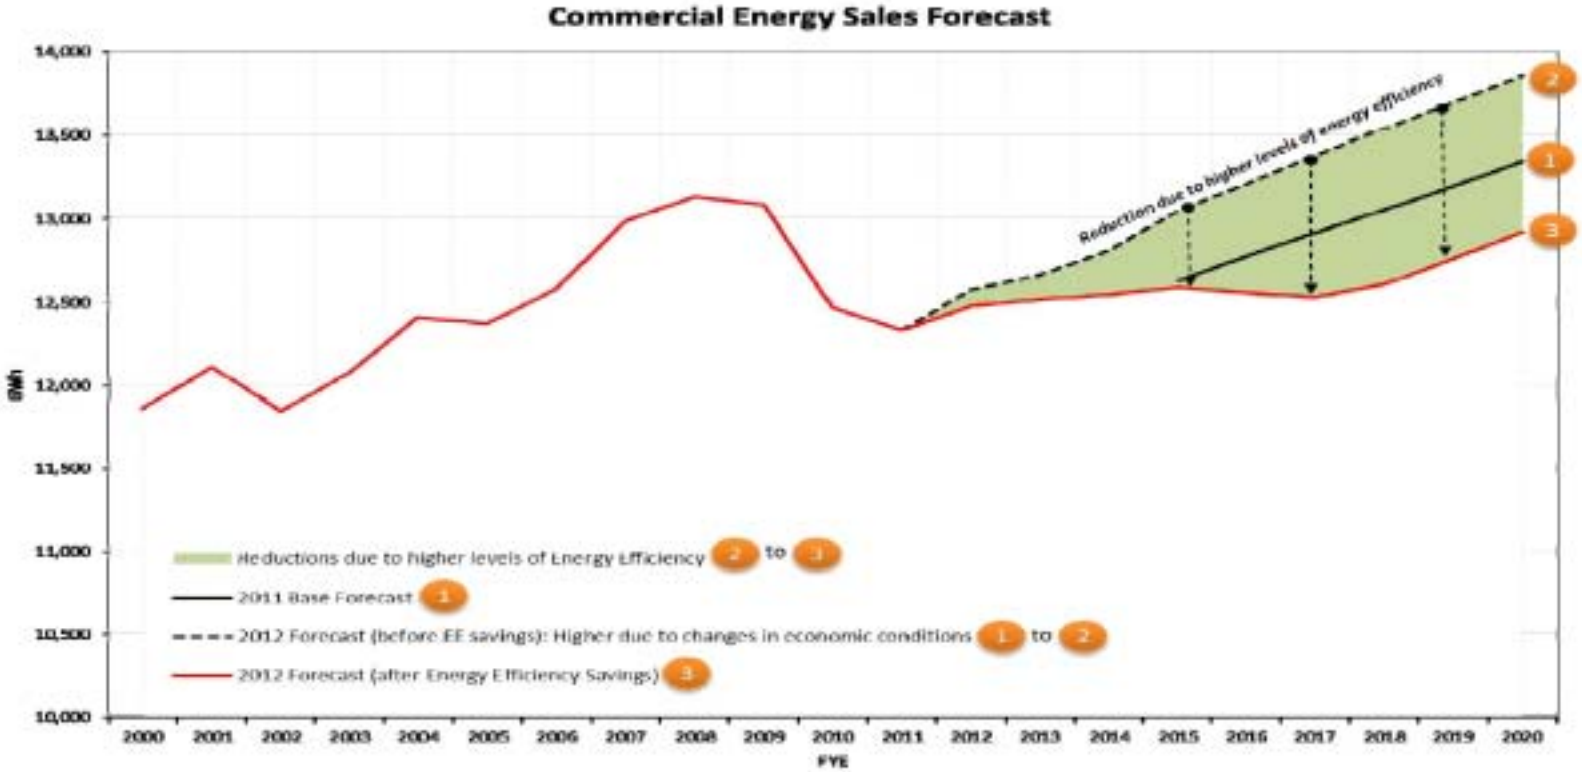


AR0070118

Commercial Energy Sales

Components of Change

- ✓ Service employment forecast slightly higher.
- ✓ Commercial construction activity down but positive absorption.



Commercial Energy Sales

Number of Commercial Customers

Recent Evidence

- ✓ There is a delay in bill collection. There are approximately 750 accounts past due, as result of the AMI implementation. LADWP is working to resolve this issue.

Commercial Energy Sales
Average Sales per Customer

Recent Evidence

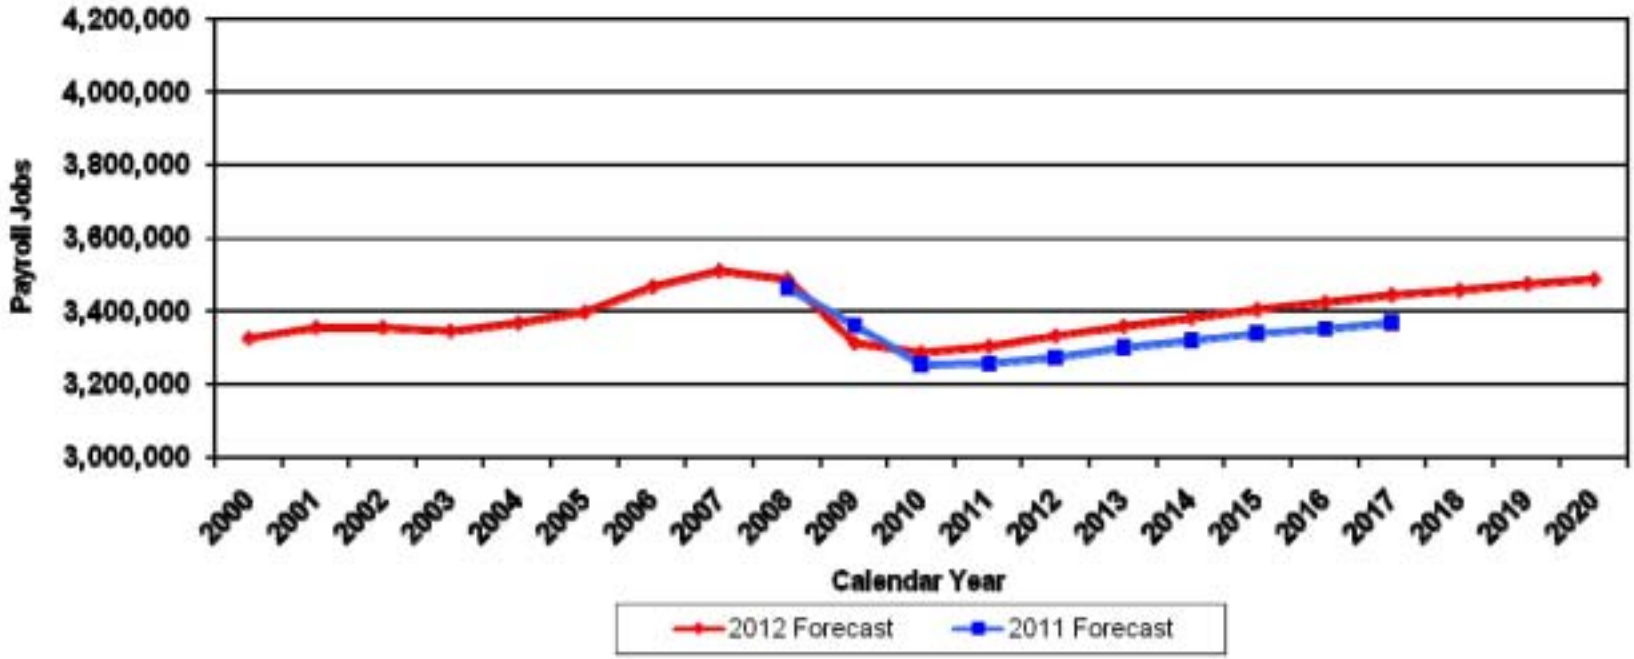
- ✓ Sales per customer per month peaked in July 2008 at 9265 KWH per month.
- ✓ Currently sales per customer per month are 8614 KWH.
- ✓ Weather normal sales per customer per month is 8690 KWH.

Commercial Energy Sales

Local Employment in Service Sector

LA County Commercial Services Employment

- ✓ Changing service delivery models – Internet and Big box retailers are two examples.
- ✓ Employment does not return to former high by 2020.



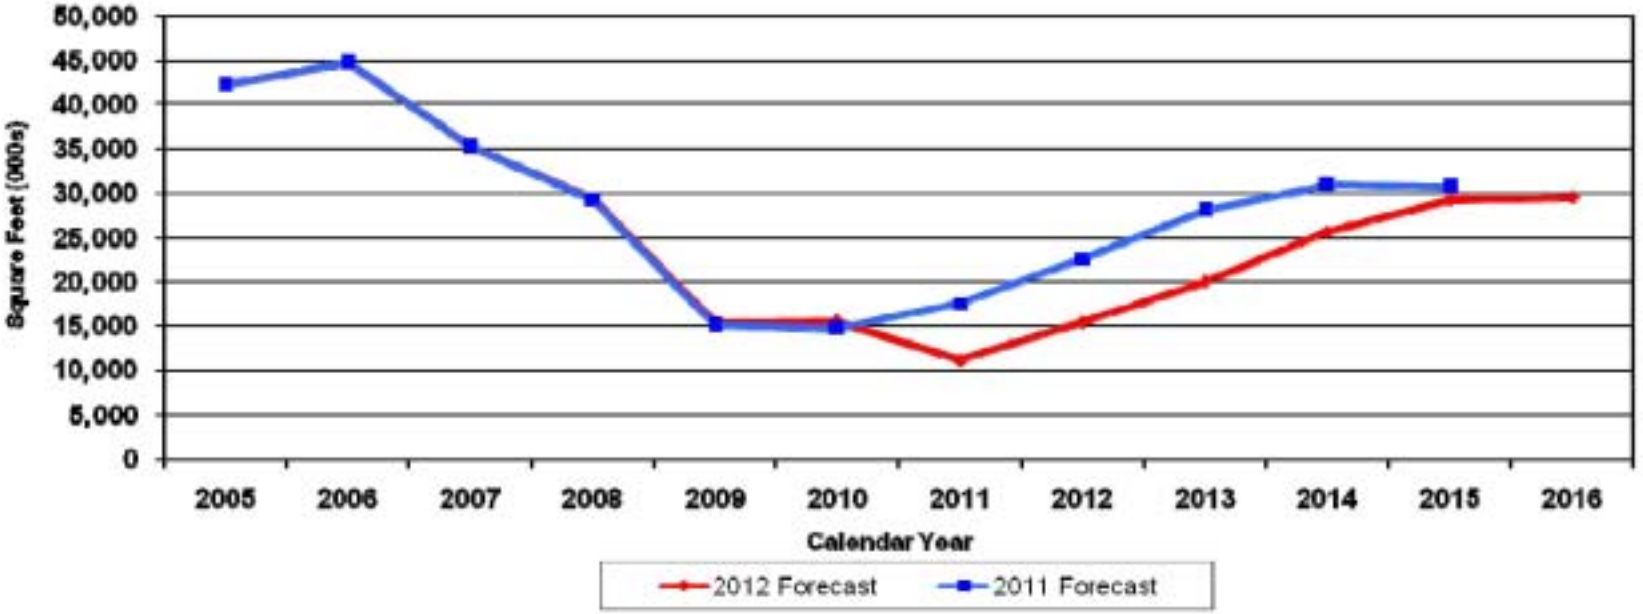
AR0070122

Commercial Energy Sales

McGraw-Hill Construction Forecast

Commercial Floorspace Additions

- ✓ Construction activity at historically low levels.
- ✓ Office vacancy rates in San Fernando Valley at 18 percent.
- ✓ New models for delivering commercial services require smaller physical presence.



AR0070123

Industrial Energy Sales

Components of Change

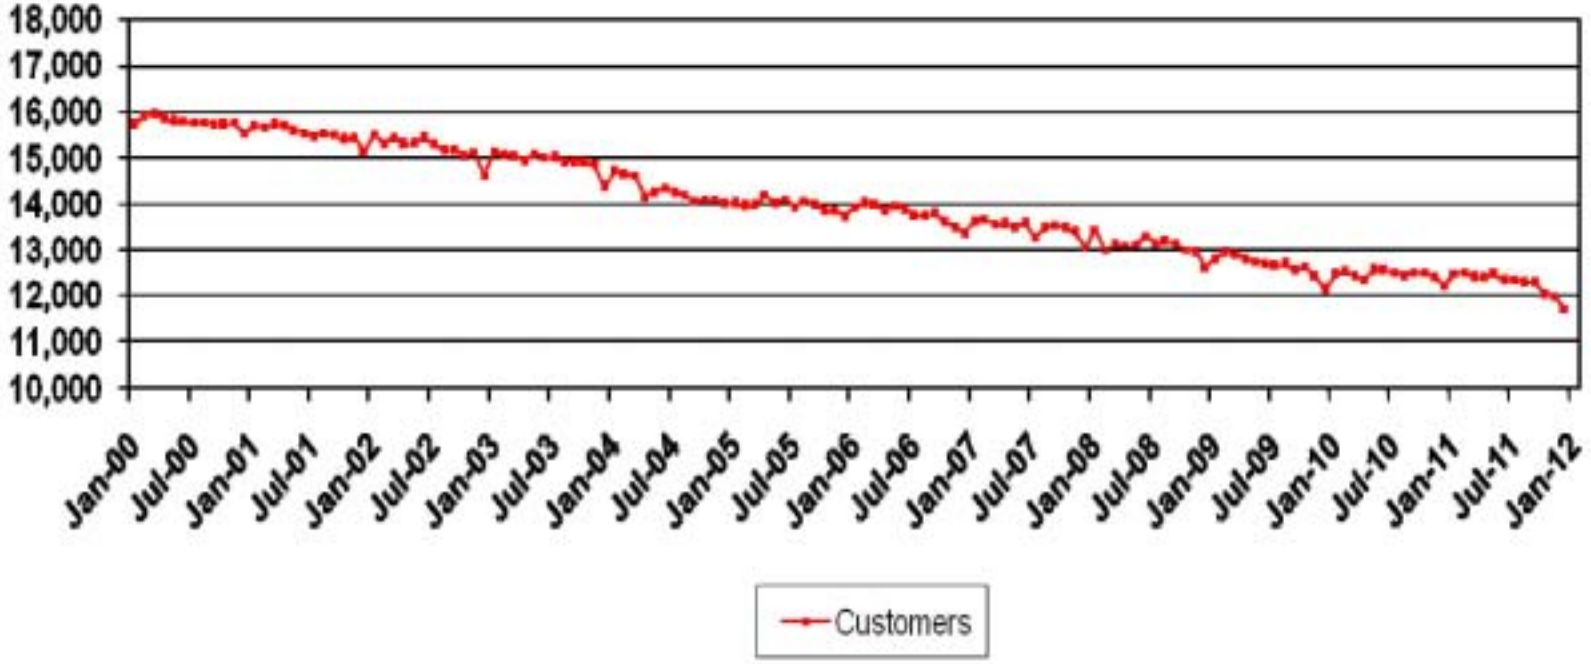
- ✓ Land use issue: Once industrial land is vacated, residential and commercial buildings tend to replace it. 3 to 4 percent vacancy rates in the industrial sector.
- ✓ Manufacturing that is staying tends to be high-value added manufacturing and process industries.
- ✓ Other manufacturing continues to move offshore or to the States with better business climate.
- ✓ No EE or rooftop solar in the Industrial Forecast. All EE and solar assigned to Residential, Commercial and Streetlight sectors.

Industrial Energy Sales

Number of Industrial Customers

Recent Evidence

- ✓The number of Industrial customers is continually and relentlessly declining.
- ✓The decline began in the 1970s.
- ✓The forecast is for the heavy process industries to remain although no new heavy industry will be built. It is the light industry and assembly jobs that are disappearing.

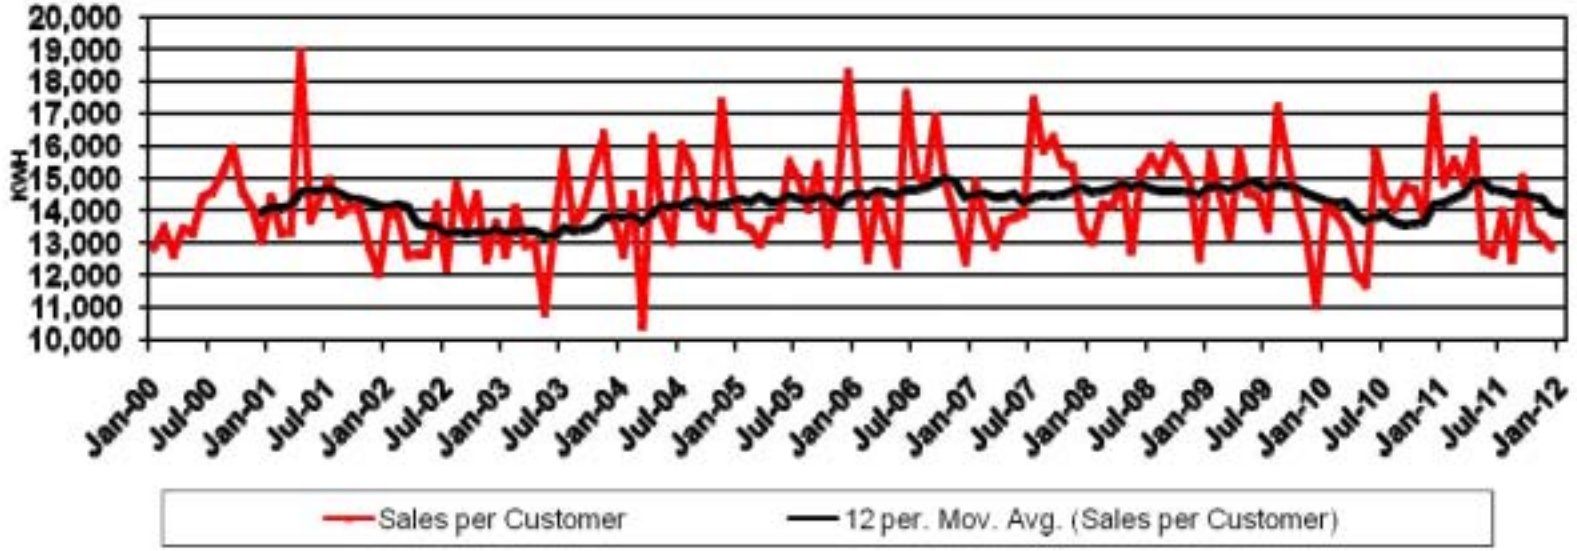


Industrial Energy Sales
Average Sales per Customer

Recent Evidence

✓Sales per customer per month peaked in October 2006 at 15026 KWH per month. High consumption partially attributed to a large self-generation unit being off-line at a refinery.

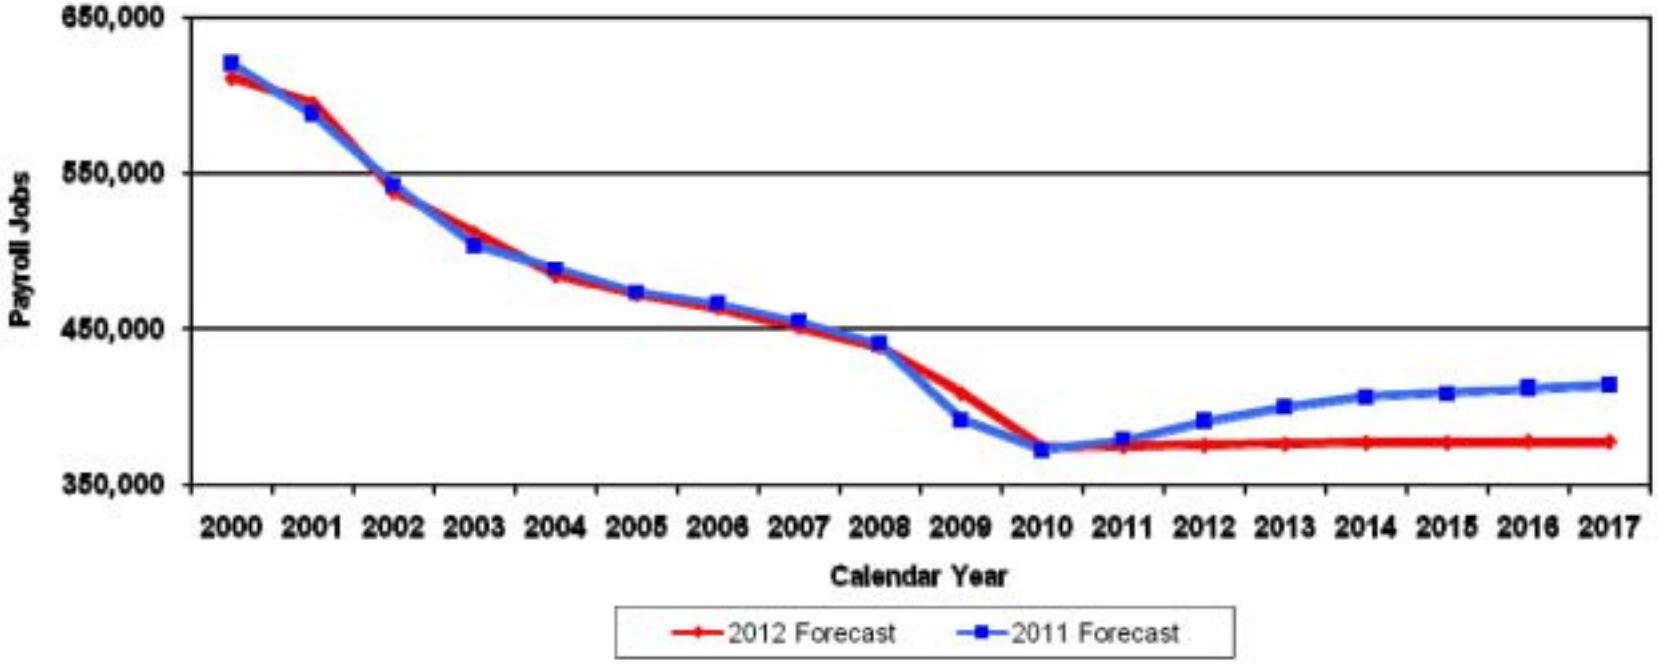
✓Currently sales per customer per month are 14000 KWH.



Industrial Energy Sales
Local Manufacturing Employment

LA County Manufacturing Employment

✓Future employment forecast is flat. If Los Angeles continues to lose manufacturing jobs then there will be a mismatch with the education level of the population and available high paying jobs. It could lead to significant population out-migration.

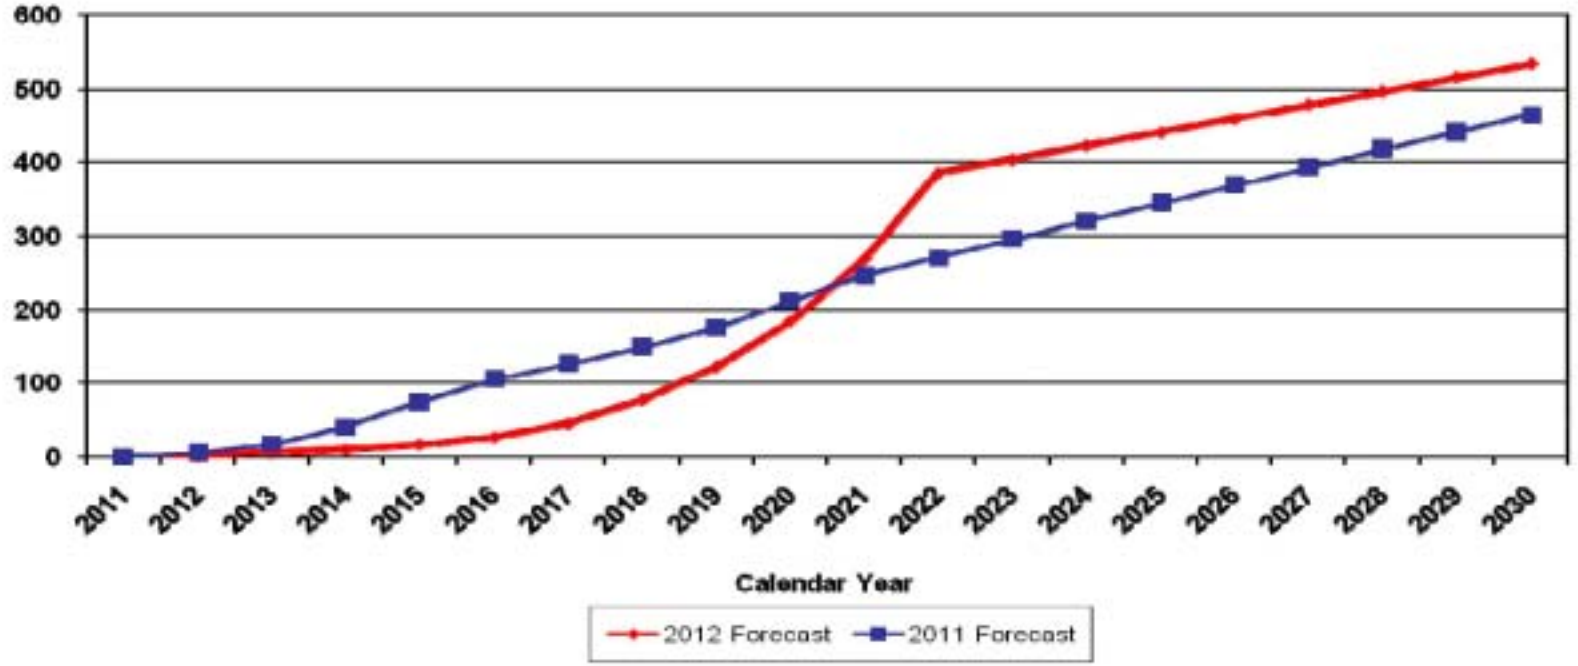


AR0070127

Electric Vehicle Sales

Load Growth

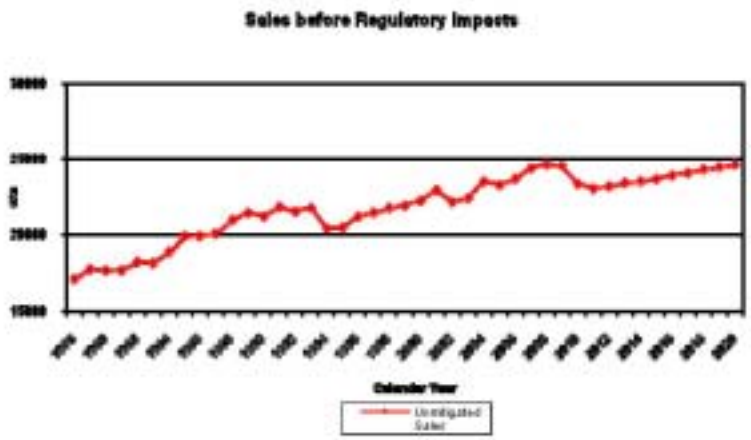
- ✓2012 forecast developed by the Plug-in Electric Vehicle Collaborative.
- ✓Also adopted by California Energy Commission



Plausibility

- Comparing unmitigated 2012 Sales Forecast to historical sales.
  - Unmitigated means forecasting sales based on economics alone before the impacts of environmental programs are considered.
  - Forecasted sales decline from 2008 to 2011 is largest in the past 30 years but smaller in scale.
  - No growth from economic factors in the next ten years. Next decade similar to what occurred in the 1990s before additional regulation.
  - LA is a mature economy.

Peak-to-Through Analysis		
Years	GWH Decline	Percent Decline
2008-2011	1,564	6.4%
1992-1994	1,421	7.0%
2000-2002	572	2.6%
1979-1980	322	1.8%
1981-1982	145	0.8%



Appendix B Energy Efficiency

Energy Efficiency (EE) is a key strategic element in LADWP IRP planning efforts. EE is a very cost-effective supply-side resource, and serves an important and multi-faceted role in meeting customer demand. One of the most widely recognized examples of EE is the replacement of incandescent lights with compact fluorescent lamp (CFL) bulbs. CFLs consume up to 75 percent less energy than incandescent bulbs while producing an equivalent amount of illumination, and last up to 10 times longer.

The reduction in energy demand that EE enables, translates into a number of benefits:

- Deferred need to build physical generation assets
- Reduced RPS compliance costs
- Reduced environmental footprint, including lower GHG emissions
- Potential for local job creation opportunities

The following subsections summarize the background of LADWP's EE program, and then review the most recently completed EE potential study that was conducted in 2010 and finalized in February 2011. Based on the study results, a plan is recommended with identified savings and costs targets. For more specific details regarding the 2010 study, see the reference at the end of this appendix.

It should be noted that efforts are in progress to commission a new EE Potential Study that will supersede the 2010 study. In 2012, the Board of Water and Power Commissioners adopted a goal of achieving 10 percent EE by 2020, with a target of up to 15% by 2020 pending the results of the new study. The cases evaluated in this 2012 IRP have all incorporated 10% EE by year 2020, with higher levels of up to 17% by 2032. Next year's IRP will incorporate the findings and recommendations of the new potential study as they are finalized and approved.

B.1 Background

LADWP has active EE programs that have been in place for several years. Since 2000, LADWP has spent approximately $315.2 million on its EE programs, which have reduced consumption by approximately 1,377 GWh. LADWP continues its commitment to developing robust, cost-effective EE programs with measurable and verifiable goals.

LADWP offers numerous EE programs and services for residential, commercial, industrial, governmental, and institutional customers to promote the efficient use of energy through the installation of energy efficient equipment. Examples include:

- The Commercial Lighting Efficiency Offer (CLEO), which provides rebates for a variety of high efficiency lighting measures to retrofit existing buildings. The CLEO program enjoys sustained high rates of participation and has achieved 433 GWh of

AR0070130

energy savings since 2000.

- The Chiller Efficiency Program, which provides incentives for customers to replace old electric chillers with new, high-efficiency units. Chillers provide space conditioning for larger buildings and the program has reduced associated peak electrical demand by more than 52 MW since 2001.
- The Small Business Direct Install (SBDI) Program, which assists eligible small businesses (A1 rate customers) in Los Angeles in becoming more energy efficient through free lighting assessments and free lighting retrofits (up to $2,500 in cost). SBDI began in 2008 and has achieved 149 GWh of energy savings since its inception.
- The Custom Performance Program, which provides performance-based incentives for energy efficiency measures not included on LADWP's menu-based EE programs. Measures supported include controls and control systems, high efficiency motors, and data server virtualization. The Custom Performance Program has achieved 200 GWh of energy savings since 2006.
- The Refrigerator Exchange Program, which delivers new Energy Star refrigerators to eligible residential customers, and picks-up/recycles customers' old, inefficient refrigerators. This program has replaced and recycled more than 53,000 refrigerators since 2007, achieving an energy savings of 49 GWh.

However successful LADWP's EE program has been, for a variety of reasons it did not meet targets that were set back in 2006. A summary the program since 2006 is presented in Table B-1.

Table B-1. LADWP EE PROGRAM PROGRESS-TO-DATE

	FY 06-07	FY 07-08	FY 08-09	FY 09-10	FY 10-11	FY 11-12	Cumulative FY 06-12
LADWP Adopted Targets (2006) - Net GWh	58	275	315	300	280	255	1,483
Actual Energy Savings Achieved - Net GWh	58	118	270	156	154	107	863
Actual % of Adopted Target	100%	43%	86%	52%	55%	42%	58%
Actual Energy Savings - Gross GWh	68	139	318	184	181	126	1016
Approved EE Budget ($million)	28	79	77	93	69	70	416
Revised EE Budget ($million)	n/a	n/a	n/a	>50	50	55	
Actual EE Funds Spent ($million)	14	38	68	44	50	37	251
Actual % of Budget	51%	48%	88%	48%	72%	68%	62%
Effective Cost - $/kWh	$0.018	$0.023	$0.018	$0.020	$0.023	$0.035	$0.291

Some key points regarding Table B-1 are as follows:

- The economic outlook in 2006, which the targets were based on, was more elevated then what actually transpired. As the higher outlook in 2006 failed to materialize, in retrospect the prior EE targets were overly ambitious.
- Since 2006, regulatory requirements have increased (OTC, RPS, GHG, etc.), resulting in additional demands outside of the EE program.

AR0070131

- Revenue streams required to support EE programs did not materialize. A spending freeze in 2009 and spending cutback in 2010 resulted in underfunding which hindered the attainment of program goals.
- Actual load profiles were less than forecasted, further affecting program performance.

An assessment of LADWP's EE program was undertaken in 2010. The assessment, also known as an Energy Efficiency Potential Study, includes an updated plan for moving forward.

B.2 Energy Efficiency Potential Study

Per Assembly Bill 2021 (AB 2021), publically owned utilities such as LADWP, must identify and develop all potential achievable, cost-effective EE savings and establish annual targets. Furthermore, utilities are required to conduct periodic "Potential" studies to update their forecasts and targets. The most recent study was carried out in late 2010 and is the basis for the EE recommendations contained in this 2011 IRP.

For more in-depth information, see the study referenced at the end of this appendix. This section presents a brief summary of the methodology and findings.

The 2010 Potential Study objectives were as follows:

- To estimate savings possible through utility programs and other interventions (such as the American Recovery and Reinvestment Act)
- Identify energy-efficiency technologies and measures that will produce savings
- Link the energy saving measures with utility programs to achieve savings
- Provide guidance for setting 10-year targets for CEC

The analysis methodology is shown in Figure B-1.

AR0070132

Figure B-1. 2010 Energy Efficiency Potential Study analysis approach.

Some of the key factors that were considered in the study include:

- Changes in the customer base since the last study
- Building codes
- Adoption of new appliance standards
- Naturally-occuring conservation
- Trends in appliance satuations
- How customers use electricity today
- Technological changes in appliances and equipment

The resulting baseline forecast for the overall customer base is shown in Figure B-2.

AR0070133

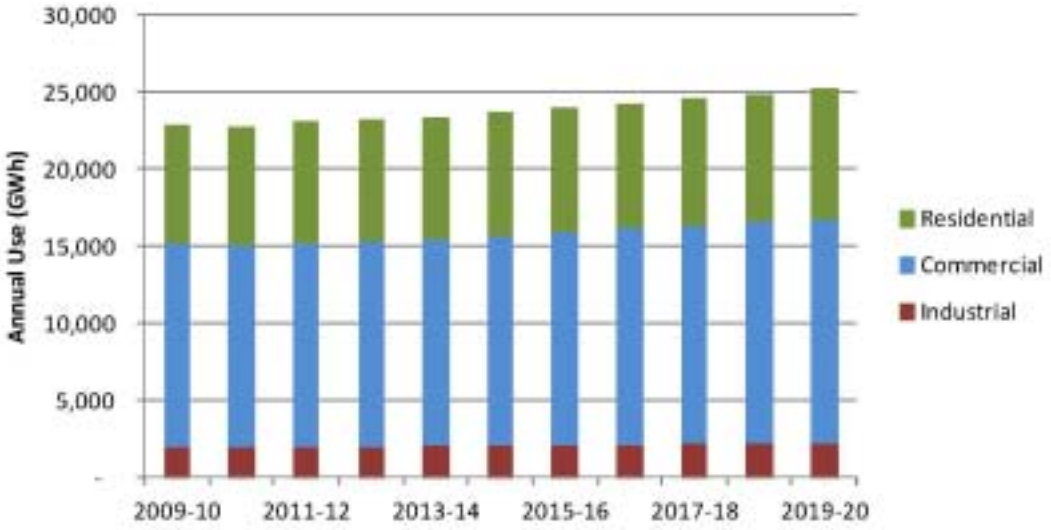


Figure B-2. Baseline forecast results through 2019-20.

Segmented forecasts for the industrial, commercial, and residential sectors are shown in Figures B-3, B-4, and B-5.

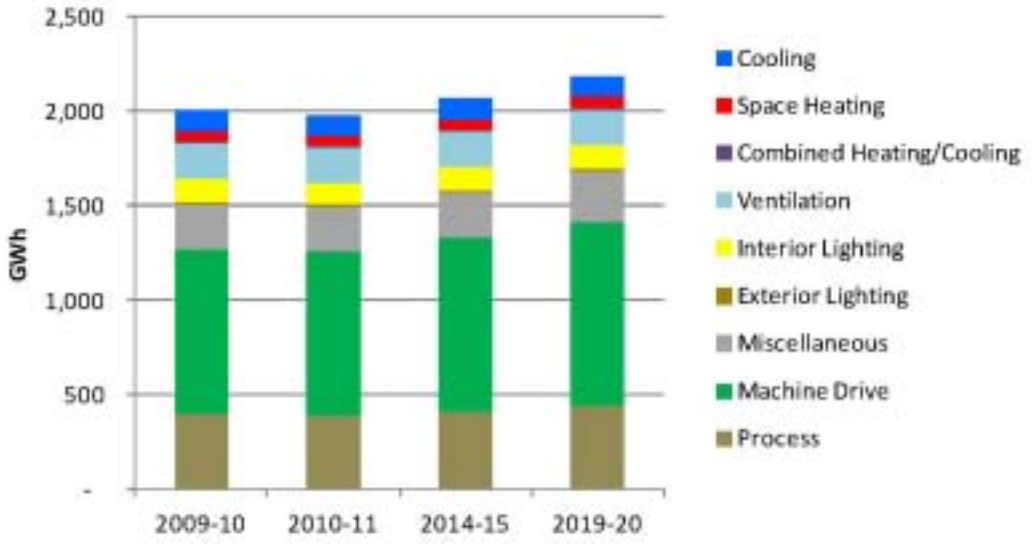

Figure B-3. Industrial sector baseline forecast results.

AR0070134

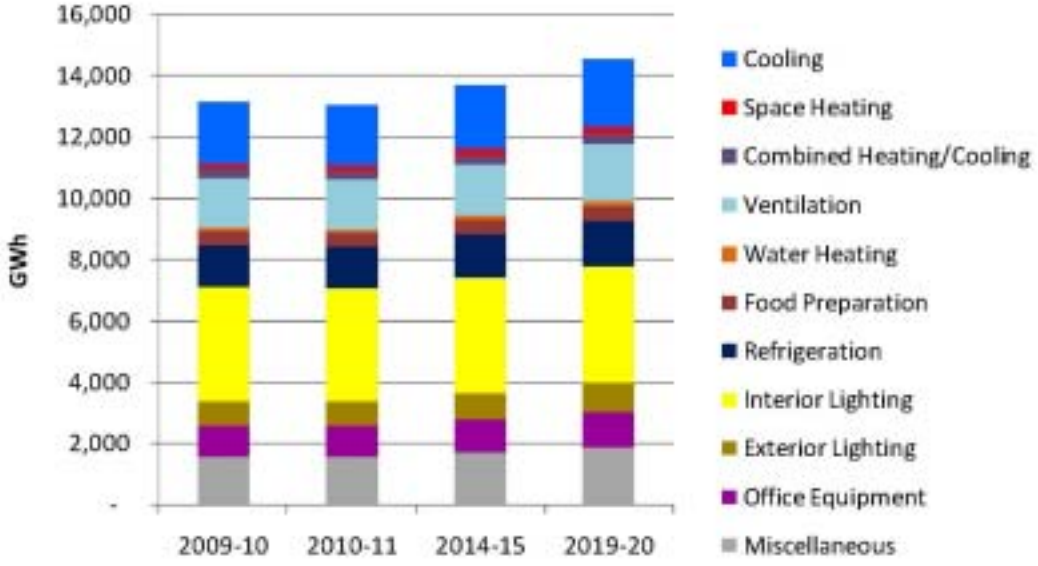

Figure B-4. Commercial sector baseline forecast results.

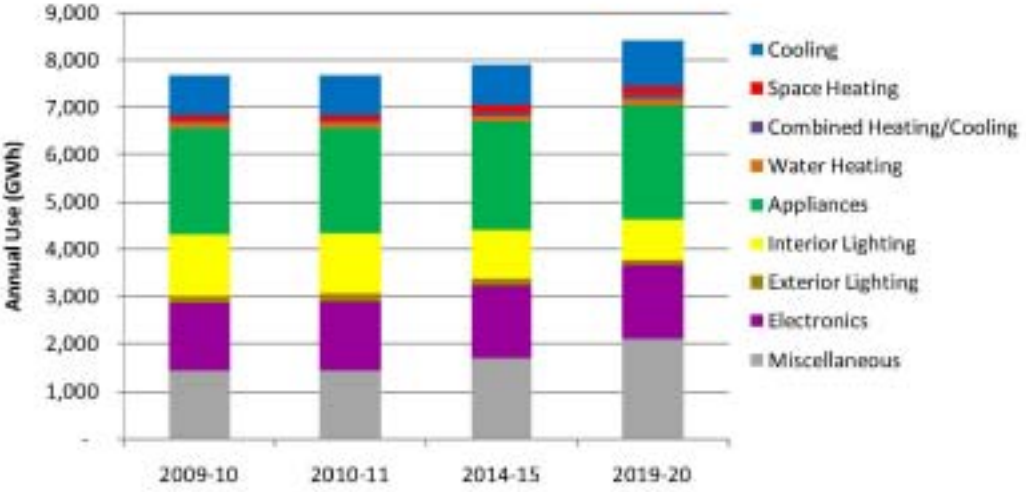

Figure B-5. Residential sector baseline forecast results.

The study evaluated a multitude of measures for potential inclusion into LADWP's EE program, including:

- Existing program elements
- High-efficiency air conditioners (higher efficiency levels, variable refrigerant flow systems)
- High-efficiency lighting (CFLs, LED lamps)
- Upgraded insulation in buildings
- Retrocommissiong and routine maintenance
- Programmable Communicating Thermostats and Energy Management Systems

AR0070135

B.3 EE Study Results and Plan

To understand the study results the following terms are defined:

2010 Potential Study Definitions

Term	Definition
Technical Potential	Customers are assumed to install most efficient option regardless of costs.
Economic Potential	Customers are assumed to install most efficient cost-effective option.
Maximum Achievable Potential	Sets maximum targets for savings. Assumes "ideal" implementation conditions and customer preferences.
Realistic Achievable Potential	Includes realistic parameters for implementation; incorporates real-world limitations: Advance program potential: Utility pays 100% of incremental cost to upgrade to EE measures. Base program potential: Utility pays 50% of incremental cost.

Key drivers/assumptions influencing EE potential levels are:

- Program budgets are assumed to grow over time
  - Financing impacts
  - Federal grants impact
- Staffing levels and other required resources will increase with program expansion
- Avoided costs will rise with changes to the generations mix

The study found that there is a realistic potential to reduce energy consumption from the baseline forecast by 8.6% by year 2019-20. Figure B-6 shows the cumulative % energy savings through fiscal year 2019-20, and Figure B-7 shows the cumulative absolute savings.

AR0070136

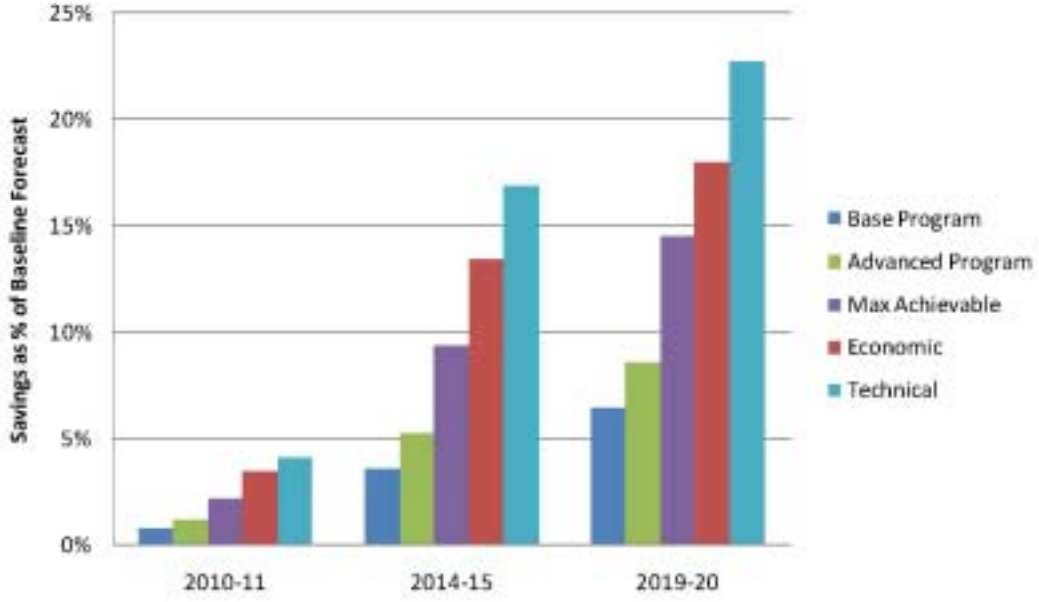

Figure B-6. Cumulative energy savings as a percentage of the baseline forecast.

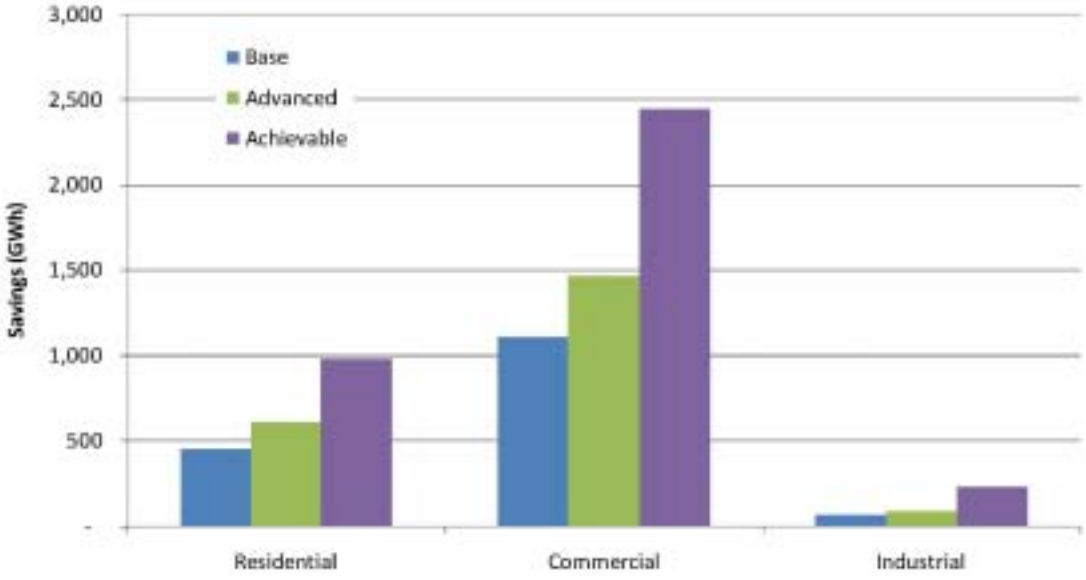

Figure B-7. Cumulative energy savings in GWh.

The Potential Study found that the net present value of avoided energy costs exceeds the NPV of program costs (including incentive payments, administrative costs and customer contributions) in both the Base and Advanced programs. Table B-2 and Figure B-8 illustrate the cost and benefit findings.

AR0070137

Table B-2. Financial Metrics

	Total Savings (GWh)	Total Cost ($Million)	Total Benefits ($Million)	Net Benefits ($Million)	Benefit/ Cost	Cost of Conserved Energy (cents/kWh)
Base Program	18,719	$1,073	$1,092	$18	1.02	5.73
Advanced Program	25,290	$1,411	$1,483	$72	1.05	5.58
Max Achievable	46,209	$2,139	$2,681	$542	1.25	4.63

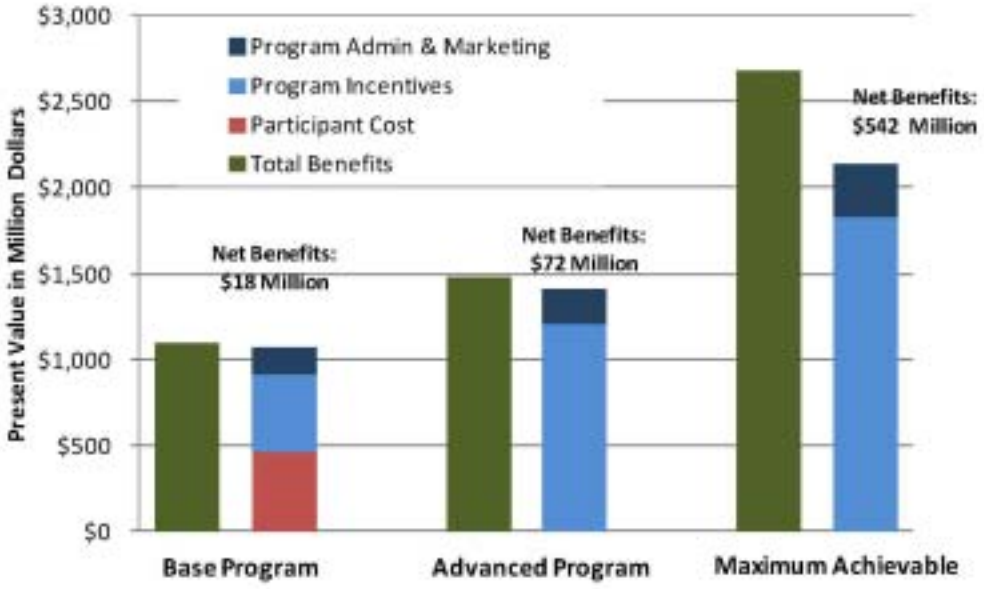

Figure B-8. Cost and benefits for base and advanced programs.

The analysis includes an assessment of the current program portfolio and the development of recommended changes.

Residential Programs

LADWP currently has the following existing residential EE programs:

Consumer Rebate
Refrigerator Turn-In and Recycle
Low Income Refrigerator Exchange
Compact Fluorescent Lamp (CFL) Distribution

AR0070138

The following recommendations resulted from the 2010 potential study:

1. LADWP should keep its existing programs, with the exception of CFL Distribution which should be replaced with a broader lighting initiative adapted to revised lighting standards.
2. Two new programs should be adopted, (1) Low-income, and (2) Whole House Performance.

A continued effort towards public outreach is also recommended to maintain and broaden public awareness of available EE benefits, and to promote participation.

Figure B-9 illustrates potential residential EE program savings for fiscal year 2019-20.

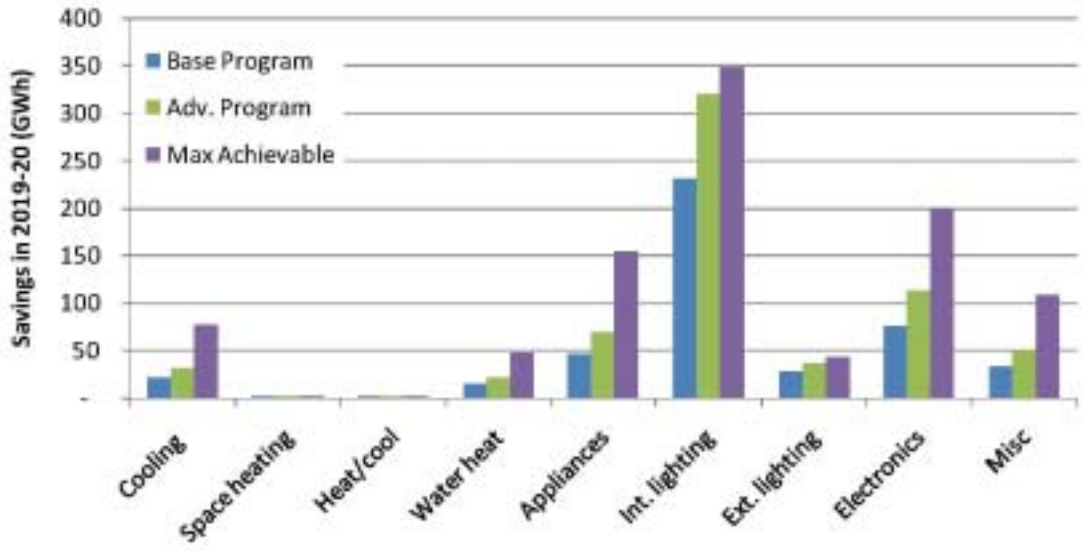

Figure B-9. Potential residential EE program savings in 2019-20.

Commercial and Industrial (C&I)

LADWP currently has the following existing C&I EE programs:

Commercial Lighting Efficiency
Chiller Efficiency
Refrigeration
Customer Performance
Small Business Direct Install
New Construction Incentive
Financing Programs
Energy Audits
Technical Assistance

AR0070139

The following recommendations resulted from the 2010 potential study:

1. LADWP should keep its existing program elements, but should adapt the lighting program to educate customers on the expanded choices in energy efficiency bulbs available that will comply with new lighting standards.

Figures B-10 and B-11 illustrate potential commercial and industrial savings for year 2019-20.

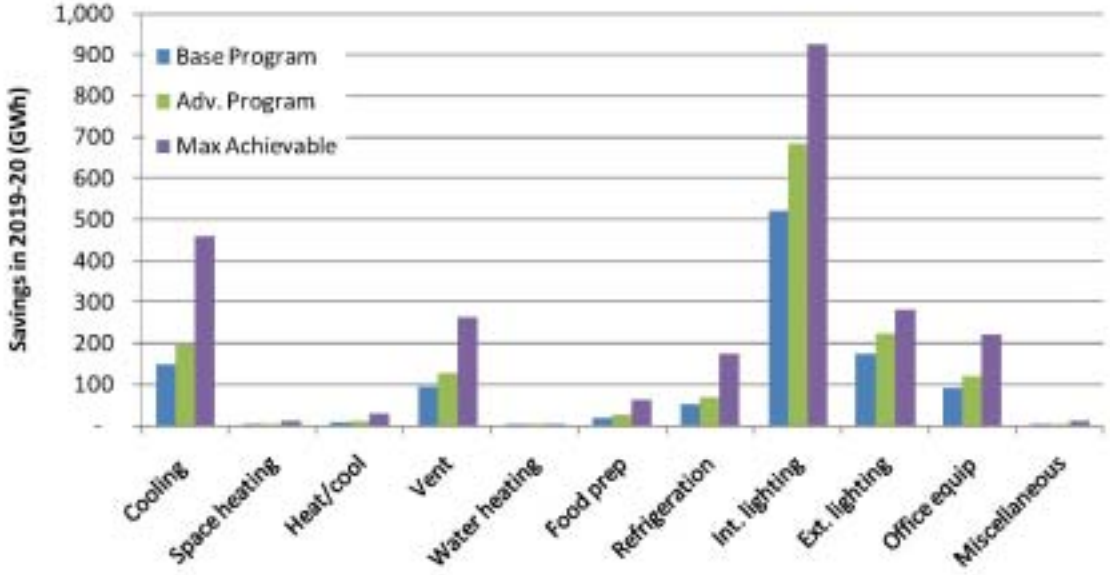

Figure B-10. Projected commercial EE savings in 2019-20.

AR0070140

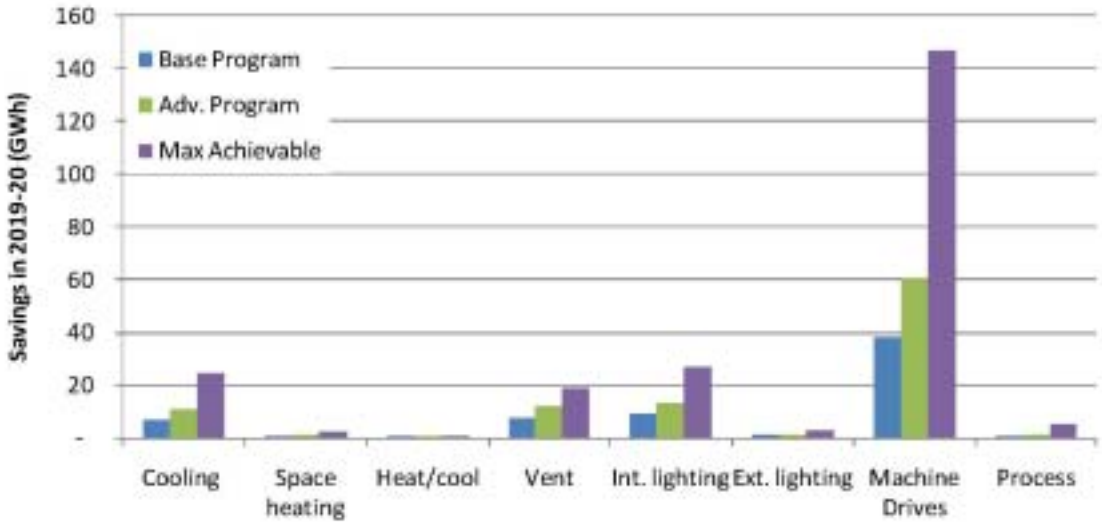

Figure B-11. Projected industrial EE savings in 2019-20.

Appendix C Environmental Issues

C.1 Overview

LADWP's mission includes a role as an environmentally responsible public agency. LADWP continues to develop and implement programs to improve the environment, including:

- Increasing the use of renewable energy to meet the needs of LADWP's customers (20 percent by December 31, 2010 and 33 percent by December 2020 through the development of wind, solar, geothermal, and biomass energy sources and acquiring the associated transmission required to transmit such energy to Los Angeles.
- Prioritizing the use of Energy Efficiency (EE), Demand Side Management (DSM), renewable Distributed Generation (DG), and other renewable resources.
- Continuing the modernization of LADWP's in-basin generating stations, including the repowering of four older, less-efficient utility steam boiler units with advanced gas turbine generating units.

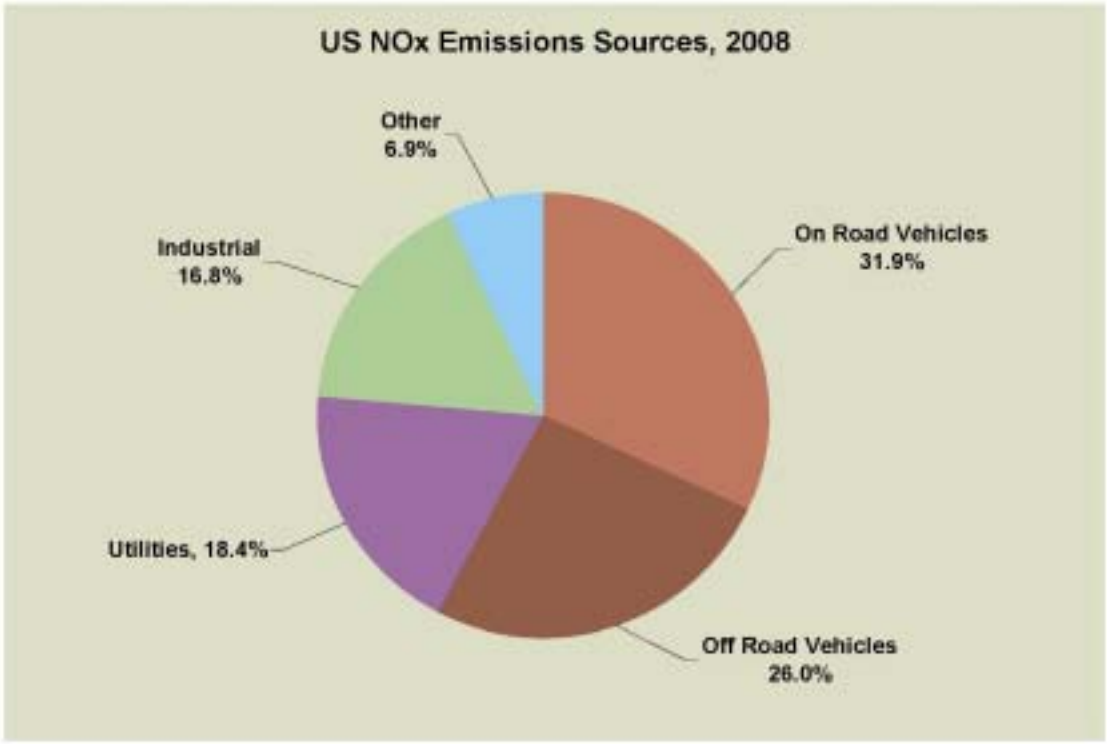
This Appendix provides information on a number of environmental issues and policies including oxides of nitrogen (NO_X) emissions, GHGs and climate change, power plant once-through cooling, (OTC), and mercury emissions.

C.2 Emissions of Oxides of Nitrogen (NO_X)

Oxides of nitrogen, or NO_X, is the generic term for a group of highly reactive gases, all of which contain nitrogen and oxygen in varying amounts. Many of the oxides of nitrogen are colorless and odorless. However, one common pollutant, nitrogen dioxide (NO_2), is a major precursor for "smog," which can be seen as a reddish-brown layer over many urban areas. Oxides of Nitrogen is also a precursor to the formation of ozone, and the South Coast Air Basin (SCAB), in which Los Angeles is situated, has the one of the highest ozone levels in the United States.

NO_X forms when fuel is burned at high temperatures, as in a combustion process. Figure C-1 shows the primary man-made sources of NO_X as reported by the United States Environmental Protection Agency (U.S. EPA) in 2008. The U.S. EPA first set standards for NO_2 in 1971, setting both a primary standard (to protect health) and a secondary standard (to protect the public welfare) at 0.053 parts per million (53 ppb), averaged annually. The Agency has reviewed the standards twice since that time, but chose not to revise the standards at the conclusion of each review. All areas in the U.S. meet the current (1971) NO_2 standards.

AR0070144



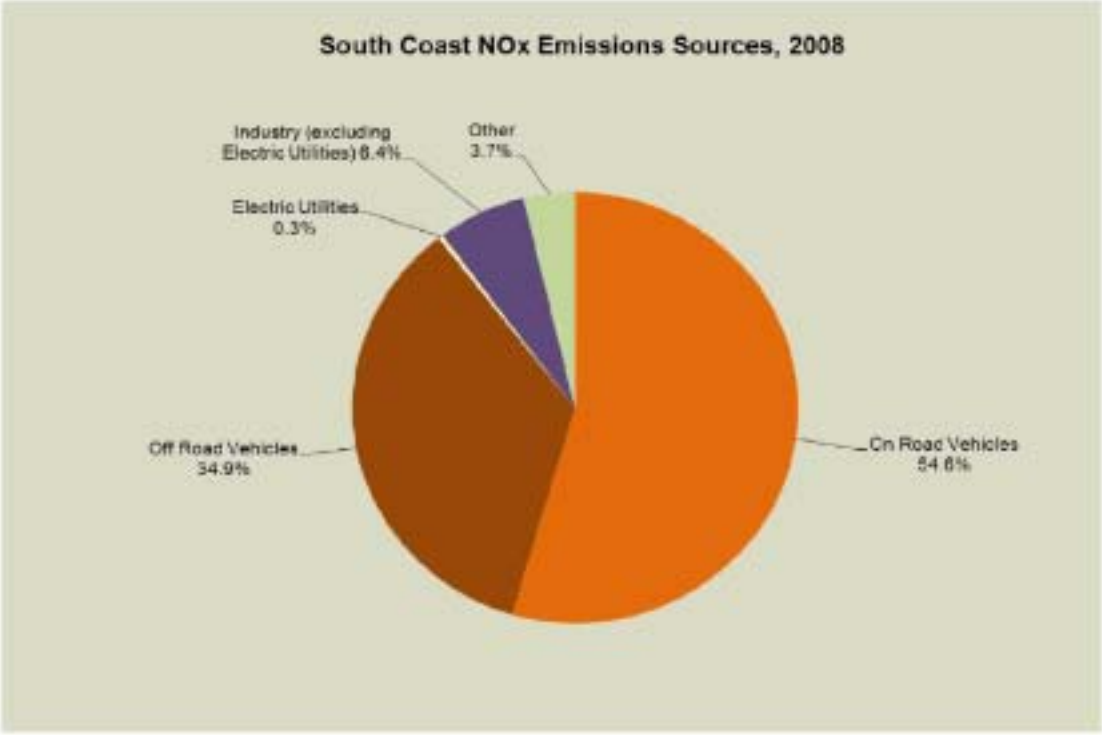
Source: U.S. Environmental Protection Agency

Figure C-1. NO_X emission sources in the U.S.

The SCAB (including Los Angeles, Orange, San Bernardino, and Riverside counties) has some of the worst air quality in the United States due in part to the level of NO_X emissions. The majority of NO_X emissions result from mobile sources such as on-road and off-road vehicles, and not stationary sources such as power plants.

The California Air Resources Board (CARB) estimates in its 2010 Almanac of Emissions and Air Quality that emissions in the SCAB were 742 tons of NO_X per day. This is down from 820 tons per day in 2008 due to additional regulatory requirements for stationary sources, and more efficient cars. CARB projects in their Almanac that SCAB NO_X emissions will continue to decrease from 56 tons per day to 52 tons per day. Figure C-2 shows the estimate 2008 NO_X emission sources.

AR0070145



Source: California Air Resources Board

Figure C-2. Local NO_X sources in 2010.

For comparison, the average daily NO_X emissions from LADWP's in-basin generating stations (Harbor, Haynes, Scattergood, and Valley) combined was 0.65 short tons of NO_X per day in 2008, which represents 0.08 percent of the 2008 average daily NO_X emissions in the South Coast Air Basin. The low NO_X emissions from LADWP's in-basin generating stations are due to the use of natural gas at all facilities and the installation of advanced emissions control systems.

Forecasts project that South Coast Air Basin NO_X emissions will continue to decrease over the next decade. Targets for 2015 are 580 tons per day, while the 2020 target is 468 tons per day. The majority of this reduction is expected to come from a reduction in vehicle emissions; total tons emitted from stationary sources during this time period are only projected to decrease from 56 tons per day to 52 tons per day.

A major tool employed by the SCAQMD to reduce NO_X emissions from stationary sources is the RECLAIM (Regional Clean Air Incentives Market) trading program. RECLAIM is a market-driven regulatory program started in 1994 that superseded the SCAQMD's existing NO_X rules for facilities with NO_X emissions exceeding 4 tons per year. These "command and control" rules limited the emission rates of stationary combustion equipment and have been replaced by a facility-wide emissions cap, which gradually declines each year. Facilities receive emission allocations, called RECLAIM Trading Credits (RTCs), in which one credit grants the right to emit one pound of NO_X. Facilities must have sufficient RTCs in their RECLAIM facility accounts to cover their actual emissions. RECLAIM is a market-driven program because the RTCs can

AR0070146

be bought and sold, which allows for the emissions reductions to be made in the most cost-effective manner.

All of LADWP's in-basin power plants now have advanced pollution control equipment, which reduces NO_X emissions by at least 90 percent. However, the allocation of RTCs to each of LADWP's power plants declines over time, and the entire future allocation of RTCs was reduced about 22.5 percent by the SCAQMD in 2005. Using the resource planning studies and other considerations, the environmental assessment results show that the projections meet LADWP's NO_X goals.

C.3 Greenhouse Gas Emissions and Climate Change

C.3.1 Federal Efforts To Address Climate Change

Federal Climate Change Legislation

Several Congressional bills have been proposed in recent years to regulate GHG emissions under a federal cap-and-trade program, but none have garnered enough support for passage by both the House of Representatives and the Senate. In 2010, focus shifted to the U.S. EPA and the authority it has to regulate GHG emissions under the Clean Air Act (discussed in more details below).

Federal Regulation of Greenhouse Gases Under the Clean Air Act

In the absence of federal legislation, GHG emissions may still be regulated through the U.S. EPA through its authority under the Clean Air Act. In April 2007, the Supreme Court ruled in *Massachusetts v. EPA* that the U.S. EPA must make a determination when it comes to regulating motor vehicle emissions. The Supreme Court ruling gives the U.S. EPA the authority to regulate GHGs under the Clean Air Act for mobile and stationary sources. On December 7, 2009, the U.S. EPA Administrator signed two distinct findings regarding GHGs under section 202(a) of the Clean Air Act:

- Endangerment Finding: The Administrator found that the current and projected concentrations of the six key well-mixed GHGs--carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6)--in the atmosphere threaten the public health and welfare of current and future generations.
- Cause or Contribute Finding: The Administrator found that the combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG emissions which threatens public health and welfare.

In December 2009, U.S. EPA published its findings in the *Federal Register*, stating: "The Administrator finds that greenhouse gases in the atmosphere may reasonably be anticipated both to endanger public health and to endanger public welfare." The impacts of climate change that will cause harm to human health and welfare of current and future generations include but are not limited to: increased drought; more heavy downpours and flooding; more frequent and intense heat waves and wildfires; greater sea level rise; more intense storms; and harm to water resources, agriculture, wildlife, and ecosystems.

AR0070147

EPA Tailoring Rule for Regulating Stationary Sources under the Clean Air Act

The Environmental Protection Agency finalized its "Tailoring Rule," which establishes a phased timetable for implementing Clean Air Act permitting requirements for GHG emissions from large stationary sources. The rule provides that Prevention of Significant Deterioration (PSD) requirements will first apply to GHG emissions effective January 2, 2011. This initial phase will apply to new and modified facilities that would already be required to obtain PSD permits as a result of their non-GHG emissions, and whose construction will result in an increase in GHG emissions of at least 75,000 tons CO_{2e} per year. A second phase of the program will commence on July 1, 2011, and will impose PSD requirements on new facilities that emit at least 100,000 tons CO_{2e} per year, as well as modified facilities whose emissions will increase by at least 75,000 tons CO_{2e} per year. In addition to these PSD requirements, the Tailoring Rule sets comparable emission thresholds and timetables for new and existing facilities to obtain operating permits under Title V of the Clean Air Act. It is anticipated that LADWP's Scattergood generating station will be subject to the new permitting requirements under the EPA's Tailoring Rule.

C.3.2 Western Climate Initiative (WCI)

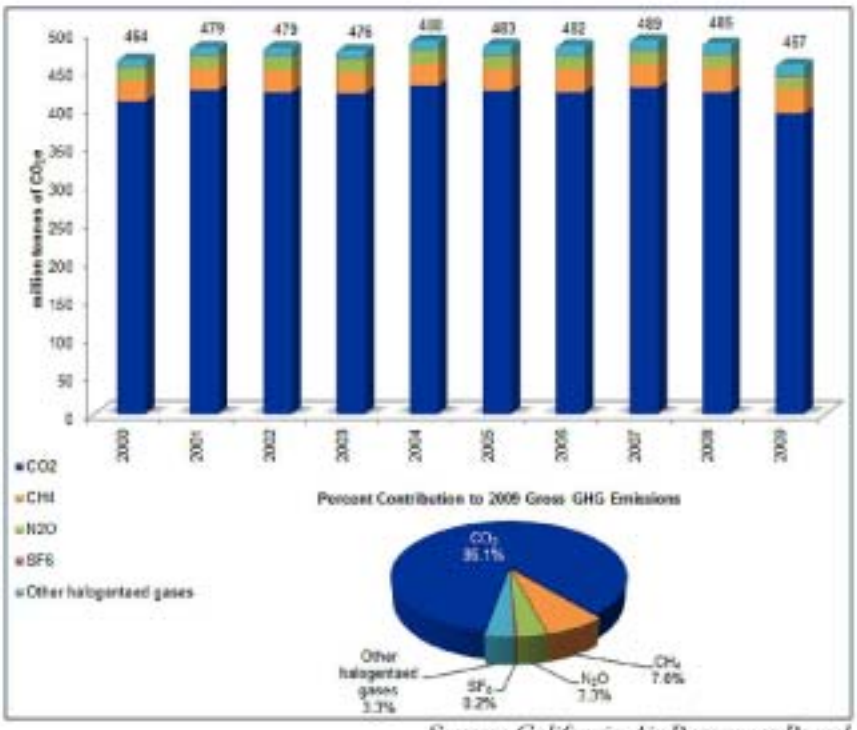
Originally established by the Western Governor's Association in February 2007, the WCI has been reduced to a collaboration of only California and Quebec to reduce GHG emissions 15 percent below 2005 levels by 2020. The primary mechanism for achieving these reductions will be through a regional cap-and-trade program.

CARB is in the process of developing regulations to link California's market with Quebec.

C.3.3 California Efforts to Address Climate Change

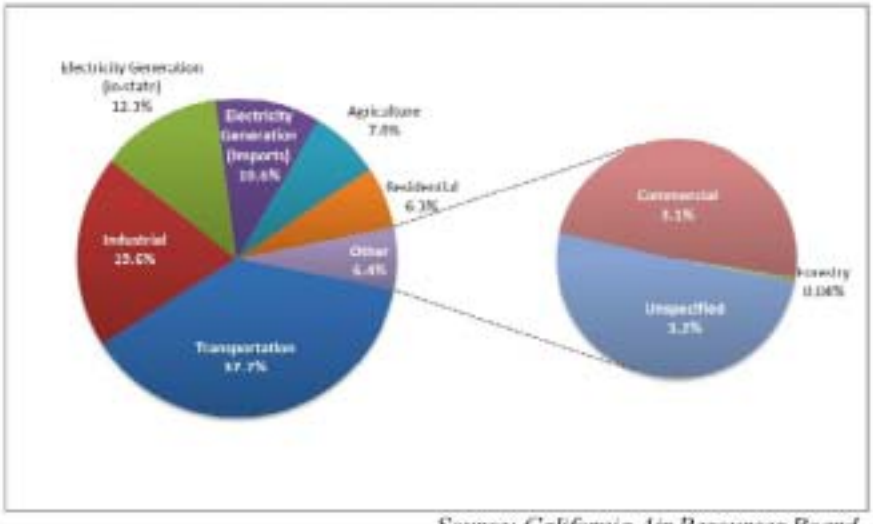
This section presents an overview of the California greenhouse gas emissions inventory and trends from 2000 through 2009. A new edition of California's greenhouse gas emission inventory was released April 6, 2012. It includes emissions estimates for years 2000 to 2009. Figure C-3 depicts the general trend in emissions from 2000 to 2009, and Figure C-4 displays 2009 statewide emissions by economic sector.

AR0070148



Source: California Air Resources Board

Figure C-3. California GHG emissions, 2000-2009.



Source: California Air Resources Board

Figure C-4. 2009 California GHG emissions by Economic Sector.

As California strives to achieve its benchmark goals under AB 32, the California inventory will become an increasingly valuable tool to keep track of greenhouse gas emissions from each sector. Maintaining and updating greenhouse gas inventory methodologies and data are

AR0070149

imperative for a successful greenhouse gas reduction program. In 2009, total California GHG emissions were 457 million tons of carbon dioxide equivalent (MMT CO_2e), net emissions were 453 MMT CO_2e, reflecting the influence of sinks (net CO_2 flux from forestry). While total emissions have increased by 8.8 percent from 1990 to 2009, emissions decreased by 8.8 percent from 2008 to 2009 (185 to 457 MMT CO_2e). The total net emissions between 2000 and 2009 decreased from 459 to 453 MMT CO_2e, representing a 1.3 percent decrease from 2000 and a 6.1 percent increase from the 1990 emissions level. The transportation sector accounted for approximately 38 percent of the total emissions, while the industrial sector accounted for approximately 20 percent. Emissions from electricity generation were about 24 percent with almost equal contributions from in-state and imported electricity.

California Governor's Executive Order S-3-05

On the state level, Governor Schwarzenegger signed Executive Order S-3-05 on June 1, 2005 which established the following GHG targets:

- By 2010, reduce emissions to 2000 levels
- By 2020, reduce emissions to 1990 levels
- By 2050, reduce emissions to 80 percent below 1990 levels

California SB 1368: Greenhouse Gas Emissions Performance Standard

SB 1368 was signed into law on September 29, 2006 and requires the California Public Utilities Commission (CPUC) and the California Energy Commission (CEC) to establish a GHG emissions performance standard and implement regulations for all long-term financial commitments in baseload generation made by load serving entities (LSEs) including local publicly-owned electric utilities (POUs). The CPUC adopted its regulations for the investor-owned utilities and other LSEs in January, 2007. The CEC adopted similar regulations for POUs in August 2007. Strategies implemented by the CPUC and CEC under SB 1368 are expected to result in a combined GHGs emissions reduction of over 15 million metric tons (MMT CO_2e) by 2020. The GHG emissions performance standard is based on the emissions profile of combined-cycle, natural gas fired generating units. The CPUC's regulations establish an emissions performance standard of 1,100 pounds (0.5 metric tons) of CO_2 per megawatt hour (MWh) of electricity. This standard was established in consultation with the CPUC and the CARB and is the same as the emissions performance standard adopted by the CPUC for the LSEs.

The broad objectives of these regulations are to internalize the significant and under-recognized cost of emissions and to reduce potential financial risk to California consumers for future emission control costs. Specifically, these regulations are intended to prohibit any LSE from entering into or renewing a long-term financial commitment for baseload generation that exceeds the GHG emissions performance standard, currently set at 1,100 pounds per MWh.

These regulations would require POU's, within 30 days of making a long-term financial commitment to a baseload facility, to certify to the CEC that such a commitment complies with these regulations and provide back-up material to support such commitment. The

AR0070150

regulations then provide for CEC review of these compliance filings and a determination of whether or not the commitment, and the underlying facility as described in the commitment, complies with these regulations. Additionally, the CPUC may open an investigatory proceeding and gather additional information if it believes that covered procurements made by a POU do not comply with these regulations.

At its December 14, 2011 business meeting, the California Energy Commission granted a Petition to "initiate a new rulemaking proceeding to ensure that the current practices of California POUs meet the requirements of SB 1368 and California's Emissions Performance Standards" specifically as it relates to three coal-fired power plants including the San Juan Generating Station, Navajo Generating Station and the Intermountain Power Project. The Commission directed Commission Staff to prepare an order instituting rulemaking that encompassed the various issues raised by the Petitioners and other stakeholders. At its January 12, 2012 business meeting the Commission adopted an order instituting rulemaking (OIR) 12-01-12-7, which initiated a proceeding to discuss, and if warranted implement possible changes to the EPS regulations.

AB 32: The California Global Warming Solutions Act of 2006

In 2006, the California Legislature passed and Governor Schwarzenegger signed Assembly Bill 32, the Global Warming Solutions Act of 2006, which declared that global warming poses a serious threat to the economic well-being, public health, natural resources, and environment of California. It set into law a 2020 GHG emissions reduction goal that would require the reduction of statewide emissions of GHGs[1]. In 2007, the ARB established a 1990 statewide greenhouse gas emissions baseline of 427 MMT of carbon dioxide equivalent (CO_2)[2] and adopted a regulation for mandatory emissions reporting from the most significant sources that contribute to statewide emissions, including all electricity consumed in the state as well as imported electricity. The 2020 target was set at the 1990 baseline level of 427 MMT CO_{2e}.

The AB 32 Scoping Plan

In December 2008, the CARB adopted the AB 32 Scoping Plan, which serves as California's blueprint for reducing greenhouse GHG emissions. Key elements of the AB 32 Scoping Plan's recommendations for reducing California GHG emissions to 1990 levels by 2020 include:

- Expanding and strengthening existing energy efficiency programs as well as building and appliance standards
- Achieving a statewide renewables energy mix of 33 percent.
- Developing a California cap-and-trade program that links with other Western Climate Initiative partner programs to create a regional market system
- Expand use of Combined Heat and Power (CHP) by 30,000 GWh statewide

[1] GHGs covered by AB 32 include the following: carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

[2] Carbon dioxide equivalent or CO_{2e} means the amount of carbon dioxide by weight that would produce the same global warming impact as a given weight of another greenhouse gas, based on the best available science, including from the Intergovernmental Panel on Climate Change.

AR0070151

- Establishing targets for transportation-related GHG emissions for regions throughout California and pursuing policies and incentives to achieve those targets
- Adopting and implementing measures pursuant to existing State laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard
- Creating targeted fees, including a public goods charge on water use, fees on high global warming potential gases, and a fee to fund the administrative costs of the state's long term commitment to AB 32 implementation

All programs developed under AB 32 contribute to the reductions needed to achieve this goal, and will deliver an overall 15% reduction in greenhouse gas emissions compared to the "business-as-usual" scenario in 2020 if nothing was done at all. In 2010, the ARB made revisions to the expected 2020 emission reductions in consideration of the economic recession and the availability of updated information from development of measure-specific regulations. ARB staff re-evaluated the baseline in light of the economic downturn and updated the projected 2020 emissions to 545 MMTCO$_2$e. Two reduction measures (Pavley I and the Renewables Portfolio Standard (12% → 20%)) not previously included in the 2008 Scoping Plan baseline were incorporated into the updated baseline, further reducing the 2020 statewide emissions projection to 507 MMTCO$_2$e. The updated forecast of 507 MMTCO$_2$e is referred to as the AB 32 2020 baseline. Reduction of an estimated 80 MMTCO$_2$e are necessary to reduce statewide emissions to the AB 32 Target of 427 MMTCO$_2$e by 2020.

Executive Order S-21-09

On September 15, 2009, Governor Schwarzenegger signed Executive Order S-21-09, which, among other things, ordered CARB to work with the Commissions to ensure that a regulation adopted under authority of AB 32 to encourage the creation and use of renewable energy sources shall build upon the RPS program developed to reduce GHG emissions in California and shall regulate all California publicly owned utilities, like LADWP. In addition, Executive Order S-21-09 provides that CARB may delegate policy development and implementation to Commissions, that CARB is to consult with the CAISO and other balancing authorities on impacts on reliability, renewable integration requirements and interactions with wholesale power markets in carrying out the provisions of Executive Order S-21-09, and that CARB is to establish the highest priority for those resources with the least environmental costs and impacts on public health that can be developed most quickly and that support reliable, efficient, and cost-effective electricity system operations including resources and facilities located throughout the Western Interconnection.

AB 32 Cap-and-Trade Regulation (Adopted October 20, 2011)

The cap-and-trade program is a key element in California's climate plan. The cap-and-trade program sets a statewide limit on sources responsible for 85 percent of California's greenhouse gas emissions, and establishes a price signal needed to drive long-term investment in cleaner fuels and more efficient use of energy. The program is designed to provide covered entities the flexibility to seek out and implement the lowest-cost options to reduce emissions. The program covers about 350 businesses, representing 600 facilities and it starts in 2013 for electric utilities and large industrial facilities, while distributors of transportation, natural gas and other fuels join in 2015. The ARB expects to link with Quebec in 2013.

AR0070152

Although the program commenced on January 1, 2012, the enforceable compliance obligation starts with the 2013 GHG emissions. The first auction of California carbon allowances occurred in November 2012.

Combined Heat and Power

Assembly Bill 1613 (Blakeslee, 2007) as amended by AB 2791 (Blakeslee, 2008), created the Waste Heat and Carbon Emissions Reduction Act of 2007, which requires among other things that a local publicly owned electric utility serving retail end-use customers to establish a program that allows retail end-use customers to utilize combined heat and power (CHP) systems that reduce emissions of greenhouse gases by achieving improved efficiencies utilizing heat that would otherwise be wasted in separate energy applications and that provides a market for the purchase of excess electricity generated by a combined heat and power system, at a just and reasonable rate, to be determined by the governing body of the utility. LADWP is in compliance with this requirement as it offers a Standard Energy Credit for distributed generation, including CHP.

As part of the ARB's 2008 Climate Change Scoping Plan, a CHP measure was included that calls for 4,000 MW of new CHP capacity that would result in an estimated reduction of 6.7 million metric tons of annual GHG emission reductions and displace 30,000 GWh of electricity demand by 2020. Governor Brown's Clean Energy Jobs Plan includes a target of 6,500 MW of additional installed CHP capacity over the next 20 years. Faced with the slow development of new CHP in California, the Energy Commission updated its CHP market assessment to update the potential for new CHP and to understand the amount of new CHP that current policy may provide, and the emissions reductions gained from old, retiring CHP and its associated capacity. Understanding the full range of opportunities, motivations, policy successes, and remaining regulatory barriers for CHP across industrial, commercial, and residential sectors will help determine where the opportunities for development of new facilities are the greatest. This information will be used to develop policies and regulations to encourage CHP and support the state's GHG emissions reduction goals.

The California Energy Commission provided an update in February 2012 for a CHP Market Assessment that was originally conducted in 2009. Market penetration estimates of CHP were presented for three market development scenarios — a Base Case reflecting continuation of existing state policies and two additional cases (Medium and High) that show the market impacts of additional CHP policy actions and incentives. The CEC's report suggests that the cumulative statewide market penetration for the base case is 1,888 MW, down from 2,998 MW as originally projected in 2009. The 2012 market scenarios, in general, show lower cumulative market penetration than the 2009 scenarios. The Base Case results show that, under the current policy landscape, CHP will fall short of the ARB Scoping Plan market penetration target. The report suggests that "additional policy measures, represented in the Medium and High Cases, are needed to raise market penetration up to the Scoping Plan target." The updated 2012 assessment suggests that the LADWP service territory's share of new CHP under the base case market penetration scenario is 15 percent overall. The assessment suggested a range for LADWP's new

AR0070153

CHP capacity (MW) starting with the base case at 224 MW by 2020 increasing to 281 MW by 2030, up to the high case of 557 MW by 2020 increasing up to 698 MW.[3]

C.3.4 LADWP's Efforts To Address Climate Change

Since 1998, LADWP has taken steps to move away from dependence on coal generating resources, including the divestiture of power purchase agreements with Colstrip and Coronado Generating Stations, the shutdown of Mohave Generating Station in December 2005, and the discontinuation of involvement in the development of Unit 3 at Intermountain Generating Station. Table C-1 shows the downward trajectory in LADWP's power generation portfolio CO_2 emissions and CO_2 emissions intensity between 1990 and 2011.

Table C-1. HISTORICAL LADWP POWER GENERATION CO_2 EMISSIONS

Year	Total CO_2 Emissions from Owned & Purchased Generation (metric tons)	Total CO_2 Emissions from Owned & Purchased Generation minus Wholesale Power Sales (metric tons)	Total Owned & Purchased Generation (MWh)	LADWP System CO_2 Intensity Metric (lbs CO_2/MWh)
1990	17,925,410	17,764,874	25,481,532	1,551
2000	18,464,480	16,992,238	28,806,750	1,413
2001	18,086,034	16,663,305	28,032,375	1,422
2002	16,873,841	16,237,832	26,808,569	1,388
2003	17,274,623	16,710,232	27,337,694	1,393
2004	17,609,759	16,604,943	28,138,391	1,380
2005	16,928,681	15,854,278	28,301,700	1,319
2006	16,838,147	15,885,136	29,029,883	1,279
2007	16,461,774	15,523,035	29,141,703	1,245
2008	16,232,608	15,650,115	29,394,809	1,217
2009	14,646,410	13,829,395	28,041,998	1,151
2010	13,771,186	12,844,288	27,490,878	1,104
2011	14,169,324	13,631,178	27,025,925	1,156
Difference between 1990 and 2011	-3,756,086	-4,133,696	1,544,393	-395
% Change from 1990	-21%	-23%	6%	-25%

Notes:
1. Calculated CO_2 emissions for specified sources using fuel data and fuel-specific emission factors from 40 CFR Part 98 Subpart C Table C-1..
2. Calculated CO2 emissions for unspecified power purchases using MWh purchased x default emission factor (1,100 lbs CO_2/MWh).

[3] California Energy Commission, "Consultant Report: Combined Heat and Power: Policy Analysis and 2011-2030 Market Assessment," ICF Consulting, February 2012, Publication No. CEC, 200-2012-002, Appendix D.

AR0070154

SF6 Emissions

In February 2010, CARB adopted a new regulation to reduce SF6 emissions from gas insulated electrical switchgear as part of the AB 32 program. This new regulation imposes a declining limit on a utility's annual average SF6 emissions rate starting at 10 percent in 2011 and decreasing to 1 percent in 2020, as well as new recordkeeping and reporting requirements.

Over the past decade, LADWP has been proactive in reducing SF6 emissions by implementing its own internal program to reduce emissions through equipment replacement, repair, and process improvements. This voluntary effort to reduce SF6 emissions demonstrates LADWP's commitment to environmental stewardship and puts LADWP in a good position to comply with the new emission limits imposed by the SF6 regulation.

C.4 Power Plant Once-Through Cooling Water Systems

Power plants with "once-through cooling" (OTC) systems draw or take in water from coastal/estuarine water, via intake pipes, to cool turbines used to generate electricity. After the water is used for cooling it is discharged to a nearby water body. OTC systems can impact the marine environment.

LADWP has three coastal generating plants that utilize OTC. The new state wide OTC Policy and upcoming 316 b Federal Rule requires minimizing and/or reducing the impacts on marine life.

In order to reduce these impacts, LADWP has committed to completely eliminate OTC by replacing it with closed cycle cooling to comply with the Statewide OTC policy and upcoming Federal rule.

In addition, LADWP has already implemented the following:

- In the 1970's LADWP installed a velocity cap (a large disk-shaped structure just upstream of the ocean water intake pipe) at its Scattergood Generating Station to control IM. In 2006, LADWP conducted an effectiveness study on its velocity cap and the results showed that it is 96% effective.

- To date, LADWP has reduced the number of power plant units that utilize OTC from 14 to 9, reducing ocean water use from 1904 MGD to 1571 MGD, an overall reduction of ocean water usage by 17%.

- LADWP has spent over $600 million dollars to replace the older generating units with more efficient generating units (known as "repowering") at its Haynes and Harbor Generating Stations. This has resulted in a reduced use of coastal waters.

AR0070155

To further reduce impacts and completely eliminate OTC, LADWP plans to do the following:

- By 2013, the Haynes 5&6 repowering project will be completed, reducing the number of OTC units to 7. This will decrease ocean water use from 1571 MGD to 1110.2 MGD, an overall reduction of 43% from 1990 ocean water usage levels.

- By 2015, the Scattergood 3 repowering project will be completed, further reducing the number of OTC units to 6 and decreasing ocean water use from 1110.2 MGD to 839.8MGD, an overall reduction of 56% from 1990 ocean water usage levels.

- By 2020, the Scattergood 1&2 repowering project will be completed, further reducing the number of OTC units to 4 and decreasing ocean water use from 839.8 MGD to 563.3MGD, an overall reduction of 70% from 1990 ocean water usage levels.

- By 2024, the Haynes 1&2 repowering project will be completed, further reducing the number of OTC units to 2 and decreasing ocean water use from 563.3 MGD to 338.7 MGD, an overall reduction of 82% from 1990 ocean water usage levels.

- By 2026 the Harbor 5 repowering project will be completed, further reducing the number of OTC units to 1 and decreasing ocean water use from 338.7 MGD to 230 MGD, an overall reduction of 87% from 1990 ocean water usage levels.

- By 2029, the final repowering project, Haynes Unit 8 will be completed, reducing the number of OTC units to 0, resulting in 100% elimination of OTC.

Figure C-5 shows LADWP's reduction in OTC usage from 1990 to 2029.

AR0070156

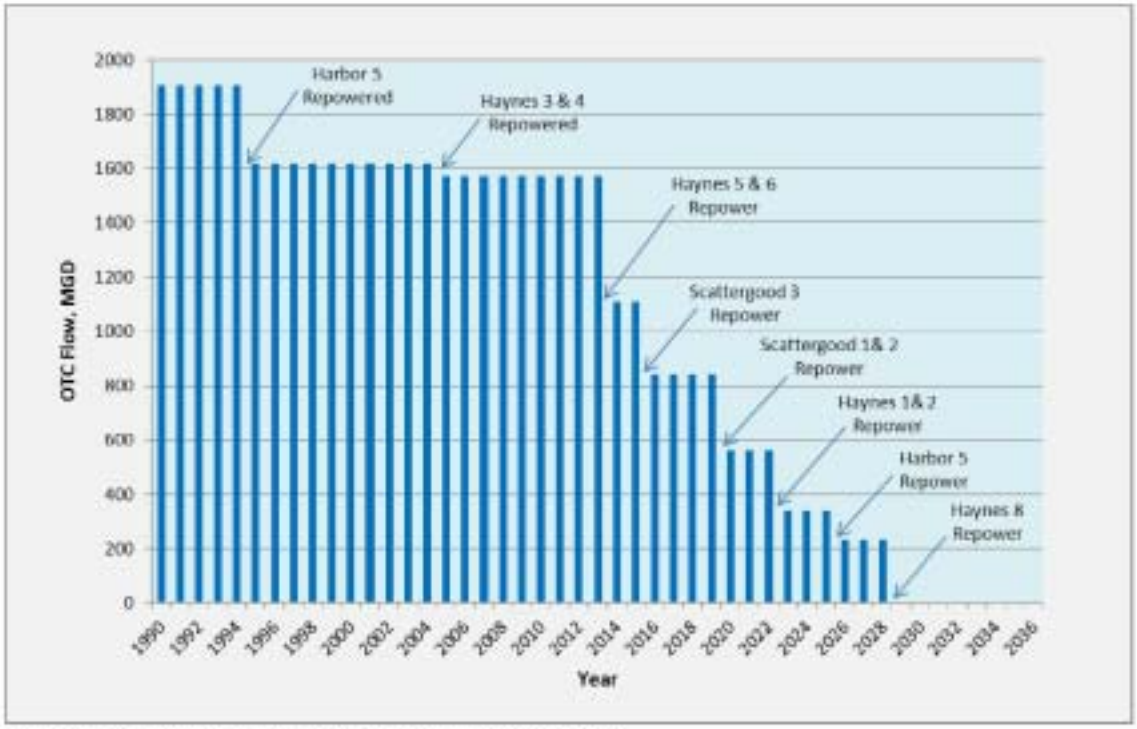


Figure C-5: LADWP OTC reduction from 1990 to 2029.

AR0070157

C.4.1 USEPA 316(b) Requirements for Cooling Water Intake Structures

EPA's Clean Water Act Section 316(b) Phase II Cooling Water Intake Structure Rule (Rule) released in 2004 was subsequently challenged and ultimately heard in both the Second Circuit Court and in the U.S. Supreme Court. The Second Circuit Court issued its decision on January 25, 2007, and determined that the restoration and cost-benefit elements of the original 2004 Rule were unlawful and that other fundamental components of the 2004 Rule, such as the impact reduction performance standards attainable for certain technologies, were to be remanded for further evaluation and demonstration by U.S. EPA. The U.S. Supreme Court was subsequently asked to weigh in on the ability to use the "wholly disproportionate" cost-benefit test in the application of the 316(b) regulations. On April 1, 2009, the Supreme Court affirmed that a cost-benefit analysis can be used by regulatory agencies. While the various challenges proceeded through the court processes, U.S. EPA gave the states permission to continue with implementation and enforcement of the Clean Water Act 316 (b) requirements using "Best Professional Judgment (BPJ) when reauthorizing facility National Pollutant Discharge Elimination System (NPDES) permits.

During this period, LADWP completed the required Characterization Study to identify baseline biological impacts in order to determine an appropriate impingement mortality (IM) and entrainment (E) reduction method. However, when the Rule was remanded to U.S. EPA to re-study and then re-propose a rule, it essentially remanded the Rule and placed the fulfillment of its associated requirements on hold. At that point, LADWP stopped any further work necessary to comply with the suspended Rule and has been awaiting the outcome of U.S. EPA's effort to re-propose a new rule. The UP EPA publicly noticed the new proposed rule for existing facilities on April 19, 2011 and the comment period ended on August 18, 2011. The US EPA is under a settlement agreement with the Riverkeeper to have a final rule by no later than July 2012. In the meantime, EPA has given the State Permitting Authorities permission to continue with the regulation of Section 316 B with the use of BPJ.

C.4.2 SWRCB 316(b) Requirements for Cooling Water Intake Structures

On June 30, 2009, the SWRCB released its draft Once-Through Cooling Water Policy for public review and comment, with the accompanying Supplemental Environmental Document released on July 14, 2009. Comments were due September 30, 2009. Subsequent policy drafts were issued on November 23, 2009 and March 22, 2010 with corresponding comment periods. The final Policy version was adopted on May 4, 2010 and became effective on October 1, 2010. The adopted Policy has major implications for the coastal power plants making it extremely difficult to continue the use of OTC retrofitted with IM and E impact control technology; making the use of cooling towers the only certain compliance path. The Policy proposes a two-track compliance pathway. Track I requires OTC flows to be reduced commensurate with wet closed cycle cooling (CCC) or a 93 percent flow reduction and essentially requires the installation of cooling towers. If Track I can be demonstrated as "not feasible" a Track II compliance option is available. A Track II compliance pathway requires the biological impacts to be reduced on a unit by unit basis to a level comparable with (i.e., within 10 percent) what would exist with CCC. New consecutive 36-month IM and E baseline studies will be required if a Track II compliance pathway is pursued. Until compliance is achieved, interim measures are required, which include flow reductions when

AR0070158

there is no unit load and mitigation measures (commencing five years from the effective date of the policy and continuing until the facility is in full compliance). Lastly, to prevent disruption in the state's electrical power supply during implementation of the Policy, a committee of state energy and resource agencies known as the Statewide Advisory Committee on Cooling Water Intake Structures (SACCWIS) will assist the SWRCB in reviewing the required utility implementation plans along with the annual grid reliability studies in order to monitor any grid reliability impacts and schedules.

LADWP's implementation plan was the first plan to be reviewed by the SWRCB and SACCWIS. As a result, the SWRCB prepared and adopted an Amendment to the Policy on July 19, 2011. This Amendment modified LADWP's compliance schedule on a unit-by-unit basis with the following compliance dates ::12/31/2013 for Haynes Units 5&6; 12/31/2015 for Scattergood Unit 3; 12/31/2024 for Scattergood Units 1&2; 12/31/2029 for Haynes Units 1&2 and 8, and Harbor Unit 5. In addition, the Amendment requires LADWP to submit any additional information requested, by January 1, 2012, by the SACCWIS and submit the information responsive to SACCWIS to the SWRCB by December 31, 2012 in order for the SWRCB to evaluate whether further modifications to the dates are necessary. Furthermore, LADWP must commit to complete elimination of OTC and in the interim must prepare a mitigation plan and fund projects to offset impacts until each unit is fully compliant. In addition, LADWP must conduct a study or studies, singularly or jointly with other facilities, to evaluate new technologies or improve existing technologies to reduce impingement and entrainment, submit the results of the study and a proposal to minimize entrainment and impingement to the Chief Deputy Director no later than December 31, 2015, and upon approval of the proposal by the Chief Deputy Director, complete implementation of the proposal no later than December 31, 2020. LADWP is in the process of developing its mitigation plan and commencing the alternative technologies studies. The Haynes Units 5&6 repowering project has broken ground and is in its construction phase in order to meet the 2013 deadline. Also, the conceptual planning and design for the Scattergood Unit 3 project has commenced in order to meet the 2015 deadline.

C.5 Mercury Emissions

Mercury (Hg) emissions are an issue for all coal fired power plants. However, the level of such emissions varies widely based on the type of coal burned and the type of emission controls on the plants.

Coal-burning power plants are the largest human-caused source of Hg emissions to the air in the United States, accounting for over 50 percent of all domestic human-caused Hg emissions (Source: 2005 National Emissions Inventory). The EPA estimates that less than ½ of all Hg deposited within the U.S. comes from U.S. sources.

The IGS in Utah, of which LADWP is the Operating Agent, has one of the lowest mercury emission rates in the country. This is due to the fact that the existing emission control devices, which are designed to reduce sulfur dioxide and particulate matter, have the co-benefit of removing about 96 percent of the mercury from bituminous coal which is burned at IGS.

On March 15, 2005 U.S. EPA promulgated the Clean Air Mercury Rule (CAMR), which established a nationwide cap-and-trade program for mercury emissions. CAMR was designed to

AR0070159

reduce mercury emissions by 60 percent between 2010 and 2018. Several legal challenges of the CAMR ensued. As a result, the D.C. Circuit vacated U.S. EPA's Clean Air Mercury Rule on February 18, 2008. On May 3, 2011, EPA proposed NESHAPs for coal- and oil-fired EGUs under Clean Air Act (CAA) section 112(d) and proposed revised NSPS for fossil fuel-fired EGUs under CAA section 111(b). The proposed NESHAP would protect air quality and promote public health by reducing emissions of the hazardous air pollutants (HAP) listed in CAA section 112(b). In addition, these proposed amendments to the NSPS are in response to a voluntary remand of a final rule. EPA finalized its rule in December 2011.

C.6 Coal Combustion Residuals

On May 4, 2010, the U.S. Environmental Protection Agency released pre-publication co-proposals to regulate the management of coal ash from coal-fired power plants.

Coal combustion residuals (CCRs), commonly known as coal ash, are byproducts of the combustion of coal at power plants and are typically disposed of in liquid form at large surface impoundments and in solid form at landfills, most often on the properties of power plants. There are almost 900 landfills and surface impoundments nationwide.

Due to the metal constituents of the CCRs, EPA's co-proposals will establish control measures, such as liners and groundwater monitoring, which would be in place at new landfills to protect groundwater and human health. Existing surface impoundments would also require liners, with incentives to close the impoundments and transition to landfills, which store coal ash in dry form.

The proposed regulations may change the way CCRs are handled and stored at Intermountain Power Plant and Navajo generating station. If implemented, the rules would require the phase-out of wet handling systems and surface impoundments of bottom ash and the subsequent permitting and installation of lining under fly ash landfills. The facilities would have to conduct additional groundwater monitoring, and provide closure and post-closure care of the surface impoundments and landfills. For Mohave generating station, the rules, as proposed are expected to have minimal impacts because the facility did not operate any surface impoundment.

AR0070160

Appendix D Renewable Portfolio Standard

D.1 Overview

LADWP has historically maintained that its major objectives concerning integrated resource planning are; (1) providing reliable service to its customers; (2) remaining committed to environmental leadership; and (3) maintaining a competitive price.

Since its 2007 IRP, LADWP has made great strides towards achieving the 2010 goal of increasing its supply of electricity from "eligible" renewable resources to 20 percent, measured by the amount of electric energy sales to retail customers, and has met the 20 percent goal for calendar year 2010.

On April 12, 2011, the California governor signed into law the Senate Bill 2 (1X) which extends the 20 percent target to 2013, and ramps up the target to 25 percent by December 31, 2016 and 33 percent by December 31, 2020.

On December 6, 2011, the LADWP Board approved the Renewables Portfolio Standard Policy and Enforcement Program and is included in Reference D-1 and D-2.

This 2012 IRP documents how LADWP expects to maintain 20 percent renewable energy and describes the process for LADWP's continuing commitment to increase the renewable energy goal to 25 percent by 2016 and 33 percent by 2020. Additionally, LADWP will continue to encourage voluntary contributions from customers to fund renewable resources above the stated Renewable Portfolio Standard (RPS) goal, as part of its Green Power for a Green LA Program (GREEN).

D.2 Renewable Energy Requests for Proposals (RFPs)

To help meet the renewable energy goals for the GREEN Program and the RPS policy, LADWP has issued four major Request for Proposals (RFP) for renewable energy projects: January 2001, June 2004, January 2007, and March 2009. LADWP performed detailed technical and economic analysis of the proposals on a least-cost, best-fit basis. This approach considered factors such as cost, technical feasibility, project status, transmission issues, and environmental impact.

Separately, the Southern California Public Power Authority (SCPPA), of which LADWP is a member, has issued five RFPs for renewable energy projects.

D.2.1 2001 Renewable RFP

In response to the 2001 RFP, a total of 21 projects were proposed. The 120 megawatts (MW) Pine Tree wind project met LADWP's renewable, economic, technical and least-cost, best fit criteria. The Pine Tree wind project is an eighty turbine wind farm facility located in the

AR0070162

Tehachapi area, and is owned and operated by LADWP. This project was put in-service in June 2009.

The Pine Tree wind farm was expanded with ten new wind turbines that added 15 MW, for a total of 135 MW. The expansion was completed in 2011.

D.2.2 2004 LADWP Renewable RFP and the 2005 SCPPA Renewable RFP

In June 2004, LADWP issued another RFP with the intent of securing an increased portion of its power requirements from renewable resources. The goal of LADWP's 2004 RFP was to obtain about 1,300 gigawatts hours (GWhs) per year of renewable energy per year to meet the then RPS interim goal of 13 percent by 2010. A total of 57 distinct proposals were received, covering nearly all types of renewables, although wind and geothermal represented the largest share of proposed energy. Most of the proposals were from new California projects, with only a few actually located in Los Angeles. The proposals offered a mix of power purchase and ownership options.

To ensure fairness and consistency during the evaluation process of the 2004 RFP, the evaluation team included two independent entities. The team evaluated proposals through a structured process consisting of two phases. The Phase 1 evaluation included completeness and requirements screening, a technical and commercial evaluation, and an economic assessment. Proposals short-listed were then evaluated in greater detail in the Phase 2 evaluation, which included a comparison of Net Levelized Cost (NLC). The NLC of each proposal equals the levelized busbar cost of energy, in units of $/MWh, less the avoided energy and capacity costs, and adding the levelized transmission costs to cover wheeling, losses, transmission upgrades, etc.

In 2005, the Southern California Public Power Agency (SCPPA), of which LADWP is a participant, also issued an RFP for renewable resources.

Five contracts for renewable energy resulting from the 2004 and 2005 RFPs have been entered into, which provide 1,179 GWhs/yr of renewable energy from landfills, small hydro and wind.

D.2.3 2006 SCPPA and 2007 LADWP Renewable RFPs

In 2006 SCPPA issued an RFP for renewable resources, in which LADWP participated.

In January 2007, LADWP issued another RFP with the intent of obtaining approximately 2,200 GWhs of renewable energy per year to meet the RPS goal of 20 percent by 2010. A total of 59 distinct proposals were received, covering wind, solar thermal, solar photovoltaic (PV), geothermal, and biomass renewable technologies. The proposals offered a mix of power purchase and ownership options.

Three contracts for renewable energy resulting from the 2006 and 2007 RFPs have been entered into, which provide 424 GWhs/yr of renewable energy from wind and small hydro projects. Several other proposals that were received are currently being negotiated.

AR0070163

D.2.4 2008 SCPPA and 2009 LADWP Renewable RFPs

In 2008 SCPPA issued an RFP for renewable resources, in which LADWP participated.

In March, 2009, LADWP issued a fourth RFP for Renewable Resources. The intent of this RFP was to obtain a sufficient amount of renewable energy per year to achieve the RPS goals, set by the Mayor, of 20 percent by 2010 and 35 percent by December, 31, 2020.

The 2008 RFP process resulted in two contracts, which provide 834 GWhs/yr of renewable energy from wind resources. Several other proposals that were received are currently being negotiated.

D.2.5 2011 SCPPA RFP

In January 2011, the Southern California Public Power Agency (SCPPA) also issued an RFP for renewable resources, in which LADWP participated. LADWP participated in the evaluations of the RFP proposals. LADWP evaluated proposals through a structured process. The evaluation included a completeness and requirements screening, a technical and commercial evaluation, and an evaluation of deliverability of the product. The evaluation also considered the Net Levelized Cost (NLC) for each proposal. The NLC of each proposal is equal to the levelized busbar cost of energy, in units of $/MWh, less the avoided energy and capacity costs, and adding the delivery cost to LADWP's load. Other factors were also considered, including: compliance with pending State renewable portfolio standard legislation, utility scale project experience, capacity, commercial operation date, and labor issues.

In August 2011, SCPPA issued another RFP for renewable resources. The response deadline is November 30, 2012.

D.3 Renewable Project Strategy

LADWP (and SCPPA) has increased its renewable energy through successful project development and completed agreement negotiations with multiple developers and project entities resulting from the above described RFPs. Existing renewable projects that supply LADWP are geographically diverse; wind energy comes from the ridges of the California Tehachapi Mountains, the north-central hills of Oregon, the southern Washington Columbia River Gorge area, the Milford Valley of Utah, and Southwestern Wyoming. Planning for future renewable energy will continue to emphasize geographic diversity, as well as technology diversity.

The variety of renewable energy projects and technologies facilitates the Power System capability to integrate renewable energy reliably. As described in other sections of the IRP, LADWP will maintain its Balancing Authority responsibility by addressing system issues such as reserve sharing, reserve commitments, system voltage support, spinning reserves, existing and future quick response combustion turbine units, etc.

This IRP describes several fundamental principles for the RPS progression from the current 20 percent renewable energy to a potentially higher goal of 33 percent by 2020. Issues and principles affecting the future of the RPS plans are discussed below:

AR0070164

D.3.1 Issues

- The "Ramp Rate", i.e., the annual rate of progress from 20 percent to 33 percent renewables, will be subject to several factors. The time frame is 10 years, which would equate to a constant ramp of 1.33 percent per year. However, the projected ramp rate is not a straight line, but rather varies from year to year depending on factors both external and internal to the LADWP. These factors include SB 2 (1X) requirements, LADWP fiscal constraints, renewable energy technology improvement over time, renewable energy pricing, LADWP system integration limits, and transmission constraints, both in the LADWP systems and regionally.

- Steady investment in renewable resources is required to maintain a 20 percent RPS between 2010 and 2012 and to ramp to 33 percent between 2013 and 2020. There are several reasons for this path forward: Between 2010 and 2012, the projects maintaining the 20 percent RPS will become fully integrated into the system; reflecting 2010 economic conditions and allowing time for pricing adjustments and efficiencies of certain renewable industries such as solar PV to reach the marketplace. For budgeting and planning purposes, the assumed RPS implementation strategy is 1 percent annual RPS increases from 2013 thru 2015 and 2 percent from 2016 thru 2020. Of course, all of this strategy is dependent on adequate funding.

- Transmission limitations in several regions are constraining development activities. These constraints are being studied at regional, statewide, and Western Electricity Coordinating Council (WECC) levels and potential federal and state legislative actions will affect transmission availability. Further resource decisions are dependent on transmission availability and cost.

- Greenhouse Gas (GHG) and other climate change regulatory and legislative issues are pending. The eventual cap and trade methodology and market mechanisms that are implemented will influence RPS strategic and tactical decisions.

- Within the overall RPS plan, decisions as to specific projects, technologies, operational strategies, and project financial structures, will be made as the marketplace and regulatory environment change.

D.3.2 Principles

Future renewable projects will be strategically obtained with the following principles.

1. Geographic diversity is important to maintain and enhance power system reliability.

2. The use of existing LADWP assets such as transmission lines, land, and existing generation resources should be maximized.

AR0070165

3. Pursue multi-faceted development with adequate back-up strategies to handle project delays, project failures, reduced generation output, and operation or maintenance impacts.

4. Projects shall be targeted to specifically meet the Power System/Renewables Policy objectives.

5. Flexible RPS goals will be established to address the variable nature of renewable energy while conforming to applicable state and federal requirements

6. Ownership, operation, and maintenance are core objectives to maintain power system reliability and cost stability. The Power System is interested in owning projects that are based on proven technology.

7. Operation and maintenance (O&M) management is a key criterion in clustering renewable projects. Keeping projects in close proximity would reduce O&M costs due to economies of scale and personnel efficiencies.

D.3.3 Balancing Renewable Resources

Several of these principles may be overlapping or even conflicting. For example, clustering of renewable projects would decrease O&M expenditures, but too many projects in an area will not meet the needs for geographic diversity. Also, ownership goals may impact project costs and immediate availability. Obtaining tax credits and/or grants may necessitate the need for developers to own a project for a certain number of years (typically 7-10 years) to capture tax advantages; thereby lowering the ultimate cost to LADWP.

Subject to further studies, given the wind and solar projects coming on-line, limitations on the percentage of intermittent resources may be required. There may be more stringent limitation in certain resource areas, or along certain transmission systems. It is possible that no more than 15-20 percent intermittent energy can be ultimately integrated in the current electric grid. Of the 20 percent renewable energy consumed in 2010, less than $1/5^{th}$ of that amount was of an intermittent type. Most renewable resources are either small hydro or biogas having a predictable energy pattern or wind projects that have their energy output firmed and shaped by outside balancing authorities before delivery to LADWP. The total amount of intermittent energy obtained will not be increased beyond current levels unless studies demonstrate that these resources can be reliably integrated.

Wind, as shown elsewhere in this IRP, is a volatile renewable energy resource. It is recommended that LADWP's wind forecasting tools and meteorological analysis capabilities be enhanced to provide efficient integration of wind energy.

Similar studies will be required for solar projects coming on line in the next few years, and limitations of the percentage of solar will be required. Photovoltaic solar systems can have dramatic voltage changes, resulting from passing cloud cover and/or storms. Large installations of solar PV will likely need to be limited in size within a geographical area, unless it is coupled with solar thermal systems or energy storage systems.

AR0070166

The renewable energy mix of 2011 is shown on Figure D-1

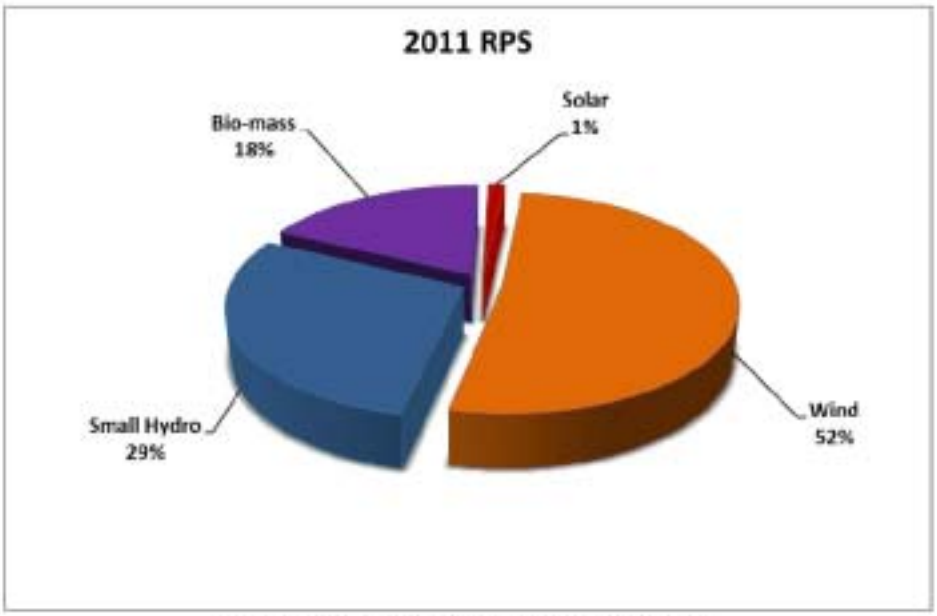

Figure D-1: 2011 Renewable Energy Mix

D.3.4 Impacts of CA Senate Bill SB 2 (1X)

On April 12, 2011, Governor Edmund G. Brown Jr. signed into law the California Renewable Energy Resources Act (herein referred to as "Act" or "SB 2 (1X)"). This Act sets new Renewable Portfolio Standard (RPS) procurement targets, new renewable resource eligibility definitions, and new reporting requirements applicable to Publicly Owned Electric Utilities (POUs). SB 2 (1X) became effective December 10, 2011, 90 days after the end of the special session in which it was enacted.

This bill expresses the intent that the amount of electricity generated from eligible renewable energy resources be increased to an amount that equals at least 20% of the total electricity sold to retail customers in California by December 31, 2013, 25% by December 31, 2016 and 33% by December 31, 2020. In addition, this bill requires POU governing boards to adopt a policy with similar goals imposed on IOUs to enforce the RPS Program on its respective utility.

According to the legislation, POU governing boards were directed to adopt "a program for the enforcement of this article" by January 1, 2012. As such, POU governing boards have discretion to interpret the following provisions:

- Procurement Target Goals
- Reasonable Progress to achieve such goals
- Procurement Requirements
- Rules to apply excess procurement for future compliance periods
- Conditions that allow for delaying timely compliance

AR0070167

- Cost limitations for procurement expenditures.

Resources obtained in compliance with SB 2 (1X) must meet the following criteria:

Category (aka "Buckets")	Percentage of RPS Target
1. Either: Have a first point of interconnection with a California balancing authority, have a first point of interconnection with distribution facilities used to serve end users within a California balancing authority area, or are scheduled from the eligible renewable energy resource into a California balancing authority without substituting electricity from another source [PUC Section 399.16(b)(1)(A)]. Or, have an agreement to dynamically transfer electricity to a California balancing authority. [PUC Section 399.16(b)(1)(B)]	**Compliance Period 1 (2011-2013):** 50% of RPS minimum from this category. **Compliance Period 2 (2014-2016):** 65% of RPS minimum from this category. **Compliance Period 3 (2017 to 2020):** 75% of RPS minimum from this category. **Post – 2020** 75% of RPS minimum from this category.
2. Firmed and shaped eligible renewable energy resource electricity products providing incremental electricity and scheduled into a California balancing authority. [PUC Section 399.16(b)(2)]	Shall be calculated as the remainder of resources which are not in either Category 1 or Category 3.
3. Eligible renewable energy resource electricity products or any fraction of the electricity generated, including unbundled RECs that do not qualify under Bucket 1 or 2. [PUC Section 399.16(b)(3)]	**Compliance Period 1 (2011-2013):** 25% of RPS maximum from this category. **Compliance Period 2 (2014-2016):** 15% of RPS maximum from this category. **Compliance Period 3 (2017 to 2020):** 10% of RPS maximum from this category. **Post – 2020** 10% of RPS minimum from this category.

The regulations promulgating this legislation by the CEC over POUs were finalized. The Fourth Edition Renewable Energy Program Overall Program Guidebook and the Fifth Edition Renewable Portfolio Standard Eligibility Guidebook were adopted by the CEC on May 9, 2012.

D.3.5 Renewable Energy Credits

The Public Utilities Code Section 399.12 (h) defines a Renewable Energy Credit (REC) as "a certificate of proof, issued through the accounting system established by the California Energy Commission…that one unit of electricity was generated and delivered by an eligible renewable energy resource." RECs include all renewable and environmental attributes, including avoided greenhouse-gas (GHG) attributes, associated with the production of electricity from the eligible renewable energy resource.

The primary method of renewable energy resource procurement will be through the development and acquisition of physical generation assets and energy purchase contracts, in which LADWP

AR0070168

will acquire the "renewable energy credit" (REC) from the renewable resource "bundled" with the associated energy.

In order for RPS compliance targets to be managed effectively, LADWP may buy, sell, or trade RECs without the associated energy (unbundled). This procurement approach will be limited by the percentage requirements established by PUC Section 399.16(b)(3), and as described in the City of Los Angeles Department of Water and Power Renewable Portfolio Standard Policy and Enforcement Program, as amended on December 2011.

AR0070169

D.4 Transmission of Renewable Energy

California and many of the western states contain a variety of resources (wind, solar, geothermal, and other "eligible" resources previously defined in the RPS Policy) that can be developed to ultimately generate electricity. However, the current transmission system was not primarily designed with these natural resources in mind.

Even with the substantial existing transmission system owned by LADWP, and the other transmissions systems in California, there is only a limited amount of transmission lines to many of the potential renewable resource locations. In order to gain access to these sources of renewable energy, LADWP is planning on building additional transmission lines and expanding the capabilities of several existing lines, and utilizing transmission lines as part of renewable purchase power agreements. These projects include:

1. Barren Ridge Renewable Transmission Project (BRRTP) - Transmission access and transmission line upgrades are needed to accommodate proposed wind projects in the Tehachapi area and solar thermal projects in the Mojave Desert, which total nearly 1,000 MW. The initial project was the construction of the Barren Ridge substation which supports the 135 MW Pine Tree Wind project. This substation interconnects with LADWP's existing 230 kV Inyo-Rinaldi transmission line (which was built to gain access to the renewable hydro-generated energy from LADWP's aqueduct system in the Owens Valley). The Inyo-Rinaldi transmission capacity needs to be increased in order to accommodate additional renewable energy projects. A full Environmental Impact Report (EIR) process is currently underway on this project.
2. Related to the BRRTP project, the potential Owens Valley Solar projects may require further upgrades to the Inyo-Barren Ridge segment of this transmission line and a generation tie-line into the project area. Depending on ultimate solar build-out in the Owens Valley, additional new transmission may be required.
3. The joint Southern California Edison/Imperial Irrigation District upgrade of Path 42 is critical for delivery of renewable generation from the IID area into the California ISO. Upgrading Path 42 requires improvements to facilities under the control of SCE and the California ISO as well as facilities under IID control. The IID upgrades consist of replacing the 220 kV circuits between the Coachella Valley Substation and the Mirage Substation with bundled circuits, two conductors per circuit. The IID portion of the upgrades would increase the capacity of IID's portion of the path by around 800 MW. The total renewable potential for the California ISO/IID Path 42 upgrades is approximately 1,400 MW.

AR0070170

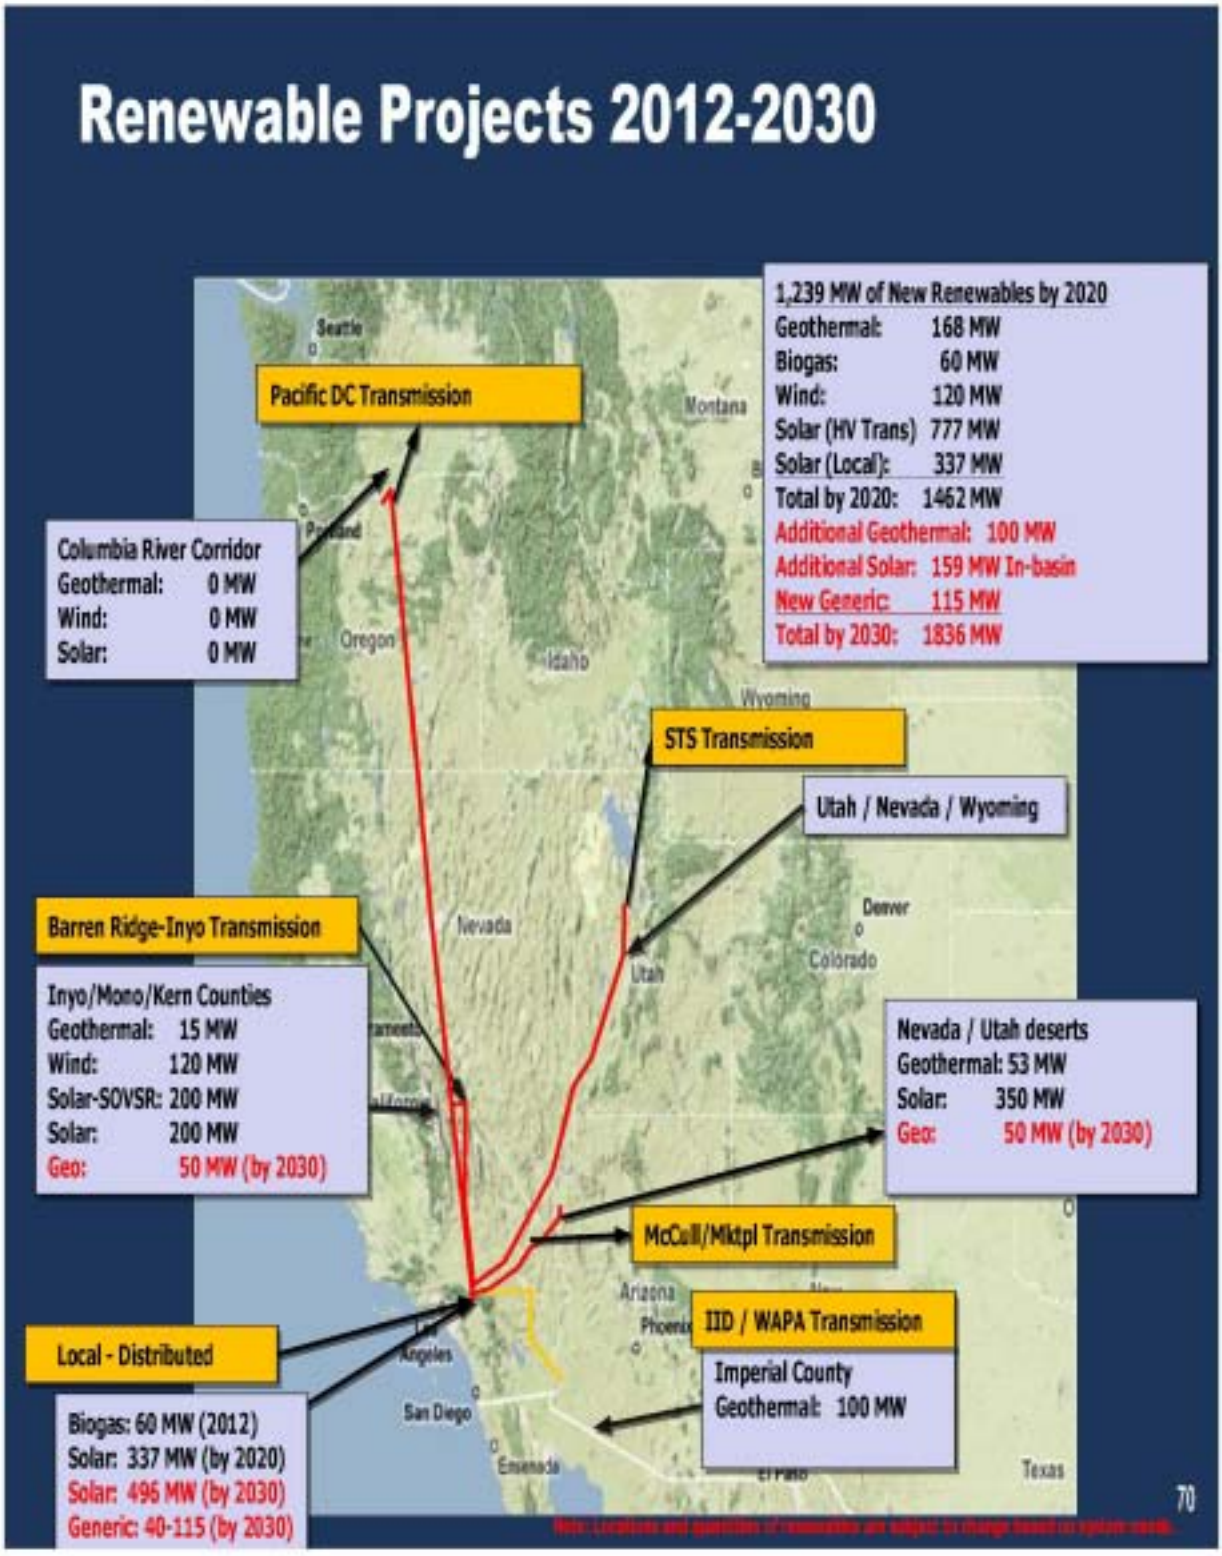

Figure D-2: Renewable Transmission Paths and Potential Resources, 2010 - 2030

AR0070171

D.5 Funding the RPS

For LADWP to develop a responsible and prudent renewable energy policy, it must balance environmental objectives such as fuel diversity, energy efficiency and clean air against its core responsibility to provide and distribute safe, reliable, and low-cost energy to its customers. That means developing a RPS that ensures LADWP's continued financial integrity and striving to mitigate the financial impact on retail customers.

The financial impact of meeting a 33 percent RPS goal will vary depending on the mix of resource types and associated costs. Generally, renewable energy costs more than traditional energy sources such as natural gas and coal. However, a diversified energy portfolio, including a larger mix of renewables, may also reduce the risk of price spikes due to fuel supply shortages.

Estimated RPS revenue requirements to comply with SB 2 (1X) compliance targets of 25 percent renewable in 2016 and 33 percent in 2020 are shown in Figure D-3. Revenues required for an additional 4000 GWh annually for 2020 and beyond will require increasing annual renewable portfolio costs from 387 million to 848 million over the next 9 years.

During the early years of the RPS program, low cost, small hydro resources and biogas comprised the bulk of the portfolio with relatively higher cost wind energy being recently introduced over the last several years. Going forward, higher cost resources such as solar, geothermal, and wind must be used to comply with RPS standards as other lower cost alternatives have been largely exhausted. As can be seen in Figure D-4, contracts for renewable projects totaling 548 GWh or 12 percent of the renewable energy supply will expire over the next 4 years and will need to be replaced with higher cost renewable resources. Maintaining the current 20 percent RPS will require additional revenue to compensate for these higher cost replacement resources.

AR0070172

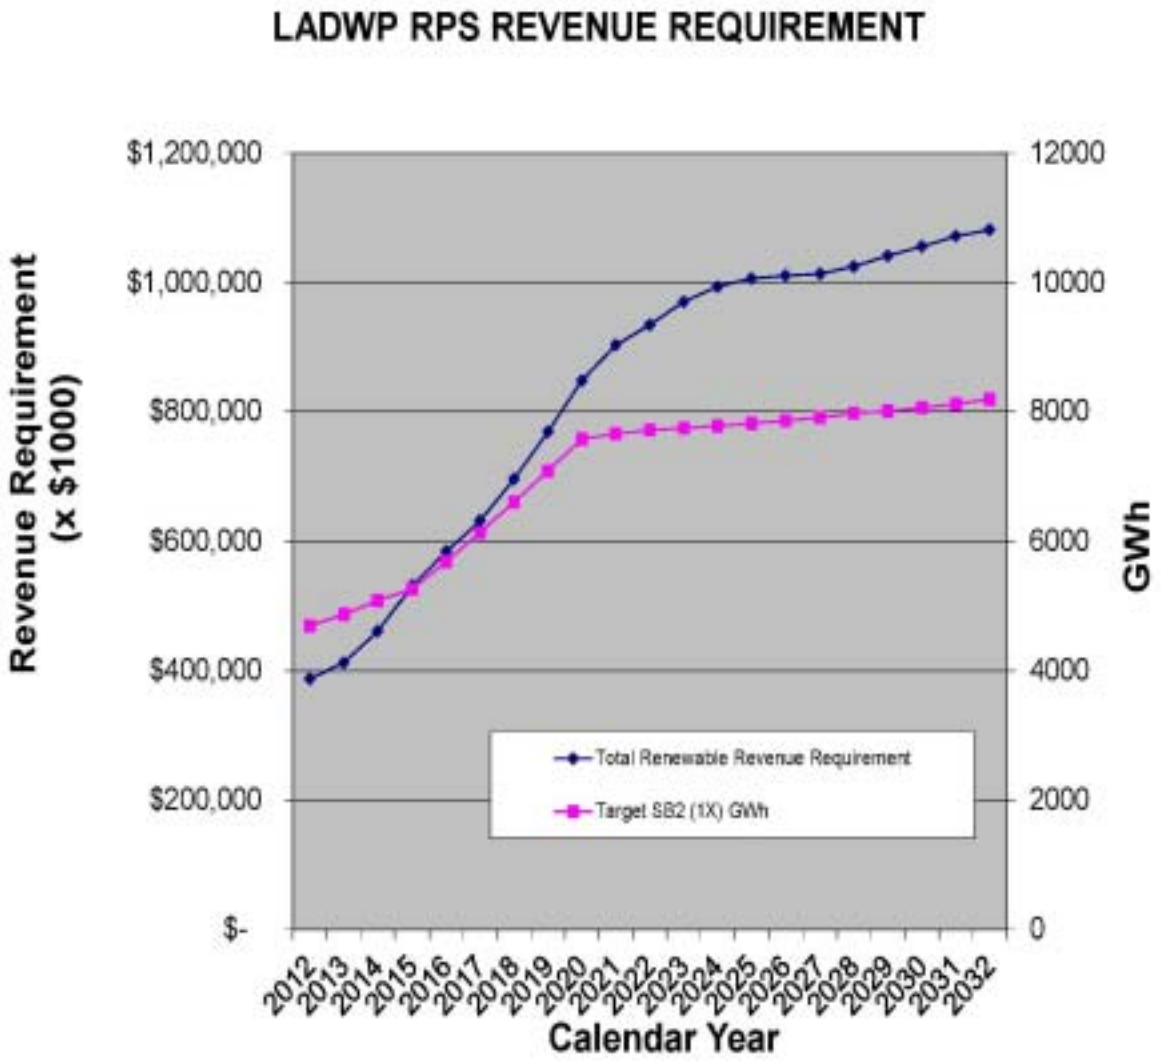

Figure D-3 – LADWP RPS Revenue Requirement 2012-2030.

AR0070173

	2012	2013	2014	2015	2016	2017	2018	2019	2020

Figure D-4. LADWP RPS supply and goals for 2011-2020.

D.6 Other LADWP Renewable Projects

LADWP has several additional projects that are in various stages of development. LADWP also has short-listed additional renewable energy projects that have been offered in response to past LADWP's Request for Proposal (RFPs) or SCPPA RFPs. These short-listed projects and other proposals from upcoming RFP's will be used to select future projects, subject to the criteria enumerated within this section.

The eligibility of wind, solar, and geothermal projects to count toward renewable energy targets is well understood. LADWP has also procured biogas and is considering the use of certain types of biomass. Energy generated from this category is RPS-eligible.

AR0070174

D.6.1 Biogas and Biomethane

Biogas continues to be one of the few renewable energy resources available that provides dispatch and base load characteristics, which effectively makes it a reliable and predictable renewable energy resource. Biogas is also needed to support other renewable resources that have low capacity factor characteristics, such as wind and solar. By capturing biogas for the use of electricity generation rather than flaring it and creating a secondary source of greenhouse gas emissions, utilities are clearly reducing the total amount of greenhouse gases emitted. Furthermore, by injecting biogas into the existing natural gas pipeline system, utilities are effectively offsetting the cost of building additional unnecessary infrastructure to supply biomethane to California.

The current California Energy Commission (CEC) Overall Program Guidebook of May, 2012 defines biogas as "includes digester gas, landfill gas, and any gas derived from an eligible biomass feedstock", and biomethane or pipeline biomethane as "biogas that has been upgraded or otherwise conditioned such that it meets the gas quality standards applicable to the natural gas transportation pipeline system into which the biogas is first accepted for transportation."

Digester gas is typically derived from the anaerobic digestion of agricultural or human or animal waste and biomass is typically defined as any organic material not derived from fossil fuels, including agricultural crops, agricultural wastes and residues, waste pallets, crates, dunnage, manufacturing, construction wood wastes, landscape and right-of-way tree trimmings, mill residues that result from milling lumber, rangeland maintenance residues, biosolids, sludge derived from organic matter, and wood and wood waste from timbering operations. The CEC also considers landfill gas (LFG) - gas produced by the breakdown of organic matter in a landfill - a renewable fuel.

In keeping with capturing the intent of the California legislature to increase use of renewable fuels, the LADWP amended its RPS policy when the CEC issued its third edition of the Guidebook in January 2008. Language from the then CEC Guidebook stated, "RPS-eligible biogas (gas derived from RPS-eligible fuel such as biomass or digester gas) injected into a natural gas transportation pipeline system and delivered into California for use in an RPS-certified multi-fuel facility may result in the generation of RPS-eligible electricity."

The LADWP's gas-fired generating units capable of burning a mixture of biogas/biomethane and conventional natural gas fall under the CEC multi-fuel designation. The CEC Guidebook stated, "…only the renewable portion of generation will count as RPS eligible, and only when the Energy Commission approves a method to measure the renewable portion."

Pursuant to the CEC Guidebook, the LADWP calculates the amount of RPS-eligible electricity produced at its gas-fired generating units by multiplying the total generation of the facility by the ratio of the quantity of biogas used to the quantity of total gas used by the facility. Both the energy generated and the quantity of gas used must be measured on a monthly basis.

The LADWP currently produces RPS-eligible energy derived from biogas/biomass. Digester gas produced at the Hyperion Wastewater Treatment facility is piped to the adjacent Scattergood Generating Station, where it is used to produce RPS-eligible energy. Additionally, the LADWP

AR0070175

procures biogas/biomass-derived renewable energy via gas-fired microturbines located at several landfills throughout Los Angeles.

The LADWP currently holds contracts with developers to purchase pipeline biomethane. Under these contracts, the LADWP obtains LFG from several landfill sites located outside California. LFG produced by the landfills is scrubbed and filtered to pipeline grade and injected into the interstate natural gas pipeline system for delivery to the LADWP's most efficient gas-fired generating units.

In its latest edition of the RPS Eligibility Guidebook (5th Edition)[1], the CEC has noted that it has suspended the RPS eligibility related to biogas and put certain conditions of suspension and eligibility limitations in place, as described in Resolution No. 12-0328-3[2]. The suspension, which took effect on March 28, 2012, was adopted by the CEC Commissioners to provide the CEC staff with additional time to evaluate issues surrounding the continued eligibility of biomethane as a result of changes in law under SB 2 (1X). The suspension will remain in effect until the Energy Commission takes subsequent action to lift the suspension.

The California Legislature is currently proposing legislation that will revise the current eligibility requirements of biogas for entities who procured this resource prior to the effective date of the suspension. If legislation is executed, the CEC will subsequently modify its RPS Eligibility Guidebook to comply with such new requirements pertaining to the eligibility of Biogas.

D.6.2 Municipal Solid Waste

- The current CEC criteria sets forth several conditions for RPS-eligibility of municipal solid waste (MSW) conversion facilities: The facility uses a two-step process to create energy whereby in the first step (gasification conversion) a non-combustion thermal process that consumes no excess oxygen is used to convert MSW into a clean burning fuel, and then in the second step this clean-burning fuel is used to generate electricity. The facility and conversion technology must meet certain criteria which include the following:
- The technology does not use air or oxygen in the conversion process, except ambient air to maintain temperature control.
- The technology produces no discharges of air contaminants or emissions, including greenhouse gases as defined in Section 42801.1 of the Health and Safety Code.
- The technology produces no discharges to surface or groundwaters of the state.
- The technology produces no hazardous wastes.
- To the maximum extent feasible, the technology removes all recyclable materials and marketable green waste compostable materials from the solid waste stream before the conversion process, and the owner of operator of the facility certifies that those materials

[2] Notice of Correction to Resolution on Suspension of the RPS Eligibility Guideline related to Biomethane, issued April 5, 2012. Available at: http://www.energy.ca.gov/portfolio/notices/2012-04-05_Notice_of_Correction_to_Resolution_on_Suspension_Biomethane_TN-64618.pdf

AR0070176

will be recycled or composted

The facility certifies that any local agency sending solid waste to the facility diverted at least 30 percent of all solid waste it collects through solid waste reduction, recycling, and composting

The LADWP currently does not procure energy from any MSW combustion or conversion facilities, but may consider projects that meet all CEC criteria.

AR0070177

D.7 Power Content Label

In 1997, Senate Bill 1305 was approved, which required Energy Service Providers (ESP) to report to their customers information about the resources that are used to generate the energy that they sell. A form, called the Power Content Label, would be used for this purpose, which would also provide a common reporting method to be used by all ESPs.

In addition, the 2002 Senate Bill 1078 established California's Renewable Portfolio Standard (RPS) which included both a requirement for electric utilities to report annually to their customers the resource mix used to serve its customers by fuel type, and to report annually to its customers the expenditures of public goods funds used for public purpose programs. The report should contain the contribution of each type of renewable energy resource with separate categories for those fuels considered eligible renewable energy resources, and the total percentage of eligible renewable resources that are used to serve the customers' energy needs.

LADWP's 2011 Power Content Label is shown in Table D-1. As LADWP has two separate renewable programs, the RPS policy and GREEN, both of these programs are reported on the Power Content Label.

Table D-1: LADWP's 2011 Power Content Label

POWER CONTENT LABEL

Annual Report of Actual Electricity Purchases for LADWP
Calendar Year 2011

ENERGY RESOURCES	LADWP Power ACTUAL MIX	LADWP Green Power ACTUAL MIX	2011 CA POWER MIX** (for comparison)
Eligible Renewable * **	**19%**	**100%**	**14%**
-- Biomass & waste	3%	0%	2%
-- Geothermal	0%	0%	5%
-- Small hydroelectric	6%	0%	2%
-- Solar	0%	0%	0%
-- Wind	10%	100%	5%
Coal	41%	0%	8%
Large Hydroelectric	3%	0%	13%
Natural Gas	17%	0%	37%
Nuclear	11%	0%	16%
Other	0%	0%	0%
Unspecified sources of power*	**9%**	**0%**	**12%**
TOTAL	**100%**	**100%**	**100%**

* "Unspecified sources of power" means electricity from transactions that are not traceable to specific generation sources.

** Percentages are estimated annually by the California Energy Commission based on the electricity sold to California consumers during the previous year.

*** This is in accordance with Los Angeles City Council's action on 10-5-04 for File No. 03-2688 (RPS)

For specific information about this electricity product, contact LADWP at 1-800-DIAL-DWP. For general information about the Power Content Label, contact the California Energy Commission at 1-800-555-7794 or www.energy.ca.gov/consumer.

AR0070178

Reference D-1 – LADWP Renewables Portfolio Standard Policy and Enforcement Program Amended December 2011 - Board Resolution:

WHEREAS in August 2000, the Board of Water and Power Commissioners (Board) approved a resolution that authorized the Los Angeles Department of Water and Power (LADWP) to adopt an Integrated Resource Plan that established a goal of meeting 50 percent of projected load growth through a combination of Demand-Side-Management, Distributed Generation, and Renewable Resources; and

WHEREAS in 2002, the California Legislature passed Senate Bill 1078 that established the California Renewables Portfolio Standard (RPS), and a goal for all investor-owned utilities to increase their use of renewable resources by at least 1 percent per year, until 20 percent of their retail sales were procured from renewables by 2017; and

WHEREAS publicly-owned utilities like LADWP were exempt from California Senate Bill 1078, however they were encouraged to establish renewable resource goals consistent with the intent of the California Legislature; and

WHEREAS on June 29, 2004, the Los Angeles City Council adopted a LADWP RPS Framework and requested that the Board establish a RPS Policy, including achieving "20 percent renewable energy by 2017" and "incorporating this RPS into all future energy system planning"; and

WHEREAS on October 15, 2004, the Los Angeles City Council adopted a resolution approving the inclusion of existing LADWP hydroelectric generation units greater than 30 megawatts in size, excluding the Hoover hydroelectric plant, as part of the City's RPS list of eligible resources; and

WHEREAS on June 29, 2005, the Los Angeles City Council approved LADWP's Renewables Portfolio Standard Policy, which was designed to increase the amount of energy LADWP generated from renewable power sources to 20 percent of its energy sales to retail customers by 2017, with an interim goal of 13 percent by 2010; and

WHEREAS in December of 2005, the Board recommended that LADWP accelerate the RPS goal to obtain 20 percent renewables by 2010, which recommendation included updating LADWP's Integrated Resource Plan to include this goal, proceeding with the negotiation and contract development for renewable resources proposed and selected in LADWP's 2004 RPS and Southern California Public Power Authority 2005 RPS, supporting the cost of accelerating the RPS, and maintaining the financial integrity of LADWP's Power System during times of natural gas price volatility; and

WHEREAS on April 11, 2007, the Board amended LADWP's RPS Policy by advancing the date of the goal that required 20 percent of energy sales to retail customers be

AR0070179

generated from renewable resources to December 31, 2010 and by establishing renewable energy procurement ownership targets and

WHEREAS, on May 20, 2008 the Board approved an amended RPS Policy, which included an additional RPS goal that required 35 percent of energy sales to retail customers be generated from renewable resources by December 31, 2020, expanded the list of eligible renewable resources, and provided new energy delivery criteria, and

WHEREAS, the California Renewable Energy Resources Act will become effective on December 10, 2011, and requires the governing board of a local publicly owned electric utility such as LADWP to adopt a program for enforcement, in accordance with Public Utilities Code Section 399.30(e), by January 1, 2012.

NOW THEREFORE BE IT RESOLVED that the Board of Water and Power Commissioners of the City of Los Angeles hereby adopts the Renewables Portfolio Standard Policy and Enforcement Program Amended December 2011, approved as to form and legality by the City Attorney, and on file with the Secretary of the Board.

I HEREBY CERTIFY that the foregoing is a full, true, and correct copy of a resolution adopted by the Board of Water and Power Commissioners of the City of Los Angeles at its meeting held

Secretary

AR0070180

Reference D-2 – LADWP Renewables Portfolio Standard Policy and Enforcement Program Amended December 2011:

City of Los Angeles Department of Water and Power
Renewables Portfolio Standard Policy
and
Enforcement Program
Amended December 2011

1. Purpose:

On April 12, 2011, Governor Jerry Brown signed into law the California Renewable Energy Resources Act (herein referred to as "Act" or "SB 2 (1X)"). This Act sets new Renewable Portfolio Standard (RPS) procurement targets, new renewable resource eligibility definitions, and new reporting requirements applicable to local Publicly Owned Electric Utilities (POUs). It is anticipated that SB 2 (1X) becomes effective on December 10, 2011, ninety days after the end of the special legislative session (1X) in which it was enacted.

This RPS Renewables Portfolio Standard Policy and Enforcement Program (RPS Policy) as amended, represents the continued commitment by the Los Angeles Department of Water and Power (LADWP) to renewable energy resources. It is being adopted in accordance with the newly added Section 399.30 (e) of the Public Utilities Code (PUC), requiring the governing boards of POUs to adopt "a program for enforcement of this article" on or before January 1, 2012.

The SB 2 (1X) also requires the California Energy Commission (CEC) to "adopt regulations specifying procedures for enforcement of this article", which include a public process under which the CEC may issue a notice of violation and correction against a POU for failure to comply. The CEC is further required to refer violations of its regulations to the California Air Resources Board which may impose penalties to enforce the Act consistent with California Assembly Bill 32, (AB32 - California Global Warming Solutions Act of 2006).

It is the intent of LADWP to comply with the provisions of the Act, and with applicable enforcement regulations adopted by the CEC pursuant to the Act. It is also the intent of LADWP to update this RPS Policy, as necessary, after the CEC adopts regulations specifying procedures for enforcement.

The Board of Water and Power Commissioners of the City of Los Angeles (Board) retains its jurisdiction to enforce the RPS Policy in accordance with PUC Section 399.30 (e).

2. Background:

In 2002, California Senate Bill 1078 (SB 1078) added Sections 387, 390.1 and 399.25, and Article 16 (commencing with Section 399.11) to Chapter 2.3 of Part I of Division 1 of the PUC, establishing a 20 percent RPS for California investor-owned electric utilities.

AR0070181

SB 1078 provided that each governing board of a local POU be responsible for implementing and enforcing a RPS that recognizes the intent of the Legislature to encourage renewable resources and the goal of environmental improvement while taking into consideration the effect of the standard on rates, reliability, and financial resources.

On June 29, 2004, the Los Angeles City Council passed Resolution 03-2064-S1 requesting that the Board adopt an RPS Policy of 20 percent renewable energy by 2017 setting applicable milestones to achieve this goal, and incorporate this RPS into a future Integrated Resource Plan (IRP)

On May 23, 2005, the Board adopted a LADWP RPS Policy that established the goal of increasing the amount of energy LADWP generates from renewable power sources to 20 percent of its energy sales to retail customers by 2017, with an interim goal of 13 percent by 2010. On June 29, 2005, the Los Angeles City Council approved the LADWP RPS Policy

On April 17, 2007, the Board amended the LADWP RPS Policy by accelerating the goal of requiring that 20 percent of energy sales to retail customers be generated from renewable resources by December 31, 2010. In addition, the amended policy established a "Renewable Resource Surcharge" and also established renewable energy procurement ownership targets.

The Board subsequently approved a RPS Policy, as amended April 2008, which included an additional RPS goal of requiring that 35 percent of energy sales to retail customers be generated from renewable resources by December 31, 2020, expanded the list of eligible renewable resources, and provided new energy delivery criteria

In 2010, LADWP achieved its RPS goal of 20 percent

3. RPS Compliance Targets

To promote stable electricity prices, protect public health, improve environmental quality, provide sustainable economic development, create new employment opportunities, reduce reliance on imported fuels, and ensure compliance with applicable state law, the following RPS compliance targets are hereby adopted:

1. For the period of January 1, 2011 to December 31, 2013, LADWP will procure sufficient electricity products from eligible renewable energy resources to achieve an average of 20 percent of retail sales during such period
2. LADWP will increase its procurement of electricity products from eligible renewable energy resources to achieve 25 percent of retail sales by December 31, 2016, based on an average percentage of retail sales calculations for the period of January 1, 2015 to December 31, 2016
3. LADWP will increase its procurement of electricity products from eligible renewable energy resources to achieve 33 percent of retail sales by

AR0070182

December 31, 2020 based on an average percentage of retail sales calculations for the period of January 1, 2020 to December 31, 2020.

4. For each calendar year after 2020, LADWP will procure sufficient electricity products from eligible renewable energy resources to achieve a minimum 33 percent of retail sales based on an average percentage of retail sales calculations for the period of January 1 to December 31 in each such calendar year.

The LADWP will continue to encourage voluntary contributions from customers to fund renewable energy resources in addition to the stated RPS compliance targets in accordance with its Green Power for a Green L.A. Program or any successor program.

4. Eligible Renewable Energy Resources

Prior to the enactment of SB 2 (1X), the LADWP RPS Policy defined the following technologies as "eligible renewable resources": biodiesel biomass conduit hydroelectric (hydroelectric facilities such as an existing pipe, ditch, flume, siphon, tunnel, canal, or other manmade conduit that is operated to distribute water for a beneficial use); digester gas; fuel cells using renewable fuels; geothermal; hydroelectric incremental generation from efficiency improvements; landfill gas; municipal solid waste; ocean thermal, ocean wave, and tidal current technologies; renewable derived biogas (meeting the heat content and quality requirements to qualify as pipeline grade gas) injected into a natural gas pipeline for use in renewable facility; multi-fuel facilities using renewable fuels (only the generation resulting from renewable fuels will be eligible); small hydro 30 Mega Watts (MW) or less, and the Los Angeles Aqueduct hydro power plants; solar photovoltaic, solar thermal electric, wind, and other renewables that may be defined later."

All renewable energy resources approved by the Board as part of its renewables portfolio in accordance with applicable law and previous versions of this RPS Policy, including without limitation those on Appendix A, will continue to be eligible renewable energy resources. Those renewable energy resources will count in full towards LADWP's RPS targets adopted in section 3 under this updated RPS Policy.

For RPS resources procured after the effective date of SB 2 (1X), "eligible renewable energy resource" means a generation facility that meets eligibility criteria under applicable law, including a "Renewable Electrical Generation Facility" as defined in Section 25741 (a) of the Public Resources Code and "Eligible Renewable Energy Resource" as defined in PUC Sections 399.12 (e) and 399.12.5.

5. Long-Term Resource and Procurement Plan

The LADWP will integrate the RPS Policy into its long-term resource planning process and the RPS Policy will not compromise LADWP's IRP objectives of service reliability, competitive electric rates, and environmental leadership. Future IRPs will incorporate

AR0070183

and expand upon RPS compliance targets, and further define plans for procuring eligible renewable energy resources by technology type and geographic diversity.

Each year, the Board accepts an annual fiscal year budget including a Fuel and Purchased Power Budget (FPP), which defines the specific expenditures for renewable energy resources. The annual fiscal year budget, including the FPP, will comprise the LADWP Renewable Energy Resources Procurement Plan, as required under SB 2 (1X).

6 Procurement of Eligible Renewable Energy Resources

The LADWP will procure eligible renewable energy resources based on a competitive method and least-cost, best-fit evaluators. Furthermore, preference will be given to projects that are located within the City of Los Angeles or on City-owned property and are to be owned and operated by LADWP to further support LADWP's economic development and system reliability objectives.

Notwithstanding the foregoing, LADWP will also procure eligible renewable energy resources through programs such as a Distributed Generation Feed-In Tariff, Senate Bill 1 (SB1) Customer Net Metered Solar PV, other local renewable energy programs, or similar procurement processes. These transactions will be made in as cost-effective a manner as is feasible in each respective instance, with pricing that reflects applicable legal requirements and market conditions, prevailing policy, and competitive methods. Short-term renewable energy transactions will be needed as well, on a limited basis, to manage LADWP's RPS eligible renewable energy resources portfolio effectively based on prevailing wholesale practices.

Before December 31, 2010, LADWP pursued its 20 percent RPS goal in a manner which resulted in a minimum of 40 percent renewable energy generation ownership that LADWP developed or that LADWP procured through contracts with providers of renewable energy. Further, with respect to the foregoing contracts with providers, such contracts provided for LADWP ownership or an option to own, either directly or indirectly (including through joint powers authorities).

On or after January 1, 2011, a minimum of 75 percent of all new eligible renewable energy resources procured by LADWP will either be owned or procured by the LADWP through an option-to-own, either directly or indirectly (including through joint powers authorities) until at least half of the total amount of eligible renewable energy resources by Megawatt-hour (MWh), is supplied by eligible renewable energy resources owned or optioned either directly or indirectly (including through joint powers authorities) by LADWP.

The first priority for LADWP will be to pursue outright ownership opportunities, and the second priority will be consideration of procuring option-to-own, cost-based renewable energy resources. In comparing outright ownership to "option-to-own," option-to-own projects must show clear economic benefits, such as pass-through of Federal or State

AR0070184

tax credits or incentives, which could not otherwise be obtained, or the need to evaluate new technology. The option-to-own will be exercisable with the minimum terms necessary to obtain and pass those tax credits and/or incentives to LADWP and/or upon a reasonable amount of time to evaluate the operation of the new technology.

7. Portfolio Content Categories

As required by SB 2 (1X), eligible renewable energy resources procured on or after June 1, 2010, will be in accordance with PUC Sections 399.16 (b) and (c). Section 399.15 (b) defines eligible renewable energy resources in three distinct portfolio content categories, commonly known as "buckets". LADWP will ensure that the procurement of its eligible renewable energy resources on or after June 1, 2010, will meet the specific percentage requirements set out in Section 399.16 (c) for each bucket in each compliance period.

These buckets and percentage requirements are summarized in Table 1 below.

AR0070185

Table 1 Procurement Content Categories and Percentage Requirements

Category (aka "Buckets")	Percentage of RPS Target
4. Either: Have a first point of interconnection with a California balancing authority, have a first point of interconnection with distribution facilities used to serve end users within a California balancing authority area, or are scheduled from the eligible renewable energy resource into a California balancing authority without substituting electricity from another source [PUC Section 399.16(b)(1)(A)]. Or, have an agreement to dynamically transfer electricity to a California balancing authority. [PUC Section 399.16(b)(1)(B)]	**Compliance Period 1 (2011-2013):** 50% of RPS minimum from this category. **Compliance Period 2 (2014-2016):** 65% of RPS minimum from this category. **Compliance Period 3 (2017 to 2020):** 75% of RPS minimum from this category. **Post 2020:** 75% of RPS minimum from this category.
5. Firmed and shaped eligible renewable energy resource electricity products providing incremental electricity and scheduled into a California balancing authority. [PUC Section 399.16(b)(2)]	Shall be calculated as the remainder of resources which are not in either Category 4 or Category 5
6. Eligible renewable energy resource electricity products, or any fraction of the electricity generated, including unbundled RECs, that do not qualify under Bucket 1 or 2. [PUC Section 399.16(b)(3)]	**Compliance Period 1 (2011-2013):** 25% of RPS maximum from this category. **Compliance Period 2 (2014-2016):** 15% of RPS maximum from this category. **Compliance Period 3 (2017 to 2020):** 10% of RPS maximum from this category. **Post 2020:** 10% of RPS maximum from this category.

The LADWP will define the specific scheduling methods, including firming services, as needed, to maintain transmission system reliability and compliance with these procurement content categories and specified percentage requirements.

Subject to the provisions of PUC Section 399.16 (c), renewable electricity products procured prior to June 1, 2010, are exempt from these portfolio content categories and will continue to count in full toward LADWP's RPS compliance targets.

AR0070186

8 System Rate Impact.

The LADWP may not make any major financial commitment to procure renewable resources prior to evaluating the rate impact and any potential adverse financial impact on the City transfer

9 Compliance Considerations:

In accordance with this RPS Policy, the Board will review the annual fiscal year budget and Renewable Energy Resources Procurement Plan, and will ensure that reasonable progress is being made towards compliance with the RPS compliance targets.

Reasonable progress may include activities that further the development and procurement of eligible renewable energy resources. Such activities may include, but are not limited to, real estate purchases for future project development, project planning and environmental permitting for either renewable energy projects or transmission in support of renewable energy projects, and other engineering, planning, budgeting, contracting and regulatory compliance activities.

In accordance with PUC Section 399.30 (d) (2), under exceptional circumstances the Board may adopt conditions that allow for delaying timely compliance with the RPS compliance targets, consistent with PUC Section 399.15 (b). Such conditions may include permitting interconnection or environmental delays, transmission constraints, resource availability, or operational limitations

In accordance with PUC Section 399.30 (d) (3), under exceptional circumstances the Board may adopt cost limitations for procurement expenditures consistent with PUC Sections 399.15 (c) and 399.15 (d).

In accordance with PUC Section 399.30 (d) (1), under exceptional circumstances the Board may adopt rules permitting LADWP to apply excess procurement in one compliance period to subsequent compliance periods in the same manner as allowed for retail sellers pursuant to PUC Section 399.13

10. Reporting and Notice Requirements:

The LADWP will provide a monthly RPS Progress Report to the Board of Commissioners. Additionally an annual report will be provided to its customers and the CEC containing all information required to be reported pursuant to SB 2 (1X), SB 1078, SB 107, and related regulations.

Per PUC Section 399.30 (e), the Board will adopt the program for enforcement at a publicly noticed Board meeting offering all interested parties an opportunity to comment. No less than 30 days' notice shall be given to the public of any meeting held for

AR0070187

purposes of adopting the program. No less than 10 days' notice shall be given to the public before any meeting is held to make a substantive change to the program.

Per PUC Section 399.30 (f), LADWP will post notice whenever the Board will deliberate in public on its Renewable Energy Resources Procurement Plan. LADWP will either notify the CEC of the date, time, and location of the meeting in order to enable the CEC to post the information on its Internet Web site, or provide the CEC with the uniform resource locator (URL) that links to this information. In addition, upon distribution to the Board of information related to LADWP's renewable energy resources procurement status and future plans, for the Board's consideration at a noticed public meeting, LADWP shall make that information available to the public and shall provide the CEC with an electronic copy of the documents for posting on the CEC's Internet Web site, or provide the Uniform Resource Locator (URL) that links to the documents or information regarding other manners of access to the documents.

Per PUC Section 399.30 (g), LADWP shall annually submit to the CEC documentation regarding eligible renewable energy resources procurement contracts that it executed during the prior year.

Per PUC Section 399.30 (l), LADWP shall report, on an annual basis, information on (1) expenditure of public goods funds for eligible renewable energy resources development, (2) the resource mix used to serve its retail customers by energy source, and (3) status in implementing the RPS and progress toward attaining the RPS.

LADWP will continue to provide a Power Content Label Report to its customers as required by SB 1305 (1997) and AB 162 (2009), and an annual report of the total expenditure for eligible renewable energy resources funded by voluntary customer contributions.

AR0070188

11 Use of Renewable Energy Credits

The primary method of renewable energy resource procurement will be through the development and acquisition of physical generation assets and energy purchase contracts where the "Renewable Energy Credit" (REC) is "bundled" with the associated energy. PUC Section 399.12 (h) provides the REC definition.

In order for RPS compliance targets to be managed effectively, LADWP may buy, sell or trade RECs without the associated energy (unbundled). This procurement approach will be limited by the percentage requirements established by PUC Section 399.16 (b) (3) and as described in section 7 above.

RPS Policy & Enforcement Program
Appendix A – List of LADWP RPS Resources prior to SB 2 (1X)

PPM SW Wyoming – Pleasant Valley Wind	Cottonwood Power Plant
Linden Wind	Division Creek P. P.
PPM Pebble Springs Wind	Big Pine Power Plant

Franklin Power Plant	LADWP JFB Parking Lot
Sawtelle Power Plant	LA Convention Center Cherry St Parking Lot
Harwee Power Plant	Council District 6 Field Office

AR0070189

Appendix E Power Reliability Program

Reliability represents one of the three main objectives of LADWP (see Figure 1-1). However, many people have trouble understanding what reliability is and why it so important.

The reliability discussed in this section refers to the electricity delivery infrastructure, and its job of delivering electricity to its customers in a safe and effective manner.

A good analogy would be one's car – how reliable it is at performing its job depends on how well it is maintained. As the years go by, certain components of a car began to fail (e.g., brakes, battery, water pump, etc.) and need to be replaced. Likewise, certain components of the electrical distribution infrastructure (e.g., poles, cables, transformers, etc.) eventually reach the end of their service lives. Unless they are replaced, they will begin to fail, causing various problems including power outages. As discussed later in this section, the level of outages caused by aging system components has reached an unacceptable level.

Ironically, the more successful a utility is in terms of reliability, the less awareness and attention it is given. For the general public, the historically high level of electric service has engrained an expectation of high reliability, to the extent that it is not given much thought – when a light switch is flipped, we expect the lights to turn on. It is only when the light doesn't turn on (or goes off during a power outage) that much public notice is given to the electricity delivery infrastructure.

The difficulties in managing reliability include the following:

- Because the consequences of deficient reliability are not experienced until electricity delivery is compromised, the need to allocate appropriate capital resources to better maintain system integrity – before problems occur – may not be fully appreciated by those outside the utility.
- External regulatory mandates are demanding a growing share of LADWP's limited financial resources. As rate actions have been delayed over recent years, inadequate revenues have resulted in underfunding for reliability programs.
- Reliability levels that become unacceptable due to deferral of infrastructure upkeep and replacement are more difficult to recover from and in the end are more costly.

History of High Reliability

Reliable electric power has been a cornerstone objective of LADWP since it began offering municipal electricity in 1917. Historically, LADWP's Power System reliability has consistently placed in the top quartile of the electric utility industry. However, as a result of aging electrical distribution infrastructure, reliability levels started to decrease in the early to mid-2000s. There are significant challenges for LADWP to halt the decline and to restore reliability to acceptable levels.

AR0070190

The City of Los Angeles (City) was founded in 1781 and incorporated in 1850. Since then, Los Angeles has grown to the Nation's second largest City with a population of almost 4 million residents. Most of this growth occurred between 1920 (when there were roughly 580,000 residents) and 1970 (when the City had grown to over 2.8 million residents). This incredible growth of 2.2 million residents – roughly 56 percent of today's population – coincided with the mass electrification of homes and businesses throughout the country. During this time, LADWP installed tremendous amounts of electrical infrastructure to ensure that these growing numbers of new homes and businesses were supplied with reliable electric service. Figure E-1 shows the number of electrical distribution poles categorized by age, and illustrates that the bulk of the installations were made within the timeframe of this growth period.

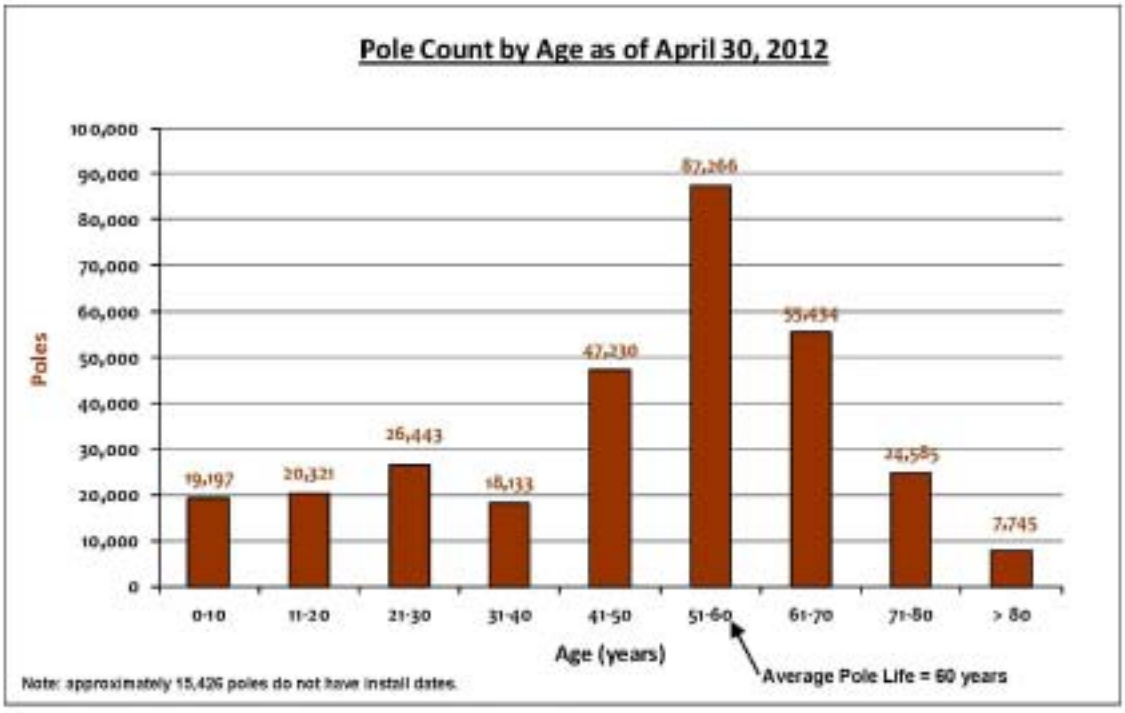

Figure E-1. Pole count by year range installed.

Reliability Levels Decrease

As a testimony to the initial design and installation of this electrical infrastructure, it had reliably served the residents of the City for 40 to 70 years. However, as stated previously, reliability began to deteriorate in the early to mid-2000's. Increasing outage rates, including several high profile outages, have resulted in service reliability concerns.

Table E-1 below summarizes several significant service interruptions since FY 2005-06.

AR0070191

Table E-1. MAJOR POWER OUTAGES SINCE FY 2005-06

Date of Event	Type	Duration (days)	Outages (sustained)	Customers Affected (sustained)
December 31, 2005 - January 4, 2006	Wind/Rain	3.56	189	79,918
July 21-28, 2006	Heat	6.89	1033	46,981
January 5-8, 2007	Wind	2.92	150	62,725
April 12-16, 2007	Wind / Rain	3.57	218	105,796
August 30 - September 7, 2007	Heat	7.33	858	60,891
September 21-24, 2007	Rain	2.11	86	42,452
January 4-7, 2008	Rain	3.02	129	57,981
January 24-28, 2008	Rain	4.66	119	54,236
November 15-17, 2008	Fire/Wind	2.08	200	133,524
October 13-16, 2009	Rain	2.95	156	93,754
October 27-30, 2009	Wind	2.81	176	87,763
January 18-24, 2010	Wind/Rain	5.84	319	172,883
September 27-30, 2010	Heat	2.92	228	32,010
October 4-7, 2010	Rain	2.83	116	103,112
December 19-23, 2010	Rain	4.96	139	52,786
March 20-22, 2011	Wind/Rain	2.22	196	106,491
November 30 - December 4, 2011	Wind	3.75	419	222,567

The increase in problems appears to be the result of an aging infrastructure and a significant amount of deferred maintenance and deferred reliability-enhancing capital work. Several years of limited funding and reduced staffing levels are underlying contributors to the deferred infrastructure replacement cycle, maintenance, and capital improvements.

Reliability Performance Indicators – SAIFI and SAIDI

Like all other electricity utilities in the US, LADWP uses a number of metrics to measure the performance and reliability of its electric power system. The two primary metrics are called SAIFI and SAIDI.

System Average Interruption Frequency Index (SAIFI): SAIFI is the average number of sustained service interruptions per customer during the year. It is the ratio of the annual number of interruptions to the number of customers. In other words, it measures how many times the

AR0070192

average customer has been out of service. 1.1 is the recent national average. In 2002, LADWP's SAIFI index was 0.49; in 2011 it was 1.03.

System Average Interruption Duration Index (SAIDI): SAIDI is the average duration of interruptions per customer during the year. It is the ratio of the annual duration of interruptions (sustained) to the number of customers. In other words, it measures how long the average customer was without power. 90 minutes is the recent national average. In 2002 LADWP's SAIDI index was 59.29; in 2011 it was 214.44.

The trends for both SAIDI and SAIFI are shown in Figure E-2.

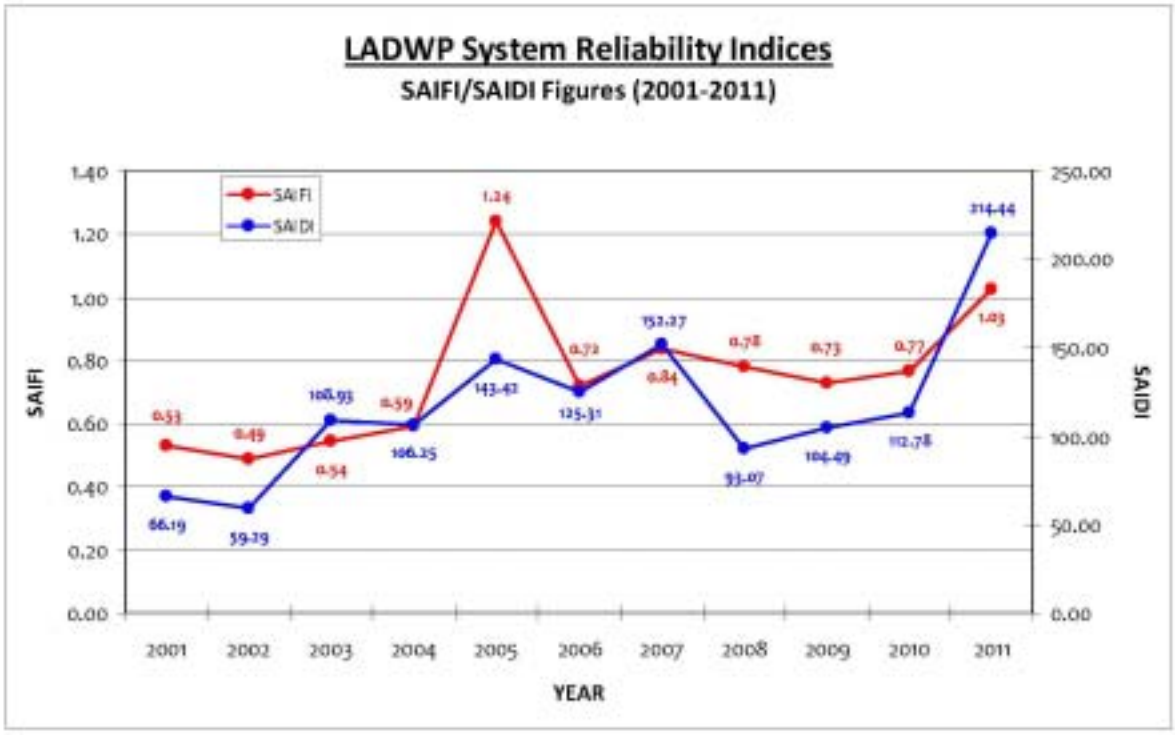

Figure E-2. LADWP's reliability indices.

The PRP is Initiated

As a result of deteriorating service, in 2007 Power System staff and independent industry expert consultants developed recommendations encapsulated in an initiative called the Power Reliability Program (PRP). The PRP is recognition that an infrastructure based industry, such as an electric utility, requires substantial re-investments in the infrastructure to have a viable and reliable system, and that these investments need to be stepped up on a permanent ongoing basis to support reliability in the long term.

The goals of the PRP include:

- Mitigating problem circuits and stations based on the types of outages specific to the facility

AR0070193

- Implementing proactive maintenance and capital improvements that take into account system load growth and the inspections and routine maintenance that must take place to identify problems before they occur
- Establishing replacement cycles for system components that are in alignment with the equipment's life cycle

The system components that are being replaced include the following (see Figure E-3.):

- Power Poles
- Underground Cable
- Distribution and Substation Transformers
- Substation Circuit Breakers
- Overhead Transmission

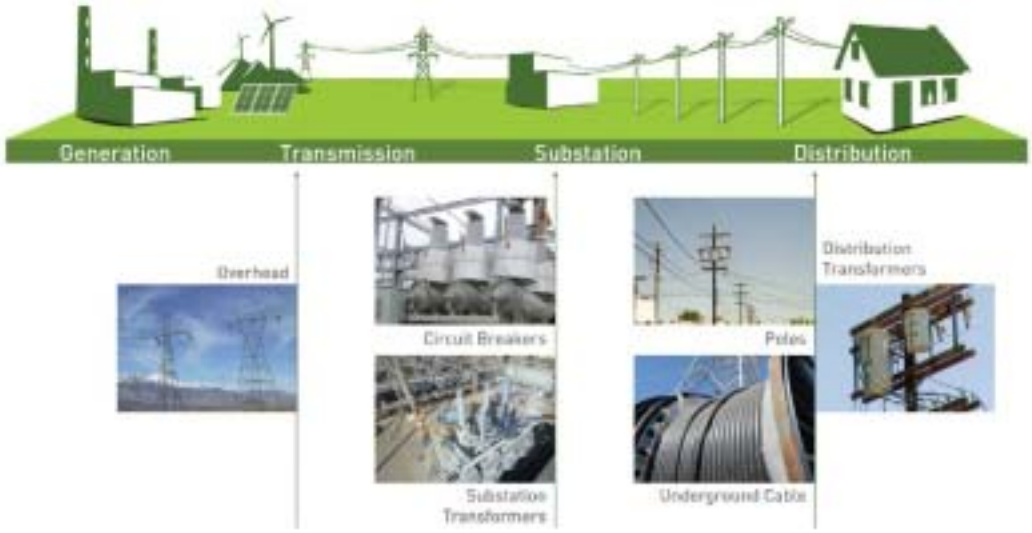

Figure E-3. Power System infrastructure assets for electricity delivery.

Infrastructure Replacement

Through the PRP, LADWP has moved forward with increased infrastructure replacement in key areas to reduce the average age of the critical components of its power system. While improvements have been made to reduce the age of certain equipment, more investment is required.

Increased investment in transformer and underground cable replacement in recent years has reduced outages related to these aspects of the distribution system; however, investment in overhead facilities has continued to lag targeted levels with a corresponding increase in overhead-related outages. Despite recent investments, there is an increasing amount of critical infrastructure components that are operating beyond their useful life.

AR0070194

Asset Replacement Cycles

LADWP utilizes metrics to track the age, condition and impact on reliability for each major type of asset in its infrastructure. Table E-2 presents proposed and actual replacement cycles for PRP asset elements. Given the number and age of each asset element, a key consideration is to replace these assets at a rate that corresponds to their respective service lives. Replacement cycles that exceed the average service life by a factor of 2 or 3 puts the system at increased risk of service interruption.

Table E-2. REPLACEMENT CYCLES FOR INFRASTRUCTURE ASSETS

		Recommended		Actuals	Projected	Budgeted FY 2012-13	
Asset	Count	Replacement Cycle (years)	Proposed Replacement Rate (units/year)	FY 2010-11	CY 2011-12	Actual Replacement Rate	Replacement Cycle (years)
Poles	321,780	60	5,000	2,481	2,100	1,820	166
Underground Cable (miles)	4,500	75	50	68	52	28	161
Distribution Transformers	126,000	60	2,400	2,606	2,400	2,400	53
Large Substations Transformers	88	45	2	1	1	2	45
Local Substation Transformers	360 (approx.)	50	7	3	7	7	50
Substation Circuit Breakers	4,934	50	100	33	33	0	∞
Overhead Transmission (miles)	3,623	Maintenance & Capital Upgrade	100	0	1	0	∞
Underground Transmission (miles)	124	75	1 ckt./yr. (approx., 2 mi. each)	1	0	0	∞

Pole Replacement Program

Since approximately 70% of LADWP's system is overhead, pole and cross arm replacements are a major driver of reliability. As shown in the Figure E-4, the majority of LADWP's poles currently exceed their useful 60 year life. While the recommended replacement rate is 60 years, over 80,000 poles (26%) are more than 60 years old. Therefore, additional investment in pole replacement is warranted.

AR0070195

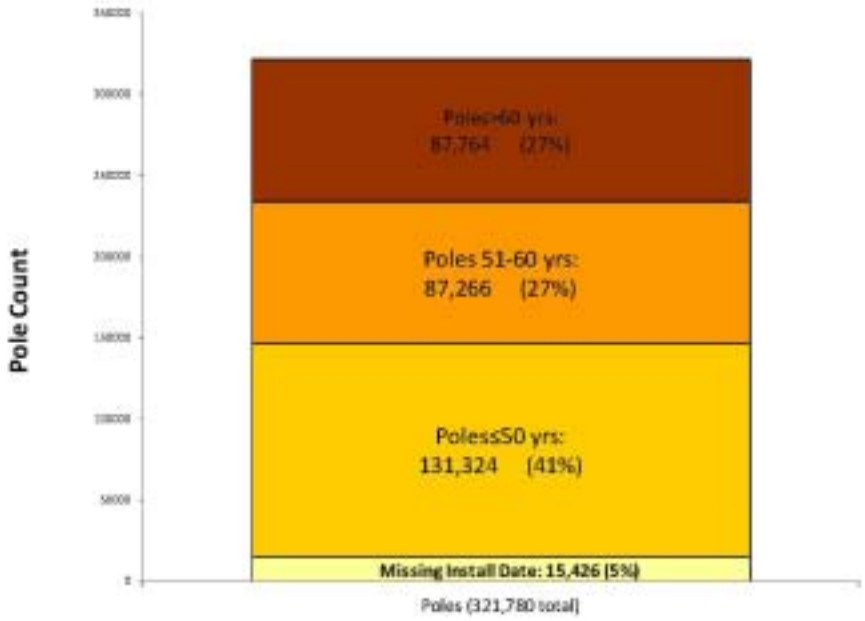

Figure E-4. Pole aging.

A growing number of these poles are in need of expeditious replacement. The following picture illustrates the poor condition of some of LADWP's older poles.

Picture: Pole condition illustrative.

LADWP identifies the poles that are most critically in need of replacement and replaces them as soon as possible. However, LADWP is not replacing poles and cross-arms at a pace that is keeping up with the aging of the system.

AR0070196

Funding for pole replacement has LADWP on a 166 year replacement cycle which is more than double the ideal 60 year cycle. Figure E-5 below shows the recent pole replacement amounts and target levels to 2017.

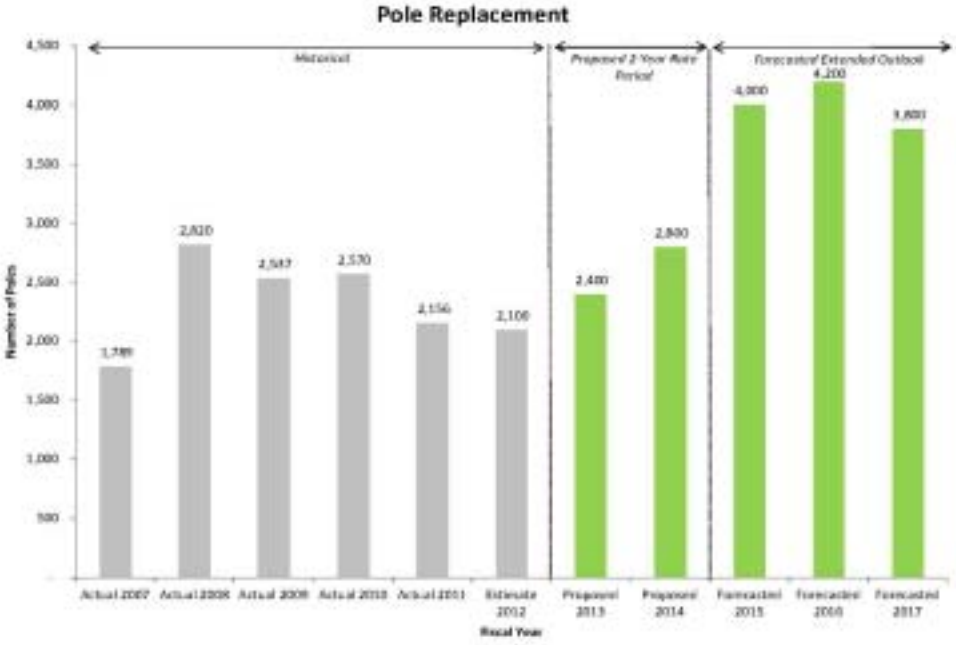

Figure E-5. Historical and forecasted pole replacement (FY 2007 – 2017).

To move towards the ideal life cycle, replacements will need to ramp up to around 5,000 per year over the next several years, pending available funds.

Underground Cable (UG) Replacement Program

LADWP has replaced on average 53 miles per year of UG cable over the past five years. Replacements have targeted cable failures that have caused outages contributing 27% to overall SAIFI. A pilot cable replacement program focused on the 5 worst performing UG circuits and produced a better than 50% reliability improvement; these circuits reflected 66% of common outage causes. LADWP's recent program compare favorably with best practices for utilities with aging underground cable. In an attempt to balance spending and rate levels, the proposed expenditures target replacement of 27 miles of UG cable per year for the next two years. While recent gains should help mitigate any short term decrease in reliability, over time it is likely that reliability could decrease.

Following LADWP's current replacement schedule, cable will be replaced every 159 years compared to a more ideal level of 72 years. In the past five years, the PRP has provided funding for the replacement of cable as shown in Figure E-6. Due to limited funding, the cable replacement program targets were reduced in order to more fully address replacement of other infrastructure assets.

AR0070197

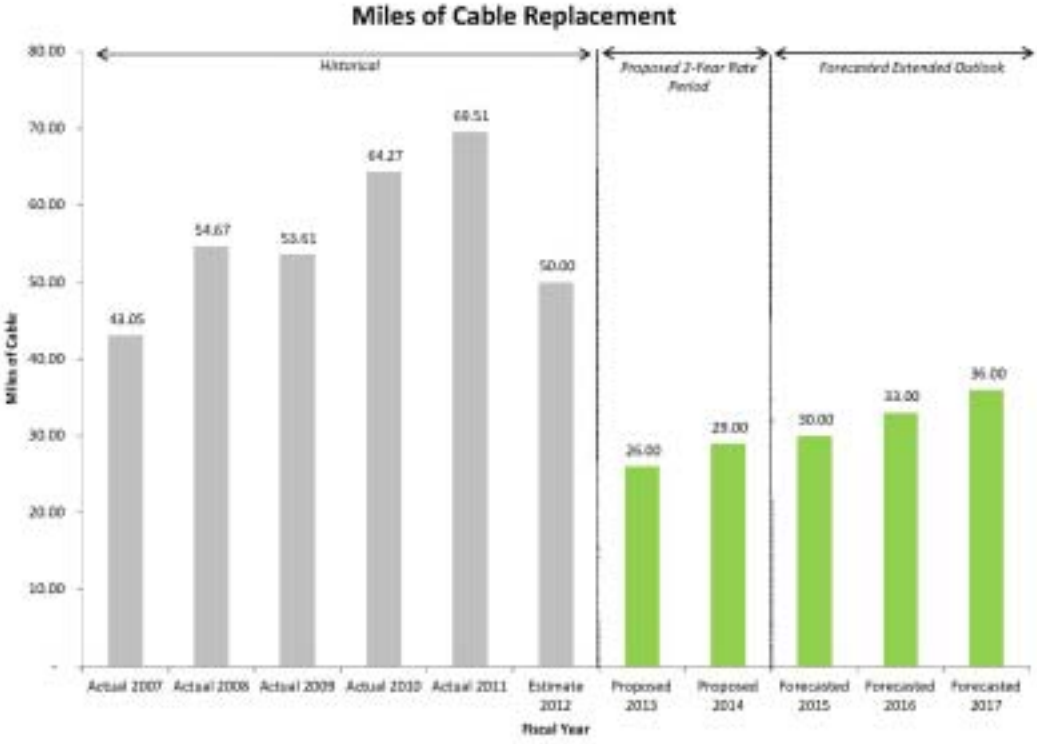

Figure E-6. Historical and forecasted cable replacement (FY 2007-2017).

Notwithstanding this decreased replacement target, cables identified as in critical need of replacement, like the one shown in picture below, are scheduled for replacement as soon as possible.

Picture: Illustrative of Cable Scheduled for Replacement.

AR0070198

Distribution Transformer Replacement Program

Transformers play a critical role in the delivery of electricity to the city of Los Angeles. Many factors shorten the life of a transformer including: corrosion; moisture; physical damage; electrical surges; heat; loading; and, age. Transformer failures have been trending up in the past four years. With respect to age, overhead transformers have an average age to failure of 35 years; underground transformers at 23 years; and PAD transformers at 27 years. As shown in Figure E-7, the vast majority of LADWP's 957 transformer banks are over 40 years old with a significant number of those over 50 years old.

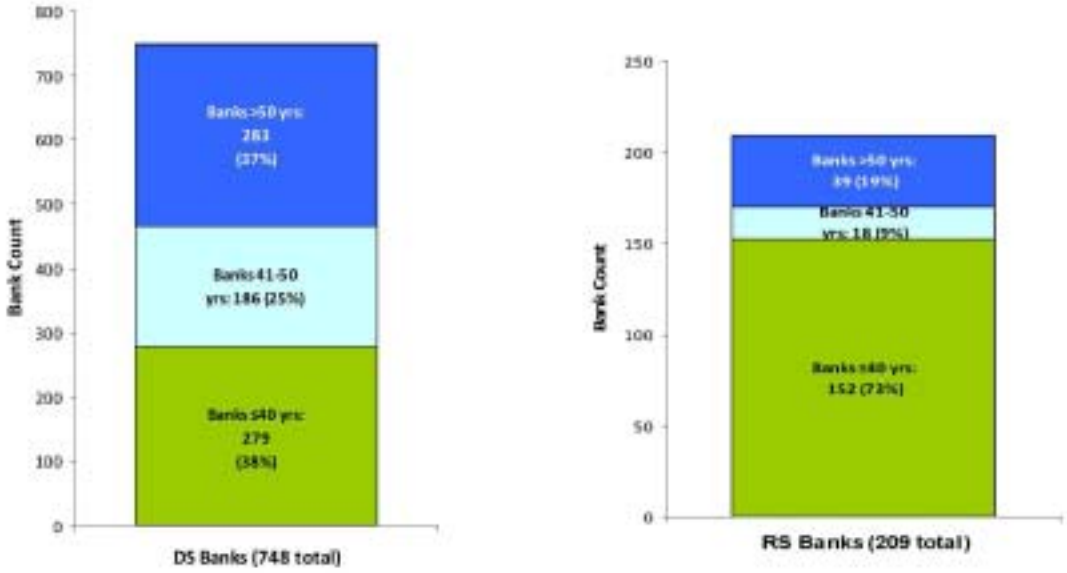

Figure E-7. DS and RS bank aging.

In recent years the PRP has provided funding to replace significant numbers of transformers as shown in Figure E-8.

AR0070199

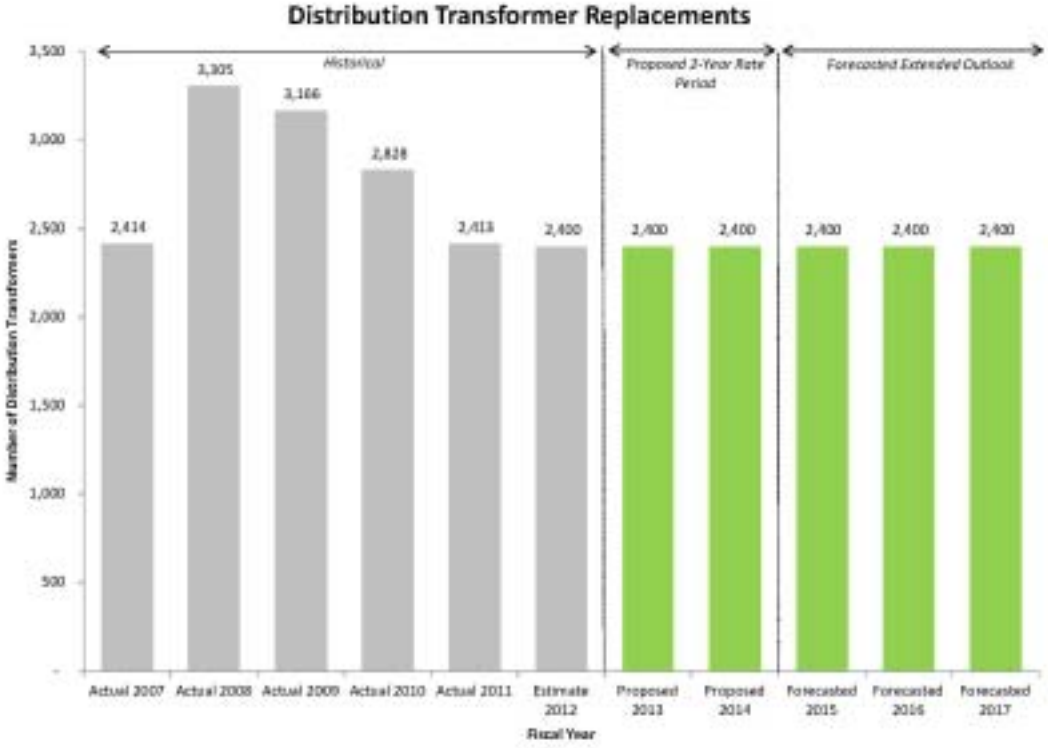

Figure E-8. Historical and forecasted distribution transformer replacements (FY 2007-2017).

Expected transformer replacements are expected to average 2,400 for the next five-years. Existing units may be run until closer to overload status, but new business related installations will continue as in the past. However, the risks of additional failures will be at least partially mitigated by maintaining an appropriate replacement inventory to permit prompt corrective actions.

Work Backlog

Another objective of the PRP is to reduce the backlog of needed work on the distribution system.

LADWP maintains a list of known required distribution system repairs and replacements that have not been completed. The size of this backlog has grown in recent years, as illustrated in Figure E-9. To bring down the nearly 41,000 repair orders in the queue to a desired base or on-going level of 2,000-5,000 would take 3 million work hours to catch up. Proposed funding levels do not provide enough for this catch-up. Based on forecasted PRP investment levels, the repair order backlog is projected to increase to approximately 44,000 tickets in 2017.

AR0070200

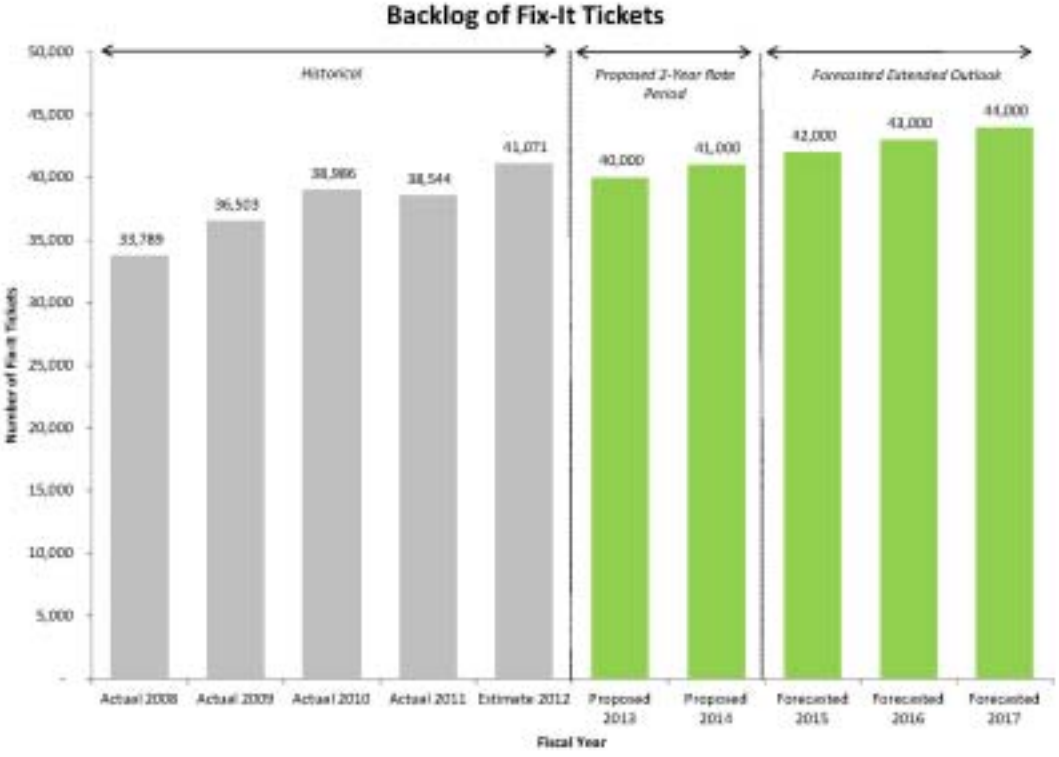

Figure E-9. Historical and forecasted backlog of repair orders (FY 2008 – FY 2017).

Funding Challenges

Funding of the PRP has been inconsistent since its inception. As shown in Figure E-10, the initial years of the program resulted in some reliability gains as outages decreased from 6,323 in 2006 to 4,523 in 2009. Funding levels since then, however, were below levels proposed when the PRP was initially designed in 2007. The numbers of outages are no longer declining. During FYE 2012, funding was cut by over $100 million from the previous year, given the limited resources available without the rate action proposed during 2011.

AR0070201

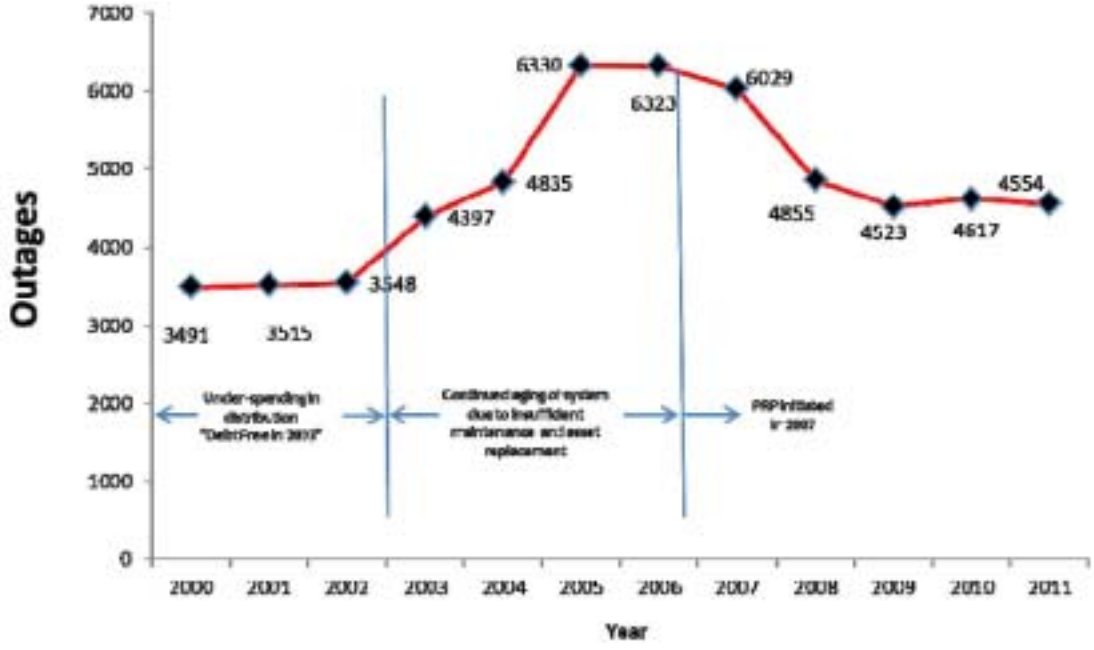

Figure E-10. Total outages between 2000-2011.

Asset Management Process

Reliability improvement in light of aging infrastructure and limited resources has become a critical issue for many utilities including LADWP. Both customers and policy makers are demanding increased service levels at the same time that funding for additional initiatives is limited due to financial constraints and competing priorities. LADWP's investment decisions will balance the following factors:

- Strict Asset Management Principles,
- A Rigorous Reliability Analysis; and
- Staffing and Other Resource Optimization.

LADWP's approach to addressing these challenges will be based on a systematic analytical approach to manage the available resources and expenditures to meet basic service needs in a manner that attempts to maintain overall reliability.

PRP - Summary and Recommendations

Reliability of the electricity delivery infrastructure is a key objective of LADWP. Historically, LADWP had attained adequate levels of reliability relative to the utility industry. However, beginning in the mid 2000's reliability began to decrease, the main cause being aging infrastructure. Deferred maintenance and investment did not keep pace with replacement needs, and the number and duration of outages began to increase. In response, LADWP initiated the Power Reliability Program in 2007 to address infrastructure reliability and lower the replacement

AR0070202

cycles of infrastructure components to acceptable ranges that account for their expected service lives.

The PRP experienced initial successes, but as funding levels became constrained, outage levels, which had been decreasing, reversed and began to increase. Adequate funding is critical to restoring reliability to levels that LADWP customers expect and deserve. Figure E-11 presents the actual annual expenditures from FY 2008 to FY 2012, along with proposed spending levels through FY 2017. While the "Preferred T&D Reliability Expenditures" shown on the figure is the level of expenditure required to fully fund the PRP, the "Basic T&D Reliability Expenditures" is the projected expenditures to be available for the program.

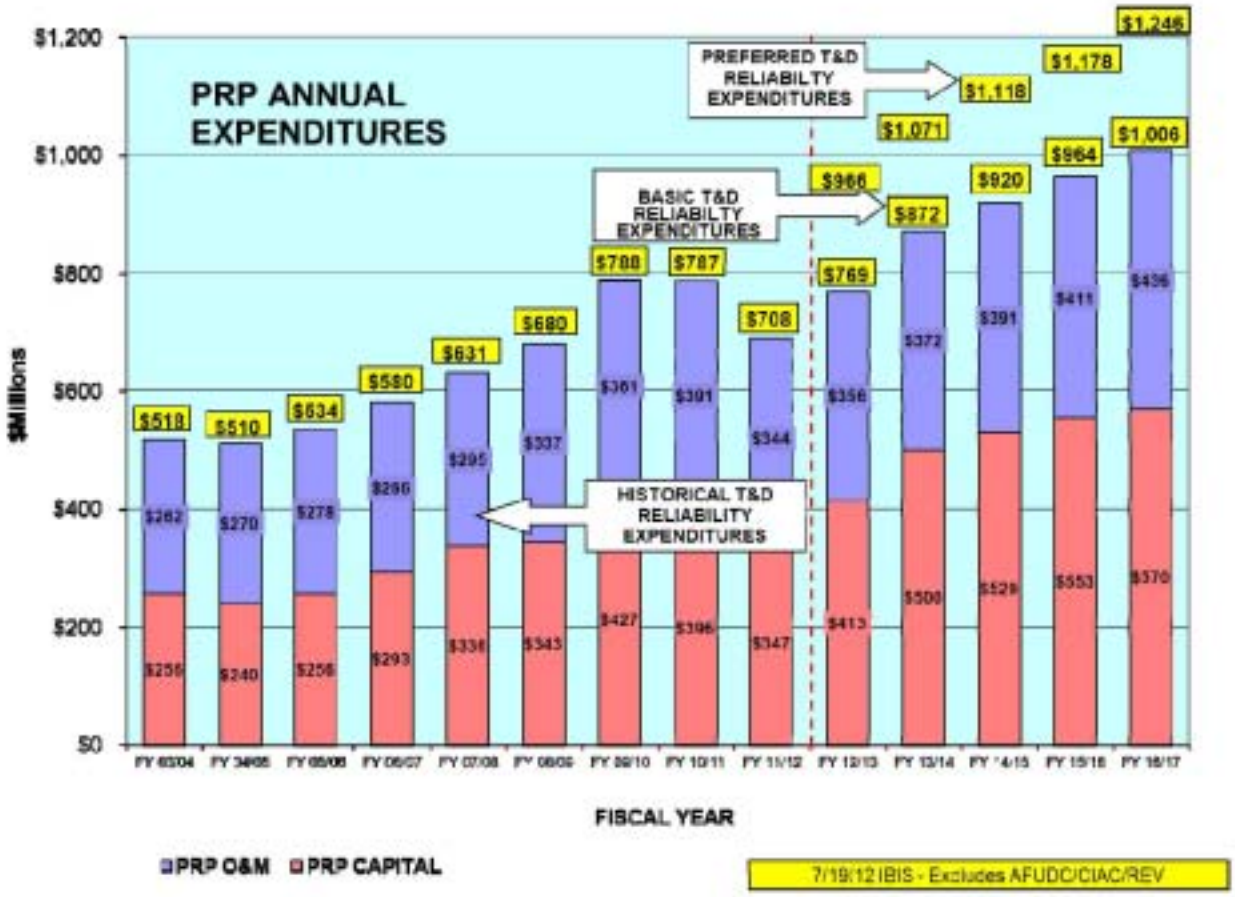

Figure E-11. Historical and proposed replacement targets and funding through FY 2017.

AR0070203

Appendix F Generation Resources

F.1 Overview

LADWP's generation resources are presented in this Appendix. Resources that are not wholly owned by LADWP are available either as long-term power purchase agreements or as entitlement rights resulting from undivided ownership interests in facilities that are jointly-owned with other utilities. Most of these additional resources are available through LADWP's participation in the Southern California Public Power Authority (SCPPA). Each project participant with respect to jointly-owned units is responsible for providing its share of construction, capital, operating, and maintenance costs.

F.2 Resources

Generation resources for LADWP are comprised of the following five categories:

- In-Basin Thermal Generation
- Coal Fired Thermal Generation
- Nuclear-Fueled Thermal Generation
- Large Hydroelectric Generation
- Renewable Resources and Distributed Generation

F.2.1 In-Basin Thermal Generation

LADWP is the sole owner and operator of four electric generating stations in the Los Angeles Basin (the "Los Angeles Basin Stations"), with a combined net maximum generating capability of 3,415 megawatts (MWs) and a combined net dependable generating capability of 3,329 MWs. Natural gas and digester gas are used as fuel for the Los Angeles Basin Stations. Low-sulfur, low-ash residual distillate is used for emergency back-up fuel for some of the stations.

LADWP's natural gas-fueled generating plant capabilities are shown in Table F-1.

AR0070204

Table F-1. NATURAL GAS GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Capability (kW)	Net Dependable Capability (kW)
Harbor	1	1995	85,340	82,000	452,000[2]
	2	1995	85,340	82,000	
	5	1995	75,000	65,000	
	10	2002	60,500	47,400	
	11	2002	60,500	47,400	
	12	2002	60,500	47,400	
	13	2002	60,500	47,400	
	14	2002	60,500	47,400	
Haynes	1	1962	230,000	222,000	1,525,000[3]
	2	1963	230,000	222,000	
	5	1966	343,000	292,000	
	6	1967	343,000	243,000	
	7	1970	2,000	1,599	
	8	2005	264,350	250,000	
	9	2005	182,750	162,500	
	10	2005	182,750	162,500	
Scattergood	1	1958	163,200	183,000	796,000
	2	1959	163,200	184,000	
	3	1974	496,800	450,000	
Valley	5	2001	60,500	43,000	556,000[4]
	6	2003	182,750	159,000	
	7	2003	182,750	159,000	
	8	2003	264,350	215,000	
Total				3,414,599	3,329,000

Notes:

1. COD refers to Commercial Operation Date.
2. Harbor Generating Station Net Dependable Plant Capability is 452 MW, reflecting Units 1 and 2 reduced performance during hot-weather conditions.
3. Haynes Generating Station Net Dependable Capability is 1,525 MW reflecting 8, 9, and 10 reduced performances during hot weather conditions; and Unit 7 used for auxiliary power only. Unit 5 Net Maximum Unit Capability was decreased to 292 MW to reflect LP hot-reheat piping derating. Unit 6 Net Dependable Unit Capability is 238 MW reflecting 243 MW transformer derating during hot weather conditions. Unit 4 was decommissioned in November 2003 and Unit 3 was decommissioned in September 2004.
4. Valley Generation Station Net Dependable Capability limited to 556 MW reflecting reduced performance during hot weather conditions.

Haynes Generating Station

The largest of the Los Angeles Basin Stations is the Haynes Generating Station, located in the City of Long Beach, California . The Haynes Station currently consists of eight generating units (Unit 7 is used for auxiliary power only) with a combined net maximum capability of 1,556 MWs and a net dependable capability of 1,525 MWs. This station includes a 575 MW

AR0070205

combined-cycle generating unit installed in February 2005. The combined-cycle generating unit includes two combustion turbines and a common steam turbine. The combustion turbines can each operate with the steam turbine independently or together in a two on one configuration (and are counted by LADWP as three generating units). LADWP plans to repower unit 5 and 6 with six 100 MW simple-cycle gas turbine units targeted by June 2013.

Valley Generating Station

The Valley Generating Station is located in the San Fernando Valley. The Valley Station began its repowering in 2001 with a simple-cycle, 60.5 MW gas–turbine generator. Repowering was completed in 2004 with the installation of a combined-cycle generating unit consisting of two gas turbines with heat recovery steam generators, which supplies one steam turbine with a combined net maximum capability of 576 MWs. The total net dependable capacity for the Valley Station is 556 MWs.

Harbor Generating Station

The Harbor Generating Station is located in Wilmington, California. The Harbor Station was repowered in 1995 with a combined-cycle generating unit (counted as three units). Five additional peaking combustion turbines were installed in 2002 for a total of eight generating units. These activities resulted in the Harbor Station's net maximum capability of 466 MWs and a net dependable capability of 452 MWs.

Scattergood Generating Station

The Scattergood Station is located in Playa del Rey, California and is comprised of three steam generating units with a net maximum capability of 817 MWs and a net dependable capability of 796 MWs. Units 1 and 2 also burn digester gas from the adjacent Hyperion Wastewater Treatment Plant.

All of these generating stations are certified to burn biogas. This will allow the electricity produced from the biogas to be qualified for the Renewable Portfolio Standard.

F.2.2. Coal-Fired Thermal Generation

LADWP's coal generating capacity comes from the Navajo Generating Station and the Intermountain Generating Station (IGS). IGS is also referred to as the Intermountain Power Project (IPP). Coal generating resources are summarized in Table F-2.

AR0070206

Table F-2: COAL GENERATING RESOURCE

Plant Name	Unit	COD[1]	Net Max Capability (Total kW)	Net Max Capability (LADWP kW)	Net Dependable Capability (LADWP kW)	LADWP Expiration	LADWP Share
Intermountain	1 2	1986 1987	900,000 900,000	401,553 401,553	401,553 401,553	15Jun2027	44.617%
Intermountain	1 2	1986 1987	900,000 900,000	36,000 36,000	36,000 36,000	15Jun2027	4% (UP&L)
Intermountain	1 2	1986 1987	900,000 900,000	163,512 163,512	149,500 149,500	15Jun2027	18.168% (Recallable)
Total				1,202,130[2]	1,174,106[2]		
Navajo	1 2 3	1974 1974 1975	750,000 750,000 750,000	159,000 159,000 159,000	477,000[3]	31Dec2019	21.2%
Total				1,679,130	1,651,106		

Notes:

1. COD refers to Commercial Operation Date.
2. IPP's Net Capacity available maybe less than 1202 MW due to Excess Power Recall. The LADWP entitlement is 44.617% direct ownership plus a 4% purchase from Utah Power & Light Company, plus 86.281% of up to 21.057% of muni's and co-op's recallable entitlement which can vary (shown is that of summer 2012). The nominal net Maximum Unit Capability and Net Dependable of both Units 1 and 2 is 900 MW.
3. LADWP's contract entitlement is 21.2% of Navajo's total net generation.

Intermountain Power Project (IPP)

General. The IPP consists of: (a) a two-unit coal-fired, steam-electric generating plant located near Delta, Utah, with net rating of 1,800 MWs and a switchyard located near Delta, Utah; (b) a rail car service center located in Springville, Utah; (c) certain water rights and coal supplies; and (d) certain transmission facilities consisting primarily of the Southern Transmission System. Pursuant to a Construction Management and Operating Agreement between the Intermountain Power Authority (IPA) and LADWP, IPA appointed LADWP as project manager and operating agent responsible for, among other things, administering, operating and maintaining IPP.

Power Contracts. Power is provided to LADWP under three separate agreements.

- Pursuant to a Power Sales Contract with IPA (the "IPP Contract") and a Lay-Off Power Purchase Contract with Utah Power & Light Company ("UP&L") and IPA, LADWP is entitled to 44.617 percent of the capacity of the IPP (currently equal to 803 MWs). The IPP Contract terminates in 2027 and may be renewed by LADWP under certain circumstances, subject, in addition, to legal and regulatory mandates.

- Pursuant to a Power Purchase Agreement with UP&L, LADWP purchases capacity and energy equivalent to the capacity and energy made available to UP&L pursuant

AR0070207

to its 4 percent entitlement in the IPP (currently equal to approximately 72 MWs) until 2027, subject to certain renewal rights, which are dependant upon certain factors including the renewal of the IPP Contract.

- LADWP also has available additional capacity in the IPP through an excess power sales agreement with certain other IPP participants (the "IPP Excess Power Sales Agreement"). Under the IPP Excess Power Sales Agreement, LADWP is entitled to a maximum 18.168 percent of the capacity of IPP (equal to approximately 327 MWs). However, this amount varies as portions of it may be recalled by other participants. Of the maximum possible 327 MW allowed under this Agreement, approximately 209 MW is the summer 2012 entitlement amount.

Fuel Supply: IPA sold its 50 percent undivided interest in the Crandall Canyon Mine in Emery County, Utah and 50 percent undivided interest in the West Ridge Mine in Carbon County, Utah, in 2010. As part of the sale, a continued long term contract for fuel from the West Ridge Mine for IPP was agreed to at about 20 percent of the annual 6,000,000 ton coal requirement. LADWP, in its role as Operating Agent, manages all fuel supply contracts on behalf of IPA, including several long-term coal supply agreements that can provide approximately 60 percent of the coal requirements for the IPP. Spot market and opportunity purchases provide the balance of the fuel requirements for the facility. Additional information regarding IPP's fuel procurement strategy is found in Appendix H.

Over the past several years, the IPP units have had several substantial modifications, including cooling tower additions, high pressure turbine replacements, boiler capacity additions, distributed control system replacement, scrubber outlet modifications and rebuilds, and induced draft fan drive replacement. These modifications have decreased emissions and increased plant efficiency. They have also increased the plant's capacity by 110 MW, resulting in a 68 MW increase in capacity for LADWP.

Navajo Generating Station

The Navajo Generating Station (NGS) is located near the City of Page, Arizona. Salt River Project (SRP) is the operating agent for the Navajo Station. The Navajo Station is a coal-fired electric generating station and consists of three units with a combined net maximum capacity of 2,250 MWs. LADWP's entitlement of the Navajo Generating Station capability is 21.7 percent. On March 23, 1976, LADWP, Arizona Public Service Company (APS), Nevada Power Company (NPC), SRP, Tucson Electric Power Company (TEP) and the U.S. Department of Interior executed the Navajo Project Co-Tenancy Agreement effecting the co-owners' participation, and the operation and maintenance of the Navajo Project for as long as the land lease with the Navajo Nation is in effect until December 31, 2019 and throughout the lease extension thereafter. Negotiations are currently under way between the Navajo Nation and SRP, on behalf of the NGS participant owners, to renew the terms of the lease and all rights of way (ROWs) and grants related to the NGS site, transmission and railroad until December 31, 2044.

The station's SO_2 scrubbers, which were installed in 1999, continue to operate in full compliance with federal regulations for SO_2. The plant-wide compliance number has been under the emission limit of 0.10 pounds per million Btu.

AR0070208

NGS also completed its Low NO_x burner Separated Overfire Air (SOFA) retrofit project in late March 2011. The Low NO_x-SOFA installation on all three units' boilers has contributed to a successful reduction of NO_x emissions by 40%, representing an annual NO_x emissions reduction of 14,800 tons/year. The NO_x emission is now under the limit of 0.24 pounds per million Btu.

Stringent NO_x emissions control standards currently being considered by the federal government for the pending Regional Haze Best Available Retrofit Technology (BART) ruling may require Navajo Generating Station to install Selective Catalytic Reduction (SCR) systems which carry a capital cost of approximately $550 million (or $137 million for LADWP). Should the new regulations require the installation of baghouses in addition to the SCRs, the combined capital cost of both SCRs and baghouses would amount to $1.13 billion (or $240 million for LADWP). The installation of these SCRs and baghouses could begin as early as 2017 and as late as 2029. On the other hand, if only Non-Selective Catalytic Reduction (NSCR) is required, the capital cost will be $40 million (or $8.5 million for LADWP).

In March 2011, the Environmental Protection Agency (EPA) released another proposed rule called the Utility Maximum Achievable Control Technology (MACT) that sets the national emissions standards for hazardous air pollutants (HAP) for electric generating units (EGUs). This rule calls for compliance of monitoring systems for Hg, particulate matter, and SO_2 (or HCl), hourly data collection, quarterly submission of emissions data, and new work practice standards for dioxins, furans, and other organic HAPs that would require regular "tune ups" of boilers to optimize combustion. These MACT modifications could be as much as $148.5 million (or $31.5 million for LADWP) or less depending on the required compliance systems.

The EPA also proposed federal regulations governing the disposal of coal ash and other coal combustion byproducts (CCBs) under the Resource Conservation and Recovery Act (RCRA). Under this rule, CCBs may be classified as either RCRA Subtitle C hazardous waste or RCRA Subtitle D non-hazardous waste. The regulation of CCBs under RCRA Subtitle C would impose staggering compliance costs on the power industry including NGS. An unfavorable ruling would jeopardize fly ash sales, trigger significant capital improvement to minimize environmental releases of coal ash and other byproducts, involve additional manpower to manage new programs, and require additional monitoring of the ash disposal landfill. Such coal ash disposal initiatives could amount to approximately $10 million (or $2.1 million for LADWP).

AR0070209

F.2.3. Nuclear-Fueled Thermal Generation

LADWP's nuclear-fueled generating plant capabilities are shown in Table F-3.

Table F-3. NUCLEAR GENERATING RESOURCES

Plant Name	Unit	COD[1]	License Expiration	Net Max Capability (Total kW)	Net Max Capability (LADWP kW)	Net Dependable Capability (LADWP kW)	LADWP Share[2]
LADWP Direct Ownership Interest:							
Palo Verde	1 2 3	1986 1986 1988	2045 2046 2047	1,333,000 1,336,000 1,334,000	75,981 76,152 76,038	74,727 74,898 74,784	5.7%
LADWP Entitlement Interest Through SCPPA:							
Palo Verde	1 2 3	1986 1986 1988	2045 2046 2047	1,333,000 1,336,000 1,334,000	52,787 52,906 52,826	51,916 52,034 51,955	3.96% (SCPPA)
Total					386,690	380,314	

Notes:
1. COD refers to Commercial Operation Date.
2. LADWP's contract entitlement is 9.66 percent of generation comprised of 5.7 percent direct ownership in Palo Verde and another 67 percent power purchase of SCPPA's 5.91 percent ownership of Palo Verde.

Palo Verde Nuclear Generating Station (PVNGS) is located approximately 50 miles west of Phoenix, Arizona. PVNGS consists of three nuclear electric generating units (numbered 1, 2 and 3), with a net design electrical rating of 1,333 MW (Unit 1), 1,336 MW (Unit 2) and 1,334 MW (Unit 3) and a net dependable capacity of 1,311 MW (Unit 1), 1,314 MW (Unit 2) and 1,312 MW (Unit 3). PVNGS's combined net design capacity is 4,003 MW, and its combined net dependable capacity is 3,937 MW. All three units have been operating under 40-year Full-Power Operating Licenses from the Nuclear Regulatory Commission (NRC) expiring in 2025, 2026, and 2027, respectively. In April 2011, the NRC approved Palo Verde's application to extend the units' operating licenses to 20 years beyond the original term, allowing Unit 1 to operate through 2045, Unit 2 through 2046, and Unit 3 through 2047. APS is the operating agent for PVNGS. For the fiscal year ended June 30, 2011, PVNGS provided over 3.1 million megawatt-hours ("MWhs") of energy to the Power System. LADWP has a 5.7 percent direct ownership interest in the PVNGS (approximately 224 MW of dependable capacity). LADWP also has a 67.0 percent generation entitlement interest in the 5.91 percent ownership share of PVNGS that belongs to SCPPA through its "take-or-pay" power contract with SCPPA (totaling approximately 156 MWs of net dependable capacity), a joint powers authority in which LADWP participates, so that LADWP has a total interest of approximately 380 MW of net dependable capacity from PVNGS. Co-owners of PVNGS include APS; the SRP Agricultural Improvement and Power District, a political subdivision of the state of Arizona, and the Salt River Valley Water Users'

AR0070210

Association, a corporation (together, the "Salt River Project"); Edison; El Paso Electric Company; Public Service Company of New Mexico; SCPPA, and LADWP.

The aftermath of the Fukushima earthquake and tsunami prompted the U.S. nuclear industry to form a task force under the direction of Palo Verde's Chief Nuclear Officer to take immediate actions in ensuring the reliability of all U.S. nuclear plants. Palo Verde itself has established a task force to evaluate the plant's safety and emergency preparedness. An initial assessment of the plant systems, safety policies, and emergency procedures revealed significant differences between Palo Verde and Fukushima. Palo Verde's low-seismic location, robust pressurized water reactor design, redundant safety features, ample effluent water supply, and multiple back-up power sources make a similar catastrophe in Arizona highly improbable. Despite the seemingly substantial advantages, Palo Verde, in conjunction with other nuclear agencies, is continuously working to make sure that the plant is adequately prepared to meet beyond design basis events, respond to extended loss of power supply situations, and mitigate potential fire and flood events. While evaluations are still in progress, among the initial recommendations are plans to accelerate fuel removal from the spent fuel pools and possibly purchase a standby diesel generator as reinforcement to the existing back-up power sources.

F.2.4 Large Hydroelectric Generation

LADWP's large hydroelectric facilities include the Castaic Pumped Storage Power Plant and an entitlement portion of the Hoover Power Plant. LADWP's hydroelectric plant capabilities are shown in Table F-4.

AR0070211

Table F-4. LARGE HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Capability (LADWP kW)	Net Dependable Capability (LADWP kW)	LADWP Expiration	LADWP Share
Castaic[2]	1 2 3 4 5 6 7	1973 1974 1976 1977 1977 1978 1972	212,500 265,000 265,000 265,000 265,000 265,000 56,000	250,000 265,000 270,000 265,000 265,000 265,000 55,000	1,175,000	Owned Asset	100%
Hoover[3]		1936	2,079,000	491,000	468,000	30Sep2017	25.16%
Total				2,126,000	1,643,000		

Notes:

1. Commercial Operation Date.
2. Castaic Power Plant is re-rated at 1,175 MW. Castaic Power Plant Units 2, 4, 5, 6 modernizations were completed September 2004, June 2006, July 2008, and December 2005 respectively. Unit 3 modernization was completed in June 2009.
3. LADWP's entitlement is 25.16% of the plant's contingent capability of 1,951 MW (or 491 MW). The reduced entitlement is due to lower lake levels resulting from the western drought, which has abated recently. The current Hoover net plant capability as of April 20, 2012 is 1,861 MW. The 15.4229% is LADWP's share of total Hoover generation.

AR0070212

Castaic Pump Storage Power Plant.

The Castaic Pump Storage Power Plant (the "Castaic Plant") is located near Castaic, California. The Castaic Plant is LADWP's largest source of hydroelectric capacity and consists of seven units with a net dependable capacity of 1,175 MWs. The Castaic Plant provides peaking and reserve capacity for LADWP's load requirements.

Hoover Power Plant.

General. The Hoover Power Plant (the "Hoover Plant") is located on the Arizona-Nevada border approximately 25 miles east of Las Vegas, Nevada and is part of the Hoover Dam facility, which was completed in 1935 and controls the flow of the Colorado River. The Hoover Plant consists of 17 generating units and two service generating units with a total installed capacity of 2,080 MWs. LADWP has a power purchase agreement with the United States Department of Energy Western Area Power Administration ("Western") for 491 MWs of capacity (calculated based on 25.16 percent of 1,951 MWs of total contingent capacity) and energy from the Hoover Plant through September 2017. The facility is owned and operated by the United States Bureau of Reclamation.

Drought Conditions. The long drought conditions and low lake levels have been improved recently, consequently LADWP's capacity entitlement at the Hoover Plant has increased to 468 MWs (calculated based on 25.16 percent of 1,861 MW output capability as of April 20, 2012).

F.2.5 Renewable Resources and Distributed Generation

LADWP's Renewable Resources and Distributed Generation consists of

- Eligible renewable small hydro resources as shown in Tables F-5, F-6 and F-7.
- Renewable and distributed generation resources as shown in Table F-8.

AR0070213

Table F-5. OWENS VALLEY SMALL HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Unit Capability (LADWP kW)	Net Max Plant Capability (LADWP kW)	Net Dependable Capability (LADWP kW)
Haiwee[3]	1 2	1927 1927	2,800 2,800	3,600 3,600	4,200	0
Cottonwood[3]	1 2	1908 1909	750 750	1,200 1,200	1,900	400
Division Creek	1	1909	600	680	680	400
Big Pine[4]	1	1925	3,200	3,050	3,050	400
Pleasant Valley[5]	1	1958	3,200	2,700	2,700	0
Total					12,530	1,200[2]

Note:

1. Commercial Operation Date.
2. Owens Valley combined Net Dependable Plant Capability is 1.2 MW based on 20-years of historical data. 1.2 MW consists of 0 MW from Haiwee and Pleasant Valley and 0.4 MW each from Cottonwood, Division Creek and Big Pine.
3. Haiwee maximum unit capability is 3.6 MW each when feed is taken from North Haiwee Reservoir. Cottonwood Power Plant Units 1 and 2 were re-wound to higher Net Maximum Unit Capability of 1.2 MW.
4. Big Pine Net Maximum Unit Capability is limited to maximum flow through penstock.
5. Pleasant Valley Power Plant output is limited to Division of Safety of Dams (DOSD) reservoir level restriction.

AR0070214

Table F-6. OWENS GORGE SMALL HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Unit Capability (kW)	Net Max Plant Capability (kW)	Net Dependable Capability (kW)
Upper Gorge	1	1953	37,500	37,500	37,500	36,500
Middle Gorge	1	1952	37,500	37,500	37,500	36,500
Control Gorge	1	1952	37,500	37,500	37,500	36,500
Total[2]					112,500	109,500

Notes:

1. Commercial Operation Date.
2. Owens Gorge Net Dependable Plant Capability was decreased to 109.5 MW to reflect re-watering flow.

The Owens Gorge and Owens Valley Hydroelectric generating units (the "Owens Gorge and Owens Valley Hydroelectric Generation") are located along the Owens Valley in the Eastern High Sierra. The Owens Gorge and Owens Valley Hydroelectric Generation are a network of hydroelectric plants which use water resources of the Los Angeles Aqueduct and three creeks along the Eastern Sierras. The water flow fluctuates from year to year; as a result, water flow may be reduced from seasonal norms from time to time.

San Francisquito Canyon and at the Los Angeles and Franklin Reservoirs. LADWP also owns and operates 12 units located north of the City along the Los Angeles Aqueduct in San Francisquito Canyon and at the Los Angeles and Franklin Reservoirs. The net aggregate dependable plant capability of these smaller units is 24 MWs under average water conditions. Table F-7 summarizes these 12 units.

AR0070215

Table F-7. AQUEDUCT SMALL HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Unit Capability (kW)	Net Max Plant Capability (kW)	Net Dependable Capability (kW)
Foothill (PP4)	1	1971	11,000	9,900	9,900	2,900

Sawtelle (PP6)	1	1986	640	650	650	130
Total[3]					83,050	24,230

Note:

1. Commercial Operation Date.
2. San Francisquito Power Plant 2, Unit 1 has been out of service since 1995. The plant's Unit 2 stator heating limits capacity to 8 MW during hot weather condition. The plant's Unit 3 has a new generator with refurbished turbine as of the end of 2006. The contract specification is 18 MW output, but the unit was tested to only 16 MW due to low water flow and restricted downstream capacity. Assumed maximum actual output is 18 MW.
3. Aqueduct combined Net Dependable Plant Capability reflects low water availability during winter.

AR0070216

Notes:

[1] Table include LADWP's renewables and distributed generating sources from LADWP-owned and contracted projects. This table is based on data from the April 10, 2012 RPS Master Project List and contract sources.

[2] The full-load continuous rating of a generator unit under specified conditions as designated by the manufacturer.

[3] Maximum Plant Capability reflects water flow limits at hydro plants; or sum of each unit at renewable plants.

[4] Net Dependable Plant Capability reflects the amount of generating capability that can depend on during the peak demand hours of a day. Dependable capacity of a renewable technology plant is estimated by applying a Dependable Capacity Factor (DCF) to the plant nameplate capacity. The conservative factor is used until LADWP gains more actual amount of operating experience with renewable technologies. DCFs currently used are as follow:

- Digester Gas 1.00
- Geothermal 0.90
- Landfill Gas 1.00
- Muncipal Solid Waste Conversion 1.00
- Small Hydroelectric 1.00
- Solar Photovoltaic 0.27
- Wind 0.10 (projects with firming contracts are rated at firming levels)

AR0070217

Appendix G Distributed Generation

G.1 Overview

Distributed Generation (DG) is a concept of installing and operating small-scale electric generators, typically less than 20 megawatts MW, at or near an electrical load and interconnected to the electric utility distribution system. The most common technologies used today for DG are turbines and internal combustion engines (ICEs). However, new technologies including fuel cells, microturbines, and solar PVs are now being developed. The promise of DG is to provide electricity to customers at a reduced cost and more efficiently than the traditional utility central generating plant with transmission and distribution wire losses. Other benefits that DG could potentially provide, depending on the technology, include reduced emissions, utilization of waste heat, improved power quality and reliability and deferral of transmission or distribution upgrades.

DG can be customer installed or utility installed. The benefits for customer installed DG include waste heat recovery, backup power and power quality. The benefits for utility installed DG include generation, transmission and distribution infrastructure deferral, and reduction of delivery losses.

This Appendix describes DG on the grid, ICE technologies, fuel cells, and PV technologies.

G.2 Distributed Generation on the Grid

The introduction of competition into the electric marketplace has driven the development of new electrical generation technologies. Most technologies being developed for DG applications are more costly than traditional generating resources. However, it is anticipated that, with advances in the technologies and a greater demand for DG, costs will decrease, and more systems will be installed.

As of 2010, LADWP has approximately 161 GWh of combined heat and power and 79 GWh coming from landfill or process gas that is put into the electrical grid. Most of the combined heat and power DG is made up of 20 MW or larger natural gas combustion engines. The amount of customer DG installed in the future will depend on several factors including reliability, cost of the technologies, and natural gas and electricity prices. With stable electricity prices and high natural gas prices, customer generation becomes less attractive. Additionally, as of September 1, 2012, about 6,200 LADWP customers have installed over 56 MW of solar PV energy systems with the help of LADWP's Solar Incentive Program.

LADWP has installed 3 MW of solar PV energy systems on LADWP and City of Los Angeles (City) facilities to generate clean, renewable energy for the LADWP grid. LADWP has also installed various other DG technologies for demonstration purposes to understand the operating issues and benefits associated with various equipment and to promote the development of new clean, efficient technologies.

AR0070218

Tables G-1 and G-2 provide projections of Cogeneration and PV capacity and energy used in the 2012 IRP. Cogeneration forecast is from 2012 Retail Energy and Demand Forecast.

Table G-1. PROJECTED DISTRIBUTED GENERATION COGEN - CUMULATIVE

NOTE: Solar Distributed generation includes the Solar Incentive Program (SIP), Feed in Tariff program (FiT) and Utility Built Solar (UBS)

AR0070219

G.3 Internal Combustion Engines

ICEs include reciprocating engines and combustion turbines. Improvements have been seen recently in the emissions and efficiencies of reciprocating engines and combustion turbines. Combustion turbines have typically been in the multi-MW size, but recently small-scale combustion turbines, or microturbines, have been developed.

Microturbines are machines ranging in size from 28 kilowatts (kW) to 500 kW, which include a compressor, combustor, turbine, alternator, recouperator, and generator. They have the potential to be located on sites that have space limitations to produce power. The advantages of microturbines are that there are a small number of moving parts, are compact in size, are lightweight, and can utilize waste fuels.

LADWP has installed nearly 2 MW of microturbines, the first of which was located at LADWP's Main Street Center in 1999. Additional microturbines have been installed at LADWP facilities and the Lopez Canyon landfill.

G.4 Fuel Cells

A fuel cell combines hydrogen and oxygen to produce electricity through an electrochemical process. Besides electricity, fuel cells produce water and heat. If the oxygen source is air, then small amounts of NO_X may also be emitted. Fuel cells produce energy at relatively higher efficiencies and emit far fewer air pollutants than combustion technologies. Fuel-cell power plants are now becoming commercially available for use by electric power producers, industrial facilities, and large commercial buildings. Smaller systems for residential, small commercial buildings and transportation applications are expected to be commercially available in the near future. The pricing for these products is expected to become competitive due to several factors:

- A fuel cell is a fairly simple technology with reasonably priced components.
- Significant recent investments in the technology are accelerating the development of fuel cells, and costs are decreasing.
    - Integrating fuel processing and power conditioning equipment can be a significant cost with regard to fuel cells, but reductions are likely as more fuel cells are manufactured and installed.

Under a pilot project, LADWP installed a total of four 200-250 kW fuel cell power plants in various locations in Los Angeles that have provided considerable experience and data. All four fuel cell plants have accomplished the task and the fuel cells have been removed from service.

G.5 Photovoltaics

Solar energy is converted to electricity using two power technologies: PV systems and solar thermal power systems. PV systems convert sunlight directly into electricity. PV systems are

AR0070220

modular, portable, highly reliable, and have low environmental impact, making them ideal for power applications of all sizes. Several large PV systems capable of powering hundreds of homes are now connected to utility grids throughout the United States. Many utilities are installing these systems on the rooftops of schools and their customers are installing them on the rooftops of their houses. LADWP has recently seen the popularity of local customer owned solar generation skyrocket due to the combination of utility paid incentives and recent federal tax law changes, as well as declining solar equipment costs.

A typical 4 kW alternating current (AC) residential rooftop solar power system produces 6,600 kW-hours per year. Presently, LADWP has installed about 1.3 MW of PV at LADWP facilities and other City facilities. LADWP incentives have supported the installation of over 51 MW on its customers' properties, as of May 1, 2012. In 2006 state legislation SB1 required all utilities to offer incentives to customers to install solar energy systems through 2016. LADWP's solar incentive program has been developed with a goal of encouraging the installation of 280 MW of customer installed solar PV systems by 2016 with a budget of $313 million over 10 years, however because of LADWP's lower electric rates, a higher incentive amount has been offered which will reduce the expected amount of customer installed solar to approximately 165MW. An additional 150MW of distributed solar is expected to be installed through a new feed-in tariff program.

The energy generation characteristics of a typical PV installation are that the output peaks around 1:00 p.m., and that 90 percent of a solar PV system's energy is produced from 10:00 a.m. to 4:00 p.m. during a typical summer day in California. Another point worth noting is that a solar PV system can be designed to coincide more closely to the system load profile by altering the module's orientation. While this will increase the energy produced during the peak load of the utility, it will result in an overall lower amount of energy produced for the day. Cloud cover also affects the energy output of a solar photovoltaic installation. The type of clouds will either raise or lower the output of the PV system. Darker rain clouds will lower PV output, but a light marine layer may actually produce more energy than the nameplate rating of the modules due to light reflecting off of the modules, back to the atmosphere, and then back to the modules. This does not happen often but does cause design issues that must be taken into account.

G.6. Combined Heat and Power (CHP) Program

Combined heat and power (CHP) systems, or also known as thermal cogeneration, simply capture and utilize excess heat generated during the production of electric power. CHP systems offer economic, environmental and reliability-related advantages compared to power generation facilities that produce only electricity. Distributed power generation systems, which are frequently located near thermal loads, are particularly well suited for CHP applications.

Currently CHP installed in the LADWP Power System consists primarily of cogeneration projects of industrial and commercial customers. This totaled to approximately 265 MWs nameplate capacity operating in the LADWP's service area. Some cogeneration projects sell excess energy to the LADWP under interconnection agreements.

Current barriers to the expansion of CHP can be attributed to:

AR0070221

- Natural gas price volatility in recent years has caused uncertainty in the economic feasibility of CHP projects
- Diminishing industrial customer base in recent years has reduced CHP developable potential
- Reliability and economic issues made small systems infeasible
- Added cost from utility replacement reserve requirements
- Uncertain Green House Gas emissions add costs to CHP electric generation
- Air quality siting restriction for new carbon-based CHP electric generation

LADWP is developing CHP target goals to incorporate CHP generation in its future resource mix. LADWP is currently considering development of the following self-owned CHP projects:

- Terminal Island Renewable Energy Project is a fuel cell plant to produce 4 MW of electricity and process heat using methane gas
- Los Angeles Bureau of Sanitation Alternative Technologies Projects to convert waste to heat

To encourage customer-developed CHP, shift demand from electric grid, and provide accurate price signals to customers, LADWP is currently offering a Standard Energy Credit (SEC) to its customers for excess energy they sell to LADWP. The SEC is based on LADWP marginal generation cost, and is updated and posted monthly. In the future, for renewable CHP, LADWP will provide a renewable premium based on the energy market plus the SEC. For non-renewable CHP, LADWP will continue to purchase CHP excess energy at the SEC.

Current Net Metering Incentives offered to customers require

- Customer must purchase electric services from LADWP to be eligible for interconnection
- Customer submits completed Standard Offer Agreement for interconnection and qualification for the CG Rate
- Customers pay for all costs associated with time-of-use metering, interconnection, and safe grid-parallel operation of the generation facilities
- For cogeneration facilities greater than one megawatt, the customer is required to install remote monitoring equipment for LADWP
- Customer maintains adequate insurance on generating facilities
- Excess power reimbursements are made to the customer at end of billing period at the CG Rate
- The interconnection agreement has a three year term and requires approval by the General Manager initially and for renewal and extension

Inclusion of the CHP goals under the IRP process will help communicate CHP program information and facilitate stakeholder feedback

AR0070222

(This page intentionally left blank)

Appendix H Fuel Procurement Issues

H.1 Overview

This Appendix presents issues and strategies related to LADWP procurement of both natural gas and coal.

H.2 Natural Gas

LADWP generates about 22 percent of energy from natural gas-fired generation. Or, in other words, almost one-fourth of LADWP's energy generation is exposed to the risks of gas price volatility. This percentage will increase in the future as coal is removed from LADWP's resource portfolio, and with the integration of additional variable energy resources. Figure H-1 below graphically illustrates the daily natural gas spot market price (including delivery charges to LADWP's gas plants) and the large price fluctuations from the year 2002 to 2006.

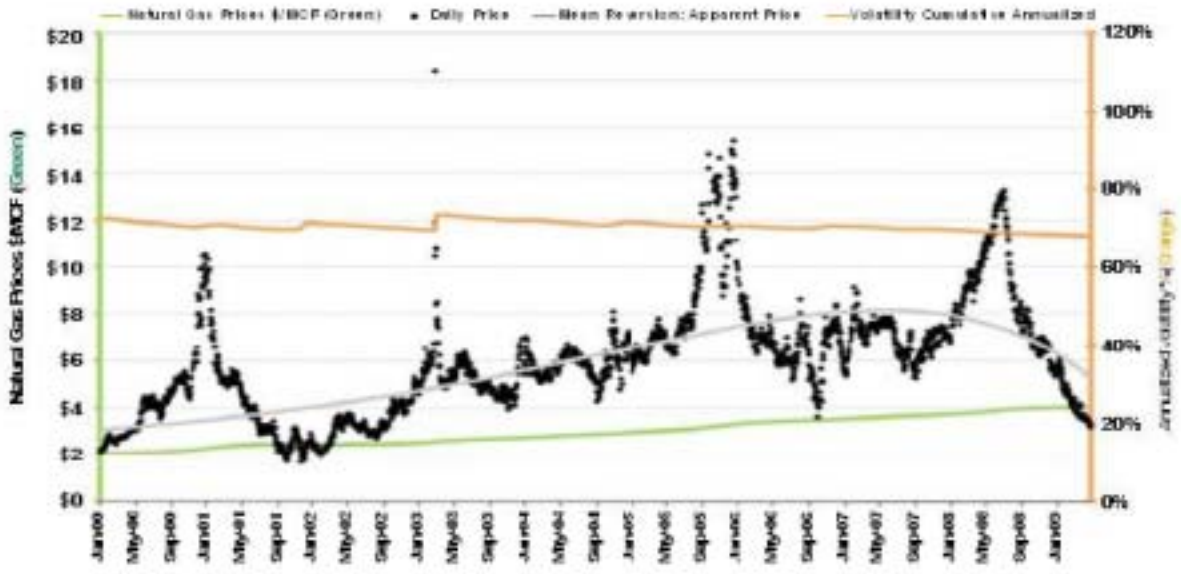

Figure H- 1. Natural gas daily spot prices.

As is shown on Figure H-1, the natural gas market has been very volatile with extreme variations of prices. Since gas currently plays such an important role in LADWP's generation portfolio, it is paramount that the impact of gas price volatility to the resource plan be mitigated.

To minimize LADWP's exposure to natural gas price volatility, LADWP has implemented a variety of actions since the 2000 IRP, which include:

AR0070224

1. Created a financial risk management program to mitigate natural gas price spikes and a comprehensive gas procurement strategy to support renewable generation and long term financial goals.
2. Established executive controls over energy risk management and natural gas hedging activities by creating an Executive Risk Policy Committee to provide clearance for all major hedging decisions.
3. Established a Fuels and Risk Advisory Working Group to examine forecasting methodologies, term hedging strategies and other items of importance to fuel procurement.
4. LADWP obtained approval from the Los Angeles City Council to delegate its award authority to LADWP's General Manager for approving limited term and price gas procurement contracts. LADWP also approved pro forma NAESB (North American Energy Standards Board) contracts for use in procuring natural gas. Additional authority was obtained for procurement of up to 10-year strips of biogas.
5. LADWP has participated with SCPPA in purchasing an active gas reserve in the Pinedale anticline area of Wyoming. This reserve is currently producing for SCPPA over 50,000 million British thermal units (MMBtu)/day, of which LADWP receives approximately 83 percent of the project.
6. LADWP has also replaced approximately 1,100 megawatts (MW) of electrical generation with combined cycle technology. This technology is much more efficient in generating electricity than the generating units that were replaced, resulting in a 30 percent to 40 percent decreased usage of natural gas to generate the same amount of electricity.
7. As a result of implementing the greater use of renewable energy, LADWP's usage of natural gas and coal will be reduced considerably. A general discussion on natural gas pricing issues is provided in the following subsections.

H.2.1 Natural Gas Pricing Issues

Gas delivered to the burnertip for electric generation in California is comprised of three elements: 1) commodity costs; 2) interstate transportation; and 3) intrastate transportation. Other concerns include regulatory/legal issues, gas price volatility, support for renewables and gas supply issues.

Commodity Costs

Natural gas for electric generation is produced primarily outside California in areas known as basins, such as the Green River Basin near Opal, Wyoming; the San Juan Basin near San Juan, New Mexico; and the Permian Basin in west Texas. Gas produced from individual wells is gathered by small pipeline systems and delivered into a gas plant that processes the raw gas into pipeline quality gas for delivery to markets. Prior to the 1980s, this pipeline gas was sold as a bundled product by various interstate pipelines to distribution companies in the individual states, such as the Southern California Gas Company (SoCal) and the Pacific Gas & Electric Company (PG&E). Eventually interstate gas rates were restructured so that interstate pipelines became

AR0070225

transport-only businesses with the gas marketing function spun off to the market via unregulated affiliates or independent marketers.

Intensified exploration in non-traditional producing areas of the country, chiefly the so-called shale gas, has produced a surplus of gas, which has pressured prices lower recently and will continue to do so in the foreseeable future. The development of Liquefied Natural Gas (LNG) import terminals in the United States has been delayed by a number of factors, including regulatory requirements, environmental issues, safety concerns, and economic uncertainty. Development of resources known to exist in the United States offshore continental shelf, especially in view of the blowout of a deep underwater well near the coast of Louisiana, continues to experience similar issues. In light of the burgeoning supply of shale gas some LNG import terminals have applied to the FERC to convert to export terminals.

Interstate Transportation

The interstate pipeline companies that formally sold bundled gas along with their transportation services have now focused primarily on the transportation of gas from producing basins to interconnections with the individual state's local distribution companies. The jurisdiction for the regulation of these companies falls under the authority of the Federal Energy Regulatory Commission (FERC). California is currently served by seven interstate pipelines although only four are actually directly connected to supply basins. The other three redistribute gas from other interstates. Volatility in gas prices into California has arisen because of various supply-related issues, variations in liquidity stemming from fewer suppliers in the aftermath of the market adjustment following 2000-2001, financial trading of commodities by funds, and weather-related events throughout the country. Limited price discovery has also added an element of uncertainty in gas transactions. Additional pipeline capacity to California is readily available through expansions of existing pipelines and interruptible capacity. LADWP has firm capacity on the Kern River pipeline approximately equal to its forecasted average gas requirement although there is a certain amount of uncertainty in this forecast depending upon the degree of implementation of renewables.

Intrastate Transportation

SoCal is the sole provider of intrastate gas transportation services in Southern California. These services consist primarily of delivering gas from the interconnections with interstate pipelines near the California border, but also include storage, balancing, wheeling, parking, and loaning of gas. Ever since May 1988, SoCal has been relieved of its obligation to serve the so-called non core customers, those who are able to make their own arrangements for procuring their own gas. All electric generators such as LADWP are deemed non-core or transport-only customers. The rate charged by SoCal for this transportation only service is regulated by the California Public Utilities Commission (CPUC). This rate is the lowest for any customer class (outside of any special negotiated rate) because it provides the minimum service and provides as close to cost-of-service pricing as possible. LADWP's active participation in SoCal's rate cases at the CPUC was instrumental in achieving this distinction.

Additional services relating to the delivery of gas are available from SoCal, but the rates are subject to negotiation and, usually, CPUC approval. Generally speaking, these services are of more value to marketers than to municipal generators, but in any case add to the cost of delivered gas.

AR0070226

One issue that has emerged from the recent price volatility in Southern California is whether or not SoCal has the ability to accept all the gas that will be filling the expanded interstates over the next few years. The CPUC has addressed this issue in a recent proceeding into the adequacy of SoCal's system to serve the expected load on its system. So far no conclusions can be made but SoCal is confident that they have the problem in hand because of their recent completion of various system upgrades increasing takeaway capacity by approximately 21 percent. SoCal has been able to settle rate allocation issues to allow its intrastate transmission system to accommodate the delivery of LNG Gas supplies into its system. In addition SoCal is planning system upgrades to provide more reliability in the southern part of their system which should increase overall system reliability. SoCal has also announced its intention to improve reliability with a Pipeline Safety Enhancement Program which will, among other things, replace significant portions of older transmission lines.

Regulatory/Legal Issues

Several issues at the CPUC and FERC also impact pricing. SoCal revised its rates on October 2008 to accommodate the delivery of LNG into California, through the implementation of what is known as the Firm Access Rights (FAR) decision, now termed Basic Transportation Service or BTS. Implementation of BTS has affected the role of transportation pricing and the distribution of receipt point allocations for deliveries into the California market. The BTS program has been renewed for another three years. The Department has obtained BTS rights that match with its firm Kern River Interstate capacity. Another issue regarding the SoCal system, is the Wobbe Index. The Wobbe Index relates to the energy content of the natural gas delivered into SoCal's system which affects operating characteristics of gas turbines and emissions levels. The Wobbe Index has risen to prominence due to environmental concerns which may substantially affect SoCal's service to electric generators. The CPUC has already allowed SoCal to set sufficiently high limits on the Wobbe Index for gas coming into its system. This will chiefly benefit LNG sourced gas although there is a challenge being mounted by the South Coast Air Quality Management District (SCAQMD). The SCAQMD has adopted a new rule, Rule 1333, which proposes to monitor the effects of any increase in the Wobbe Index and could be interpreted as an attempt to regulate the distribution of natural gas. It is anticipated that the CPUC will oppose this initiative, and at this point in time, SoCal has filed a lawsuit to set aside Rule 1333.

The FERC has approved new tariff sheets for the Kern River pipeline in which LADWP has a substantial interest. Kern River had applied for a significant rate increase, but lost after a long proceeding at the FERC. The rate case was settled by most of the interested parties and refunds were distributed. The Department is in the process of seeking approval of restated transportation contracts to reflect the newly approved tariffs which will make the Department's contracts consistent with the contracts of all the other Kern River shippers and insure rollover rights when the contracts eventually expire.

Gas Price Volatility

During the winter 2000-2001 gas prices were highly volatile. This was somewhat repeated in milder form briefly in early 2003 and the second half of 2005. For the most part, extreme volatility has subsided with prices remaining at substantially lower levels than in previous years due to the recession. Forward pricing indicates that gas prices will move relatively sideways with a slight bias

AR0070227

upward, in part due to the competing effects of the economy and increased supplies of shale gas. The industry has endeavored to reduce volatility through a massive effort of injecting gas into storage for winter use, thereby eliminating the perception of a huge overhang of expected gas purchases during the winter heating season. Due to the abundance of shale gas production, storage levels at the end of the injection season have typically reached record levels.

Gas Supply Issues

- New drilling techniques make it possible to extract natural gas from deep shale rock formations. The advances mean the United States has more abundant natural gas resources than previously believed. Gas advocates say it could significantly alter the future U.S. energy market.
- Horizontal drilling ($1.06-$1.34 /thousand cubic feet (Mcf)) vs. vertical drilling ($1.71 Mcf): horizontal wells open up much larger area of the resource-bearing formation.
- Hydraulic Fracturing (or fracking): Injecting a mixture of water and sand at high pressure to create multiple fractures throughout the rock, liberating trapped gas. Environmental issues have become more prominent.
- Combination of the Horizontal drilling and fracking.
- With more drilling experience, U.S natural gas reserves are likely to rise dramatically in the next few years. At current level of demand, U.S. has about 90 years of proven and potential supply.
- Preliminary estimates suggest that shale gas resources around the world could be equivalent to or even greater than current proven natural gas reserves.

H.2.2 Natural Gas Procurement Strategy

LADWP retained the services of PriceWaterhouse Coopers (PwC) in 2003 to assess, validate, and verify LADWP's current gas procurement strategy. Their report assessed the current strategy, suggested changes and enhancements to that strategy, and prepared a preliminary plan and timetable for implementing the changes.

As a result of PwC's review of gas operations, LADWP decided to adopt a program of protecting its gas costs from price volatility through financial hedging. The appropriate authority was sought and received by the City Council to employ financial hedges for up to ten years and physical hedges for up to five years, and to limit spending for this effort to no more than $15 million per year.

In addition, an Executive Risk Policy Committee was formed with senior management as members to provide oversight over the energy risk management activities of LADWP, including natural gas. Several actions have taken place.

First, LADWP's Financial Services Organization (FSO) negotiated individual ISDA (International Swaps and Derivatives Association) agreements with potential counterparties for the swaps to

AR0070228

hedge gas prices. Fiscal Year 03-04 was the first complete year for using financial hedging to cap gas prices over a portion of forecasted gas requirements.

Second, LADWP obtained approval of two ordinances from the Council authorizing the Board of Water and Power Commissioners to delegate its award authority to the General Manager for approving gas procurement contracts. Subsequently the Board approved two separate pro forma NAESB (North American Energy Standards Board) contracts for use in procuring natural gas for up to one year, and for up to five years in duration. A number of the one-year NAESB agreements are now being used to buy gas. Five year strips of gas for physical risk management purposes were completed in late 2008 using the 5-Year NAESB authority. In addition, in mid 2009 the 5-Yr NAESB was used to obtain strips of biogas which contributes to the LADWP's Renewable Portfolio Standard goal. Additional hedging with natural gas is on hold due to the reduced gas usage and current hedge status limit set by the City Charter.

Third, LADWP participated through SCPPA in a Request for Proposal (RFP) process soliciting proposals for a term supply of natural gas for 30 years for up to an average of 27,500 MMBtu/Day with a discount to index. The agreements were negotiated but the deal was never completed because difficulties with the economy greatly reduced the anticipated discount offered under the prepay.

Fourth, LADWP has participated with the SCPPA in purchasing an active gas reserve in the Pinedale anticline area of Wyoming. Savings from this purchase have totaled approximately $52,000,000 for the six and a half years of ownership. Further production is indicated by virtue of the fact that neighboring production has been approved for drilling on 10-acre spacing, up from the current 20-acre spacing, by the Wyoming Division of Oil, Gas and Conservation. Other production adjacent to the SCPPA properties has already shown promise although development depends upon a number of environmental challenges.

PwC noted that LADWP's previous gas procurement strategy was highly dependent on spot market purchases and lacked the flexibility necessary to appropriately manage the price risk involved in gas buying, trading, and transportation activities. They argued at the time that price risk was a critical issue because gas was playing an increasingly important role in LADWP's future due to increased reliance on natural gas-fired generation. (Note that the 2030 IRP had recommended repowering four natural gas-fired generating stations and adding six gas-fired simple cycle combustion turbines to make up for a sale of a portion of LADWP's interest in the coal-fired Mohave plant, to replace units that were over 40 years old, and to meet anticipated load growth). Additionally, the increased use of renewables, such as wind and solar projects, may require higher levels of reserve margins because of their variable and intermittent nature, with the higher reserve margins being provided by gas-fired generation. Also, gas price volatility and constraints on the SoCal intrastate transportation system required LADWP to place more importance on gas supply management.

Of major significance, the Department has sought a minor change in its hedging authority to allow it to purchase up to 10 year supplies of biogas only. Using this authority the Department was able to purchase a maximum of 10,000 MMBtu/day of landfill gas from Shell Energy North America. This amount accounts for about 2% of the Department's committed goal of achieving 33 % renewables by 2020.

AR0070229

Implementation Actions

LADWP has adopted strategies to reduce exposure to daily gas price swings, by the use of monthly spot purchases, implementation of index based financial swaps, physical term purchases, and ownership of gas reserves. Monthly spot purchases lock in first of the month indexes and reducing the volumes subject to floating daily prices. The reserve acquisition will reduce overall costs through amortization of the purchase price for the reserve. Additional administrative procedures were put in place to further strengthen deal tracking and audit trails.

An important initiative was put into play to obtain delegated authority from the City Council to allow LADWP management to execute SoCal's Master Service Contracts. This contract allows the LADWP to take advantage of additional services offered by SoCal such as storage, parking, loaning and wheeling. The initiative was completed in early 2008.

Additional Actions To Be Considered

With respect to transportation and storage options, LADWP will need to evaluate its options in view of the aggressive schedule adopted by the Board of Commissioners in meeting its goals for implementation of renewable technologies for generation and elimination of coal-fired generation. The successful completion of both these goals will significantly impact the need for natural gas generation. To this end, LADWP has begun to develop standardized methods for evaluating capacity projects. Factors to consider in evaluating options including:

- Cost of being short gas supply
- The amount of fuel carried in inventory for emergencies
- The type of fuel carried in inventory for emergencies
- Cost of alternatives
- Demand Side Management (DSM)
- Spot power purchases
- Alternative generation costs
- Service interruptions and preparation for emergency fuel supply
- Political and budget impacts
- Cost of being over-contracted for off-peak periods
- Cost of new capacity (initial capital and demand and charges)
- Value of excess capacity sold on short-term basis

These factors are applied to the contracting options that range from meeting baseload requirements to meeting peak requirements.

SoCal is LADWP's only available intrastate transportation supplier by virtue of its authorized franchise. Since SoCal provides 100 percent firm full requirements service, LADWP's transportation need is met. Storage is being developed by others. In the meantime, LADWP may participate in SoCal's auction to acquire an appropriate amount of inventory space, injection rights and withdrawal capacity on a year to year basis. Storage is most effective contiguous to load centers. However, the most geologically effective sites in the greater Los Angeles area have already been developed by SoCal Storage service. Storage is primarily useful for minor load balancing and, to some extent, hedging. Given the robustness of SoCal's distribution system in

AR0070230

particular, and the interstate transportation system in general, storage is not necessary for emergency backup supply for power generation.

H.2.3 Proposed Actions

LADWP proposes to take the following actions to provide additional flexibility in implementing its natural gas procurement strategy:

- Increase the long-term natural gas hedging price cap. LADWP's authority for purchasing financial swaps for long-term natural gas is currently limited to $10.00 per MMBtu.
- Increase the short-term physical natural gas purchase price cap. LADWP's authority for purchasing short-term natural gas is currently limited to a rolling twelve months at $20.00 per MMBtu.
- Obtain delegated authority to execute SoCal's Master Services Contracts (MSC) along with the attachments for ancillary services as soon as the new MSC is published by SoCal after several regulatory proceedings have been concluded which may affect the form of MSC.
- Increase the term limitation for its short-term power purchases. LADWP's authority for purchasing short-term power is currently limited to a rolling eighteen months from date of execution. And likewise increase to eighteen months the 1-year gas NAESB contracts for short term gas purchases as has been done for electric deals.
- Seek authority to enter into long-term power purchase hedging contracts. LADWP is currently not authorized to enter into such arrangements.

In summary, LADWP has attempted to mitigate the impacts of volatile natural gas supplies and prices by acquiring a natural gas field, utilizing financial hedging contracts, and repowering over 1,000 MW of electrical generation with more efficient combined cycle technology.

H.2.4 Liquefied Natural Gas

LADWP has been carefully monitoring for years the development of LNG throughout the country, and in particular the many projects aimed at California. Generally, LADWP has been supportive of the concept but has not taken an active role in any proposed project. LADWP supports making additional supplies available to the market in California for reliability and cost reasons. This will be especially true as more states implement environmental regulations that will limit the amount of electricity produced from coal resources and shift much of the energy production to natural gas.

Currently there are no active LNG projects in California though several have been planned. Environmental issues and price containment from non-conventional shale gas have made project development a challenge. And in fact the current trend is to build or convert existing import terminals to export terminal due to the expanding production of shale gas nationwide.

AR0070231

H.3 Coal Procurement Strategy for the Intermountain Generating Station

H.3.1 Intermountain Generating Station

The Intermountain Power Agency (IPA) owns the Intermountain Generating Station (IGS). LADWP receives part of the power from IGS under a power purchase agreement with IPA that currently runs through 2027. LADWP is additionally under contract with IPA to oversee the operations of IGS and is known in that role as the Operating Agent. One of LADWP's duties as the Operating Agent is to arrange for the procurement of coal or coal assets, including any transportation services needed to get the procured coal to IGS. All contracts for coal procurement or coal asset ownership are done under the name of IPA. Management approval for coal procurement or coal asset ownership is given by the Intermountain Power Project Coordinating Committee (IPPCC), which is made up of IGS power purchasers (including LADWP), and the IPA Board of Directors (which does not include LADWP). Future coal procurement and coal asset ownership and related strategic development are therefore, done at the discretion and approval of the IPPCC and IPA Board of Directors on behalf of the power purchasers and owners of IGS.

H.3.2 Coal Supply – A Role for the Operating Agent

In its role as Operating Agent, LADWP administers, on behalf of IPA, a diversified portfolio of coal supply contracts that should by design hedge IGS power purchasers against escalating coal prices. The portfolio contains a combination of long-term, mid-term, and short-term coal supply contracts, which are either market price-based, fixed price-based, or cost of production price-based.

H.3.3 Coal Portfolio

The current coal procurement portfolio mix is as follows:

Long-term fixed pricing (with contracts beyond 2013):	60 percent
Short-term market pricing (spot market purchases):	40 percent

In all, the Operating Agent procures up to six million tons of coal per year for IGS based on current capacity factors. At present, IPA has in place coal contracts which can supply all of the coal needs of IGS through 2013, with a significant portion of the coal needs beginning 2014 also already in place.

Historically, the vast majority of coal procured for IGS has come from Utah sources. The procurement of coal in the near- and far-term will likely be done in a similar manner as described above, with the percentages of the pricing methodologies in the portfolio mix being determined with pricing and security of supply in mind. While Utah coal is expected to remain a key part of the IGS coal supply for the next 20 years, Utah sources of coal are diminishing. Thus, it is prudent for to the Operating Agent (with IPPCC and IPA Board of Directors guidance and approval) to seek out sources from new Utah mines and from other Rocky Mountain States. For

AR0070232

several years the Operating Agent has procured short-term contract coal from more than a half dozen sources in Colorado and Wyoming. This will have to be done to a greater extent in the future. Since travel time using IPA-owned unit-trains increases while traveling greater distances to the out-of-state sources, the Operating Agent has already made arrangements to lengthen IPA's unit-trains, obtain additional railcar capacity, and expand IPA's railcar operation and maintenance facility.

H.4 Alternative Fuels for Basin Generation

Although there will be ample supplies and delivery capacity for natural gas to power all Basin generation for the foreseeable future, there is some concern that that LADWP will become too dependent on a single fuel. As a consequence, a great deal of thought has been put into identifying potential backup supplies in the event of an emergency.

Among those considered are liquefied natural gas and ultra-low sulfur (CARB) diesel. Both fuels present unique storage, handling, operational, and/or environmental problems. Both are deemed too expensive to implement.

The greatest disaster that could possibly affect the LADWP's ability to generate electrical energy for native load would be a massive earthquake such as the Northridge Earthquake that afflicted Los Angeles in 1994. During that event, due to transmission line problems, the entire power system in Los Angeles was islanded and all available basin generation was put on line. No power was brought in from the Pacific Intertie and minimal power from Palo Verde, Navajo, Mohave or Intermountain power was available. Natural gas demand for power increased by 200,000 MMBtu/Day and was provided by a minority supplier in a timely fashion. This situation persisted for over two weeks until field crews could repair damage to transmission lines. No power plants were damaged as a result of the quake, but some were temporarily taken off line until the situation stabilized. All generation was eventually brought on line within a few hours of the quake. If the quake were much more severe, damage to the power plants' turbines would have necessitated them to be taken off line. The gas delivery system, both SoCal's distribution system as well as the interstate transmission systems, were not harmed by the Northridge quake. Characteristically, gas pipelines are imbedded in sand-filled trenches that allow the pipes to move about when the earth shifts, thereby reducing the possibility of breaking. Major transmission lines bring gas from the East and cross the San Andreas Fault, which move all the time, but rarely cause delivery outages. Thus it would appear that the gas delivery infrastructure is more robust than the power plants that depend on it.

We can conclude from this that although it might seem desirable to maintain some type of backup supply of fuel for in-Basin power plants, the existing natural gas supply system is likely both adequate and reliable enough to withstand a major disruption event.

However as a matter of prudent management of electric operations, the issue of backup fuel supplies or some other accommodation is being actively studied by the Fuels and Risk Advisory Working Group.

AR0070233

Appendix I Transmission System

I.1 Transmission Resources

LADWP is one of only a handful of electric utilities that own and operate a system with both alternating current (AC) and direct current (DC) transmission lines. The typical utility is exclusively an AC system with a shorter geographical reach than the LADWP network. LADWP employs its DC lines to import bulk power across state lines from markets and plants in Utah/Wyoming, Washington and Oregon. To lower transmission losses, AC/DC conversion equipment is utilized to interconnect its long distance DC lines with the AC system. Table I-1 lists LADWP's transmission resources.

Table I-1. BREAKDOWN OF TRANSMISSION RESOURCES

Voltage Class	AC/DC	Circuit-Miles
Out-of-Basin		
±500kV	DC	1,068
500kV	AC	1,069
345kV	AC	189
287kV	AC	350
230kV	AC	353
Out-of-Basin Circuit-Miles		3,029 (81%)
In-Basin		
230kV	AC	521
138kV	AC	153
115kV	AC	44
In-Basin Circuit-Miles		718 (19%)
Total Circuit-Miles		**3,747 (100%)**

As Table I-1 shows, the majority of LADWP's transmission assets are located outside of the Los Angeles Basin. Originally constructed to supply lower cost electricity to its customers and thereby maintain lower electricity rates, these assets are vitally important to LADWP's attainment of its 33% RPS goal by 2020. Excess transmission capacity is sold on a non-discriminatory basis in a wholesale market under an open-access transmission tariff largely conforming to FERC Order 890.

AR0070234

A one-line diagram of the key bulk power transmission lines is shown in Figure I-1. The transmission capabilities of the different systems are summarized in Table I-2.

Table I-2. IMPORT CAPABILITY OF TRANSMISSION RESOURCES

Transmission System	Transfer Rating (MW)	LADWP Share (MW)
East-to-LA Basin	4,000	3,566
West-or-River	10,623	3,273
East-of-River	9,256	1,456[1]
Pacific DC Intertie @ NOB	2,990	1,196
Owens Valley Transmission	450	450
Intermountain	2,400	1,428

[1]As of 6/1/2012

AR0070235

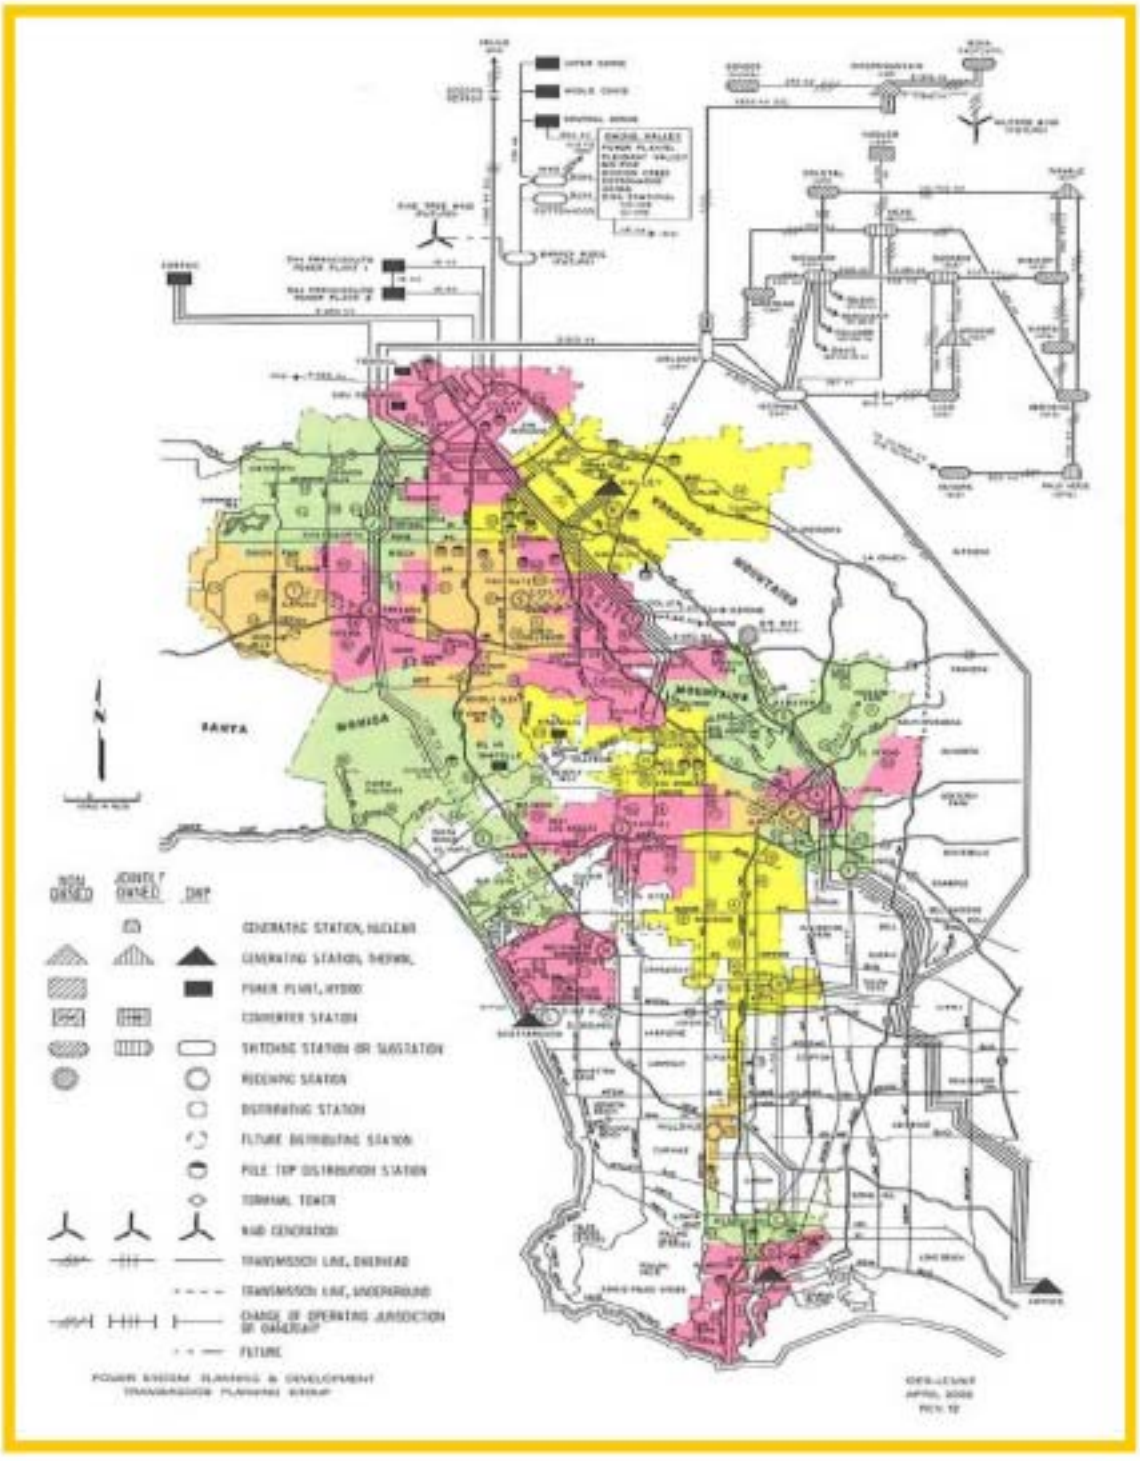

Figure I-1. LADWP Power System diagram.

AR0070236

I.2 Basin Transmission System

LADWP's basin transmission network is comprised of overhead and underground lines ranging from 115kV to 230kV; 4 switching stations that tie together multiple Transmission System circuits; and 20 receiving stations that serve as gateways to the distribution system and as tie points for basin power plants.

Because LADWP serves a metropolis, system reinforcements, additions, and improvements are often challenging; construction in crowded thoroughfares inconveniences so very many people. Compounding this challenge is the very real need to invest in an aging transmission infrastructure, parts of which date back to 1916. LADWP continues to explore and exercise feasible options to increase the utility of its resources, including dynamically rating critical belt-line segments. Even so, it is clear that long-term investments must be made in the near-term. According to the Ten-Year Transmission Assessment released in November 2010, LADWP's transmission system is capable of handling expected system peak loads for the next four years when supported by approved remedial actions to address vulnerable, critical double contingencies.

Further, the annual Ten-Year Transmission Assessments have consistently identified the need to install Scattergood-Olympic – 230kV Line 1 for many years now. With each passing year, the urgency becomes more apparent so that now even remedial actions have limited benefit. For this reason, LADWP is moving forward with the installation. With construction slated to begin in 2012, the new 15-mile long Scattergood-Olympic 230kV Line 1 in the Westside should be in-service before Summer 2015. Information on this project is available at the following website: http://www.ladwp.com/ladwp/cms/ladwp013744.jsp.

I.3 East-to-LA Basin Transmission System

The East-to-LA Basin System (see Table I-3) transmits power into the Los Angeles Basin from distant resources in Utah and the Desert Southwest. The Adelanto Converter Station receives power from the Intermountain DC corridor. The Victorville Switching Station is similarly joined to the task of receiving power from the West-of-River System.

Table I-3. EAST TO LA BASIN TRANSMISSION SYSTEM

Transmission Line	Voltage Class (kV)	Transfer Limit (MW)	LADWP Ownership (%)	LADWP Scheduling (%)
Victorville-Century Lines 1&2 Victorville-Rinaldi Adelanto-Toluca Adelanto-Rinaldi	287 500 500 500	4,000	100	100

AR0070237

I.4 West-of-the-River System

LADWP's West-of-River (WOR) system transmits power from the Mead/McCullough/Marketplace area to the Adelanto/Victorville area along WECC's WOR (Path 46). Path 46 facilitates transportation of electricity from the Navajo Generating Station (Page, Arizona) and the Palo Verde Generating Station (Wintersburg, Arizona) to Southern Nevada and to Southern California, respectively. Until the 1580 MW Mohave Generating Station was shut down in 2005, the Mohave-Lugo 500kV and the Mohave-Eldorado 500kV Lines primarily interconnected that station to the WECC power grid. Since 1996, LADWP has been selling available capacity in the wholesale markets via OASIS. The Palo Verde-Devers 500kV Line No. 1, of which LADWP has 368MW of bi-directional transmission service rights, and 368MW of bi-directional transmission service rights between Devers and Sylmar, is common to both the West-of-River System and the East-of-River System. Both systems are also related in that the capacity ratings are seasonally adjusted according to the Southern California Import Transmission (SCIT) Operating Nomogram.

The WOR system is summarized on Table I-4 and shown on Figure I-2.

AR0070238

Table I-4. WOR TRANSMISSION SYSTEM

	Transmission Line	Voltage Class (kV)	Allocation (MW)	LADWP Entitlement (MW)
North	McCullough-Victorville Lines 1&2 Hoover-Victorville	500 287	2,592	2,592

		WOR Total	10,623	3,273

Figure I-2. LADWP West-of-Colorado transmission resources.

AR0070239

I.5 East-of-the-River (EOR) System

LADWP's East-of-the River (EOR) system transmits power from the north-central and central areas of Arizona to the McCullough/Marketplace/Mead area along the WECC EOR (Path 49). Path 49 facilitates transportation of electricity from Navajo Generating Station (Page, Arizona) and Palo Verde Generating Station (Wintersburg, Arizona) to Southern Nevada and to Southern California, respectively. The Palo Verde-Devers 500kV Line No. 1, of which LADWP has 368MW of bi-directional transmission service rights, and 368MW of bi-directional transmission service rights between Devers and Sylmar, is common to both the West-of-River System and the East-of-River System. Both systems are also related in that the capacity ratings are seasonally adjusted according to the Southern California Import Transmission (SCIT) Operating Nomogram.

The EOR system is summarized on table I-5 and shown on Figure I-3.

AR0070240

AR0070241

I.6 Owens Valley Transmission Line

Essentially a segmented single line, the Owens Valley System is becoming increasingly important as a corridor to import renewable resources that support LADWP's RPS goals. Developers have proposed interconnecting renewable resource projects totaling more than 2950MW. These projects have been placed in the interconnection queue but require the construction of LADWP's Barren Ridge Renewable Transmission Project, described in Section 2.4.8 of this IRP.

The Owens Valley transmission system is summarized on Table I-6 and shown on Figure I-4.

Table I-6: Owens Valley Transmission System

AR0070243

I.7 Intermountain System

The Intermountain System is comprised of three WECC paths operated by LADWP on behalf of the Intermountain Power Authority:

- WECC Path 27, the 488-mile Intermountain Power Project DC Line, was upgraded from 1920MW to 2400MW in May 2011. The increased capacity has been accommodating transmission of wind energy from Utah (see Table I-7 and Figure I-5).
- WECC Path 28, the 50-mile Intermountain-Mona 345kV line ties Pacificorp to LADWP's Balancing Authority Area (see Table I-8 and Figure I-6).
- WECC Path 29, the 144-mile Intermountain-Gonder 230kV line ties NV Energy to LADWP's Balancing Authority Area (see Table I-9 and Figure I-7).

AR0070244

Table I-7. WECC PATH 27

AR0070247

I.8 Pacific DC Intertie System

Also known as WECC Path 65, the Pacific DC Intertie is a ±500kV DC line stretching from the Pacific Northwest to the Los Angeles Basin. This corridor provides the means for LADWP to import wind energy and hydroelectricity created from spring runoffs. For the Pacific Northwest, it provides access to low cost generation resources during cold winter months. As described in 2.4.8 of this IRP, research into the various technological options to increase the capacity of the Pacific DC Intertie is being conducted.

AR0070249

Appendix J Integration of Intermittent Energy From Renewable Resources

J.1 General Integration Principles

One of the main responsibilities of power system operators is to maintain the balance between the total aggregate electrical demand of the system's customers and the amount of energy generated to meet that demand on an instantaneous basis. Conventional electrical generation technologies, such as nuclear, coal, natural gas and large hydro are controlled and dispatched by the power system operators throughout the day to maintain this instantaneous balance between demand and generation.

However, some renewable resources generate energy following the vagaries of nature in a variable and intermittent manner, and the energy from these renewable resources is generally not controlled by power system operators but received dynamically as it is produced. For example, solar resources only produce energy during daylight hours, and wind resources only produce energy when the wind is blowing. Such renewable resources are often referred to as variable and intermittent renewable generation technologies.

It is anticipated that the amounts of energy generated from solar and wind resources will be substantial and increasing over time. The percentage of solar and wind resources compared to the total capability of a utility's power system may also be defined as "percent penetration." Percent penetration can be measured either by a capacity or energy method. Either measurement method is important; since a utility may use this information to determine the maximum amount of intermittent resources that a power system can accommodate without impairing the utility's ability to reliably maintain the required instantaneous balance between demand and generation.

Because power system operators cannot control or dispatch the production of energy from most renewable resources, the remainder of the power system must be controlled and dispatched to accommodate both the changes in renewable energy production and the changes in customer demand. In general, with the addition of increasing amounts of variable and intermittent renewable generation, the conventional controllable generation resources of a power system must become more flexible in their ability to rapidly ramp up or ramp down their output in order to successfully and reliably integrate new renewable generation.

J.2 Findings of System Integration Studies

In the last several years, LADWP has been increasing its efforts to acquire renewable resources. In 2003, 3 percent of energy sold to its customers was generated from renewable energy resources. This increased substantially to 20 percent in 2010, and 33% is mandated in 2020. With the much higher percentage of renewables coming on line, a variety of modifications will need to be made to the Power System to successfully and reliably integrate these higher penetrations of renewable resources. In preparation, LADWP has conducted preliminary studies on integrating renewable resources, and has also reviewed many renewable resource integration studies published over the last several years.

AR0070250

These studies have yielded some common observations and recommendations regarding the integration of intermittent renewable resources into power system generation portfolios. Some common observations of these studies include the following:

1. Larger power systems with robust transmission systems tend to have a greater ability to integrate intermittent wind and solar resources.
2. Individual wind power plants tend to have a high variability in the amount of energy produced (see Figure J-1, which illustrates the power output from the Pine Tree Wind Farm, rated at 135 MW with 90 wind turbines located over 7,100 acres).
3. Wind energy production impacts a power system's regulation (minute to minute generation variability), load following (hourly variability), and unit commitment decisions (day-ahead flexibility) (see Figure J-2, which illustrates the instantaneous generation for the Pine Tree Wind Farm for a single day).
4. Wind is usually categorized primarily as an energy resource. The dependable capacity value of a wind farm to the power system is much lower than the rated capacity of the wind turbines.
5. There is a financial cost to integrate intermittent wind and solar renewable projects into existing power systems, and this cost increases with increasing amounts of intermittent renewable resources.
6. Wind energy production patterns are not usually aligned with daily load patterns. Wind production tends to be greatest in the evenings when the daily load is near its minimum.

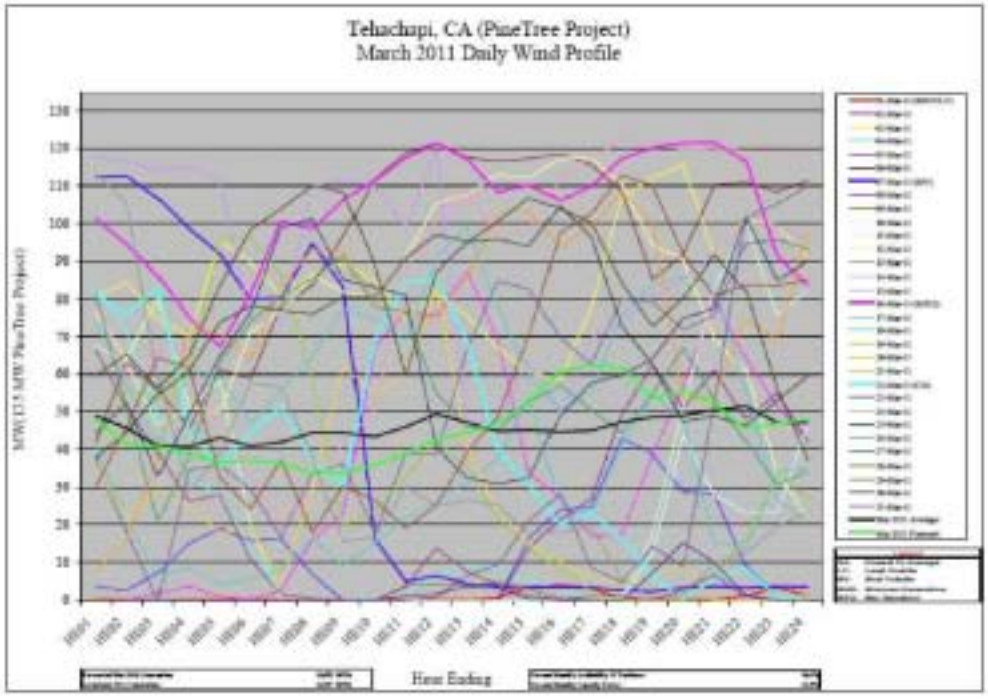

Figure J-1. Wind farm daily wind profiles.

AR0070251

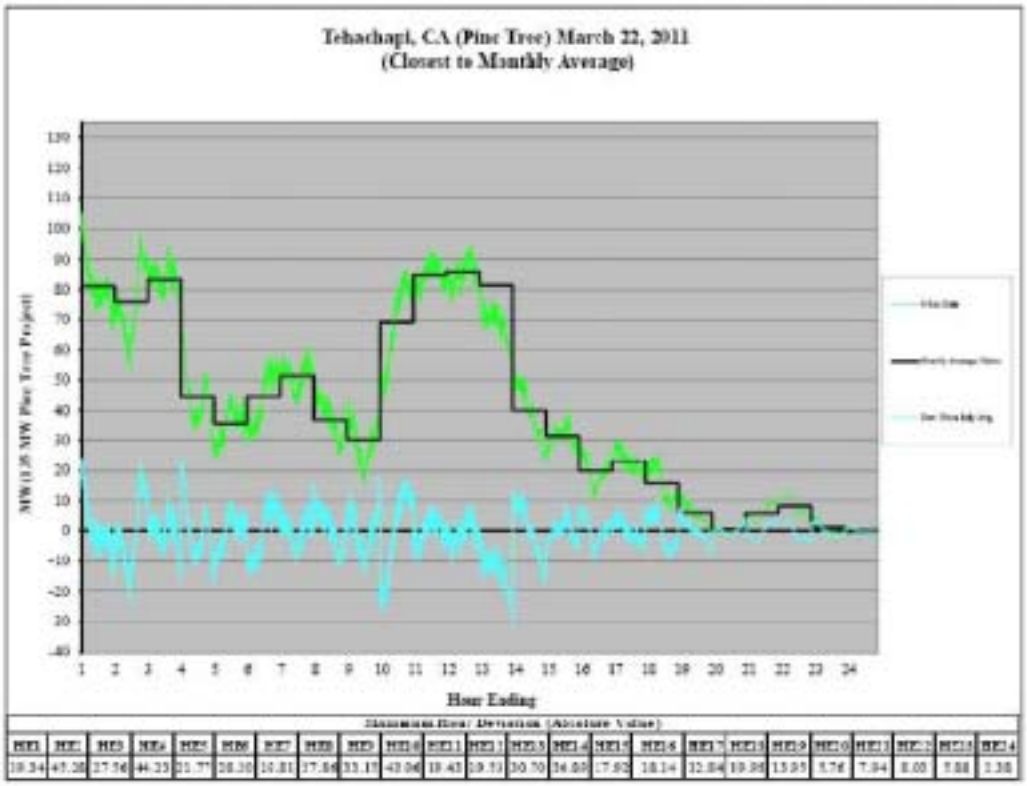

Figure J-2. Wind farm variability measured instantaneously.

7. In many cases high wind energy production during low power system energy demand hours represents the greatest challenge for power system operations.

8. Average daily and monthly wind energy production profiles are not representative of actual hourly production, due to the high variability in hourly energy production (see Figure J-1).

9. Solar energy production patterns are more closely aligned with daily load patterns than with wind energy production patterns, yet also exhibit variable and intermittent characteristics (see Figure J-3, which illustrates instantaneous output from LADWP's 10 MW Solar Photovoltaic facility located at Adelanto, California. Output tends to be smooth (about 40% of the days), or semi-volatile or volatile (about 60% of the days).

10. Energy generated from Solar PV technology is highly sensitive to cloud cover. These PV systems can experience variations in output of + 50 percent in 30 to 90 seconds, and + 70 percent in five to 10 minutes. When a single large sized PV facility experiences these rapid changes in power output, the Power System must also be able to react just as quickly with other generation resources to accommodate such rapid changes. The capabilities of a power system's dispatchable resources will limit the size of a single utility scale solar PV facility.

11. In the current energy market, the energy from renewable resource generation will tend to displace the marginal resource, which is typically natural gas. However, if future financial burdens are applied to carbon fuels such as coal, and coal becomes the marginal resource,

AR0070252

then coal energy may tend to be displaced by renewable resources.

Figure J-3. Solar photovoltaic power generation days at the 10 MW Adelanto facility.

Some common recommendations from these renewable energy integration studies include the following:

1. Successful integration of intermittent renewable resources requires an investment in transmission and generation resources and cooperative operational agreements between power system operators and energy providers.
2. New generation should be able to operate flexibly, meaning it should be able to start and stop quickly and to cycle on and off many times throughout the year. It should also be able to ramp (change the amount of energy it produces) quickly and operate at low generation levels.
3. State-of-the-art forecasting, particularly for wind resources, needs to be made available to power system operators.
4. Variable generators need to have NERC reliability standard compliant features, including low-voltage ride-through, voltage control, and reactive power control.
5. Wind and solar energy production must be curtailable by power system operators if variable energy production negatively affects power system reliability. The power system operators also must have the ability to set power ramp rates for wind and solar projects if needed to ensure power system reliability.
6. Natural gas fired combustion turbines and pump-storage hydro plants are effective tools for integrating intermittent renewable resources into existing power systems. Other energy storage devices described in Appendix K may also assist in integrating intermittent renewable resources.
7. Customer demand response programs may work well in integrating intermittent renewable resources.

Further studies, planning and system modeling will be needed as additional renewable resources come on-line to maintain power system reliability.

AR0070253

Appendix K Energy Storage

K.1 Overview

This Appendix provides a review of the general requirements of grid-scale energy storage systems (ESSs) and ESS technologies, followed by a copy of a February 2012 resolution by the Water and Power Board of Commissioners regarding energy storage targets, and a copy of AB 2514.

K.2 Requirements of Grid-Scale Energy Storage Systems

LADWP plans to meet its 33 percent renewable generation goal by acquiring and self-developing eligible renewable resources including wind and solar. Because wind and solar are intermittent resources by nature, integrating them into the power system is a major challenge. One method of integrating these intermittent generating resources will be large-scale ESSs. The LADWP currently has electrical storage capacity of 1175 megawatts (MW) of pumped storage at the Castaic Lake Hydroelectric Pumped Storage Plant. The ESSs used in the system should be cost effective and provide economical benefit to LADWP.

The ESS power and energy requirements vary widely with the particular grid support application (Figure K-1). Power quality applications require ESSs with high power capability and short storage capacity, while grid support systems require high power output and medium storage capability. Grid-connected renewable energy generation requires large-scale energy storage and large power capability.

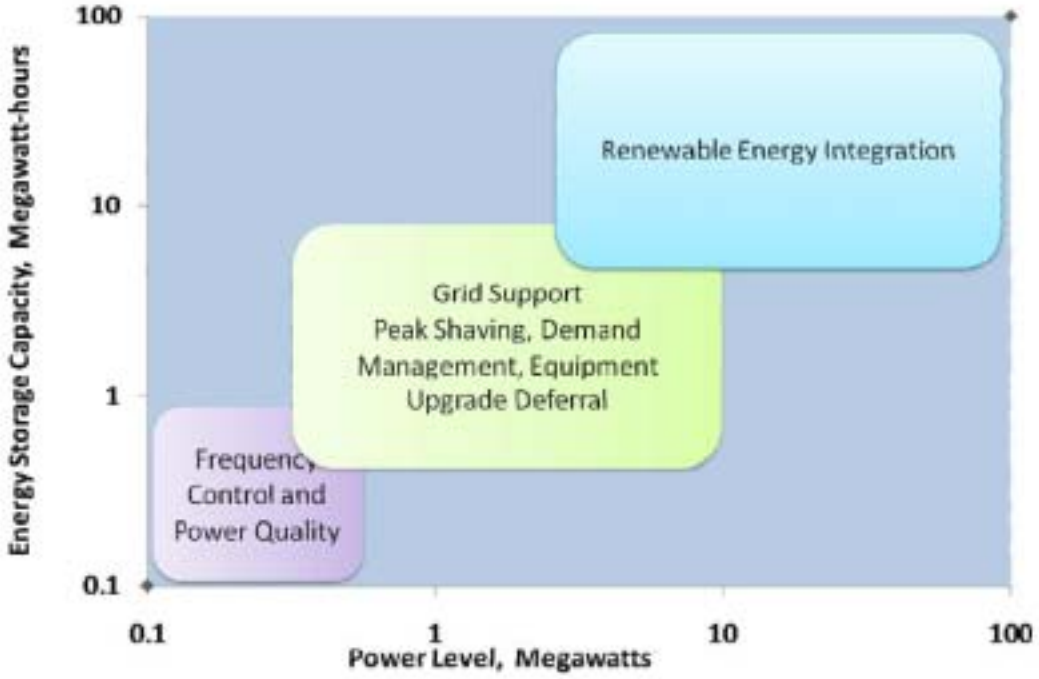

Figure K-1. Requirements of grid-scale ESS.

AR0070254

Electrical ESSs are critical for the integration of intermittent renewable energy sources, load shifting, and improving the stability and reliability of the electricity grid. Such electrical ESSs must be capable of storing hundreds of megawatt-hours (MWhs) and operating without significant degradation for 15-20 years at a cost comparable to today's power plants.

K.3 Energy Storage System Technologies

LADWP is presently in the process of assessing various advanced electrical energy storage technologies to meet its renewable energy program goals. The technologies that look promising for grid-scale energy storage are rechargeable batteries, compressed-air energy storage (CAES), pumped hydro-storage, flywheels energy storage (FES), and supercapacitors. Table K-1 summarizes the salient characteristics of the various energy storage technology options. Among these options, CAES and pumped hydroelectric systems are the technologies most suited for storing large quantities of electrical energy for long periods of time. Rechargeable batteries can support applications requiring a few minutes to a few hours of energy storage. However, hybrid ESSs consisting of rechargeable batteries and other electrical storage systems are likely to meet a wide range of requirements.

Table K-1. COMPARISON OF VARIOUS ESS TECHNOLOGIES

Electrical Storage Technology	Power	Energy Storage Capacity	Duration of Discharge	Advantages	Challenges / Issues
Lead Acid	< 1 MW	0.1 kWh - 1 MWh	1 - 5 hours	low cost, mature technology	limited cycle life low energy density
Lithium-Ion	< 2 MW	0.1 kWh - 10 MWh	1 - 8 hours	high energy density, high power density	high cost, safety in large systems, life,
Sodium Sulfur	< 40 MW	< 250 MWh	1 - 24 hours	high energy density, modest power density	high temperature operation, cost, safety of large systems, life
Redox Flow	< 5 MW	< 15 MWh	1 - 24 hours	long life, safe, easily scalable, medium cost	low energy density, low power density
Compressed Air	25 MW - 3000 MW	1 GWh	1 - 24 hours	high capacity, low cost	special site requirements
Pumped Hydro	100 MW - 4000 MW	15 GWh	4 - 24 hours	mature, high capacity, low cost	special site requirements
Flywheels	< 1 MW	< 10 MWh	< 1 hour	high power density	low energy density, high cost
Supercapacitors	< 1 MW	< 100 kWh	< 1 minute	high power density, long life, high efficiency	low energy density, high cost
Superconducting Magnetic Storage	< 10 MW	< 1 MWh	< 30 minutes	high power density, high efficiency	high cost

AR0070255

K.3.1 Rechargeable Batteries

Rechargeable batteries, upon being charged, convert electrical energy into chemical energy within reactant materials. The chemical energy can be returned as electrical energy upon discharge of the batteries. The rechargeable batteries being considered for the grid support applications described in this appendix are Lithium-Ion Batteries, Sodium-Sulfur (NaS) Batteries, and Redox Flow Batteries. The key challenges for these battery systems are summarized in Table K-2.

Lithium-Ion Batteries

The basic chemistry of these batteries is the same as that of the batteries used in cell phones, laptops, and other portable electronic devices. Large batteries can be fabricated using the same chemistry to provide ESSs for the grid. These batteries consist of carbon-based anode materials and lithiated metal oxide (metals such as cobalt, nickel, and manganese) cathode materials along with an organic electrolyte. Other material choices include lithium titanate for the anode and lithium iron phosphate for the cathode. The cells are sealed to prevent exposure of the battery chemistry to moisture and oxygen. These batteries offer specific energy values as high as 200 watt hour per kilogram (Wh/kg) and 400 watt hour per liter (Wh/L). They are three to six times lighter than lead acid batteries for the equivalent capacity and allow for fast charging and discharging. Operational life of about five years has been demonstrated. Further research is currently being done to improve battery-life characteristics for automotive applications. Cost and safety are the key challenges for widespread deployment of these types of batteries. Lithium iron phosphate and lithium titanate are particularly attractive for automotive applications because of their lower cost and higher abuse tolerance, albeit at a moderate reduction in energy density to 100 Wh/kg. AES Energy Storage is current installing a 32 MW lithium-ion storage system to regulate the 100-MW Laurel Mountain Wind Farm in West Virginia. Similarly, A123 Systems and AES have jointly deployed a 2 MW system (see Figure K-2). The current cost for lithium-ion batteries is between $650-$1000/kWh and $400-$2000/kW. Current costs of lithium-ion batteries are coming down because of ongoing developments in the automotive industry and are expected to reach $250/kwh by 2020.

Figure K-2. Lithium-ion batteries.

Sodium-Sulfur Battery

This type of battery was developed prior to lithium ion batteries and uses metallic sodium and elemental sulfur. A sodium-ion conductive ceramic separates both electrodes. Redox and Lithium-Ion batteries can operate at ambient temperatures, but NaS batteries must operate at

AR0070256

about 450°C and must be maintained at this high temperature by appropriate thermal insulation. Repeated heating and cooling cycles will reduce the life of NaS batteries. Since NaS batteries consist of reactive materials maintained at high-temperatures, engineering measures are required to ensure safe operations. Notwithstanding these challenges, large-scale NaS battery installations have been demonstrated worldwide, with the largest installed unit being 34 MW, 245 MWh for a wind power stabilization application in Northern Japan by NGK Insulators Inc. (see Figure K-3). Thus far in the U.S., about 40 MWs have been deployed for grid support and integration with wind energy systems. General Electric USA has recently announced its intention to develop and manufacture NaS batteries for renewable energy system integration. The projected cost of large-scale NaS batteries is $450/kW and $400/kWh.

Figure K-3. Sodium-sulfur batteries.

Redox Flow Batteries

In a redox flow battery (see Figure K-4), the chemicals produced in the cell stack during electrical charging are pumped out of the cell stack and stored as a solution in tanks. The solutions are then re-circulated through the cell stack when the energy needs to be regenerated. Since large amounts of energy can be stored as solutions in tanks, the redox flow battery concept is particularly suitable for large-scale energy storage applications. The Vanadium Redox Battery (VRB) is one of the best known examples of a redox flow battery that has been scaled up to MWh sizes; systems with the power level of 2 MW and storage capacity of 12 MWh have been demonstrated. Many units based on VRB technology are in operation worldwide. Some of the flow battery systems have been in operation for over 30 years with minimal maintenance. The life cycle emission from these batteries is less than 25 percent of that of lead-acid batteries. The capital cost for these batteries is in the range of $1000/kW and $300/kWh. With a 15-year life span, the amortized cost of this system is comparable to that of lead acid batteries.

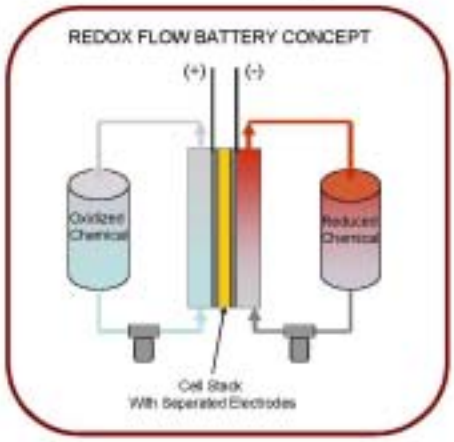

Figure K-4. Redox flow batteries.

AR0070257

Table K-2: KEY CHALLENGES OF BATTERY SYSTEMS

Vanadium Redox Battery	Lithium Ion Battery	Sodium-Sulfur Battery
High cost of vanadium Negative environmental impact of using large quantities of a biologically active heavy metal such as vanadium Low-efficiency Low to Moderate power density Loss of efficiency by cross diffusion of constituents, Low storage capacity of solutions	Operational safety of large-scale batteries Degradation after 2000 cycles on deep discharge which translates to about 3-4 years of operation. High cost of materials to achieve high-energy density.	High temperature operation of the battery (400°C) adds to cost, maintenance and safety Rapid degradation of sealing elements when subjected to thermal cycling. Degradation of battery over 1000 cycles High cost arising from materials and manufacturing methods.

K.3.2 Compressed Air Energy Storage

CAES systems compress large masses of air during periods of low energy demand (off-peak) and then expand the air in turbogenerators to produce power during periods of peak demand. Heating the compressed air before sending it through the turbogenerator results in a three-fold increase in the power that could otherwise be generated without the heater. Compressed air stores mechanical energy that can be released very rapidly. However, the stored energy density of CAES systems is relatively small compared to liquid fuel (gasoline, diesel). Currently, about 80-85 percent of the mechanical work for compressing the air is lost as waste heat during the compression. New air compressor devices that recover the heat generated will substantially increase the efficiency.

K.3.3 Pumped Hydroelectric Storage

Pumped Hydroelectric Storage (PHS) is one of the most widely used ESS technologies. The PHS system involves pumping water from a lower reservoir to a higher reservoir when electricity is available (generally at night) and then flowing water down through hydroelectric generators to produce electricity when additional power capacity is needed (typically at midday during periods of peak demand). PHS systems require a particular geographical topology where reservoirs can be situated at different elevations and where sufficient water is available. PHS systems constitute 3-4 percent of the current worldwide power generation capacity. The typical size of these PHS systems is around 1000 MW, and the storage capacity can exceed thousands of MWhs based on the size of the reservoirs and the hydroelectric generator assets involved. The round-trip efficiency of these systems usually exceeds 70 percent. Installation costs of these systems tend to be high because of the geographical siting requirements. System cost is estimated to be $4000/kW and $200/kWh.

AR0070258

K.3.4 Flywheel Energy Storage

FES systems work by using an electric motor to accelerate a rotor (flywheel) to a very high speed, maintaining the energy in the system as rotational energy using very low-friction bearings and engaging an electric generator to convert the rotational energy back to electricity by decelerating the flywheel. FES technology is a good fit for managing relatively limited amounts of electricity for short periods of time and is being considered as a strong contender for frequency control of the grid. Beacon Power Corporation has developed a flywheel system for frequency control of the grid and is currently testing several installations of prototype equipment.

K.3.5 Supercapacitor Energy Storage

Supercapacitor Energy Storage (SES) and Ultracapacitor Energy Storage (UES) systems are targeted to fill the gap between capacitors and batteries. These devices can deliver large amounts of power for short periods of time and can be used to dampen the in-rush current noise caused by the start-up and shut down of large motors and generators in large power system facilities. However, these devices are not likely to be good candidates for large-scale energy storage.

K.3.6 Superconducting Magnetic Energy Storage

Superconducting Magnetic Energy Storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil, which has been cryogenically cooled to a temperature below its superconducting critical temperature. SMES technology is highly efficient, but manufacture of actual commercial equipment has been hard to achieve. This technology appears to be too immature for large scale commercialization.

AR0070259

K-4 Benefits

Quantifiably advances in ESS technologies, and implementation will result in several benefits as shown on Table K-4.

Table K-4. BENEFITS OF ENERGY STORAGE SYSTEMS

LADWP Approach	Benefits	Metrics
Use Battery Energy Storage to supply energy when the generation dips from the wind or solar generators during peak demand periods or demand increases	Lower electricity cost	Lowering peak demand needed from expensive combustion turbine generators with wind and solar generation
Use Battery Energy Storage to supply energy when the generation dips from the wind or solar generators or during system disturbances	Reduced power interruptions and increase reliability	Fewer and Shorter outages
	Reduced costs from better power quality	Fewer momentary outages
		Fewer severe sags and swells
		Lower harmonic distortion
Use Battery storage energy from green power reduces CO2 Emissions	Reduced damages as a result of lower GHG/carbon emissions	Percentage of green power relative to total power generated.
Increase of battery storage from green power to reduce need for oil or gas		
Reduce reliance on non renewable resources	Greater energy security from reduced oil consumption	Percentage of green energy utilized

LOS ANGELES DEPARTMENT OF WATER AND POWER (LADWP) BOARD APPROVAL LETTER

TO: BOARD OF WATER AND POWER COMMISSIONERS	DATE: February 2, 2012
ARAM BENYAMIN Senior Assistant General Manager – Power System RONALD O. NICHOLS General Manager	SUBJECT: **LADWP Energy Storage Targets**
	FOR COMMISSION OFFICE USE: RESOLUTION NO. 012 168 FEB 07 2012 COPY RESO TO : 2. SK. A&M - Power Supply 2-17-12
CITY COUNCIL APPROVAL REQUIRED: Yes ☐ No ☒	IF YES, BY WHICH CITY CHARTER SECTION:

PURPOSE

To comply with State Assembly Bill 2514 (AB 2514), which became law on January 1, 2011, the Board of Water and Power Commissioners (Board) must take action by March 1, 2012, to initiate a process to determine appropriate targets, if any, for the LADWP to procure viable and cost-effective energy storage systems.

BACKGROUND

The AB 2514 became law on January 1, 2011. The bill requires the governing board of a local publicly owned electric utility, such as LADWP, to initiate a process by March 1, 2012, to determine appropriate targets, if any, for LADWP to procure viable and cost-effective energy storage systems by certain dates. AB 2514 further requires that if determined to be appropriate, this Board shall adopt procurement targets by October 1, 2014, for LADWP to procure viable and cost-effective energy storage systems to be achieved by a first target date of December 31, 2016, and a second target date of December 31, 2021.

Furthermore, AB 2514 requires the Board to re-evaluate the determinations made regarding the energy storage system procurement not less than once every three years and for LADWP to report to the California Energy Commission regarding the energy storage system procurement targets and policies that may be adopted by the Board, and any modifications made to those targets as a result of the Board's re-evaluations.

The LADWP's 2011 Power System Integrated Resource Plan provides a review of the general requirements of grid-scale energy storage systems and technologies, which may serve as an initial framework to determine appropriate targets, if any, for LADWP to procure viable and cost-effective energy storage systems.

RECOMMENDATION

It is recommended that your Honorable Board adopt the attached Resolution initiating a process to determine appropriate energy storage system targets, if any, consistent with AB 2514.

RESOLUTION NO 012 168

WHEREAS, State Assembly Bill 2514 (AB 2514) became law on January 1, 2011, requiring the governing board of a local publicly owned electric utility, such as the Los Angeles Department of Water and Power (LADWP), to initiate a process by March 1, 2012, to determine appropriate targets, if any, for LADWP to procure viable and cost-effective energy storage systems by certain dates; and

WHEREAS, if determined to be appropriate, the Board of Water and Power Commissioners (Board) shall adopt procurement targets by October 1, 2014, for LADWP to procure viable and cost-effective energy storage systems to be achieved by a first target date of December 31, 2016, and a second target date of December 31, 2021, and

WHEREAS LADWP's 2011 Power Integrated Resource Plan (IRP) provides a review of the general requirements of grid-scale energy storage systems and technologies and includes a proposed energy storage demonstration project, which may serve as an initial framework to determine appropriate targets, if any, for LADWP to procure viable and cost-effective energy storage systems; and

WHEREAS, pursuant to AB 2514, the Board shall re-evaluate the determinations made regarding energy storage system procurement not less than once every three years; and

WHEREAS, LADWP shall report to the California Energy Commission regarding any energy storage system procurement targets and policies that may be adopted by this Board, and any modifications made to those targets as a result of the Board's reevaluations

NOW, THEREFORE, BE IT RESOLVED that the Board of Water and Power Commissioners of the City of Los Angeles hereby initiates a process directing LADWP to determine appropriate targets, if any, for LADWP to procure viable and cost-effective energy storage systems by December 31, 2016, and December 31, 2021 pursuant to AB 2514.

BE IT FURTHER RESOLVED that LADWP shall report back to this Board prior to October 1, 2014, regarding potential procurement targets, if any, for LADWP to procure viable and cost-effective energy storage systems, at which time this Board may determine whether it is appropriate to adopt such targets.

I HEREBY CERTIFY that the foregoing is a full, true, and correct copy of a resolution adopted by the Board of Water and Power Commissioners of the City of Los Angeles at its meeting held FEB 07 2012

FEB 07 2012

Barbara E. Moschos

Secretary

Assembly Bill No. 2514

CHAPTER 469

An act to amend Section 9620 of, and to add Chapter 7.7 (commencing with Section 2835) to Part 2 of Division 1 of, the Public Utilities Code, relating to energy.

[Approved by Governor September 29, 2010. Filed with Secretary of State September 29, 2010.]

LEGISLATIVE COUNSEL'S DIGEST

AB 2514, Skinner. Energy storage systems.

Under existing law, the Public Utilities Commission (CPUC) has regulatory authority over public utilities, including electrical corporations, as defined. The existing Public Utilities Act requires the CPUC to review and adopt a procurement plan for each electrical corporation in accordance with specified elements, incentive mechanisms, and objectives. The existing California Renewables Portfolio Standard Program (RPS program) requires the CPUC to implement annual procurement targets for the procurement of eligible renewable energy resources, as defined, for all retail sellers, including electrical corporations, community choice aggregators, and electric service providers, but not including local publicly owned electric utilities, to achieve the targets and goals of the program.

The existing Warren-Alquist State Energy Resources Conservation and Development Act establishes the State Energy Resources Conservation and Development Commission (Energy Commission), and requires it to undertake a continuing assessment of trends in the consumption of electricity and other forms of energy and to analyze the social, economic, and environmental consequences of those trends and to collect from electric utilities, gas utilities, and fuel producers and wholesalers and other sources, forecasts of future supplies and consumption of all forms of energy.

Existing law requires the CPUC, in consultation with the Independent System Operator (ISO), to establish resource adequacy requirements for all load-serving entities, as defined, in accordance with specified objectives. The definition of a "load-serving entity" excludes a local publicly owned electric utility. That law further requires each load-serving entity to maintain physical generating capacity adequate to meet its load requirements, including peak demand and planning and operating reserves, deliverable to locations and at times as may be necessary to provide reliable electric service. Other existing law requires that each local publicly owned electric utility serving end-use customers to prudently plan for and procure resources that are adequate to meet its planning reserve margin and peak demand and operating reserves, sufficient to provide reliable electric service to its customers. That law additionally requires the utility, upon request, to provide

AR0070266

the Energy Commission with any information the Energy Commission determines is necessary to evaluate the progress made by the local publicly owned electric utility in meeting those planning requirements, and requires the Energy Commission to report the progress made by each utility to the Legislature, to be included in the integrated energy policy reports. Under existing law, the governing body of a local publicly owned electric utility is responsible for implementing and enforcing a renewables portfolio standard for the utility that recognizes the intent of the Legislature to encourage renewable resources, while taking into consideration the effect of the standard on rates, reliability, and financial resources and the goal of environmental improvement.

This bill would require the CPUC, by March 1, 2012, to open a proceeding to determine appropriate targets, if any, for each load-serving entity to procure viable and cost-effective energy storage systems and, by October 1, 2013, to adopt an energy storage system procurement target, if determined to be appropriate, to be achieved by each load-serving entity by December 31, 2015, and a 2nd target to be achieved by December 31, 2020. The bill would require the governing board of a local publicly owned electric utility, by March 1, 2012, to open a proceeding to determine appropriate targets, if any, for the utility to procure viable and cost-effective energy storage systems and, by October 1, 2014, to adopt an energy storage system procurement target, if determined to be appropriate, to be achieved by the utility by December 31, 2016, and a 2nd target to be achieved by December 31, 2021. The bill would require each load-serving entity and local publicly owned electric utility to report certain information to the CPUC, for a load-serving entity, or to the Energy Commission, for a local publicly owned electric utility. The bill would make other technical, nonsubstantive revisions to existing law. The bill would exempt from these requirements an electrical corporation that has 60,000 or fewer customers within California and a public utility district that receives all of its electricity pursuant to a preference right adopted and authorized by the United States Congress pursuant to a specified law.

Under existing law, a violation of the Public Utilities Act or any order, decision, rule, direction, demand, or requirement of the CPUC is a crime.

Because certain of the provisions of this bill require action by the CPUC to implement, a violation of these provisions would impose a state-mandated local program by creating a new crime. Because certain of the bill's requirements are applicable to local publicly owned electric utilities, the bill would impose a state-mandated local program.

The California Constitution requires the state to reimburse local agencies and school districts for certain costs mandated by the state. Statutory provisions establish procedures for making that reimbursement.

This bill would provide that no reimbursement is required by this act for specified reasons.

AR0070267

The people of the State of California do enact as follows:

SECTION 1. The Legislature finds and declares all of the following:

(a) Expanding the use of energy storage systems can assist electrical corporations, electric service providers, community choice aggregators, and local publicly owned electric utilities in integrating increased amounts of renewable energy resources into the electrical transmission and distribution grid in a manner that minimizes emissions of greenhouse gases.

(b) Additional energy storage systems can optimize the use of the significant additional amounts of variable, intermittent, and offpeak electrical generation from wind and solar energy that will be entering the California power mix on an accelerated basis.

(c) Expanded use of energy storage systems can reduce costs to ratepayers by avoiding or deferring the need for new fossil fuel-powered peaking powerplants and avoiding or deferring distribution and transmission system upgrades and expansion of the grid.

(d) Expanded use of energy storage systems will reduce the use of electricity generated from fossil fuels to meet peak load requirements on days with high electricity demand and can avoid or reduce the use of electricity generated by high carbon-emitting electrical generating facilities during those high electricity demand periods. This will have substantial cobenefits from reduced emissions of criteria pollutants.

(e) Use of energy storage systems to provide the ancillary services otherwise provided by fossil-fueled generating facilities will reduce emissions of carbon dioxide and criteria pollutants.

(f) There are significant barriers to obtaining the benefits of energy storage systems, including inadequate evaluation of the use of energy storage to integrate renewable energy resources into the transmission and distribution grid through long-term electricity resource planning, lack of recognition of technological and marketplace advancements, and inadequate statutory and regulatory support.

SEC. 2. Chapter 7.7 (commencing with Section 2835) is added to Part 2 of Division 1 of the Public Utilities Code, to read:

Chapter 7.7. Energy Storage Systems

2835. For purposes of this chapter, the following terms have the following meanings:

(a) (1) "Energy storage system" means commercially available technology that is capable of absorbing energy, storing it for a period of time, and thereafter dispatching the energy. An "energy storage system" may have any of the characteristics in paragraph (2), shall accomplish one of the purposes in paragraph (3), and shall meet at least one of the characteristics in paragraph (4).

(2) An "energy storage system" may have any of the following characteristics:

AR0070268

(A) Be either centralized or distributed.

(B) Be either owned by a load-serving entity or local publicly owned electric utility, a customer of a load-serving entity or local publicly owned electric utility, or a third party, or is jointly owned by two or more of the above.

(3) An "energy storage system" shall be cost effective and either reduce emissions of greenhouse gases, reduce demand for peak electrical generation, defer or substitute for an investment in generation, transmission, or distribution assets, or improve the reliable operation of the electrical transmission or distribution grid.

(4) An "energy storage system" shall do one or more of the following:

(A) Use mechanical, chemical, or thermal processes to store energy that was generated at one time for use at a later time.

(B) Store thermal energy for direct use for heating or cooling at a later time in a manner that avoids the need to use electricity at that later time.

(C) Use mechanical, chemical, or thermal processes to store energy generated from renewable resources for use at a later time.

(D) Use mechanical, chemical, or thermal processes to store energy generated from mechanical processes that would otherwise be wasted for delivery at a later time.

(b) "Load-serving entity" has the same meaning as defined in Section 380.

(c) "New" means, in reference to an energy storage system, a system that is installed and first becomes operational after January 1, 2010.

(d) "Offpeak" means, in reference to electrical demand, a period that is not within a peak demand period.

(e) "Peak demand period" means a period of high daily, weekly, or seasonal demand for electricity. For purposes of this chapter, the peak demand period for a load-serving entity shall be determined, or approved, by the commission and shall be determined, or approved, for a local publicly owned electric utility, by its governing body.

(f) "Procure" and "procurement" means, in reference to the procurement of an energy storage system, to acquire by ownership or by a contractual right to use the energy from, or the capacity of, including ancillary services, an energy storage system owned by a load-serving entity, local publicly owned electric utility, customer, or third party. Nothing in this chapter, and no action by the commission, shall discourage or disadvantage development and ownership of an energy storage system by an electrical corporation.

2836. (a) (1) On or before March 1, 2012, the commission shall open a proceeding to determine appropriate targets, if any, for each load-serving entity to procure viable and cost-effective energy storage systems to be achieved by December 31, 2015, and December 31, 2020. As part of this proceeding, the commission may consider a variety of possible policies to encourage the cost-effective deployment of energy storage systems, including refinement of existing procurement methods to properly value energy storage systems.

AR0070269

(2) The commission shall adopt the procurement targets, if determined to be appropriate pursuant to paragraph (1), by October 1, 2013.

(3) The commission shall reevaluate the determinations made pursuant to this subdivision not less than once every three years.

(4) Nothing in this section prohibits the commission's evaluation and approval of any application for funding or recovery of costs of any ongoing or new development, trialing, and testing of energy storage projects or technologies outside of the proceeding required by this chapter.

(b) (1) On or before March 1, 2012, the governing board of each local publicly owned electric utility shall initiate a process to determine appropriate targets, if any, for the utility to procure viable and cost-effective energy storage systems to be achieved by December 31, 2016, and December 31, 2021. As part of this proceeding, the governing board may consider a variety of possible policies to encourage the cost-effective deployment of energy storage systems, including refinement of existing procurement methods to properly value energy storage systems.

(2) The governing board shall adopt the procurement targets, if determined to be appropriate pursuant to paragraph (1), by October 1, 2014.

(3) The governing board shall reevaluate the determinations made pursuant to this subdivision not less than once every three years.

(4) A local publicly owned electric utility shall report to the Energy Commission regarding the energy storage system procurement targets and policies adopted by the governing board pursuant to paragraph (2), and report any modifications made to those targets as a result of a reevaluation undertaken pursuant to paragraph (3).

2836.2. In adopting and reevaluating appropriate energy storage system procurement targets and policies pursuant to subdivision (a) of Section 2836, the commission shall do all of the following:

(a) Consider existing operational data and results of testing and trial pilot projects from existing energy storage facilities.

(b) Consider available information from the California Independent System Operator derived from California Independent System Operator testing and evaluation procedures.

(c) Consider the integration of energy storage technologies with other programs, including demand-side management or other means of achieving the purposes identified in Section 2837 that will result in the most efficient use of generation resources and cost-effective energy efficient grid integration and management.

(d) Ensure that the energy storage system procurement targets and policies that are established are technologically viable and cost effective.

2836.4. (a) An energy storage system may be used to meet the resource adequacy requirements established for a load-serving entity pursuant to Section 380 if it meets applicable standards.

(b) An energy storage system may be used to meet the resource adequacy requirements established by a local publicly owned electric utility pursuant to Section 9620 if it meets applicable standards.

AR0070270

2836.6. All procurement of energy storage systems by a load-serving entity or local publicly owned electric utility shall be cost effective.

2837. Each electrical corporation's renewable energy procurement plan, prepared and approved pursuant to Article 16 (commencing with Section 399.11) of Chapter 2.3 of Part 1, shall require the utility to procure new energy storage systems that are appropriate to allow the electrical corporation to comply with the energy storage system procurement targets and policies adopted pursuant to Section 2836. The plan shall address the acquisition and use of energy storage systems in order to achieve the following purposes:

(a) Integrate intermittent generation from eligible renewable energy resources into the reliable operation of the transmission and distribution grid.

(b) Allow intermittent generation from eligible renewable energy resources to operate at or near full capacity.

(c) Reduce the need for new fossil-fuel powered peaking generation facilities by using stored electricity to meet peak demand.

(d) Reduce purchases of electricity generation sources with higher emissions of greenhouse gases.

(e) Eliminate or reduce transmission and distribution losses, including increased losses during periods of congestion on the grid.

(f) Reduce the demand for electricity during peak periods and achieve permanent load-shifting by using thermal storage to meet air-conditioning needs.

(g) Avoid or delay investments in transmission and distribution system upgrades.

(h) Use energy storage systems to provide the ancillary services otherwise provided by fossil-fueled generating facilities.

2838. (a) (1) By January 1, 2016, each load-serving entity shall submit a report to the commission demonstrating that it has complied with the energy storage system procurement targets and policies adopted by the commission pursuant to subdivision (a) of Section 2836.

(2) By January 1, 2021, each load-serving entity shall submit a report to the commission demonstrating that it has complied with the energy storage system procurement targets and policies adopted by the commission pursuant to subdivision (a) of Section 2836.

(b) The commission shall ensure that a copy of each report required by subdivision (a), with any confidential information redacted, is available on the commission's Internet Web site.

2838.5. Notwithstanding any provision of this chapter, the requirements of this chapter do not apply to either of the following:

(a) An electrical corporation that has 60,000 or fewer customer accounts within California.

(b) A public utility district that receives all of its electricity pursuant to a preference right adopted and authorized by the United States Congress pursuant to Section 4 of the Trinity River Division Act of August 12, 1955 (Public Law 84-386).

AR0070271

2839. (a) (1) By January 1, 2017, a local publicly owned electric utility shall submit a report to the Energy Commission demonstrating that it has complied with the energy storage system procurement targets and policies adopted by the governing board pursuant to subdivision (b) of Section 2836.

(2) By January 1, 2022, a local publicly owned electric utility shall submit a report to the Energy Commission demonstrating that it has complied with the energy storage system procurement targets and policies adopted by the governing board pursuant to subdivision (b) of Section 2836.

(b) The Energy Commission shall ensure that a copy of each report or plan required by subdivisions (a) and (b), with any confidential information redacted, is available on the Energy Commission's Internet Web site, or on an Internet Web site maintained by the local publicly owned electric utility that can be accessed from the Energy Commission's Internet Web site.

(c) The commission does not have authority or jurisdiction to enforce any of the requirements of this chapter against a local publicly owned electric utility.

SEC. 3. Section 9620 of the Public Utilities Code is amended to read:

9620. (a) Each local publicly owned electric utility serving end-use customers, shall prudently plan for and procure resources that are adequate to meet its planning reserve margin and peak demand and operating reserves, sufficient to provide reliable electric service to its customers. Customer generation located on the customer's site or providing electric service through arrangements authorized by Section 218, shall not be subject to these requirements if the customer generation, or the load it serves, meets one of the following criteria:

(1) It takes standby service from the local publicly owned electric utility on a rate schedule that provides for adequate backup planning and operating reserves for the standby customer class.

(2) It is not physically interconnected to the electric transmission or distribution grid, so that, if the customer generation fails, backup power is not supplied from the electricity grid.

(3) There is physical assurance that the load served by the customer generation will be curtailed concurrently and commensurately with an outage of the customer generation.

(b) Each local publicly owned electric utility serving end-use customers shall, at a minimum, meet the most recent minimum planning reserve and reliability criteria approved by the Board of Trustees of the Western Systems Coordinating Council or the Western Electricity Coordinating Council.

(c) Each local publicly owned electric utility shall prudently plan for and procure energy storage systems that are adequate to meet the requirements of Section 2836.

(d) A local publicly owned electric utility serving end-use customers shall, upon request, provide the Energy Commission with any information the Energy Commission determines is necessary to evaluate the progress made by the local publicly owned electric utility in meeting the requirements of this section.

AR0070272

(e) The Energy Commission shall report to the Legislature, to be included in each integrated energy policy report prepared pursuant to Section 25302 of the Public Resources Code, regarding the progress made by each local publicly owned electric utility serving end-use customers in meeting the requirements of this section.

SEC. 4. No reimbursement is required by this act pursuant to Section 6 of Article XIII B of the California Constitution because a local agency or school district has the authority to levy service charges, fees, or assessments sufficient to pay for the program or level of service mandated by this act or because costs that may be incurred by a local agency or school district will be incurred because this act creates a new crime or infraction, eliminates a crime or infraction, or changes the penalty for a crime or infraction, within the meaning of Section 17556 of the Government Code, or changes the definition of a crime within the meaning of Section 6 of Article XIII B of the California Constitution.

AR0070278

1 Introduction

1.1 Purpose of this document

The Los Angeles Department of Water and Power (LADWP) Smart Grid Deployment Plan represents a roadmap to address the anticipated future needs of the people of the City of Los Angeles. By meeting the requirements of both SB 17 and Title XIII, LADWP's Smart Grid Deployment Plan outlines the coordinated and integrated approach in implementing new technologies while maintaining or improving safety and reliability.

1.2 Smart Grid Initiative Background

Smart Grid is a national policy that grew as a response to The Energy Policy Act of 2005, which called for advanced metering. It, however, has been insufficient to achieve the desired goals of energy conservation, migration to renewable energy, and reduction of CO2 emissions from power plants. The federal Energy Independence and Security Act of 2007 called for the implementation of Smart Grid systems as a "Policy of the United States". The new Energy Independence and Security Act of 2007 authorizes $100 M each year from 2008 through 2012 to be divided between five Smart Grid demonstration projects throughout the nation. The Department of Energy is required to report within one year on the status of Smart Grid deployments and identify any regulatory or government obstacles.

Additionally, utility executives and regulators have become increasingly concerned about multiple issues that can only be addressed through an enterprise wide Smart Grid solution. The four main concerns are:

(a) Cost and uncertainty about New Generation and Transmission

(b) Environmental impacts ("Green House" gases emitted from fossil fuel power plants and proposed right-of-ways for transmission lines crossing through pristine forests, deserts and wild life areas to service urban areas) such as those proposed in AB 32, the *California Global Warming Solutions Act, 2006*.

(c) Increasing requirements for the use of Renewable and Distributed Generation (Wind, Solar, Geothermal, Hydro, and Biomass)

(d) Demographics: aging workforce

Regulated utilities in California are now responding to regulatory direction to submit plans for large-scale AMI and Smart Grid initiatives with full delineation of costs and benefits. This regulatory initiative is an aggressive step, seeking to promote customer awareness of peak load periods, and response to peak-sensitive pricing. The Smart

AR0070279

Grid deployments and the associated utility customer features are proceeding through out the State of California.

1.3 Smart Grid Definition

The Los Angeles Department of Water and Power maintains that the definition of a smart grid is a system which facilitates the integration of advanced technologies in existing networks to improve system performance, power flow control, and reliability. Such a system is characterized by the following:

(a) Increased use of cost-effective digital information and control technology to improve reliability, security, and efficiency of the electric grid.

(b) Dynamic optimization of grid operations and resources, with cost-effective full cyber security.

(c) Deployment and integration of cost-effective distributed resources and generation, including renewable resources.

(d) Development and incorporation of cost-effective demand response, demand-side resources, and energy-efficiency resources.

(e) Deployment of cost-effective smart technologies, including real time, automated, interactive technologies that optimize the physical operation of appliances and consumer devices for metering, communications concerning grid operations and status, and distribution automation.

(f) Integration of cost-effective smart appliances and consumer devices.

(g) Deployment and integration of cost-effective advanced electricity storage and peak-shaving technologies, including plug-in electric and hybrid electric vehicles, and thermal-storage air-conditioning.

(h) Provide consumers with timely information and control options.

AR0070280

(i) Develop standards for communication and interoperability of appliances and equipment connected to the electric grid, including the infrastructure serving the grid.

(j) Identification and lowering of unreasonable or unnecessary barriers to adoption of smart grid technologies, practices, and services.

1.4 Stakeholders

1.4.1 Customer

LADWP ratepayers are the Customers and will realize the monetary, social, and environmental benefits of the plan.

AR0070281

2 LADWP Smart Grid Initiatives

2.1 Smart Grid Objectives

Currently, the Department is involved in two strategic initiatives related to Smart Grid. The first is the Smart Grid Regional Demonstration Project and the second is the Smart Grid Investment Program.

The Smart Grid Regional Demonstration Project began in December of 2009, when LADWP was awarded 60.2 million dollars grant from the Department of Energy for the American Reinvestment and Recovery Act for Smart Grid Demonstrations. As a result of the award, LADWP is managing a consortium of Los Angeles metropolitan area research institutions with established energy and technology transfer programs. Together, the team is carrying out a regionally unique demonstration by using innovative technology test beds located at LADWP's partner university campuses and technology transfer laboratories to prove the viability of the demonstration technology. Additional research is being conducted to explore options for informed, enabled customers based on historical usage and pricing data. This research uses a multi-tiered rate approach to address the diversity of customer demands by exploring time-varying and time-of-use products for the end consumer. The regional demonstration project includes four interrelated project initiatives, which will be incorporated into the long term investment program:

(a) A fully integrated demonstration of Smart Grid operation and technology as applied to Demand Response.

(b) A comprehensive portfolio of research empoying a unique test bed structure to identify historical usage and consumer adoption obstacles essential for succesful adoption of Smart Grid Technologies and improved energy usage patterns.

(c) Demonstration of next generation cyber security technologies using the Regional Project as the driving source of specific system architecture and models.

(d) The integration of electric vehicles into the LADWP managed grid, addressing solutions to overcome both technical and social impediments.

The Smart Grid investment plan is a 10-year project that incorporates 11 strategic initiatives.

2.1.1 Links with the Department's Strategic Objectives

The Smart Grid Implementation Plan continues to align LADWP's efforts to implement the technology with the goal of increasing LADWP's Power System monitoring,

AR0070282

control and reliability while decreasing operating costs and gaining significant efficiencies.

2.2 LADWP Smart Grid Initiatives in Progress

"Smart Grid" is a term used to describe a variety of advanced information-based utility improvements. Smart Grid is a major enabler for many existing and potentially new Demand Side Resource programs. Smart Grid is a national policy evolving from the Energy Policy Act of 2005. Smart Grid refers to intelligent data gathering and advanced two-way digital communication capabilities overlaid on electric distribution networks to provide real-time data that enhances the utility's ability to optimize energy use. Smart Grid technologies can turn every point in the existing network—including every meter, switch and transformer—into a potential information source, able to feed performance data back to the utility instantly. Smart Grid Technologies will provide utilities with the information required to implement real-time, self-monitoring networks that are predictive rather than reactive to instantaneous system disruptions. It can enable the utility and consumer to make decisions to optimize the use of energy, improve reliability, and reduce the consumption of fossil fuels.

Section 8360 of the Senate Bill 17 defines the policy that governs the way utilities modernize transmission and distribution systems. LADWP's eleven Smart Grid Initiatives are designed to be collectively compliant with SB17. The following is the list of the initiatives:

(a) Renewable Integration

(b) Transmission Automation Initiative

(c) Substation Automation Initiative

(d) Distribution Automation Initiative

(e) AMI Metering Initiative

(f) Demand Response Initiative

(g) Communications Initiative

(h) Cyber Security Initiative

(i) System and Data Integration Initiative

(j) Feed-In Tariff Initiative

(k) Solar Incentives Program

AR0070283

2.3 Renewable Integration

LADWP has a comprehensive Integrated Resource Plan where new Wind, Solar, and Geothermal Power Plants, as well as Energy Storage, and Electric Vehicles will be incorporated into the power generation mix. Currently, the ECS/Historian Servers have been installed at Pine Tree Generation Station, and there are plans to install more of these servers at each of the power plants. These servers allow for real-time monitoring and control of renewable sources, which will be equipped with automation equipment in order to facilitate peak shaving activities and to better support the adoption and utilization of renewables.

2.4 Transmission Automation Initiative

For years, LADWP has worked in substations to meter the transmission lines and record Phasor Measurement Units (PMU). These measurements are used to determine the health of the Electrical System. LADWP will install PMUS, and upgrade Tie-Line Meters to improve measurement, provide backup metering at Tie Points, collect dynamic reads, and reroute power. The real-time data provided by PMU will be used for predicting instability in the transmission system and undertaking preventive actions.

2.5 Substation Automation Initiative

For the past five years, LADWP has implemented a comprehensive program to install a new Power System Substation Automation System (SAS) from the Energy Control Center to the Substations, transmission, and Generation Stations. Currently, 80 of the approximate 200 substations and generation stations have been updated to the new Substation Automation, and a new SCADA system has been implemented. There are approximately 70 more stations in the inventory that will be implemented over the next two to three years. Approximately 840 feeders now have remotely controlled circuit breakers and remote monitoring of megawatt loading of wire/cables. A significant amount of data is already being processed through the SCADA system and is available to the load dispatchers and other personnel on an as needed basis. At the conclusion of this project, the vast majority of feeders at all substations will be observable and controllable from the Energy Control Center.

2.6 Distribution Automation Initiative

There have been several pilot projects for the Distribution Automation relating to devices outside the substation walls (Current's Broadband over Power Line project, Ricochet Spread Spectrum project, and Telemetric Cellular project). These projects were never rolled out as the industry was still being developed and LADWP's decision was to wait until more robust solutions were available. Additionally, some of the pilot programs were never considered industry standard since it was using obsolete

AR0070284

technology. The LADWP is currently evaluating fault indicators, remotely controlled switches and automatic cap banks. These devices can be used for dynamic optimization of the distribution system.

2.7 AMI Metering Initiative

LADWP has been progressing over the past few years with the AMI Metering Initiative.

- As of 6/01/11, the LADWP has installed 162,200 AMR meters
  - Residential Meters (F meters) – 85,000 (using RF Technology and one way communication providing billing information for walk or drive by meter reading)
  - Small Commercial Demand Meters (FM meters) – 68,000 (using RF Technology and one way communication providing billing information)
  - Large Commercial Wireless Meters (A meters) – 9,000 (using Cellular Technology and two way communication providing billing information and load profile information)
- AMR meters represent approximately 10.6% of the total meters in the system but over 45% of the power revenue

Wireless meter reading and real-time pricing are available for 9,000 Large Commercial Customers with demand greater than 200kW. The newest AMI meters have the capability of short range connectivity. This feature will be used by the Home Area Network devices that display various real-time energy consumption data to the customers.

2.8 Demand Response Initiative

LADWP has had a Demand Response (DR) rate for years for large industrial users. Currently, there are 30 Megawatts of interruptible load, but very rarely has this been used because LADWP has had a philosophy to cover all its loads. This pilot program is also voluntary in that when a load reduction is required, the customer has the option to not participate and pay for the higher cost of energy. Currently, the LADWP is planning to develop a formal demand response program that will allow the Department to reduce generation cost and distribution system strain during peak consumption periods.

2.9 Communications Initiative

The component that pulls all of the initiatives together is the common communication network. Over the past ten years, thousands of miles of fiber optic cable has been installed in over 72 substations as part of a fiber optic broadband infrastructure. The plan is for all substations to have fiber optic connections within the next two years.

AR0070285

LADWP evaluates different communication protocols that can be used for the real-time control and observation of deployed automation equipment.

2.10 Cyber Security Initiative

The implementation of Smart Grid will involve a wide deployment of smart remotely controlled network capable devices. These devices can be potential points of cyber attack due to network connectivity. This is why NERC and FERC have developed strict procedures and guidelines that require utilities to treat any critical cyber asset (CCA) with great attention. The breach of CCA can result in critical damage to the power distribution system.

Due to the importance of Cyber Security, the Smart Grid will need to better understand and improve the cyber security, and more importantly, three key items will be developed:

- Grid Resilience: this effort will show how the Smart Grid can operate resiliently against physical and cyber attack.
- Operational Effectiveness: this effort will demonstrate a complete cyber security testing approach for components and installed systems.
- Redefinition of Security Perimeter: this effort will demonstrate new cyber security measures that address the expansion of this perimeter by Smart Grid technologies to the meter in residential and commercial sites.

2.11 System and Data Integration Initiative

Significant progress has been made in the Power System in implementing the best of breed systems (see **Figure 2.11-1** Power System Technology Architecture). These systems are the backbone of the business and information processes in the Power System. Additionally, significant integration between these and the corporate systems is in place.

In particular, OSIsoft's Pi Historian is a fast real time data processing system that has been purchased and installed by LADWP. The next Pi Historian initiative is to use it as a central repository for all of LADWP's real-time data and to allow access to the appropriate users of the data throughout the utility. LADWP has currently installed the Pi Historian in two locations (ECC and JFB) with a tag count of 20,000 data points. There are three pilot Pi Historian applications running at this time: 1) door/gate alarm; 2) Operation logger; and 3) Power System Dashboard real time data. Five user groups (Reliability, Planning, Station Operators, Grid Operations, and Meter) are also currently developing new applications.

In addition, LADWP is working on integrating the Meter Data Management System (MDMS), Outage Management System (OMS), and Customer Information System

AR0070286

(CIS) with various Web services. These services will be designed to provide accurate and timely information to customers regarding their consumption, billing, any pending outages and restoration statuses. The customers will have the option to adjust their accounts to set up their profile and notification preferences.

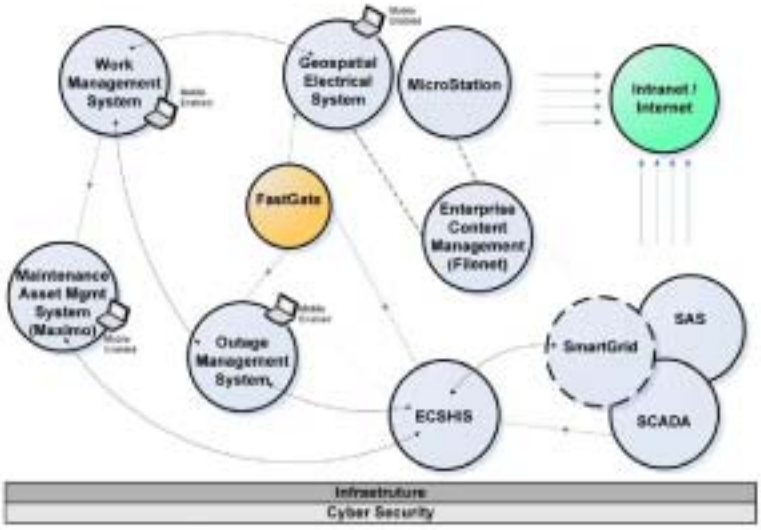

Figure 2.11-1 Power System Technology Architecture

2.12 Feed-In Tariff Initiative (FiT)

FiT seeks to purchase energy from small and medium-scale renewable energy projects (from 30 kilowatts up to one megawatt in AC capacity) within the service territory of LADWP under a long-term Standard Offer Power Purchase Agreements (SOPPA). The SOPPA terms are standard for all participants, can be up to 20 years in duration, and participants will be paid the bid base price of energy plus Time-of-Delivery (TOD) multipliers. FIT is a distributed generation (DG) program designed for the local Los Angeles market, and gives LADWP customers the opportunity to sell energy to LADWP from using their property as the DG site.

2.13 Solar Incentive Program (SIP)

The LADWP Solar Photovoltaic Incentive Program provides financial incentives to LADWP customers who purchase and install their own solar power systems. LADWP currently also provides an additional incentive payment for systems using PV modules manufactured in the City of Los Angeles.

LADWP currently provides a Los Angeles Manufacturing Credit (LAMC) for qualifying photovoltaic equipment manufactured in Los Angeles as approved by the LADWP guidelines. The goal of the LAMC is to promote local economic development through

AR0070287

manufacturing and job creation within the City of Los Angeles and to reduce costs through increased volume and competition.

3 Proposed Deployment Plan

The overall scope of the Smart Grid Deployment Plan includes the following three overlapping phases:

3.1 Implement a short term plan (one year horizon)

This plan includes the following coordinated activities:

- Create a Smart Grid System Architecture (**Table 3.1-1** *SG Architecture (Phase 1) Schedule* & **Table 3.1-2 SG Architecture (Phase 2) Schedule**)
- Create a Comprehensive Business Plan/Case (**Table 3.1-3 SG Business Plan Schedule**)
- Integration of Various Information Systems
- Participate in Standard Development
- Creation of a Multi Disciplinary matrix team

Table 3.1-1 SG Architecture (Phase 1) Schedule

Table 3.1-2 *SG Architecture (Phase 2) Schedule*

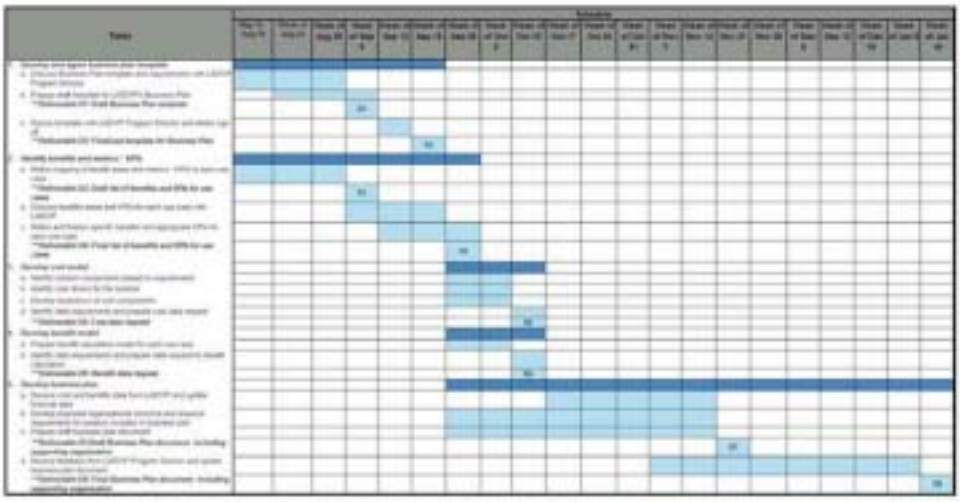

Table 3.1-3 *SG Business Plan Schedule*

3.2 Implement a mid term plan (up to five years horizon)

This plan includes the following coordinated activities:

- Complete and implement LADWP's ARRA Smart Grid Regional Demonstration Project, which focuses on Customer and Behavioral Studies, Cyber Security, Demand Response, and Electric Vehicles.

AR0070289

Figure 3.2-1 *Smart Grid Regional Demonstration Project Schedule* below shows the implementation schedule of the Smart Grid Regional Demonstration Project.

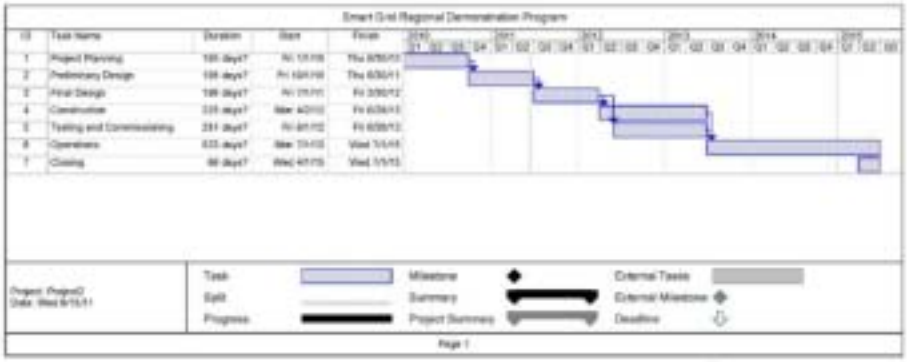

Figure 3.2-1 Smart Grid Regional Demonstration Project Schedule

- Implement the balance of the SAS project to automate all generation, substation, and transmission with the SCADA system. **Table 3.2-1** *Substation Automation Project Installation Progress Schedule* below shows the overall schedule of activities to implement the SAS project.

Table 3.2-1 Substation Automation Project Installation Progress Schedule

- Implement the balance of the projects at ECC to use all of the features and upgrades of the SAS and other systems with the new technology. **Figure 3.2-2** ***ECC Plans to be Implemented*** below shows the activities and systems to be implemented.

Figure 3.2-2 ECC Plans to be Implemented

- Implement the balance of the projects at ETC to use all of the features and upgrades of the Smart Grid systems with the new technology. **Figure 3.2-3** ***ETC Plan and Enhancements*** below shows the various activities to be implemented.

AR0070291

Figure 3.2-3 ETC Plan and Enhancements

- Implement a new CIS and Supply Chain System

The effort must be made to implement a new CIS, and a new Supply Chain Corporate System. These systems will be able to manage the new information and transaction of a Smart Grid system.

Other activities to be implemented during this phase are as follows:

- Implement the balance of the electric model with the GIS system and engineering design tools
- Create and advertise Multiple RFPs as needed to start the implementation of the Smart Grid components
- Create Multiple contracts as needed to bring the vendors on-board

3.3 Implement the full Smart Grid Features (up to 10 years)

Implement all the remaining features indicated in this plan in various phases based on the requirements and needs identified, and with the dynamics of the utility and technology environment. The phases of this significant program could include two large pilot periods where various telecommunication technologies will be tested while Smart Grid technology will be utilized to cover overhead, underground, single family residences, multi-family residences, and medium and large customers in a couple of neighborhoods. The final phase would be the full city wide implementation assuming the data and results from the pilot programs are satisfactory.

AR0070292

The full functionality of the Smart Grid could include all of the following aspects:

(a) Outage Notifications

(b) Transformer Monitoring

(c) Capacitor Controls

(d) Line Switch Controls

(e) Automatic Meter Reading

(f) Load Control of residential and commercial devices (DSM Program)

(g) Video Surveillance via Smart Grid

(h) Fault Management

(i) Transformer Deterioration

(j) Transformer Overloading

(k) Current Monitoring

(l) Cable Management

(m) Surge Protection

(n) Lighting Controls

(o) Weather

(p) Municipal Applications

(q) Other applications as they become available.

Other features could include:

- Installation of Smart Grid equipment in the City of Los Angeles Facilities
- Installation of Smart Grid equipment and potentially replacement all of the water meters
- Access to broadband capabilities (Internet access, VoIP, video) for City of Los Angeles Municipality
- Access to City of Los Angeles Municipal information via broadband connections

AR0070293

- Set up an internal LADWP organization to maintain and operate the Smart Grid equipment
- Maintain, install, and operate the Smart Grid equipment through the following organization and service components:

  1. Services
  2. Customer response center
  3. Network Operation Center (NOC)

3.4 Related Projects

The following projects are related to the Smart Grid as follows:

1. Substation Automation System: Extension and upgrade of the remaining Switching, Receiving, and Distribution Systems
2. Telecommunications system: Extension and upgrade of the telecommunications to support the Power System operations through the implementation of a fiber optic broadband network.
3. Subtransmission and distribution switches: Automation of subtransmission and distribution switches, implementing line monitoring, line switch control, and 4.8 kV line capacitor bank control.
4. Fault and outage detectors: Installation of remotely monitored fault and outage detectors which would provide a means to locate faults and outages on selected 4.8 kV distribution lines.
5. Operating orders, procedures, and processes: Re-engineering of operating orders and processes as required for monitoring and controlling changes of the Power System.

3.5 Constraints

The following are potential constraints:

- Budget/Cost
- Regulatory environment which may limit Smart Grid installations
- Internal Resources
- Political environment (City/State/Federal)

AR0070294

3.6 Urgency

The timing of LADWP's Smart Grid Deployment coincides with the initiatives by other major U.S. utilities. Additionally, the Department of Energy is encouraging utilities to invest in Smart Grid by offering grants and the regulatory environment seems to support Smart Grid as an alternative to the existing utility practice.

3.7 Procurement Process

The Smart Grid Plan will utilize the procurement process as follows:

(a) Determination of requirements

(b) Preparation of RFP(s)

(c) Vendor(s) Selection

(d) Preparation of Agreements

(e) Initial Implementation – Phase 1

(f) Phase 1 Evaluation

(g) Multi-phase implementation over the next 10 years.

4 Critical Milestones

4.1 Schedules and Critical Milestones

The Smart Grid Plan assumes a 1-year, 5-year, and 10-year implementation.

4.1.1

4.1.2 Critical Milestones

Table 4.1.2-1 Critical Milestones illustrates the critical milestones:

Milestone or Event	Significance
Smart Grid Business/Project Plan and Architecture Presentation	Get concurrence from Management
Setup of Smart Grid Project Committee	Establish Project Committee
Preparation of Smart Grid Project Requirements	Establish project requirements
Advertise Request for Proposals	Request for Proposals
Vendors Selection	Selection of qualified bidder
Board Approval	Contract approval by LADWP Board of Commissioners

AR0070295

City Council Approval	Contract approval by City of Los Angeles
Contracts Award	Execution of contract award
Implementation Phase 1	Implement Smart Grid Phase 1 (Pilot Programs)
Evaluation of Phase 1	To continue Full Implementation
Begin full deployment	Implement city wide

Table 4.1.2-1 Critical Milestones

AR0070296

5 Budget

Smart Grid equipment costs are expected to continue to drop due to technology advances and significant market changes, **Table 4.1-1** Budget Estimates for various Systems given below is our best estimate for various alternatives at this point. As RFPs are produced and responses are received, we will have a better idea as to the cost of these types of systems and process.

	Single Unit				Total

Table 4.1-1 Budget Estimates for various Systems

The pie chart below (**Figure 4.1-1** P2P Cost Graph) depicts the P2P estimated cost in the nine different categories of the smart Grid.

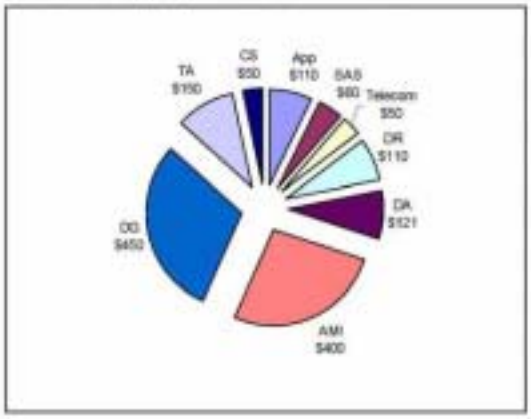

Figure 4.1-1 P2P Cost Graph

AR0070298

6 Impacts

6.1 Internal

The Smart Grid equipment will impact several areas within LADWP. **Table 6.1-1** Potential Impacts within LADWP shows some potential impacts on these organizations:

Area within LADWP	Nature of impact
Meter Reading	Automated method reading of electric meters
Control System Operations	may gain capability to control devices at all levels
Customer Service	Establish direct communications with customer
Electric Trouble Dispatch	Will process trouble calls using Smart Grid information
Engineering Design	Power network design process (OH/UG)
Distribution Line Crews	Maintain and operate new Smart Grid equipment
ITS	Provides support of Smart Grid network equipment
Water Meters	Automated method of reading water meters

Table 6.1-1 Potential Impacts within LADWP

Area within the department	Nature of impact
Energy Control Center	Will use SAS for real-time data instead of current RTU
Electric Trouble Center	Will use real-time data
Plant Control System Operations	Will use real-time data access and archived data
Substation Operations	Selected station status information will be available
Substation Maintenance	Will access intelligent relay settings and logs without having to connect directly to the devices
ITS	Provides support of ECS WAN network.
Power Systems Operation and Maintenance	Provides support of SAS application software and hardware
Engineering	Will use archived data

Table 6.1-2 Potential Impacts within department

AR0070299

6.2 External

Table 6.2-1 Potential Impacts external to LADWP shows some potential impacts on organizations that are external to LADWP:

Area external to LADWP	Nature of impact
City of Los Angeles	Gain fiber optic broadband infrastructure
Broadband Companies	May perceive competition from LADWP and receive services.
Gas Utility	Opportunities to collaborate with LADWP
State of California (CPUC)	May encourage Smart Grid installation at Los Angeles

Table 6.2-1 Potential Impacts external to LADWP

7 Smart Grid Business Plan & Evaluation Strategy

A Smart Grid business plan will be developed in conjunction with the roadmap and architecture development activities which will include cost-benefit analysis of projects for implementation of the functionality identified in the Smart Grid architecture and roadmap. The business plan documentation will outline the project description; costs associated with the implementation; and expected benefits. The financial analysis will be based on estimated benefits and costs information and will be updated throughout the course of the implementation of the projects as the actual cost data become available. The business plan development process will include an assessment to identify the benefit areas and develop an estimate of actual quantifiable benefits expected from investment into particular Smart Grid area. The benefits resulting from LADWP's Smart Grid investments could be in various areas including but not limited to better customer service, reduced operational costs, higher operational efficiency, and achievement of environmental goals. The benefit estimation will be developed using LADWP KPIs and other relevant metrics. The business plan will also include a cost model to estimate the implementation costs of each project. The cost estimates will be based on assumptions of the technology and implementation choices, and will be updated during implementation of the projects with actual costs and implementation plans.

8 Smart Grid Safety

Smart Grid Deployment Plan requires specific installation, maintenance, and operation procedures, which LADWP personnel will need training on. Additionally, the Smart Grid equipment will require compliance and resolution of issues relating to the following state regulations:

(a) California Public Utilities Commission - General Order 128 – Construction of underground electric supply and communication systems.

AR0070300

(b) California Public Utilities Commission - General Order 95 – Overhead electric line construction.

(c) California Public Utilities Commission - General Order 165 – Inspection Cycles for electric distribution facilities

(d) The Smart Grid vendors and utilities are currently handling all of these issues with success.

9 Smart Grid Operational issues

LADWP intends to own and operate the Smart Grid equipment. The ownership entails the support and ability to operate the Smart Grid network by LADWP personnel.

The following are potential operational issues:

- 24/7 operational support of the Smart Grid equipment
- Training of Crews for the operation and maintenance of the Smart Grid equipment
- 24/7 operational support of the telecommunications and fiber optic broadband infrastructure access

10 Smart Grid Performance Measurement

The critical success factors essential for plan success are as shown in **Table 10-1** Critical Success Factors:

Critical Success Factors	Measurement method
Plan Buy-in from LADWP Board	LADWP Board Approval
Plan Buy-in from City	City Council approval
Appropriate plan budget	Budget approval
Smart Grid Technical Feasibility	Market proven Smart Grid technology
Secure staffing resources	Appropriate resource leveling based on project scope
Regulatory Support for Smart Grid	City, State legislative approvals for Smart Grid implementation

Table 10-1 Critical Success Factors

AR0070301

11 Smart Grid Product Benefits Realization

The benefits will be measured as shown in **Table 11-1** Benefits:

Potential Benefits	Measurement method
Municipal fiber optic broadband Capability	No. of City of Los Angeles Broadband users
Smart Grid enabled Automated meter reading	No. of automated meter reads
Customer Energy Management Programs	No. of devices under Direct load control
Improved reliability	No. of Utility applications in service
Additional Revenue Sources	Capitalize on revenue generating opportunities

Table 11-1 Benefits

AR0070302

12 Conclusion

The Los Angeles Department of Water and Power is dedicated to integrating new technologies to improve system performance, power flow control, safety and reliability. By maintaining a high level of commitment and service for the City of Los Angeles, LADWP is taking the necessary steps to:

(a) Coordinate efforts across multiple stakeholders

(b) Integrate new technologies to supplement the power system

(c) Deliver safe, secure, and efficient electrical service well into Los Angeles's future

LADWP's overall strategic plan is inclusive of the Smart Grid Deployment plan. LADWP's focus is the City of Los Angeles, customer enhancement, utility services, and operations. LADWP looks forward to further collaborate with policymakers, customers, and stakeholders as the process of Smart Grid implementation unfolds.

AR0070303

Appendix M - Climate Change Effects on Power Generation

The association of power generation and climate change usually centers on the industry's contribution towards atmospheric Greenhouse Gas (GHG) emissions and its efforts to reduce such emissions. Throughout this IRP is discussion of various LADWP programs and projects whose key objective is to lower GHG emissions. However, an important factor to also consider in resource planning is how climate change *affects* electricity demand, or consumption, and how it impacts the process of generating electricity. Rising average temperatures, changes in precipitation amounts and patterns, more frequent extreme weather events and a rise in sea level are some of the effects that may be expected from global warming. Understanding how these effects impact power generation and incorporating that knowledge into the planning process facilitates adaptation of the power system to respond in a way that mitigates potential problems and takes advantage of any opportunities.

The effects of climate change on resource planning can be addressed on two levels: (1) how it affects *energy consumption*, and thus how much generation should be planned for and secured, and (2) how it affects *power generation* operations and the siting of new facilities.

Energy Consumption

The effects of rising temperatures on energy consumption will vary by region and season. In traditionally cooler regions, net energy use may actually decrease due to less heating requirements. In warmer regions, an increase in cooling demand will mean an increase in energy usage, specifically electricity. Within LADWP's service territory, a net increase in electricity for cooling can be expected. Along with increased temperatures, there is also an increased potential for extreme weather events, such as heat storms of longer duration. Preliminary findings are as follows:

Global Warming Impacts Affecting Energy Consumption

1. Mean temperatures will continue to rise in Los Angeles increasing Cooling Degree Days and decreasing Heating Degree Days.[1]
2. Extreme heat conditions, such as heat waves and very high temperatures, may last longer and become more common place.[2]
3. Air conditioning saturation will increase with the rise of mean temperatures.[3]

[1] Climate Scenarios for California, California Energy Commission, CEC-500-2005-203-SF

[2] Global Climate Change, California Energy Commission, CEC-600-2005-007, page 2

[3] Air conditioning market saturation and long-term response of residential cooling energy demand to climate change, D.J. Sailor, Energy 28 (2003) pages 941-951

AR0070304

These effects have been incorporated into LADWP's load forecast. Due to the ongoing nature of climate change studies and advancements, it is important that LADWP stay abreast of current findings and conclusions, and incorporate such findings as appropriate.

A recent study by the UCLA Department of Atmospheric and Oceanic Sciences[4] focuses on temperature changes in the Los Angeles region in years 2041-2060. A key attribute of the study is its high resolution perspective for the Los Angeles region, including unique predictions for individual areas such as San Pedro, Woodland Hill, San Fernando and Downtown LA. Due to the region's varied topology, some areas are expected to experience more warming than others.

The UCLA study results for the City of Los Angeles show annual average temperature increases of between 3.7 and 4.3 °F (an average increase of 4.0 °F), depending on location within the city.[5] The number of days per year in which temperatures will surpass 95 °F are shown to increase – at worst by a factor of 4.0, but again depending on location as shown in Table M-1 below:

Table M-1 – NUMBER OF DAYS WITH TEMPERATURES ABOVE 95 °F

	Number of Days Baseline	Number of Days, Study Results, Mean	Increase Factor over Baseline
Downtown	1.4	4.6	3.3
San Pedro	0.6	1.4	1.4
Venice	0.1	0.1	1.0
Sylmar	6.8	25.5	3.8
San Fernando	7.9	26.3	3.3
Woodland Hills	4.2	16.7	4.0
El Sereno	2.3	6.8	3.0
Eagle Rock	2.0	6.0	3.0
Porter Ranch	8.0	30.1	3.8

While the UCLA study looks at temperature changes in the 2041-2060 timeframe (which is beyond the 20-yr planning horizon for the 2012 IRP), the findings corroborate other studies and supports the expectation of higher future temperatures which will increase electricity use. As this study is specific to the Los Angeles region, it provides detailed information which local government, utilities (including LADWP), hospitals and other institutions can use to help prepare for the future.

[4] Hall, et al., 2012: Mid-Century Warming in the Los Angeles Region. Available at: www.c-change.LA
[5] The study includes two GHG emission scenarios – a business-as-usual scenario and an aggressive emissions mitigation scenario. The data noted here is from the business-as-usual scenario.

AR0070305

Power Generation

The impacts of climate change on power generation go beyond the need to meet increased loads and higher peak demands. The potential expressions of global warming that are the major areas of concern for power generation are extreme weather events, water availability, and rising sea levels. Consequences include decreased thermal efficiencies and siting impacts for new facilities.

Extreme Weather

From a national perspective, an increase in "extreme weather conditions" usually refers to an increase in the number, intensity and duration of hurricanes, such as on the East Coast and Gulf of Mexico, tornadoes in the Mid-West, floods, droughts, etc. These extreme events have the power to disrupt and damage power generating facilities. Fortunately, such events affecting LADWP generation sources have been relatively less frequent. However, extreme weather conditions in other areas of the country can impact LADWP by disrupting fuel supply production and transportation.

Locally, an increase in frequency of weather anomalies can be a cause for concern. In July 2006, a prolonged heat wave resulted in major service disruptions. And in November 2011, a severe wind storm resulted in extensive damage and power outages across the region, affecting over 220,000 LADWP customers. Such events stretch available resources and expose vulnerabilities in the electric delivery system. To the extent climate change contributes to an increase in such events, more human and capital resources must be provided to increase the resiliency of the electricity infrastructure to better withstand these extreme conditions; and, when outages do occur, to restore interrupted service in an expeditious manner that adequately addresses public health and safety needs.

Water Availability

Changes in weather patterns due to climate change will likely result in increased variations of water availability, with some regions experiencing more drought conditions and other areas becoming more subject to flooding. This affects power generation in a number of different ways. A decline in water levels behind hydro dams will decrease generation capacity which would have to be made up elsewhere. Changes in stream and river flows will affect the output of run-of-the river hydro facilities, which may be positive or negative. Flooding conditions could threaten the operation of generating stations, including renewable wind and solar facilities. In drought stricken areas, a scarcity of cooling water availability will increase the demand and price for water. Increased competition for water can be expected from other water consumers, including the agriculture, mining, industrial, residential and commercial sectors within the affected region.

AR0070306

For California, the research to date indicates a potential of reduced snowpack in the Sierras, which would decrease hydro-electric output. An increased likelihood of drought conditions in the U.S. Southwest would also impact hydro generation in addition to constraining sources for cooling water. Developments such as these will have negative implications for LADWP's hydro-electric and thermal generation operations.

Sea Level Rise

Sea Level Rise (SLR) is another area of ongoing study. While projections vary, the October 2010 State of California Sea-Level Rise Interim Guidance Document uses a baseline that estimates a 5-8 inch rise by year 2030. Within the 20-year planning horizon of this IRP, SLR in this range will not present a problem to LADWP's coastal generating facilities. Longer-term effects, such as what may be projected for the end of the century, would be addressed over time. Because the more pronounced effects of SLR are not anticipated to occur until 60+ years into the future, strategies to mitigate possible negative impacts can be developed and implemented in a deliberate and methodical manner. For example, generating stations are expected to be replaced every 50-55 years, and if warranted due to extreme SLR, consideration can be given to relocate inland as part of the replacement process.

Decreased Thermal Efficiency and Output

An increase in temperature due to global warming will impact the thermodynamic efficiency for power plant generating equipment. An increase in ambient temperature decreases efficiency, resulting in less output per unit of fuel. On average, an increase of 5 °F decreases efficiency by approximately 0.4 to 0.8 percent. Higher temperatures would also decrease the amount of energy capable of being generated. A 5 °F increase reduces available output by about 1.0 to 2.0 percent.[1]

New Facility Siting

The potential impacts of water availability and extreme weather events could impact the siting of new energy generation and transmission infrastructure. This would be more pronounced in areas where water availability is expected to decrease, such as the US Southwest. This doesn't necessarily preclude potential sites as candidate locations, but it may necessitate higher construction and operation costs, and incorporation of engineering designs and processes that are more weather-hardened and use less water.

Actions to Address Climate Change

Reducing GHG emissions to minimize its impact on climate change/global warming is a key LADWP strategic objective. As discussed in other parts of this IRP, LADWP is

[1] The ranges shown reflect differences across different generation methods (e.g., combined cycle vs. combustion turbine). Values shown are approximations. Relative humidity is also an influencing factor.

AR0070307

modifying its resource mix to adopt more renewable resources such as wind and solar, which do not emit GHG emissions. Replacing older inefficient gas-fired units at its in-basin generating stations will reduce the amount of fuel needed to generate electricity, which also decreases emissions. Ensuring the adoption of energy efficiency programs will offset the amount of emissions in direct proportion to the resulting energy savings – every unit of electricity saved also eliminates the corresponding amount of GHG that would otherwise be emitted. And, to further reduce GHG emissions LADWP is actively working to divest itself from its two coal power plants – the Navajo Generating Station and the Intermountain Power Project – although contractual, legal and financial issues present challenges that need to be worked out.

To prepare for and adapt to climate change, LADWP incorporates into its load forecast increases in electricity demand resulting from expected higher future temperatures. Implementation of LADWP's Power Reliability Program will increase the resiliency of its electricity delivery infrastructure, better preparing it to withstand the more frequent and prolong weather events (heat waves) that will be expected. Other considerations include a heightened awareness and accounting of potential effects on water availability, new facility siting, thermal efficiencies, and sea level rise. Although this IRP document addresses only the power side of LADWP, it is worth noting here that water conservation will play a large role in both reducing GHG emissions and as a means of adapting to the effects of climate change.

Conclusion

Global warming is a major environmental concern that warrants continuous attention. LADWP's efforts to reduce GHG emissions should continue, as should planning activities to prepare for and adapt to the future consequences of climate change. As a responsible municipal utility, LADWP should base its recommendations and actions on sound scientific studies and principles, and in concurrence with City policy.

As the science of climate change continues to evolve, LADWP should stay abreast of the latest findings and conclusions. Subsequent IRPs will monitor developments in climate change and develop/refine recommendations to mitigate any negative impacts as part of the resource planning process.

Appendix N Model Description and Assumptions

N.1 Overview

The study horizon for the model analysis is the 20 year period 2012 through 2032. In performing this modeling, it is necessary to assume certain actions are taken in each of the next 20 years. However, it must be understood that the Integrated Resource Plan (IRP) is an ongoing process. A new IRP is developed every two years. Between each 2-year interval, the most recent IRP is modified if appropriate. The key results from this IRP analysis is the action plan that will be put in place for the next 1 to 5 years. These near-term actions are important recommendations that will enable and support the goals and objectives of the long term plan.

This Appendix presents the Model Analysis and is organized as follows:

- Section N.2, Model Description, provides a description of the model selected by LADWP to simulate the operation of its power system under different futures and with different resource portfolios.
- Section N.3, Resource Selection Process/Gap Analysis, describes the method used to assess the amount of future renewables and other replacement resources required to satisfy resource adequacy requirements including a description of the valuation process used in selecting the future renewable resource portfolio.
- Section N.4, Avoided Costs and Net Revenue Losses, describes the analysis and results to determine the net revenue loss used in the evaluation of the energy efficiency and distributed generation case comparisons (Cases 5 thru 8) found in Section 4.3.3.1.
- Section N.5, Model Inputs and Assumptions, presents the major input parameters that were used in the production cost model runs.

AR0070310

N.2 Model Description

LADWP has chosen a widely used and industry accepted hourly chronological unit commitment and dispatch model to simulate the operation of the LADWP power system under different futures and with different resource portfolios. The model is the Planning & Risk model (PaR) licensed from Ventyx (an Atlanta based software firm). It uses the PROSYM unit commitment and dispatch algorithm.

PROSYM is designed for performing planning and operational studies, and as a result of its chronological structure, accommodates detailed hour-by-hour investigation of the operations of electric utilities. Because of its ability to handle detailed information in a chronological fashion, planning studies performed with PROSYM closely reflect actual operations. PROSYM considers a complex set of operating constraints to simulate the least-cost operation of the utility. This simulation, respecting chronological, operational, and other constraints, is the essence of the model.

This model looks at the LADWP load for each hour and then dispatches LADWP generation supplies on an economic basis (lowest variable cost units first) until the load is met. The model output reflects all the variable costs incurred in meeting the load for each study performed. The fixed costs for the resources are added to the modeled variable costs to develop the total power cost incurred in meeting the load.

The model is also capable of representing certain transmission constraints on a utility system. LADWP load is generally confined to the geographic area of Los Angeles. An IRP would not generally be a replacement for transmission planning activities needed in the service area. However, LADWP does have generation outside of Los Angeles and has transmission rights to other areas of the Western Interconnect. To better represent the constraints and opportunities related to these remote facilities, the modeling topology depicted on Figure N-1 was developed for this IRP.

AR0070311

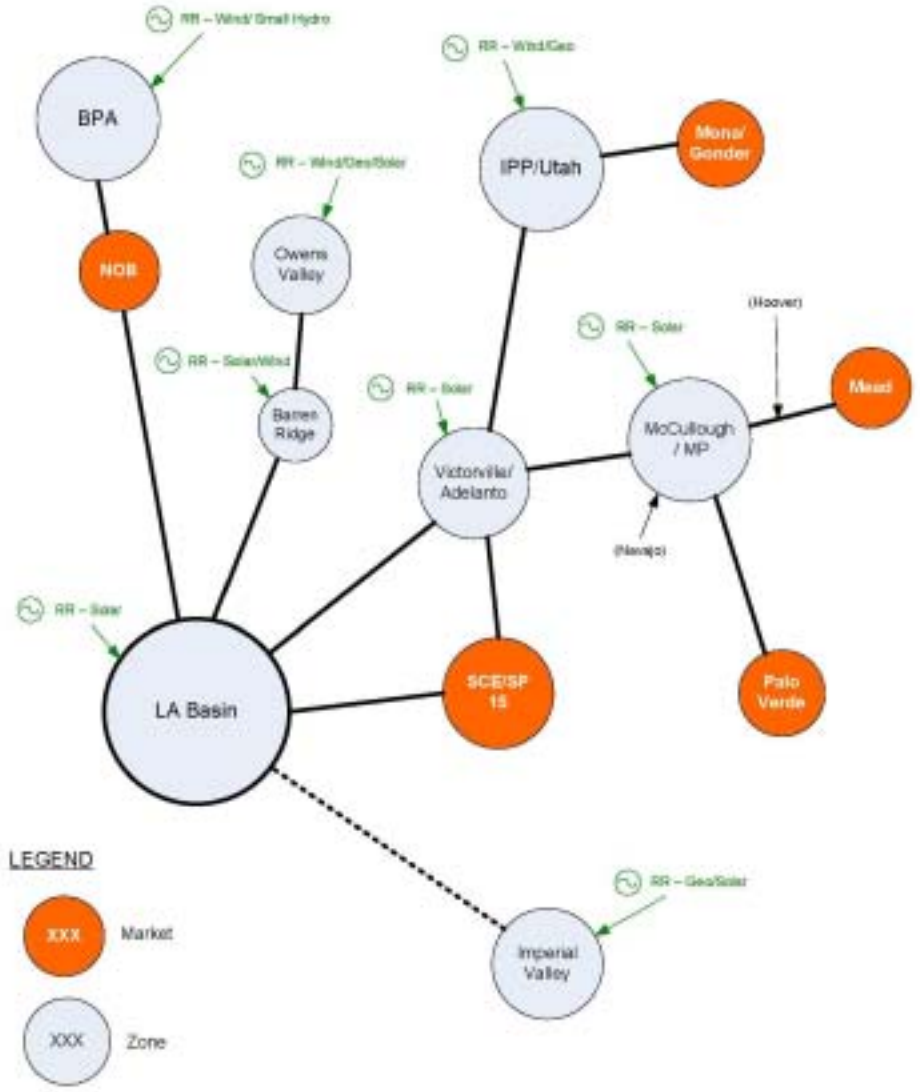

Fig N-1: LADWP Modeling Topology.

On a day-to-day basis, LADWP will buy power in spot markets if such a purchase can be done both without causing a reliability problem and if the price of the spot market power is less than the operating cost of its own power plants. Similarly, on a day-to-day basis, LADWP will sell power in spot markets if the price of power in the spot market is greater than the cost of operating an LADWP resource and the power is not needed to meet LADWP load. In an IRP analysis, it may or may not be desirable to attempt to reflect spot market activity. For this IRP, short term and long term market purchases and sales were included in the overall energy mix. For resource adequacy, some limited Q3 purchases were included to supply short term capacity deficits in future years resulting from coal divestment and load growth.

AR0070312

N.3 Resources Selection Process/Gap Analysis

The gap analysis in this IRP evaluated both a Resource Adequacy (RA) need as well as a need to meet certain goals for renewables as a percentage of billed energy (renewable need). The RA need compares available generation supplies to the load that needs to be served. For LADWP, this comparison was based on the annual peak load plus a planning reserve margin. In addition to a system wide demonstration of RA, a certain amount of generation needs to be located in the Los Angeles service territory to assure local reliability. Sections 2.4.7, 3.4.2, 4.2.1.4 and 4.3.1 of this report discuss the LADWP approach to RA.

N.3.1 Resources recommended for Resource Adequacy

The displaced energy from early coal replacement is generally replaced with a combination of renewable energy and new gas-fired combined cycle generation. Energy efficiency, demand response, and short term 3rd quarter market purchases are used to primarily satisfy load growth. Table N-1 summarizes the different replacement resources for the different cases that were evaluated.

N.3.2 Amount of Renewables Needed

To determine the amount of renewable energy necessary to meet future targets, forecasts were made for the future power demand and the amount of existing renewable capacity available to meet these requirements. The difference between the projected amount required and the amount currently being utilized is the net short that will need to be acquired to meet RPS guidelines. A description of the methodology undertaken to define the future renewable needs is outlined below.

LADWP Renewable Net Short

The net short is the generation target to be met with resources identified in this project. The calculation for the net short was performed using the following equation:

Net Short(GWh) = (Forecasted Energy Sales) x (Annual Renewable Percent Goal) – (Operating Renewable Resources – Under Construction and Pre-construction Renewable Resources - Renewable Energy Purchases)

SB 2 (1X) has established the level of renewables required by 2020 and beyond, and also sets interim targets between now and 2020. These levels and targets represent the *Annual Renewable Percent Goal* parameter in the equation. By incorporating forecasted sales, existing renewable projects, and current and forecasted renewable energy purchases, the net short can be calculated.

N.3.3 Renewable Resources Selection Process

Over the last ten years, LADWP has issued several requests for proposals for renewable energy and gained a thorough understanding of the nature and availability of the different renewable resource technologies. This knowledge was used in developing the renewable portfolio. Additionally, LADWP largely considered renewable resources within the Western Governors' Association's Western Renewable Energy Zones (WREZ). In the WREZ initiative, Qualified Resource Areas were defined as areas of dense, high-quality renewable energy resources, meeting various resource size, quality, environmental, and technical criteria. LADWP screened all resources to ensure they are located near available LADWP transmission infrastructure. Assumptions were made for the cost and performance of each technology used to convert the renewable resources to electricity. These assumptions were used in calculating the levelized cost of electricity.

A valuation process designed to provide a single ranking value to a resource was then applied. The valuation process is a method to rank the total value of separate renewable resource projects, and accounts for such parameters as transmission costs, integration costs, supply curves, load shapes, the capacity benefit provided by the resource, capital and O&M costs, financial factors and other measures This step is intended to identify resources with the combination of lowest cost and highest value. The valuation approach is similar to the bid evaluation process many utilities use when procuring renewable resources.

AR0070316

After applying the appropriate constraints, resources were selected and added progressively to the renewable resource mix based on lowest rank cost and transmission availability until the net short was mitigated. To assess and rank projects consistently, a method must be developed to measure the economics of all resources on a consistent basis. Renewable technologies all have different characteristics, with different cost requirements and energy delivery patterns. Resource valuation is a way to measure different renewable resources on a comparable basis.

N.3.4 Renewable Generation Cost

The cost of generation is calculated as a levelized cost of energy ("LCOE") at the point at which the project will interconnect to the existing transmission system. The LCOE for a project is the total life-cycle cost of generating electricity at the facility normalized by the total generation from the facility and is calculated in terms of dollars per megawatt hour ($/MWh). LCOE provides a consistent basis for comparing the economics of disparate projects across all technologies and ownership.

For each project or resource class, a pro forma financial analysis was conducted to determine the life-cycle cost. This pro forma model uses input assumptions for key project variables to determine expected revenues, costs, and year-by-year after-tax cash flow over the project life. The pro forma model used is consistent with the model used in CEC's Cost of Generation model, as well as those used in WREZ and California's Renewable Energy Transmission Initiative. It is also very similar to the model used by the CPUC to calculate the Market Price Referent (MPR), with the necessary modifications to make the calculations appropriate for renewable resources, including the modeling of tax incentives, accelerated depreciation, and other incentives.

The analysis included appropriate assumptions for each project. Some assumptions were tailored to be technology specific, such as financing terms and appropriate tax incentives. Other assumptions such as capacity factor and capital cost depended on geography and the available natural resource. Specific costs included in the generation costs were:

- Capital costs
- Generation interconnection costs ("gen-tie")
- Fixed operation and maintenance
- Variable operation and maintenance
- Heat rate (if applicable)
- Fuel costs (if applicable)
- Incentives
- Net plant output
- Capacity factor
- Economic life

AR0070317

N.3.5 Renewable Generation Cost

The integration cost of a project is the indirect operational cost to the transmission system to accommodate the generation from the project into the grid. The addition of substantial amounts of intermittent and as-available renewable resources could result in substantial generation swings on the transmission system, and the grid operator must accommodate these swings by ensuring there is sufficient regulation service, modifications to current daily ramps, additional reserve capacity, and voltage support. Additional integration costs will include wear-and-tear on resources if they are required to repeatedly cycle to adjust for the intermittent resource output.

N.3.6 Renewable Resource Capacity Value

The capacity value of a generating resource is based on its ability to provide dependable and reliable capacity during peak periods when the system requires reliable resources for stable operation. Resources that can provide firm dependable capacity will have a higher capacity value than resources that cannot. In the WREZ model, the ability of a renewable resource to generate power during the top 10 percent of the model's yearly load was used as the capacity credit. LADWP uses a more conservative approach by considering the dependable capacity which varies depending on the resource type and is a fraction of the total available capacity as shown in Table 3-4.

The baseline value of capacity is the cost of the next most likely addition of low-cost capacity, defined as the fixed carrying costs of a simple cycle gas turbine generator. This includes the capital costs, fixed operations and maintenance costs, and other fixed charges associated with the gas turbine generator capacity, expressed as a dollar per kilowatt per year ($/kW-year). The fixed carrying cost assumed in the model is $100/kW-yr. The baseline capacity value does not include variable costs, such as fuel purchases. For new projects, the capacity factor is derived from the projected generation profile for the resource. The formula for calculating capacity value ($/kW-yr) is:

$$\textit{Capacity Value (\$/MWh)} = \textit{(Dependable Capacity Factor) x (Baseline Capacity Value) / (Project Capacity Factor * 8760/1000)}$$

N.3.7 Renewable Resource Energy Value

The energy value of a resource assesses the value of its hourly output to the energy markets. Resources that produce more power during high-price, peak demand periods will have a higher energy value than resources that provide power primarily during low demand periods.

The formula for calculation of energy value is:

$$\textit{Energy Value (\$/MWh)} = \Sigma\,[\textit{(Energy Value in Time Period) x (Energy Output in Time Period)}] \,/\, \textit{Total Energy Output}$$

AR0070318

N.3.8 Renewable Energy Portfolio

Utilizing the methodology described in the previous subsections, a best-value portfolio of renewable resources was developed. This base portfolio was used in all 4 coal cases considered in this IRP and the Base EE, Base DG case which is identical to Coal Case #2. Figures N-2 and N-3 show the renewable capacity and energy production schedules for the base portfolio. To accommodate advanced levels of EE and higher levels of Solar DG for the 3 additional EE/DG Cases evaluated (6 thru 8), certain renewable projects were delayed or eliminated to accommodate the advanced levels of EE and higher levels of DG to maintain consistency with the procurement targets established by SB 2 (1X).

N.4 Avoided Costs and Net Revenue Losses – Energy Efficiency and Distributed Generation Case Comparisons (Cases 5 thru 8)

Due to the load reduction nature of energy efficiency and solar customer-net-metered (CNM) programs, generally referred to as "demand side programs" or "customer opportunity programs", customer sales are reduced leaving the utility with a potential loss of revenue if the cost savings experienced by the utility from these programs does not fully offset the lost sales revenue. The cost savings experienced by the utility from demand side programs are typically referred to as "avoided costs". The difference between the lost sales revenue and the avoided costs is referred to as the "net revenue loss". Modeling of net revenue loss addresses ratepayer concerns that the impact to customer bills and rates due to changes in utility revenues and operating costs be fully considered when comparing the cost of these demand side programs to other resource alternatives. Avoided costs described herein include only those costs that can be avoided by LADWP thru implementing demand side programs and does not consider avoided costs experienced by the customer participating in these programs nor does it consider the wider societal cost benefits of these programs.

Avoided costs are sometimes difficult to quantify since it is not always fully understood what the effect these demand side programs will have on reducing utility costs. There exists a wide range of opinions on the types of avoided costs that should be considered and how those costs are calculated. The larger avoided cost savings components of fuel, emissions, capacity savings, and reduced transfers of surplus revenue (city transfers), are fairly well understood and estimating these cost savings can be effectively performed using production cost modeling software. The production cost model program PROSYM was employed in this analysis and is further described in Section M.2. Less well understood are the system wide savings associated with deferred transmission and distribution upgrades. Distribution savings in the form of deferred upgrades to the distribution system will require further study and were not included in this analysis. Cost savings associated with deferred transmission upgrades were included and are based on upgrades that have recently occurred. Emissions cost savings from CARB's Cap and Trade program were included in this analysis where costs exceeded the emissions allocation to LADWP. Additional work to identify and further quantify avoided costs will be addressed in future IRP's.

Calculations of avoided costs and net revenue losses can vary among utilities because each utility has different cost structures and rate recovery mechanisms. Current methodologies used to calculate avoided costs for an investor-owned utility such as the Ratepayer Impact Measure (RIM) Test may not necessarily apply for vertically-integrated utilities such as LADWP that have direct control over generation, transmission, and distribution resources. It is still unclear whether this same test can be used to evaluate avoided costs for LADWP. Future IRP's will examine the appropriateness of this model for use in evaluating future avoided costs.

Demand side programs such as energy efficiency and solar CNM programs primarily reduce the fuel and variable operating and maintenance costs of marginal gas-fired generation. These programs can also offset lower cost resources such as coal or hydro depending on the size of the demand side resource and the hours over which the energy savings occur. Besides fuel savings, the utility will also experience other fixed and variable cost savings associated with generating, transmitting, and distributing electricity, and lowered compliance obligations of renewables

AR0070322

which are typically based on a percentage of overall customer sales, and city transfers which are based on a percentage of the Power System's gross revenues. As fuel prices rise, these avoided costs will increase so loss of net revenue experienced by the utility will be reduced. Because fuel market price forecasts can vary considerably from year to year, it is important that avoided costs be reexamined periodically.

N.4.1 Analysis of Avoided Costs and Net Revenue Loss - Base EE and Advanced EE

While implementation of the EE program dramatically reduces customer sales, it is important to capture the effects of this loss in revenue. A portion of this loss in revenue can be recovered from demand charges from commercial customers which is a significant portion of a commercial or industrial customer's bill. Residential minimum bill charges were not considered since EE programs would typically offset electrical usage above minimum thresholds. There are also avoided costs of supplying additional generation resources to meet load growth because the EE program reduces system load and to a smaller extent, peak demand as well. Net Revenue Loss is the remaining loss after deducting fixed demand charges from commercial and industrial customers and savings associated with avoided costs. Table N-2 lists all the avoided costs associated with EE programs considered including a brief explanation of each component of the total avoided cost.

Table N-2: EE Program Avoided Costs Considered

List of Avoided Cost	Reasons
Avoided Energy- Fuel, Renewable	**Fuel:** EE reduces customer load, which results in less generation primarily from gas units so there will be less fuel and variable O&M cost.
	Renewable: EE reduces customer sales, and at the same time RPS % is calculated based on the customer sale. Lower customer sales results in less renewable energy procurement to meet the mandated RPS percentage.
Avoided Emissions	Lower generation levels will result in lower greenhouse gas emissions. Per AB32, utilities will be charged for the CO2 emission amount beyond their allocation of allowances.
Avoided City Transfer	EE reduces customer sales which reduces total revenue thereby lowering the transfer to the City which is currently 8 percent of total revenue.
Avoided Transmission & Distribution	With reduced peak load from EE, less MW's will be needed during peak hours so some transmission and distribution upgrades can be deferred.
Avoided Capacity	With reduced peak demand due to EE, fewer peaker units will be built to meet system reserve requirements resulting in deferred capital spending.
Avoided O&M	With lower peak demand and fewer peaker units being built, there will be a savings of fixed O&M costs.
Avoided Losses	EE reduces customer sales thereby lowering the amount of energy we will need to generate to cover distribution and transmission losses.

AR0070323

Figure N-4 shows the avoided costs, fixed billing charges recovered and net revenue loss for the Base EE case. The gross revenue loss shown is $12,227 Million from FY 2012 to FY 2032 and is determined by using the forecasted average customer electricity rate in $/kWh multiplied by the EE energy savings in kWh. The total avoided cost is $6,187 Million over the next 20 years, and the recovered fixed billing charges is $2,220 Million. The small dotted area at the top of Figure N-4 shows the final net revenue loss due to the implementation of Base EE program. An observation from our study was that the net revenue loss was found to be more significant as EE GWh achievement increases.

As mentioned in the previous section, EE program reduces customer sales which means less renewable energy will be needed to meet RPS targets. With the Base EE case, the forecasted customer sales will stay below FY 2010-11 levels over the next 10 years with minimal growth thereafter. This lowered growth rate expected with the Base EE reduces the need to build ~ 800 GWh of renewable energy beginning in 2018 and will save approximately $110 Million assuming the renewable energy that is offset comes from a combination of geothermal and wind. These savings also apply to years beyond 2018 as well. This explains the large increase in avoided energy starting in 2018 (avoided fuel and renewable costs shown in the blue area in Figure N-4).

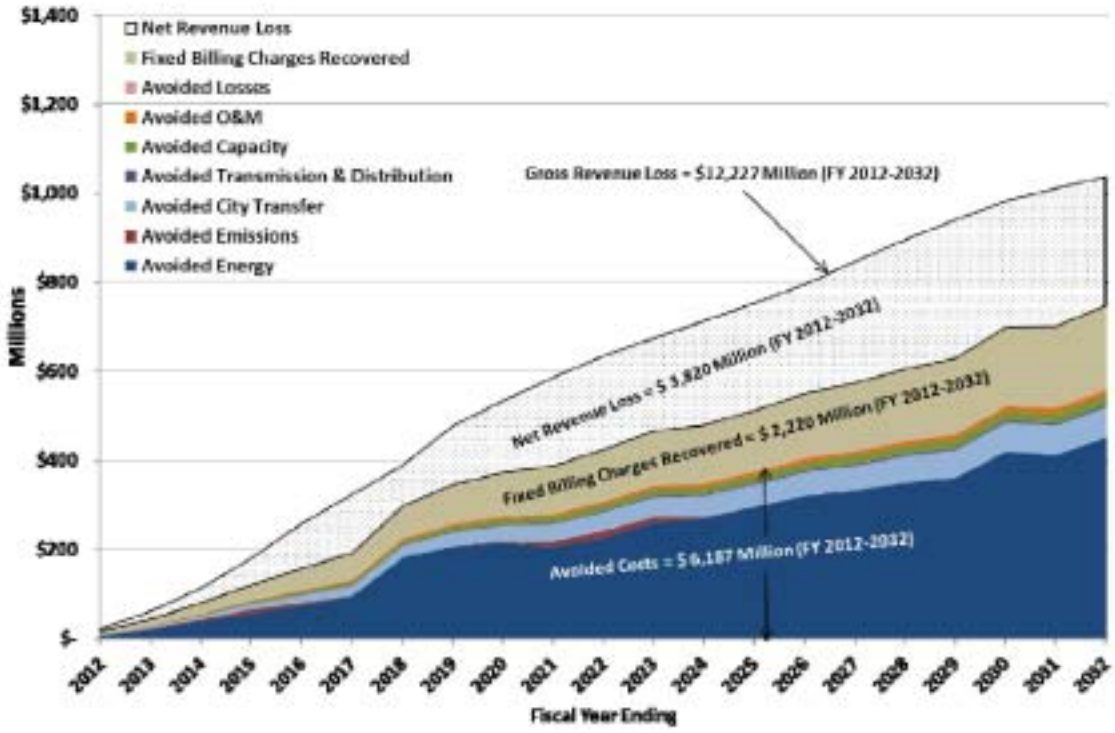

Figure N-4: Base EE Program annual Avoided Cost savings, Fixed Billing Charges Recovered and Net Revenue Loss

The associated rates breakdown associated with Figure N-4 is shown in Figure N-5.

AR0070324

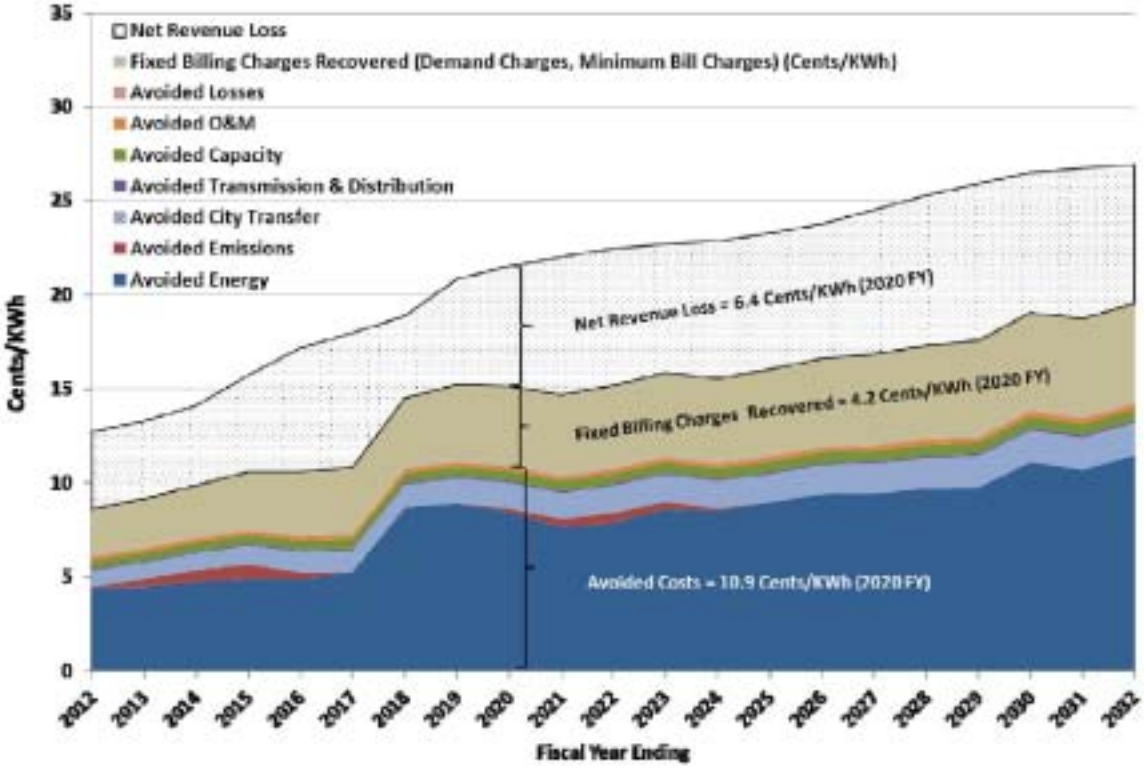

Figure N-5: Base EE Program annual Avoided Cost savings, Fixed Billing Charges Recovered and Net Revenue Loss (in Cents/kWh)

For the Advanced EE case discussed in previous section, similar figures are shown below. The total Net Revenue Loss for this Advanced EE case is $4.06 Billion, which is $240 Million higher than the Base EE case because of the higher level of energy savings (500 GWh) in the last decade. Similar to the Base EE case, the rapid increase of Avoided Energy cost in 2018 as shown in Figure N-6 is also due to the considerable savings in procuring additional renewables resulting from the lowered sales.

The associated rates breakdown associated with Figure N-6 is shown in Figure N-7.

AR0070325

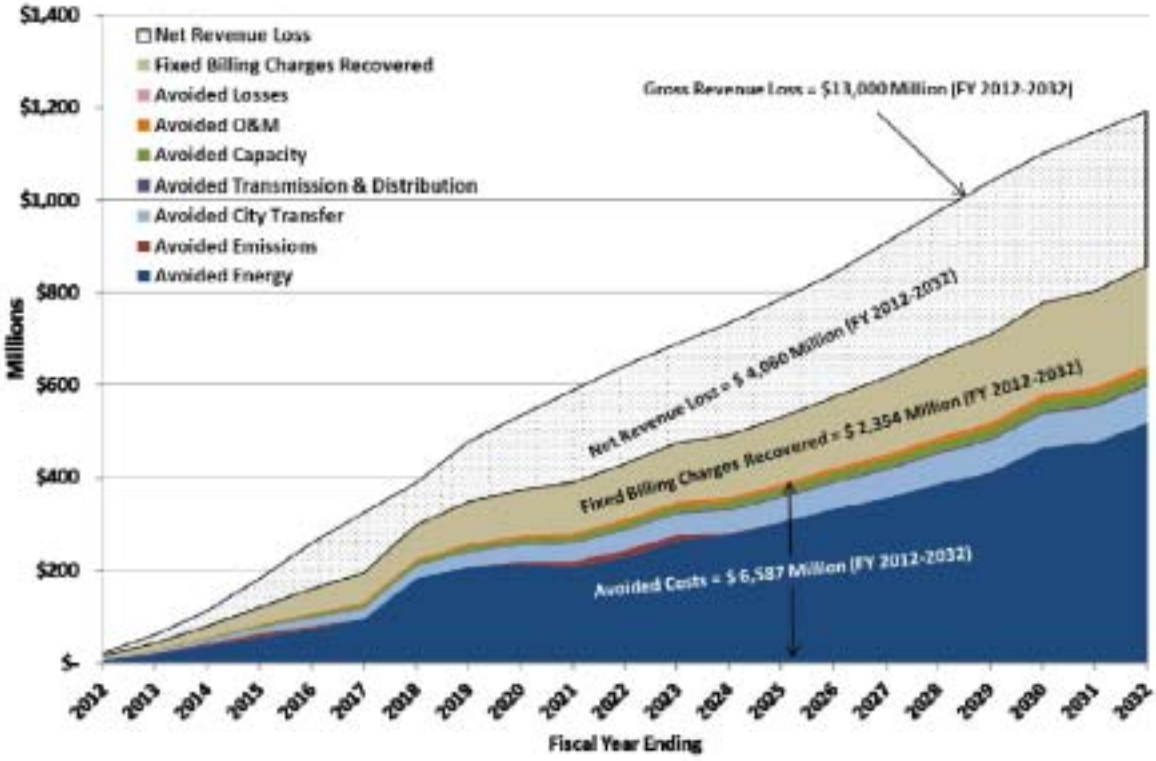

Figure N-6: Advanced EE Program annual Avoided Cost savings, Fixed Billing Charges Recovered and Net Revenue Loss

AR0070326

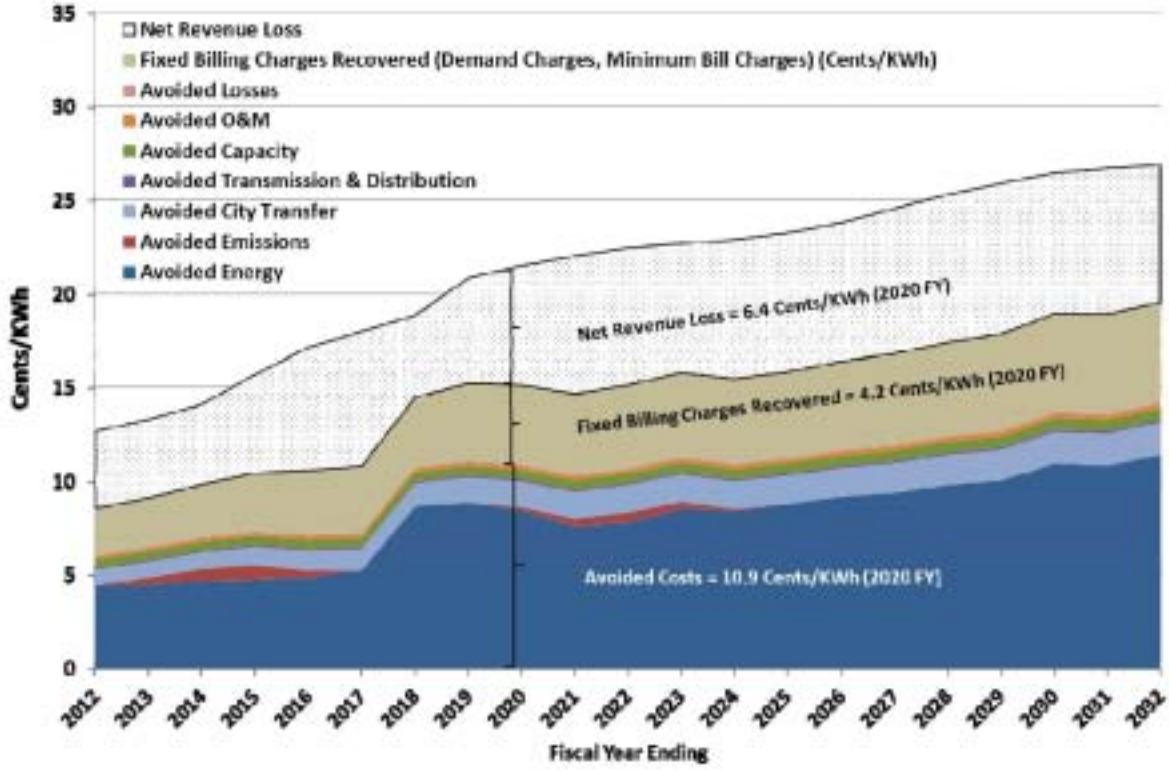

Figure N-7: Advanced EE Program annual Avoided Cost savings, Fixed Billing Charges Recovered and Net Revenue Loss (in Cents/kWh)

N.4.2 Analysis of Avoided Costs and Net Revenue Loss – Base and High Solar CNM

Two Solar DG Cases were evaluated which comprise several internal programs including Customer Net Metered (CNM) Solar (a.k.a. Solar Incentive Program), Feed In Tariff (FIT), and Utility Built Solar on City Properties. The analysis presented below is intended to represent the avoided costs and net revenue loss for the Solar CNM program only. However, in the final comparison of distributed generation and energy efficiency cases discussed in Section 4.3.3.1, many of the same avoided costs were considered with the exception that avoided renewable, avoided capacity, and avoided O&M only apply to Solar CNM due to the unique feature that demand side resources possess which is reducing peak load and reduced customer sales.

Similar to the EE programs described previously, revenue loss offset by the avoided costs described in Table N-3 and fixed billing charges recovered from minimum bill charges for residential customers must be considered in the evaluation of costs for the Solar CNM program. A smaller portion of this loss in revenue can be offset with fixed bill charges as compared to EE programs primarily because demand charges for commercial customers cannot easily be reduced using solar resources that require the utility to fully back up the customer when solar production plummets during cloudy days.

AR0070327

Table N-3: Solar CNM Program Avoided Costs

List of Avoided Cost	Reasons
Avoided Fuel	Solar DG or Customer-Net-Metered solar reduces customer load, over time, as it displaces energy generated by plants from gas utility. Solar generation profile is similar to the system load profile and will displace more expensive peaker generation resulting in lower regional system O&M costs
Avoided Renewable	Solar CNM programs reduce customer sales which reduces the amount of renewable energy expenditures to meet the mandated RPS %
Avoided Emissions	Lower generator costs will result in lower greenhouse gas emissions. For AB32 utilities will be charged for the CO2 emissions it emits and their allowances
Avoided City Transfer	Solar CNM reduces customer sales which reduces the amount of revenue collected for transfer to the City which is tied to % percentage of gross revenue
Avoided Transmission & Distribution	With lower peak load from the less MWs will be needed for the peak hours so some transmission and distribution upgrades can be deferred
Avoided Capacity	With lower peak demand due to Solar DG fewer peaker units will be built to meet system reserve requirements resulting in deferred capital spending
Avoided O&M	With lower peak demand and fewer peaker units being built there will be savings of Fixed O&M costs
Avoided Losses	Distribution losses are the losses incurred during the transfer of energy as it travels to penetrate homes that are far away and transformers down

Among Solar DG programs, the Solar CNM program impacts system costs in a similar manner as energy efficiency so the same methodology was employed. Figure N-8 shows avoided costs, recovered fixed billing charges, and net revenue loss for the Base Solar CNM case. Over the next 20 years for the Base Solar CNM, the gross revenue loss will be $1,484 Million, the total avoided cost is $878 Million, and the fixed billing charges are $257 Million. The small dotted area at the top of Figure N-8 shows the final net revenue loss as $349 Million due to the implementation of Base Solar CNM program. Like EE programs, the net revenue loss of Base Solar CNM increases as Solar CNM generation increases, however, the avoided cost is more evenly distributed throughout time since Solar CNM is a smaller program and reductions in RPS generation are less significant. The rate breakdown associated with Figure N-8 for the Base Solar CNM case is shown in Figure N-9 below.

AR0070328

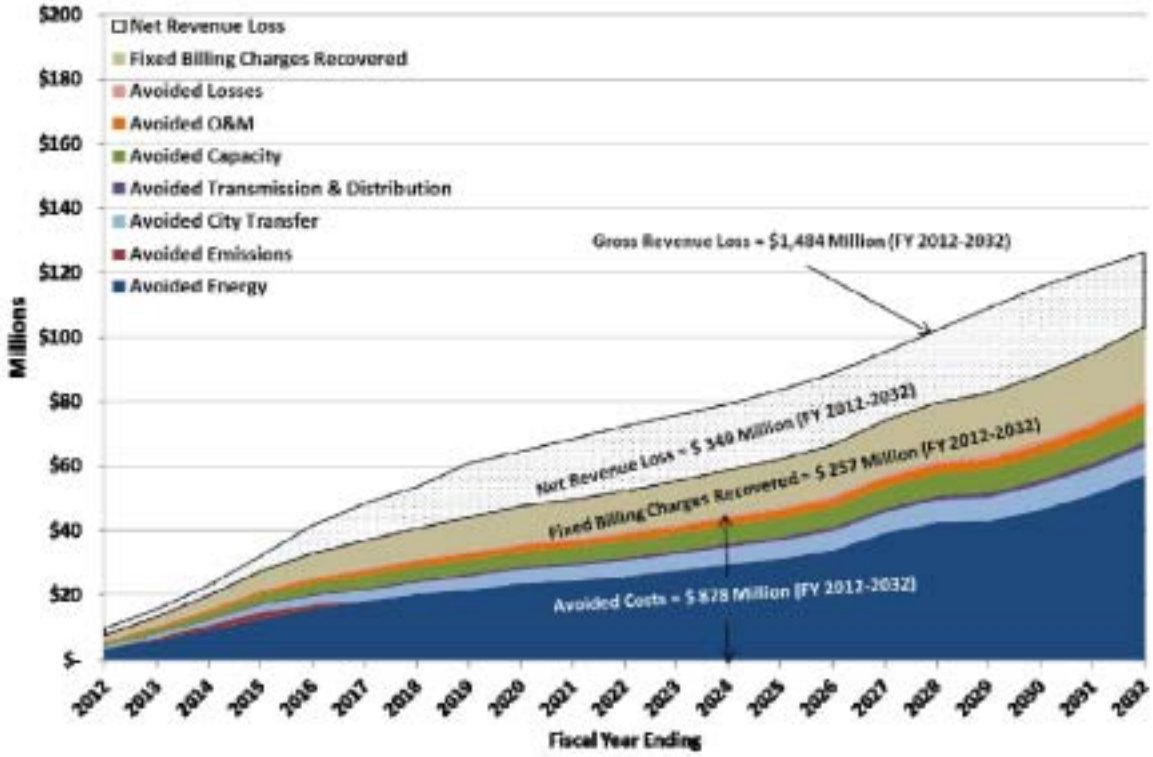

Figure N-8: Base Solar CNM Program annual Avoided Cost savings, Fixed Billing Charges Recovered and Net Revenue Loss

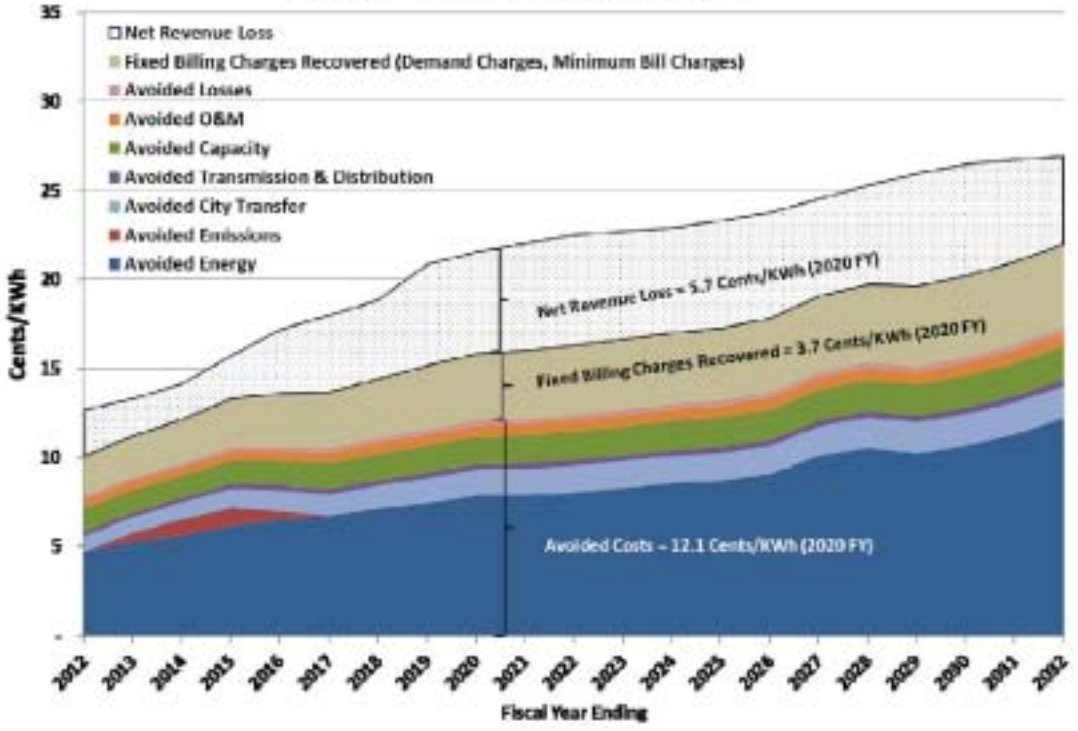

AR0070329

Figure N-9: Base Solar CNM Program annual Avoided Cost savings, Fixed Billing Charges Recovered and Net Revenue Loss (in Cents/kWh)

For High Solar CNM, similar figures are shown below in Figures N-10 and N-11. The total net revenue loss for the High Solar CNM is $566 Million, which is $217 Million more than the Base Solar CNM. The Solar CNM program results in net revenue losses so more Solar CNM generation with result in a greater loss of revenue.

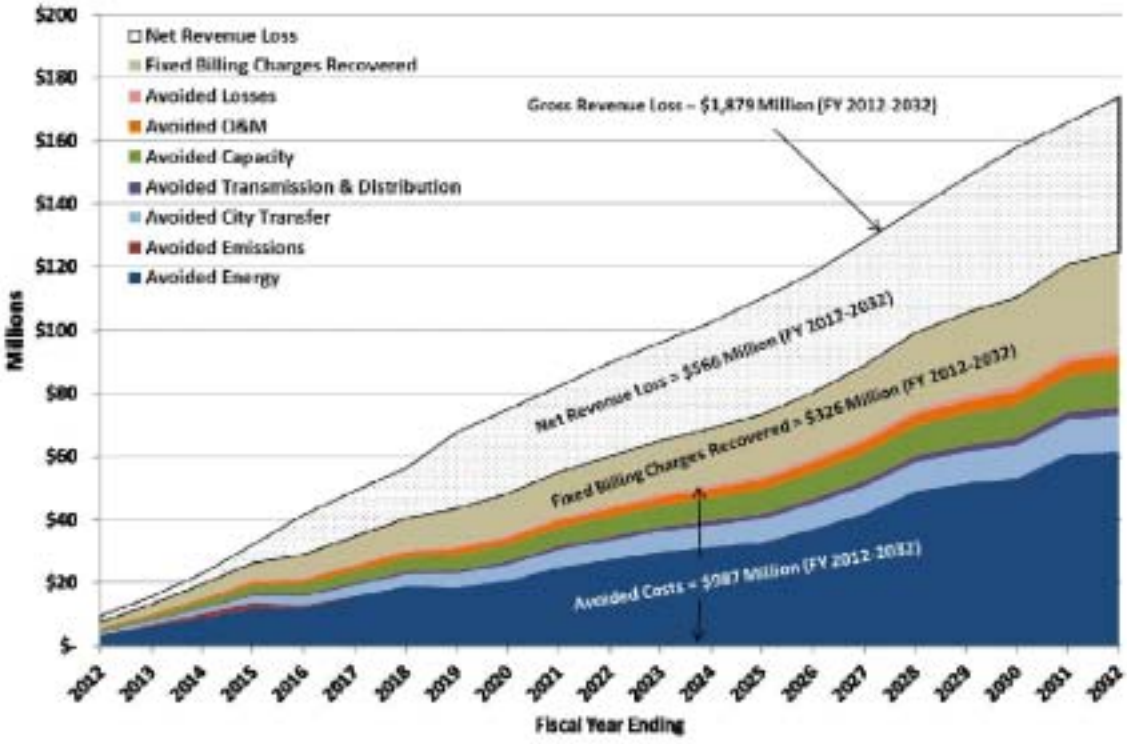

Figure N-10: High Solar CNM Program annual Avoided Cost savings, Fixed Billing Charges Recovered and Net Revenue Loss

Notes
1. Net Energy for Load model run (E) = Net Energy for Load (A) + Energy Efficiency (B) 0.665 + Solar Rooftop (C) 0.665
2. Energy Efficiency in 2012 IRP = Difference from Energy Efficiency in Forecasted IRP Years EE as Average Percentage
3. IRP Calculated Sales (H) = [E – (F 0.885) – (G 0.885) + 37] 0.955

Notes:
[1] This table is based on data from Power System Engineering Division January 1, 2012 Generation Rating and Capabilities of Power Sources sheet. This table also include data for the renewables and distributed generating resources owned and contracted by LADWP. The data are from the April 10, 2012 RPS Master Project List and project contracts.
[2] Name plate capability is the full load continuous rating of a generating unit under specified conditions as designated by the manufacturer.
[3] Unit net attained Maximum Capability when the weather and equipment are simultaneously at optimal conditions.
[4] Maximum Plant Capability reflects water flow limits at hydro plants, or sum of each unit at in-basin thermal plants, or entitlements from external thermal plants.
[5] Net Dependable Plant Capability reflects year-round outputs adjusted for low generation season. For hydro plants, winter is the low generation season. Thermal plants experience reduced performance during hot weather conditions.
[6] Dependable capacity of renewable technology plants are estimated by applying a Dependable Capacity Factor (DCF) to the plant name plate capacity. The conservative factor is used until LADWP gains more actual amount of operating experience with renewable technologies. DCFs currently used are as follow:
Digester Gas 1.00
Geothermal 0.95
Landfill Gas 1.00
Municipal Solid Waste Conversion 1.00
Small Hydroelectric 1.0
Solar Photovoltaic 0.27
Solar Thermal 0.27
Wind 0.10 (projects with firming contracts are rated at firming levels)

Appendix O Public Outreach

This Appendix O describes the public outreach that was carried out as part of the 2012 IRP process to involve the public in the development of this LADWP 2012 IRP. The appendix is arranged into four sections:

1. Outreach Overview: Describes the purpose of the public outreach effort, and outlines the outreach process and its relationship to this IRP.
2. Community Outreach Program: Provides an overview of all aspects of the outreach, including stakeholder meetings, website, and public workshops.
3. Comments and Discussion Themes: Presents a summary of the public comments inputted during the community outreach program; and discussion of themes synthesized from the public input.
4. Exhibits: Include the notes from the stakeholder meetings and public workshops, comment forms submitted at the public meetings and online, and other comments that were submitted through the website, e-mail, and US mail.

O.1 Outreach Overview

The 2012 IRP process included a public outreach effort to provide information, increase awareness, and gather public input on LADWP's long-term power resource plan. Public outreach consisted of a series of stakeholder meetings, a public workshop, and a dedicated website (www.ladwp.com/lapowerplan). Comments were gathered at the stakeholder meetings and public workshop, and were also provided through an online comment form, direct e-mail, and the US mail.

The public outreach began with two stakeholder meetings held in early 2012. Comments received at these meetings were considered in the development of the preliminary planning cases which were subsequently modeled and were analyzed.

The preliminary results were documented in the 2012 Draft IRP that was made available on the website on October 5, 2012. The draft IRP was presented at three stakeholder meetings and one public workshop held on October 11, 2012. Comments were accepted through November 5, 2012.

The many public comments and input received were synthesized into a set of discussion themes that reflect the major ideas provided by the public. The themes were reviewed and considered in developing the final recommended plan that is incorporated in this final 2012 IRP document.

AR0070340

O.2 Community Outreach Program

LADWP developed a multipronged outreach approach to allow community members and stakeholders different opportunities to provide input on the 2012 IRP. Community involvement opportunities were provided through a website, stakeholder meetings, and a general public workshop. Comments were accepted at the meetings and workshops, through the website, and via direct e-mail and the US mail. Input collected through each of these means is considered of equal importance when considered by LADWP staff.

- **Pre-Draft Stakeholder Meetings**. LADWP conducted meetings targeting specific stakeholders in early 2012, including business and industry representatives on February 8, and environmental groups on March 1. The purpose of these meetings was to discuss and collect public inputs for consideration in the development of the 2012 Draft IRP. Input collected at these meetings is included in the discussion themes found in the next section of this appendix. Discussion notes can also be found in Exhibit A.

- **Draft IRP Stakeholder Meetings and Public Workshop**. LADWP conducted three meetings targeting specific stakeholders in the fall of 2012, including environmental groups on September 21, commercial/business customer representatives on October 4, and Neighborhood Council members on October 23. A general public workshop was also held, on October 11. The purpose of the workshop and meetings was to present the 2012 Draft IRP and collect public input for consideration prior to preparing the 2012 Final IRP. Input collected at these meetings is included in the discussion themes found in the next section of this document. Discussion notes can also be found in Exhibit B.

- **Website and Online Forms**. A project website (www.ladwp.com/lapowerplan) was utilized for the 2012 IRP. The website included an announcement of the public workshop, and a section that allowed the public to submit comments and questions about the plan online. The website provided access to a complete version of the 2012 Draft IRP and associated technical appendices, as well as a stand-alone version of the Executive Summary. Comments submitted through the website can be found in Exhibit C. Comments submitted through other methods (e-mail or U.S. mail) can be found in Exhibit D.

O.3 Discussion Themes

The public workshops, stakeholder meetings, online survey, and comment forms yielded a significant amount of information from LADWP customers related to the 2012 IRP. This information has been synthesized into a set of discussion themes that reflect the major ideas provided by participants during the community outreach program:

AR0070341

The discussion themes listed below are not representative of the city at-large, and only encompass input from participants in the public workshops, attendees at the stakeholder meetings and public workshop, and members of the public who completed the online comment form, or submitted comments through e-mail or the US mail. All the ideas that were prioritized during the public workshops are included within the discussion themes, however, each theme is considered to be of equal importance, and the themes are not listed in any order of priority.

Theme: Eliminate Coal from LADWP's Energy Portfolio

Discussion

The majority of comments favored the early removal of coal from LADWP's resource portfolio. Some were concerned that Navajo would continue to operate after LADWP divestiture, and suggested the plant be shut down. Greenhouse gas emissions, along with other pollutants associated with coal energy were noted.

Related LADWP Actions:

- LADWP is proceeding with plans to replace Navajo Generating Station by 2015 – four years ahead of the SB 1368 requirement.
- The Intermountain Power Project is modeled in this IRP through 2027, but LADWP is working with the project participants to convert the IPP facility from coal to natural gas, and is hopeful that a firm conversion date can be established in time for next year's IRP analysis.

Theme: Incorporate More Renewables

Discussion

Many public comments suggested higher levels of renewables, beyond the mandated 33% by 2020. Some promoted the idea of 50% and even 100% renewables. LADWP's approach regarding this is to proceed cautiously until more is known about the operational and financial implications of higher levels. The IRP is prepared annually, and it is possible that future IRPs will include cases that incorporate higher levels of renewables.

Related LADWP Actions:

- LADWP will increase its levels of renewable resource generation in accordance with SB 2 (1X).
- LADWP will complete a study to consider issues associated with integrating increasing amounts of variable energy resources such as wind and solar, to reflect possible megawatt limits for the LADWP electric power system.

AR0070342

Theme: Incorporate More Local Solar

Discussion

Incorporate More Local Solar

Many comments promoted the adoption of higher levels of local solar, noting the abundance of sunshine in the southern California region. The benefit of providing local jobs was also noted as a supporting argument to increase penetration levels. One comment suggested investing to install solar on every house and building in Los Angeles. Regarding LADWP's current customer incentive program, multiple comments recommended hiring more inspectors to streamline the process which many see as too slow, especially when compared to other utilities.

Related IRP Recommendations

- Develop a renewable energy feed-in tariff program to encourage 150 MW of renewable generation resources to be developed by July 2013.
- Encourage the development of an additional 50 MW of customer net-metered solar projects before 2015.
- Develop up to 30 MW of solar capacity on existing properties under public/private partnership projects before 2015.

Theme: Incorporate More Distributed Generation

Discussion

Since the majority of LADWP's new Distributed Generation (DG) will come from local solar, this theme is somewhat associated with the More Local Solar theme. Most of the comments regarding more DG point to the governor's statewide goal for 12,000 MW, of which LADWP's proportionate share is assumed to be 1,200 MW. Within this 2012 IRP, the highest levels of new DG are 485 MW by 2020, and 852 MW by 2032. LADWP's concern with DG levels is maintaining reliability (see Section 3.4.4). Numerous utility studies have recommended a limit of 15% of the peak load circuit capacity – for LADWP this is approximately 980 MW. As LADWP adopts more DG per its current plan, and as more experience is gained along with more industry-wide research in this area, it is possible that future IRPs will consider higher DG levels.

Related LADWP Actions.

LADWP will continue its study of issues associated with integrating increasing amounts of variable energy resources to assess possible megawatt limits for the LADWP electric power system.

AR0070343

- LADWP will further develop its Smart Grid plans, which will facilitate the adoption of increasing levels of distributed generation.

  LADWP will investigate applications for energy storage, including those that may enable higher levels of local distributed generation.

Theme: Incorporate More Energy Efficiency and Demand Response

Discussion

LADWP's Energy Efficiency (EE) targets, based on year 2020, have increased significantly, from 8.6% approved in December 2011, to 10% approved in May 2012, with a further anticipated increase to 15%, pending completion of an updated potential study in 2013. Comments received supported more EE and Demand Response (DR) incorporated into LADWP future plans. As presented in this 2012 IRP, EE and DR are vital components within all long-term resource planning options. As the results of the upcoming potential study are developed and finalized, they will be adopted into the IRP planning strategy.

Related LADWP Actions:

In May 2012, the Board of Water and Power Commissioners approved a revised target of 15% of energy efficiency by 2023, subject to an updated potential study.

Implement 206 MW of demand response by 2020 and 500 MW of demand response by 2026.

Theme: Reduce Greenhouse Gas Emissions

Discussion

This was an overarching theme of the public comments received. Indirect societal costs, health effects, global warming and super storm Sandy were cited as reasons for accelerating the timelines to reduce GHGs. Rooftop gardens were promoted as a means to absorb CO_2. In considering the GHG impacts of fuel consumption for electricity generation, many comments pointed to the additional impacts resulting from fuel production (coal mining and gas drilling). Comments pointed out the need for considering energy efficiency, demand response, load shifting, and other technologies such as shunt reactive support to offset future additions of gas-fired capacity.

Related LADWP Actions:

- LADWP is pursuing coal replacement (see above Theme).

  LADWP is repowering its coastal generation with more efficient units.

AR0070344

- LADWP is adopting higher levels of renewables and energy efficiency, demand response, and other load shifting strategies

  Provide financial incentives to encourage customers to shift their load away from peak hours to reduce need for on-line generation and capacity additions

- Continue to investigate upgrades to the transmission and distribution system to provide voltage support and power import capabilities to minimize on-line generation

- Consider quick start generators when repowering to reduce the need for on-line generation

Theme: Look at New Case Scenarios

Discussion

Many comments suggested a scenario that contained no new gas-generation resources, an eventual portfolio of 100% renewables, and investments in EE, conservation, renewables and Demand Response. Some felt that multiple sets of potential renewable resource mixes should be considered.

Related LADWP actions

- LADWP prepares a new IRP annually and will consider new scenarios within subsequent case option development processes

Theme: Financial and Rate Concerns

Discussion

Some comments expressed concern that LADWP needs to ensure its financial stability and integrity. Many comments presented concerns with rising electricity rates and wanted to ensure that the cost and benefits were clearly presented; and recommended a comparison with other regional and out-of-state utilities. One comment suggested that LADWP keep coal for as long as possible, and that other forms of energy are not mature and are too costly. Conversely, other comments suggested that rate increases were acceptable if EE options are made available to help reduce customer bills. One comment suggested that LADWP rates are too low and the tiers are too generous – resulting in disincentives for EE and renewables.

Related LADWP actions

LADWP will continue to work with our stakeholders including the Office of the Ratepayer Advocate (ORA) to ensure that the financial requirements of meeting its mandated obligations and discretionary goals are clearly delineated and understood.

AR0070345

- Provide EE and CSM solar incentives to help customers reduce the impact that rates have on their bills

  Encourage demand response incentives and time-of-use rates to encourage shifting of load away from peak hours and reduce customer bills.

Theme: Maintain Power Reliability

Discussion

Some comments expressed concern about the state of the LADWP infrastructure, noting that the reliability program continues to be subject to budgets cuts - unlike mandated areas such as renewables. They point to the 2011 wind storm and 2006 heat storm as evidence that the infrastructure is getting older and more costly to maintain, and suggest that paying more now to address this problem will save money later.

Related LADWP actions

Continue to prioritize those infrastructure elements that are in urgent need of repair/replacement, and try to extend reliable operations with the (less than fully funded) budget provided. See Section 1.6.3 and Appendix E for more information.

LADWP will continue to work with our stakeholders and the Office of the Ratepayer Advocate (ORA) to ensure that the financial requirements of meeting its mandated obligations and discretionary goals are clearly delineated, and understood.

Theme: LADWP Should Take a Leadership Role

Discussion

Regarding renewable resources and other green energy matters, many suggested that LADWP, as a municipal utility, should lead by example, consider unconventional business models, and through its governance garner the political will to do something different.

Related LADWP actions

LADWP's first and foremost responsibility is to its ratepayers, and will continue to pursue its balanced strategy of reliability, competitive rates, and environmental stewardship. To the extent that new ideas or unconventional approaches to long term planning could potentially benefit the ratepayers, they should and will be considered.

LADWP will continue to provide transparency in its resource planning activities to encourage input from all stakeholders.

AR0070346

- Advocate for consistency and clarity in regulations that affect our ratepayers while meeting environmental objectives.

O.4 Exhibits

- **A – Stakeholder Meeting Notes and Survey/Comment Forms**
- **B – Public Workshop Notes and Survey/Comment Forms**
- **C – Website Online Survey/Comment Forms**
- **D – Other Survey/Comment Inputs**

Appendix P Abbreviations and Acronyms

P.1 Overview

This appendix presents acronyms for agencies and other entities, facilities and locations, electric industry terms, miscellany, and units of measure.

P.2 Agencies and Other Entities

APS	Arizona Public Service Company
BPA	Bonnerville Power Administration
BOS	Bureau of Sanitation
CAISO	California Independent System Operator
CARB	California Air Resources Board
CEC	California Energy Commission
City	City of Los Angeles
CPUC	California Public Utilities Commission
DOD	U.S. Department of Defense
DOE	U. S. Department of Energy
EPA	U. S. Environmental Protection Agency
EPRI	Electric Power Research Institute
FERC	Federal Energy Regulatory Commission
FSO	LADWP Financial Services Organization
IID	Imperial Irrigation District
IOU	California investor owned utilities
IPA	Intermountain Power Agency
IPCC	Intergovernmental Panel on Climate Change
IPPCC	Intermountain Power Project Coordinating Committee
ISDA	International Swaps and Derivatives Association
JPL	NASA Jet Propulsion Laboratory
LADWP	Los Angeles Department of Water and Power
NAESB	North American Energy Standards Board
NASA	National Aeronautic Space Administration
NERC	North American Electric Reliability Corporation
NPC	Nevada Power Company
NREL	National Renewable Energy Laboratory
PG&E	Pacific Gas and Electric Company
PwC	PriceWaterhouse Coopers
RTO	Regional Transmission Organization
RWQCB	Regional Water Quality Control Board
SCAQMD	South Coast Air Quality Management District
SCE	Southern California Edison
SCPPA	Southern California Public Power Agency
SoCal	Southern California Gas Company
SRP	Salt River Project
SWRCB	State Water Resources Control Board

AR0070348

TEC	Tucson Electric Company
UCLA	University of California at Los Angeles
UCSD	University of California at San Diego
USC	University of Southern California
WAPA	Western Area Power Administration
WECC	Western Electricity Coordinating Council

P.3 Facilities and Locations

BPA	Bonnerville Power Administration
BBRTP	Barren Ridge Renewable Transmission Project
BRSS	Barren Ridge Switching Station
COB	California-Oregon Border
COI	California-Oregon Intertie
EOR	East-of-the-River
HSS	Haskell Switching Station
IGS	Intermountain Generating Station
IPP	Intermountain Power Project
NOB	Nevada-Oregon Border
NTS	Northern Transmission System
PACI	Pacific AC Intertie
PDCI	Pacific High Voltage Direct Current Intertie
PTWPP	Pine Tree Wind Power Project
PVD2	Palo Verde-Devers Line No. 2
PVNGS	Palo Verde Nuclear Generating Station
SHARE	Scattergood-Hyperion Alternative Renewable Energy Project
SRP	Salt River Project
STS	Southern Transmission System
UGPP	Upper Gorge Power Plant
US	United States
WREZ	Western Renewable Energy Zone
WOR	West-of-the-River
WSPP	Western Systems Power Pool

P.4 Electric Industry Terms

A/C	air conditioning
AC	Alternating Current
AEDP	Advanced ESS Demonstration Project
AMI	Advanced Metering Infrastructure
AQMP	Air Quality Management Plan
BACT	Best Available Control Technology
BIGCC	Biomass Integrated Gasification Combined Cycle
BPJ	Best Professional Judgment
CAES	compressed air energy storage
CAMR	Clean Air Mercury Rule

AR0070349

CAP	Climate Action Plan
CCC	closed cycle cooling
CH_4	methane
CHP	combined heat and power
CLEO	Commercial Lighting Efficiency Offer
CLFR	compact linear fresnel reflector
CNG	compressed natural gas
CNM	Customer Net Metered
CO_2	carbon dioxide
CSI	California Solar Initiative
CSP	concentrating solar thermal power plants
CY	calendar year
DC	Direct Current
DC&M	Distribution Construction and Maintenance
DG	distributed generation
DNI	direct normal insolation
DR	Demand Response
DSM	Demand Side Management
E&L	Environment and Lands
ECAF	Energy Cost Adjustment Factor
EDS	Energy Dissipation Station
EE	Energy Efficiency
EHV	Extra-High Voltage
ESPs	energy service providers
ESS	energy storage system
ETD	Electric Trouble Dispatch
FAR	Firm Access Rights
FES	flywheel energy storage
FIT	Feed-in Tariff
GHG	greenhouse gas
GHGs	greenhouse gases
GREEN	Green Power for Green LA Program
GT&D	Generation, Transmission and Distribution
GWP	global warming potential
HHV	higher heating value
HRSG	heat recovery steam generator
HVAC	heating, ventilating, and air conditioning
ICEs	internal combustion engines
IGCC	integrated gasification combined cycle
IM	impingement mortality
LCOE	levelized cost of energy
LF	Load Factor
LFG	landfill gas

EDR City Directory Abstract

Environmental Data Resources, Inc's (EDR) City Directory Abstract is a component report designed to assist environmental professionals in evaluating potential liability on a target property resulting from past activities. EDR's City Directory Abstract includes a review and abstract of available city directory data for certain locations. The following is the name of the contiguous developed area for your address.

Thank you for your business.
Please contact EDR at 1-800-352-0050
with any questions or comments.

Disclaimer - Copyright and Trademark Notice

This Report contains certain information obtained from a variety of public and other sources reasonably available to Environmental Data Resources, Inc. It cannot be concluded from this Report that coverage information for the target and surrounding properties does not exist from other sources. NO WARRANTY EXPRESS OR IMPLIED, IS MADE WITH RESPECT TO THE CONTENTS OF THIS REPORT, INCLUDING, WITHOUT LIMITATION, ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR USE OR PURPOSE. ALL RISKS ASSUMED BY THE USER. IN NO EVENT SHALL ENVIRONMENTAL DATA RESOURCES, INC. BE LIABLE TO ANYONE, WHETHER ARISING OUT OF ERRORS OR OMISSIONS, NEGLIGENCE, ACCIDENT OR ANY OTHER CAUSE, FOR ANY LOSS OR DAMAGE, INCLUDING, WITHOUT LIMITATION, SPECIAL, INCIDENTAL, CONSEQUENTIAL OR SIMILAR DAMAGES. Any liability on the part of Environmental Data Resources, Inc. is strictly limited to a refund of the amount paid for this Report. Purchaser accepts this Report "AS IS". Any analyses, estimates, ratings, environmental risk levels or risk codes provided in this Report are provided for illustrative purposes only, and are not intended to provide, nor should they be interpreted as providing any facts regarding, or prediction or forecast of, any environmental risk for any property. Only a Phase I Environmental Site Assessment performed by an environmental professional can provide information regarding the environmental risk for any property. Register, its employees or agents make no representation or warranty regarding the environmental condition of the Target Property or any other property. This Report is not to be construed as legal advice.

Copyright 2018 by Environmental Data Resources, Inc. All rights reserved. Reproduction in any media or format, in whole or in part, of any report or map of Environmental Data Resources, Inc. or its affiliates, is prohibited without prior written permission.

EDR and its logos (including Sanborn and Sanborn Map) are trademarks of Environmental Data Resources, Inc. or its affiliates. All other trademarks used herein are the property of their respective owners.

SUMMARY

- *City Directories*

Sources consulted, including city cross reference and telephone directories, were reviewed at approximately five year intervals starting approximately 1920 through 2015. Where years were not necessarily available, a summary of findings for adjacent years is provided in the text of this report.

This report compiles information by geocoding the subject properties (that is, placing the addresses on a grid) for each subject property and evaluating historical records containing addresses within 1/8 mile of the subject property. There is no warranty or guarantee that all potential environmental concerns for the subject properties will be identified in this report. No warranty or guarantee is expressly made regarding the accuracy of any information contained in the enclosed databases or concerning those properties that may not be addressed in this report.

1 Introduction

Construction and demolition (C&D) materials are generated when new structures are built and when existing structures are renovated or demolished (including deconstruction activities). Structures include all residential and nonresidential buildings, as well as public works projects, such as streets and highways, bridges, utility plants, piers, and dams. While definitions of what constitutes C&D materials vary from state to state, C&D materials measured by various parties can include land clearing debris, the vegetation that is removed when a new site is developed. Typical components of C&D materials are shown in Table 1-1.

Table 1-1. Typical components of C&D Materials

Material Components	Content Examples
Wood	Framing and framing lumber, stumps, trees, engineered wood
Drywall	Sheetrock (wallboard)
Metals	Pipes, rebar, flashing, wiring, framing
Plastics	Vinyl siding, doors, windows, flooring, pipes, packaging
Roofing	Asphalt, wood, slate, and tile shingles, roofing felt
Masonry	Cinder blocks, brick, masonry cement
Glass	Windows, mirrors, lights
Miscellaneous	Carpeting, fixtures, insulation, ceramic tile
Cardboard	From newly installed items such as appliances and tile
Concrete	Foundations, driveways, sidewalks, floors, road surfaces (all concrete containing portland cement)
Asphalt pavement	Sidewalks and road structures made with asphalt binder

The U.S. Environmental Protection Agency (EPA) has targeted C&D materials for reduction, reuse, and recovery as part of its Resource Conservation Challenge (RCC).[1] The RCC is a national effort to conserve natural resources and energy by managing materials more efficiently. The goals of the RCC are to prevent pollution and promote reuse and recycling, reduce priority and toxic chemicals in products and waste, and conserve energy and materials. The RCC has identified four national focus areas.

- Municipal solid waste recycling
- Industrial materials recycling, specifically:
  - C&D materials reduction, reuse, and recycling
  - Coal combustion products
  - Foundry sands
- Green Initiatives: Green Building and Electronics
- Priority and toxic chemical reductions[1]

With respect to C&D materials, EPA has undertaken the following activities in an effort to increase the amount of C&D materials reduced, reused, or recycled:

- Conduct outreach and education with industry and public-sector partners, and
- Recognize those with successful reuse or recycling programs, and
- Participate in green efforts, such as green building programs and green highway programs.

[1] More information about the RCC can be found at www.epa.gov/rcc.

AR0070381

Furthermore, the recently-issued Executive Order 13423 requires all federal construction, renovation, and demolition projects to achieve a 50% recycling rate where markets or on-site recycling opportunities exist. EPA is committed to helping achieve that recycling rate. One of the important tasks for EPA under the RCC is to track the progress of C&D materials recovery by estimating the amount that is generated and recovered.

The purpose of this study is to determine the amount of building-related C&D materials generated and recovered in the U.S. during 2003, updating the findings of the 1998 EPA report *Characterization of Building-Related Construction and Demolition Debris in the United States* (EPA 530-R-98-010). Limited information is available on the amount of C&D materials generated and managed in the U.S. The methodology used in this report to estimate the amount of building-related C&D materials generated and recovered in the U.S. during 2003 is based on national statistical data and typical waste generation during building construction, renovation, demolition, or maintenance activities. The recovery estimate relies on 2003 data reported by state environmental agencies.

Finally, we would note that accurate measurements of C&D generation and recovery are critical in order to measure progress toward achieving increased C&D materials reuse and recycling. However, efforts to improve C&D measurement are currently hampered by a general lack of data. Thus, it should be recognized that the C&D materials estimates presented to date, including those in this report, have some level of uncertainty, and the results should be viewed in that light. Nevertheless, we believe that the estimates contained in this report reflect and are based on the best data that are currently available.

1.1 THE CONSTRUCTION INDUSTRY

1.1.1 Size of the Construction Industry

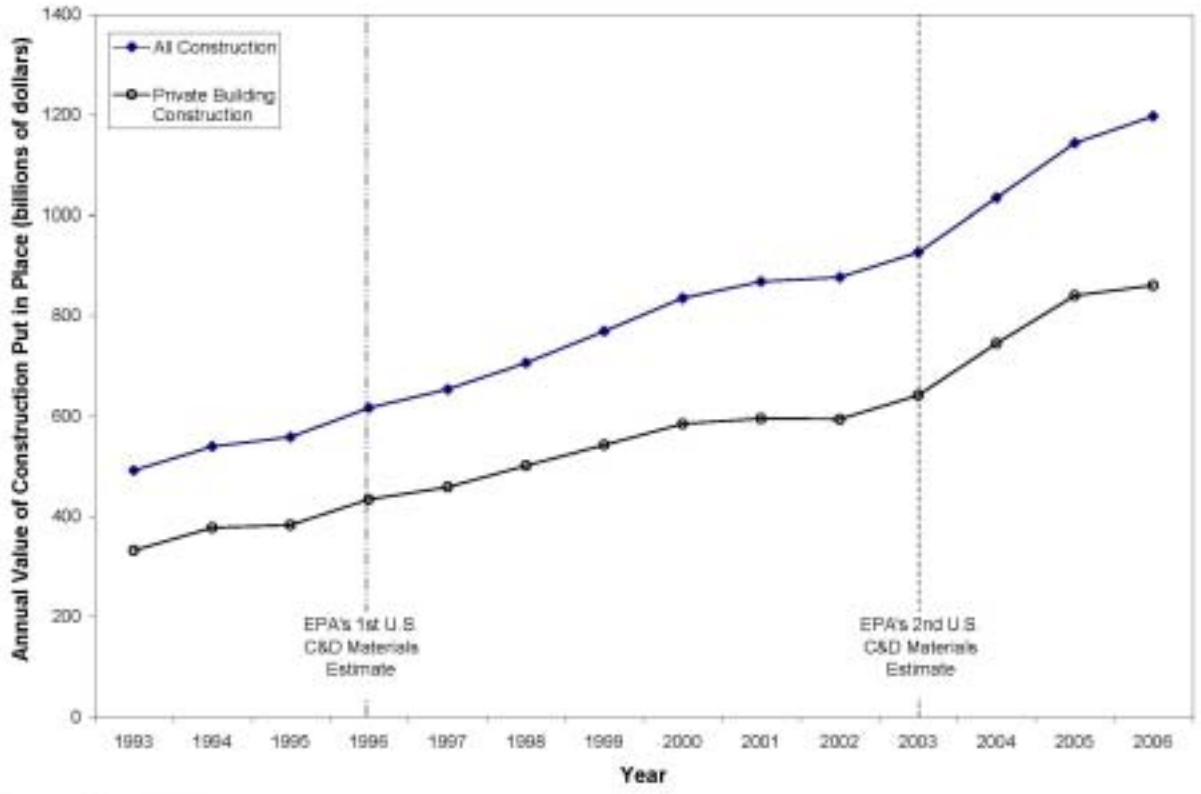
The amount of C&D materials that are generated and subsequently managed in the U.S. is dependent on the amount of activity that takes place in the entire construction, demolition, renovation, and maintenance industry. Construction is a vital sector of the economy, directly or indirectly, providing jobs and income to a large population in the U.S. Americans look to the construction industry to meet the demands of a growing population and economy. As such, federal agencies, such as the U.S. Census Bureau (USCB), regularly track the construction industry as an indicator of the economy. The construction industry is very large, yet dominated by very small businesses. For example, according to USCB data, there were 710,000 construction establishments in 2002 with 7.2 million employees, with an average employment of ten employees per establishment. In 2002, 90 percent of construction establishments had fewer than 20 employees, while only one percent of construction establishments had 100 employees or more (2005a).

The USCB uses construction spending, new home sales, and housing starts as one set of indicators of the health of the U.S. economy. The construction industry boomed during the late 1990s and into the early 2000s. Figure 1-1 shows the amount of growth in spending during that time. EPA published an estimate (in 1998) of the amount of building-related C&D materials generated in the U.S. during 1996. The estimate presented in the current report is for the amount of building-related C&D materials generated in the U.S. during 2003. Between these years, the amount of money spent on construction (for *all* structures, including buildings, roads, bridges,

AR0070382

etc.) in the U.S. increased by approximately 50%, from an estimated $620 billion in 1996 to an estimated $930 billion in 2003. These costs do not have a direct relationship with materials consumption as they may include inflation, profit, and other costs. They can be used as an indicator of construction activity, however. The USCB does not break down these amounts by structure type (building vs. non-building), but does break the amounts down by use category. Those categories (as described by the USCB) that were assumed to primarily consist of building construction were aggregated for this report[2]. The USCB, however, did not break down public construction by use category until 2002, thus only private building construction spending is shown in Figure 1-1. Between 1996 and 2003, private building construction spending increased 32%. During that same time, the population of the U.S. only increased 8%.

Figure 1-1. U.S. construction spending.



Source: USCB, 2008

1.1.2 Efforts by the Construction Industry to Increase C&D Materials Recovery

The construction industry is taking large strides to lessen its impact on the environment. In furtherance of these efforts, the Associated General Contractors of America (AGC;

[2] Based on their descriptions, the USCB categories that were assumed to consist mostly of building construction and used to estimate building construction spending for Figure 1-1 were Residential, Lodging, Office, Commercial, Health Care, Educational, Religious, Public Safety, and Manufacturing. Categories that were assumed to contain mostly non-building construction were Amusement and Recreation, Transportation, Communication, Power, Sewage and Waste Disposal, and Water Supply.

AR0070383

http://www.agc.org) created an Environmental Agenda in 2006, which lists seven goals. Four of these goals relate most to materials management, which are:

1. Encourage environmental stewardship through education, awareness and outreach.
2. Recognize environmentally responsible construction practices.
3. Identify opportunities to reduce the impact that construction practices have on the environment, including
    - Facilitating members' efforts to recycle or reduce construction and demolition debris.
    - Identifying and maximizing the contractor's role in "green" construction.
4. Identify ways to measure and report environmental trends and performance indicators of such trends.

Other efforts undertaken by the construction industry include the following:

- The Building Materials Reuse Association (BMRA; http://www.buildingreuse.org) facilitates building deconstruction and the reuse and recycling of recovered building materials. They produce information on deconstruction techniques and information on how to make a successful deconstruction or reuse business. They convene annually to transfer this knowledge among contractors, government representatives, and researchers.

- The Construction Materials Recycling Association (CMRA; http://www.cdrecycling.org) aids their members in the appropriate methods for processing material to ensure environmental protectiveness, as well as producing a high-value product. They have developed websites to reach out to any recyclers, users of recycled materials, and regulators in order to provide a better understanding of C&D materials recycling. They have developed websites that contain research and practical information for the recycling of concrete (http://concreterecycling.org), drywall (http://drywallrecycling.org), and asphalt shingles (http://shinglerecycling.org).

- The National Association of Home Builders (NAHB; http://www.nahb.org) issued Green Home Building Guidelines that contractors can follow to make their homes more "green," including reducing, reusing, and recycling construction waste. They also put on an annual Green Building Conference that brings together contractors and researchers to discuss new "green" construction techniques. The NAHB Research Center also pursued research in the area of C&D materials recycling, such as using the material on-site.

- The National Demolition Association (NDA; http://www.demolitionassociation.com) actively promotes recycling and reuse of the materials generated during a demolition. They released a report titled, "Demolition Industry Promotes C&D Recycling," in which they describe ways that the industry and government can work together to overcome recycling barriers. The "members of the National Demolition Association are committed to increasing the recycling and reuse of the material generated" on their jobsites. They state that "recycling is good for the environment, good for the nation's economy, a positive use of valuable commodity, and good for the country."

AR0070384

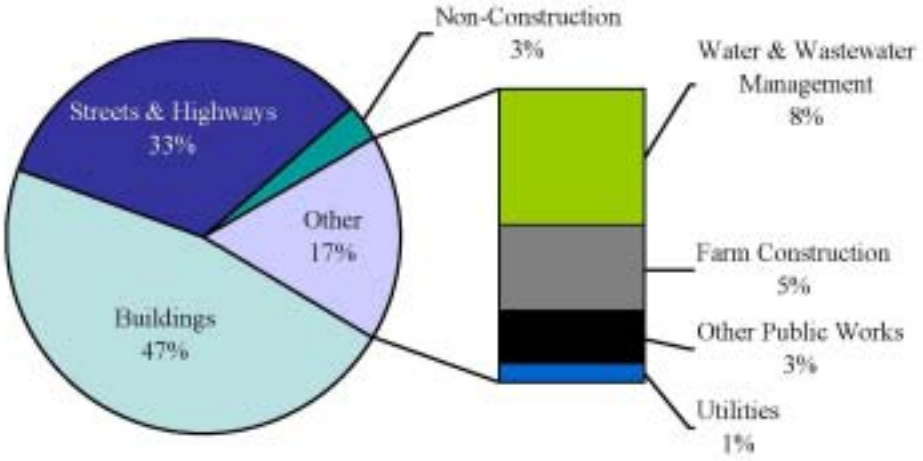
1.2 ESTIMATING BUILDING-RELATED C&D MATERIALS GENERATION AMOUNTS

There are a variety of sources of C&D materials and a variety of reasons to estimate the amount that is generated from each. C&D materials can be generated as part of normal daily life, or as part of the debris stream resulting from natural disasters. This report estimates the amount of materials generated from *building* projects that occur as a result of normal daily life, not debris resulting from disasters. C&D materials resulting from rebuilding efforts after a disaster are included in this estimate, however. In 2008, EPA published *Planning for Natural Disaster Debris,*[3] which discusses tools for forecasting disaster debris generation amounts.

One of the most common reasons to estimate the amount of C&D materials generated or recovered is to target materials for materials recovery programs. Diverting C&D materials from landfills is important because it saves natural resources, decreases greenhouse gas emissions, reduces the need for landfill space, and saves money.

Concrete is one of the most common materials used in construction. Portland cement is a key ingredient in concrete (or, more specifically, portland cement concrete). As shown in Figure 1-2, The Portland Cement Association estimated that buildings consumed only 47% of cement produced in 2003. Thus, estimating the amount of building-related C&D materials is only looking at a portion of the C&D materials stream.

Figure 1-2. Estimated consumption of portland cement in 2003.



Source: Portland Cement Association, 2006

[3] *Planning for Natural Disaster Debris* (EPA530-K-08-001) can be downloaded at http://www.epa.gov/epawaste/conserve/imr/cdm/debris.htm.

AR0070385

There are three primary aspects of a building's life cycle that impact the C&D materials stream: construction, renovation, and demolition/deconstruction. Initial construction requires the most materials to be purchased, but produces the smallest amount of waste. Per building, a demolition will generate the largest amount of waste of the three activities as all materials are typically removed and enter the waste stream. Renovations (including remodeling, replacements, and additions) are a combination of both construction and demolition, removing old materials and adding new materials.

The methodology used in this report for estimating the amount of building-related C&D materials generated used national statistical data and typical waste generation data from construction, renovation, and demolition sites. National statistical data on the amount of building construction, renovation, and demolition activity were obtained from the USCB and other national sources. Some statistical data on construction are no longer collected, where this is the case, the data used in this report were projected from older data. Typical waste generation data from construction, renovation, and demolition sites was determined as an average of waste sampling studies performed at specific job sites as reported in the literature.[5] Due to the variability of construction styles, materials, and sizes, it is unknown if the waste sampling data available are representative of the entire construction industry across the U.S. Additional waste characterization studies performed at individual job sites from around the U.S. would increase confidence in these estimates.

1.3 ESTIMATING THE RECOVERED AMOUNT OF BUILDING-RELATED C&D MATERIALS

There are four stages involved in the C&D materials management process: generating the material at a job site, transporting the material to the landfill/processor-user of recycled materials (if not used on site), processing/incinerating/disposing of the material at a recycling facility/incinerator/landfill, and, in the case of recycling, using the recycled materials. Definitions of these terms as used in this document are shown in Figure 1-3. Gauging the amount of materials that flow through any stage can be performed by surveying those that are involved in the process. Surveys can be complicated and burdensome to conduct, depending on the sample size and the response rate. As a result, few entities collect this kind of information.

Recovery of building-related C&D materials for recycling, beneficial use, reuse, or waste-to-energy in 2003 was estimated using data reported by state environmental agencies. Few states report the amount of C&D materials recovered, disposed, and/or generated, however. EPA continues to investigate additional sources of C&D materials data. Additional data on construction materials recovery would increase the confidence in this estimate.

[5] Land clearing materials were excluded from the C&D estimates in this report since the site materials composition studies used to estimate the amount of materials generated at a typical job site did not include land clearing materials.

AR0070386

Figure 1-3. C&D Materials Management Definitions

For purposes of this report, the following is a working set of definitions:

C&D materials are debris and other secondary construction or building materials during construction, renovation, and demolition activities.

Disposal means placing materials in a landfill.

Energy recovery refers to combustion of waste materials to provide energy.

Generation refers to activities during construction, renovation, or demolition that produces debris and other unused materials.

Recycling includes processing a used material, generally through size reduction, to make it usable as an ingredient in a new product. Sorting may be a necessary step for recycling if materials are delivered to a recycler in a mixed load.

Reuse is utilizing a used product or material in a manner that generally retains its original form and identity with minor refurbishments. Examples include fixtures, lumber, and doors that are refurbished for use.

Recovery refers to the reuse and recycling of materials, as well as utilizing materials for energy recovery.

Source reduction refers to activities that prevent C&D materials from being generated.

AR0070387

2 Amount of Building-Related C&D Materials Generated

Building-related C&D materials can be divided into six categories: residential construction, residential demolition, residential renovation, nonresidential construction, nonresidential demolition, and nonresidential renovation. These categories were selected based on the relationship between available statistical data and waste sampling data. The following sections describe the data used and the methods for estimating the amount of building-related C&D materials generated, on a weight basis. Tables A-1 through A-5 in Appendix A are worksheets that provide details of the calculations used to arrive at generation for each component of the C&D materials stream.

2.1 METHODOLOGY AND RESULTS

The methodology used for this study combines national statistical data on industry activity with point source waste assessment data (i.e., waste sampling at construction, renovation, and demolition sites) to estimate the amount of C&D materials produced nationally. In general, the amount of waste (tons[1]) generated is the product of the level of activity (usually area, square feet, ft^2) and the typical amount of waste generated for that activity (usually weight per unit area, pounds per square feet, lb/ft^2). Total waste amounts are generally described in terms of weight rather than volume. This is because the volume of waste materials can change through compaction or other processing. The weight, however, generally remains constant.

2.1.1 Residential Construction

The amount of waste (tons) generated from the construction of new single and multi-family homes can be determined by multiplying the total area (ft^2) of new residential construction by the typical amount of waste generated per unit area (lb/ft^2), as shown in the equation below. The total area of new residential construction can be determined by dividing the total amount spent (U.S. dollars, $) on new residential construction by the average cost of new construction (as defined by the USCB) per unit area ($/ft^2).

Total U.S. Residential Construction Waste (tons/year) =	Total Residential Construction Put-in-Place Value ($/year) / Average Cost Per Area of Residential Construction ($/ft^2)	× Average Waste Generated Per Area for Residential Construction (lb/ft^2) / 2000 lbs/ton

Waste sampling data for new residential construction were identified for 95 projects from eight sources. The results from these studies are presented in Table 2-1. Generation rates ranged from 2.41 to 11.3 lb/ft^2. The variation in types of houses, the specific practices of the builders, and the lack of uniform standards for the collection and storage of the sampled materials may explain the differences in the estimates. In addition, these estimates, which are in some places based on 1990s data, may change with time reflecting changes in material usage and practices. Results from each source were used to develop a weighted average estimate of the overall residential construction waste generation rate of 4.39 lb/ft^2. While this category contains the largest number of job site C&D materials surveys, it is important to note that it may still not be representative of

[1] The use of "tons" throughout this document refers to U.S. short tons.

AR0070388

all residential construction styles across the nation. House sizes, materials, and foundation types vary regionally and can affect the amount of waste produced during construction.

[2] Total number of privately-owned housing units started in 2003 (1,847,900) from U.S. Census Bureau, Housing Starts, Table 5, "Privately-Owned Housing Units Started by Purpose of Construction and Type of Structure: 2003 and Earlier Years," http://www.census.gov/const/www/newresconstindex.html.

[3] Weighted average of single-family detached and multi-family housing units started in 2003 (2,349 sq. ft.) from U.S. Census Bureau, Housing Starts, Table 5, "Privately-Owned Housing Units Started by Purpose of Construction and Type of Structure: 2003 and Earlier Years," http://www.census.gov/const/www/newresconstindex.html.

The USCB collected national statistical data on the amount of residential construction activity in the U.S. during 2003, including the number of construction permits and the total square feet of new construction. According to the USCB's "Current Construction Reports (C-30)," in 2003 the

AR0070389

value of new residential construction put-in-place" totaled $353 billion. Average construction cost per area ($76.80/ft^2) was found by dividing the total value, in areas where permits are required, ($282 billion) by the total area of floor space (3,627 million ft^2), both obtained from the U.S. 2004 Statistical Abstract, which reports 2003 data. The quotient of this factor and the total value of construction produce a total of 4,592 million ft^2 of new residential construction in 2003. The product of the total area and the average waste generated per unit area, 4.39 lb/ft^2, results in the total estimated C&D generation amount for residential construction of 10 million tons in 2003.

2.1.2 Nonresidential Construction

The methodology for estimating the total amount of C&D generation for nonresidential construction materials is similar to that for residential construction materials, although the design of nonresidential buildings is more varied than residential buildings. Nonresidential buildings include lodging, office, commercial, health care, educational, religious, public safety, and manufacturing facilities. There are fewer material assessments for nonresidential buildings, making the average generation rates for C&D materials more uncertain. Table 2-2 shows the results of 12 nonresidential job site waste surveys. The buildings in these surveys include a retail store, restaurant, institutional building, seven office buildings, and two public facilities. Ranging from 1.61 to 8.59 lb/ft^2, the weighted average material generation rate from these studies is 4.34 lb/ft^2.

The 2003 value of new nonresidential building construction put-in-place, as reported in the *Current Construction Reports*, is almost $257 billion. Average construction costs in 2003 were $111/ft^2, resulting in an estimated 2,318 million ft^2 of new construction. The product of the total area (in ft^2) of new construction and the average waste generation rate, 4.34 lb/ft^2, results in a C&D materials generation estimate of **5.01 million tons** for nonresidential construction in 2003. Appendix Table A-2 contains a detailed methodology.

2.1.3 Residential Demolition

When buildings are demolished, large quantities of materials are generated. The entire weight of a building, including the concrete foundations, driveways, patios, etc., may be generated as C&D materials when a building is demolished. On a per building basis, demolition waste quantities are often 20 to 30 times as much as C&D materials generated during construction.

Table 2-2. Summary of Nonresidential Construction Job Site Surveys of C&D Materials.

[a] According to the USCB (2008), "The 'value of construction put-in-place' is a measure of the value of construction installed or erected at the site during a given period. For an individual project, this includes cost of materials installed or erected, cost of labor (both by contractors and force account) and a proportionate share of the cost of construction equipment rental, contractor's profit, cost of architectural and engineering work, miscellaneous overhead and office costs chargeable to the project on the owner's books, interest and taxes paid during construction (except for state and locally owned projects). The total value-in-place for a given period is the sum of the value of work done on all projects underway during this period, regardless of when work on each individual project was started or when payment was made to the contractors. For some categories, published estimates represent payments made during a period rather than the value of work actually done during that period. For other categories, estimates are derived by distributing the total construction cost of the project by means of historic construction progress patterns."

[b] As noted in Text, the categories used for nonresidential building construction from the Current Construction Reports were lodging, office, commercial, health care, educational, religious, public safety, and manufacturing.

[3] Appendix Table A-2

The quantity of demolition material can be estimated by multiplying the number of residential demolitions per year by the average demolished area. This total is then multiplied by the typical waste generated per square foot, determined from an average of job site characterizations of C&D materials. The number of demolitions per year is estimated from "Components of Inventory Change (CINCH)" data (HUD 2007). This information is reported in two year intervals; therefore, the number of single family and multifamily units lost to demolition[1] for the period 2003-2005[2] was divided in half to determine the residential units demolished per year. This number was then added to the number of single family and multifamily units that are lost due to damage or are condemned (again divided in half) and then multiplied by 50%. The 50% estimate represents the number of units that have been condemned or lost to damage that will actually be demolished that year. While no data exist to support this estimate, experts at the U.S. Department of Housing and Urban Development found this to be an acceptable approximation. The units destroyed through intentional demolitions or disasters, such as fires or weather-related incidents between 2003 and 2005 averaged 270,000 per year.

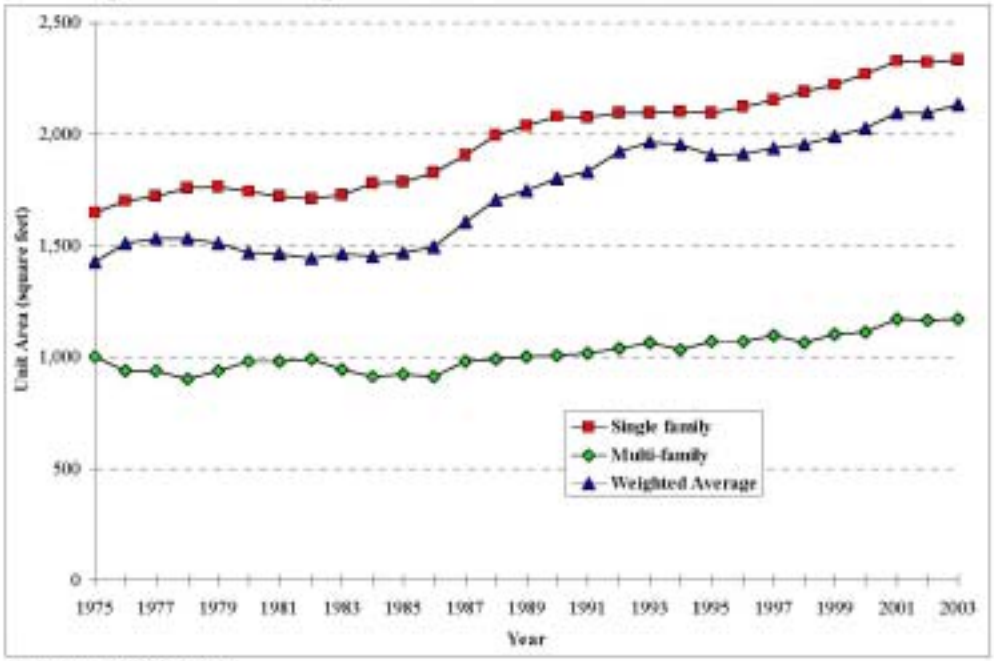
[1] The units that are lost to damage or are condemned do not reenter the housing stock unless they are repaired. These units are not accounted for in "units lost to demolition."

[2] While the years span is 2003 to 2005, the data represents the change in the amount of housing stock available in 2003 to the amount of housing stock at the same time in 2005 (a two-year span).

AR0070391

Houses of all ages and sizes are demolished, but on average, older houses are demolished more frequently and are smaller than new houses. New single-family housing units and multi-family housing units (including apartments and condominiums) built in 2003 had average areas of 2,330 ft^2 and 1,170 ft^2, respectively. Figure 2-1 shows how average new house sizes have increased over the last 28 years. Multi-family houses have remained nearly the same, while new single-family houses grew from 1,600 ft^2 to 2,330 ft^2 in 1975. Although homes demolished in 2003 may have been built before 1975, it was assumed that this area was representative of most demolished homes. Thus, the average single-family and multi-family houses are assumed to be that of 1975 (1,600 ft^2 and 1,000 ft^2), respectively, when demolished.

Figure 2-1. Average Unit Size of New Residential Construction



Source: USCB 2005b

Table 2-3 shows four single-family house demolition assessments and one multi-family deconstruction assessment.[10] The weight of houses when demolished depends critically on whether the houses have concrete foundations and basement walls. The use of masonry in exterior cladding also affects the house weight significantly. None of the single-family houses in Table 2-3 had full basements. Therefore, adjustments were made to the sampling data to develop an estimate of residential demolition materials, which reflects the likely impact of some of the demolished houses having basements. These adjustments are more fully shown in Table A-3 in Appendix A.

Table 2-3. Summary of Residential Demolition Job Site Waste Surveys

[10] Deconstruction refers to the systematic dismantling of a building in an attempt to recover as much material as possible. Demolition refers to the removal of the building through mechanical means in an attempt to remove the building as quickly and inexpensively as possible. While both methods may recover materials, the main goal of deconstruction is to recover as much material as possible. Thus, while the different methods may lead to different recovery rates, they will both have the same generation amounts and can be used for comparison in the generation estimate presented here.

(3) Concrete rubble not included

(4) Small house with no basement

(5) Average of seven single-family wood-framed houses

The USCB provides data on the types of foundations in existing houses in the *Statistical Abstract of the United States: 2004*. Forty-three percent of single-family houses have basements, 29% are on concrete slabs, and all other single-family homes have crawl spaces. The amount of concrete can range from zero for houses without basements, garages, or driveways to more than 150 lb/ft^2 for those homes with all of these structures (calculation described in Table A-3 in Appendix A). Based on these estimates, the total amount of residential demolition materials generated in 2003 was estimated to be **19 million tons**.

2.1.4 Nonresidential Demolition

The initial estimate of nonresidential demolition materials generation, for 1996, used the number of demolitions per year, the average size (ft^2) of buildings being demolished, and the typical materials generated per unit area. Prior to 1998, the number of demolition permits could serve as a source for estimating the number of demolitions per year. The Census Bureau, the source for demolition permits, discontinued demolition permit data collection after 1998 and an alternative methodology was developed for this study. For the 2003 estimate, the 1996 estimate of total area was extrapolated to 2002 using the value of demolition work published in the Economic Census by the USCB. Since the Economic Census is only published every five years and similar economic data were not available to predict an estimate for 2003, the nonresidential demolition materials estimate was held constant for 2003. This total area (ft^2) was then multiplied by the typical materials generation per unit area (lb/ft^2) taken from an average of several job site waste surveys.

The typical materials generation per unit area (lb/ft^2) was developed from material assessments. Table 2-4 shows the results of waste assessments at 27 nonresidential buildings. The assessments conducted after 1996 were added to the assessments used in the 1996 estimate. These additional assessments increased the generation factor from 155 lb/ft^2 to 158 lb/ft^2. It should be noted, however, that the lack of material assessments increases the uncertainty of this average generation rate of C&D materials. As shown in Table 2-4, the generation rates produced at these

AR0070393

sites vary widely from 36 to 358 pounds per square foot. As one might expect, nonresidential buildings vary greatly in size and materials used. Additional waste assessments would reduce the uncertainty of the estimated generation amount of nonresidential demolition debris.

[illegible]

The 1996 estimate of nonresidential demolitions was used as the basis for the 2002 estimates. The first step was to apply the new generation factor to the original 1996 data. The number of demolition projects estimated in 1996 (43,795 projects) is multiplied by the average building floor area (13,500 ft²) and the new generation factor of 158 lb/ft².[1] The adjusted 1996 baseline

[1] 1996 Statistical Abstract, Table 1206 from U.S. Energy Information Administration "Commercial Building Characteristics 1992"

AR0070394

shown in Table 2-4, is 46 million tons (an increase of approximately one million tons over the original published estimate).

The second step takes the net value of construction work in the category for wrecking and demolition contractors for 1997 and 2002 from the Economic Census. After adjusting for inflation, the growth rate was calculated from 1997 to 2002. This assumes that economic growth (measured by net value) in the wrecking & demolition industry is directly related to demolition materials generation. The growth rate of 1.4 in net value of construction work for wrecking and demolition contractors from 1997 to 2002 predicts nonresidential demolition materials to be 65 million tons in 2002 (Table 3-4). Since no data source exists for 2003, it is assumed that 65 **million** tons of nonresidential demolition materials were generated in 2003.

2.1.5 Residential Renovation

Renovation includes improvements and repairs to existing buildings, including driveways. Renovation materials consist of both construction and demolition materials as old materials are removed and new materials are added. The renovation waste stream can be fairly homogeneous such as when driveways or asphalt roofs are replaced, or heterogeneous such as when buildings are modified or enlarged.

Because of the wide variation in renovation projects, waste assessments should be separated by renovation type to determine generation per square foot. Table 2-5 shows the results of five waste assessments that have been made at residential sites, illustrating a wide variation in generation rates on a square foot basis. Renovating kitchens, bathrooms, and entire houses typically generates more waste per square foot than new construction, largely because of the demolition that accompanies remodeling. However, some renovation activities, like roof replacement, produce relatively low amounts of material on a square foot basis.

Table 2-5. Summary of Residential Renovation Job Site Surveys of C&D materials

Date	Research Group (1)	Type of data	Location	Size of Project Sq ft	C&D Debris Pounds	Generation rate lb/sq ft	Average generation lb/sq ft

1997	NAHB	SF Remodel/New roofs	Maryland	1,210	4,018	3.3	3.31

(1) NAHB: National Association of Home Builders; NIST: Portland

Renovation materials generation were estimated for this analysis by determining the number of major home improvements (from the U.S. Census Statistical Abstract and home improvement studies), and then estimating the amount of material produced by each type of improvement. Since minor improvement projects cannot be included in a study of this type, a succession of the major projects a residence can go through can be useful for making first estimates.

AR0070395

Appendix A Tables A-6, A-7, A-8, and A-9 show some of the assumptions made and the results of estimating the amount of material produced when driveways are replaced, when asphalt and wood roofs from residences having one to four units per structure are replaced, and when residential heating and cooling equipment is replaced. Based on the assumptions, driveway replacement generated 28 million tons of concrete. Asphalt roof replacement produced 7 million tons of largely asphalt shingle waste and wood roof replacement produced 2 million tons of largely wood waste. The replacement of heating, ventilating, and air conditioning (HVAC) equipment produced 2.1 million tons of materials. Remodeling kitchens, bathrooms, and other home interiors generated approximately 0.7 million tons. On this basis, the total residential renovation generation from the improvement or replacement projects itemized above, was estimated to be **37.8 million tons** in 2003.

2.1.6 Nonresidential Renovation

No information was found on the total amount of money spent on nonresidential renovation in 2003. The USCB last estimated that the total dollars spent for nonresidential renovation projects in 1992 was $155 billion. This report assumed the ratio of residential to nonresidential dollars is the same in 2003 as in 1992. Therefore, the total amount of money spent on nonresidential renovation was calculated using the amount spent on residential renovation and the ratio of residential to nonresidential renovation in 1992.

Very few material assessments are available for nonresidential renovation. Additionally, the materials assessments available do not have any consistency. Therefore, a methodology similar to the one used for residential renovation cannot be used to estimate the materials generated during nonresidential renovations. In the absence of adequate materials assessment data, total dollars spent on nonresidential and residential renovation were compared. It was assumed that the amount of materials generated is proportional to the dollars spent in these two sectors. (See Table A-5 for more details of this analysis.)

Based on the assumption that materials generation per dollar is equal to the residential rate, total nonresidential renovation materials generated was estimated to be **29 million tons** in 2003. Table 2-6 shows nine assessments that have been made at nonresidential renovation sites; these data show a wide variation in generation rates on a square foot basis. Since this estimate is based on relatively old data and few material assessments, this estimate of nonresidential renovation generation amounts has a high level of uncertainty.

AR0070396

2.2 AMOUNT OF BUILDING-RELATED C&D MATERIALS GENERATED IN 2003

Table 2-7 summarizes the estimates for C&D materials generation from the construction, demolition, and renovation of residential and nonresidential buildings in the United States in 2003. The estimated total is almost 170 million tons, with 39% coming from residential and 61% from nonresidential sources. Figure 2-2 provides a breakdown, in percent of total, of the six building sectors that generate C&D materials. The largest sector is nonresidential demolition at 39%. Residential and nonresidential renovation materials make up 22% and 39%, respectively, followed by residential demolition at 11%. New construction represents 9% of total C&D materials, with residential construction at 6% and nonresidential construction at 3%.

Table 2-7. Estimated Amount of Building-Related C&D Materials Generated in the U.S. During 2003.

Source	Residential		Nonresidential		Totals	
	Million Tons	Percent	Million Tons	Percent	Million Tons	Percent

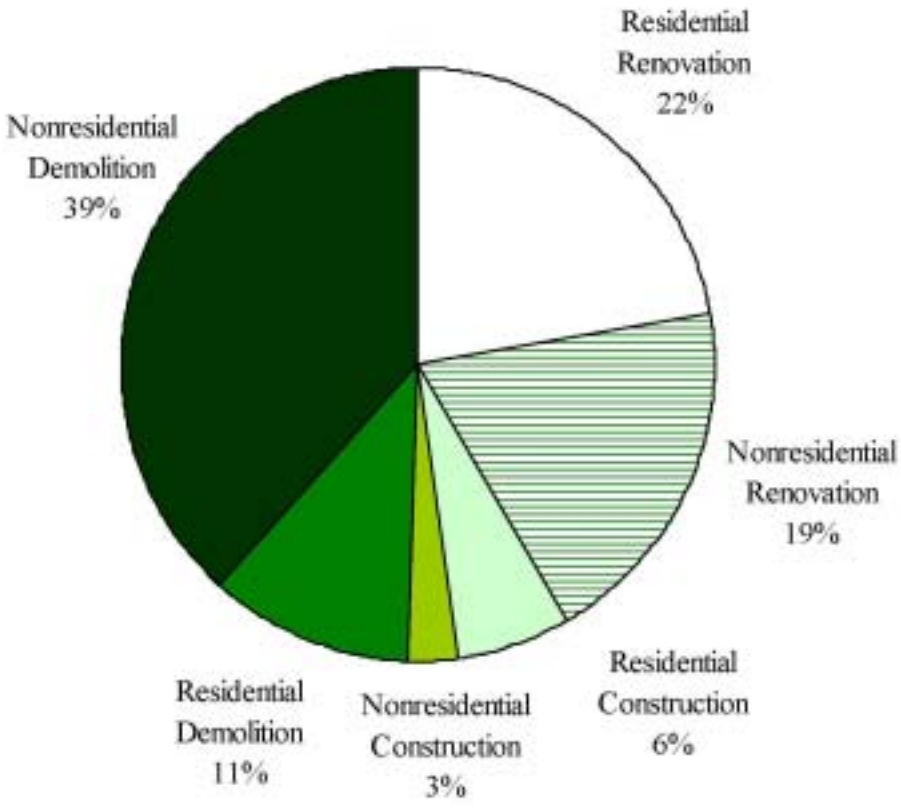
*C&D Debris generated on site (Table 2-5) or from NAICS calculated from generation Quantities that equal 0 tons or estimated to be zero

Note: Data are not added to the appropriate significant digits. Totals may not add due to rounding.

Figure 2-2. Contribution to the C&D Materials Stream by Each Building Sector

AR0070397



The 2003 estimate of 170 million tons is equal to 3.2 pounds of building-related C&D materials generated per capita per day (pcd). In 1996, this per capita rate was estimated to be 2.8 pcd. When comparing the 2003 C&D materials generation rate of 3.2 pcd to the municipal solid waste (MSW) generation rate of 4.45 pcd (EPA 2005), it is noteworthy that amount of C&D materials generated per person is less than the amount of MSW generated per person. While not every person generates C&D materials personally, population growth increases the need for buildings and infrastructure to support that growth.

The amount of C&D materials generated varies considerably from one community to another. This variation is created, in part, by the difference in construction styles, historical and current growth of the community, and local economics. In fast growing areas, the C&D waste stream from buildings consists primarily of construction materials, with much smaller quantities of demolition materials. Demolition materials are produced when older buildings are demolished to make way for the new developments. By contrast, in many urban areas demolition materials dominate the C&D stream. As definitions of "C&D materials," "generation," "recycling," "disposal," and "recovery facility" (or other similar terms) vary among states, adjustments may be required when comparing the results of this report with data reported by specific state agencies to ensure the same materials and sources are included in the comparison[12]. Similar

[12] A first example of differing definitions among states involves the definition of "generation." State A may report a "generated" amount as a sum of the amount disposed and recovered at C&D materials facilities within the state borders, regardless of what state in which the C&D materials were generated. On the contrary, State B determines

AR0070398

adjustments may also be required when comparing data from any two states. The components that make up C&D materials also vary a great deal depending on the type of construction and the methods used by the construction industry.

the amounts of C&D materials imported to and exported from their state and accounts for additions/subtractions as appropriate in their amount "generated." A second example involves the types of facilities that the state collects from. State C does not require facilities that process only concrete or asphalt pavement to report annual amounts that they receive. On the contrary, State D does require these facilities to report their amounts to the state and their amounts are included in the overall State D C&D materials recovery amounts. A third example involves incentives for using different definitions. State E levies a fee associated with various types of waste. If C&D materials have a lower fee than other materials, generators are incentivized to classify their waste as C&D materials rather than another waste, even though it might not fall within the classical definition that may be used outside of State E. These three examples are just some of the reasons why definitions play such an important role in measuring C&D materials amounts.

AR0070399

3 Building-Related C&D Materials Management

EPA's 1989 Agenda for Action endorsed an Integrated Waste Management Strategy to address the growing amount of municipal solid waste, including C&D materials generated. This strategy refers to "the complementary use of a variety of waste management practices to safely and effectively handle the municipal solid waste stream with the least adverse impact on human health and the environment." The components of the Strategy are: source reduction (or waste prevention), recycling, including off-site (or community) composting, combustion with energy recovery, disposal through landfilling and combustion without energy recovery. Components of C&D materials can be and are managed in each of these ways. Different measurement methodologies were used for each type of management method. Because many C&D processing facilities send materials to be beneficially used in a variety of markets, the term "recovery" is used here to represent the reuse, recycling, and combustion with energy recovery of C&D materials.

3.1 SOURCE REDUCTION

Currently, there are no known estimates of sources reduced on-site through improved methods and materials. Efforts including purchasing optimization during construction to avoid surplus materials and reusing existing shell and structure during renovation can reduce the amount of materials that need to be removed from the site and managed. The amount of used materials avoided through these efforts had not been documented, but any efforts to document these trends may be considered for use in future C&D materials estimations.

3.2 MATERIALS RECOVERY

C&D materials recovery includes efforts to reuse, recycle, or otherwise beneficially use C&D materials in various applications, including use in energy recovery applications. There are many drivers for C&D materials recovery. Historically, economics has been the primary driver for recovery. In locations where disposal fees were high, recovery became an economically preferable option. Materials that have traditionally retained a high value when recovered, such as metals, were recovered even in areas that had low disposal fees. These economic drivers remain in place today, but an additional factor is affecting the economics of recycling today that did not exist in the past: green building programs. Specifically, green building rating systems typically give credits for the reuse or recycling of C&D materials. Since the creation of the U.S. Green Building Council in 1993 and the spike of green buildings in 2000, demand for reuse or recycling opportunities has increased in areas where such opportunities had not existed. More information on green building can be found at www.epa.gov/greenbuilding.

3.2.1 Barriers to C&D Materials Recovery

Barriers to materials recovery still exist, however. Many buildings and building materials are not designed to be reused or recycled. EPA's Lifecycle Building Challenge is a design competition that challenges professionals and students to design building materials and assemblies for reuse and recycling. More formation can be found at www.lifecyclebuilding.org. If C&D materials will be generated at construction sites, C&D materials management should be included in the construction plan. Successful planning teams include the owner of the building,

AR0070400

the architect, and the contractor. Success stories of C&D recovery can be found at www.epa.gov/cdmaterials.

There are other barriers that exist to C&D materials recovery. In some locations, recovery facilities do not exist. Even where facilities do exist, markets have not been found for some materials for a variety of reasons. There could be a lack of demand for a material, an unwillingness to use recycled materials in place of virgin resources, or a regulatory prevention of its use. Many markets view recycled materials as inferior simply because they are viewed as wastes, yet they often have the same chemical or physical properties as comparable virgin materials, and provide comparable performance; in some cases, they provide superior performance than do virgin materials at a lower cost. EPA aims to expand recognition of the value of C&D materials so that they are more widely viewed as locally available resources, rather than un-usable discards.

Potentially harmful materials, such as asbestos, lead-based paint (LBP), and polychlorinated biphenyls (PCBs), have historically been used in the construction and maintenance of many buildings. These materials can greatly affect the recyclability of some materials, especially those derived from older buildings. In some instances, concerns about the possibility of these materials entering the recycling stream have prevented entire segments of the C&D materials stream from being recycled. The specific percentage of C&D materials that contain asbestos, lead, or PCBs is unknown. As a result, it is very difficult to determine the impact the presence of these compounds in C&D materials has on C&D materials recovery. Some data are available on the use and prevalence of these harmful materials in buildings. It was recently reported that, as of 2000, 38 million homes in the U.S. still contained LBP somewhere in the building, either on interior or exterior surfaces (Clickner et al. 2001). According to the United States Geological Survey (USGS), asbestos use in all applications (including construction) declined from approximately 7,600 tons in 2002 to approximately 5,100 tons in 2003. In fact, the consumption of asbestos in 2003 represented less than 0.6% than that of the consumption in 1973, the peak year for U.S. asbestos consumption. According to the USGS, the current primary use of asbestos in construction is in some roof coatings, not in asphalt shingles (2003). In fact, recent testing of old asphalt shingles from re-roofing activities collected at recycling centers indicates that the presence of asbestos is relatively rare and should continue to be come even more rare as these shingles are removed an replaced with non-asbestos-containing shingles (CMRA 2007). Unfortunately, asbestos testing costs and time delays can be a disincentive to recycling and, as a result, recycling rates for asphalt shingles continue to be low. LBP was banned in 1978, some uses of asbestos in buildings were banned by 1978, and PCBs were banned in 1979.

3.2.2 Quantifying Recovery of C&D Materials

There are a number of organizations that are working to overcome the barriers to C&D materials recovery. EPA works with other governmental and industry partners in funding new research, promoting safe uses for C&D materials, and in conducting education and outreach. For example, through the WasteWise partnership program, the EPA rewards those who have created successful recycling programs. For more information about WasteWise, please see www.epa.gov/wastewise. To learn more about what the EPA is doing to increase C&D materials recovery, please see www.epa.gov/cdmaterials.

AR0070401

There are various sources of C&D materials recovery data that capture different parts of the recovery stream, including surveys of contractors, surveys of recyclers, and estimates made by state environmental agencies. These sources are discussed in detail in Appendix B. While the surveys of contractors could be used for this estimate, EPA was not able to find a recent survey of recycling in the residential building sector. Additionally, those surveys of demolition and non-residential contractors may not represent actual recovery as the recycling facilities may actually dispose of a portion of the materials that they receive. While a survey of recyclers was performed, the surveyors were unable to distinguish the amount of materials derived from buildings from other materials that were present in the recycling stream. Thus, these estimates for C&D recovery cannot be compared with the amount of C&D materials generated, which only represents building materials.

Data collected by state environmental agencies on the amount generated, disposed, and recovered, on the other hand, are viewed as the most accurate source of information. Unfortunately, only eight states collect recovery and disposal or generation amounts that could be used to estimate a recovery rate (see Table 3-1). These states represent approximately 21% of the U.S. population. Thus, the weighted recovery rate estimated using the eight states' data may not be fully representative of the entire country. Additionally, state definitions of what constitutes C&D materials and recycling vary. For example, some states count C&D materials that are used as alternative daily cover in landfills and for energy recovery[13] to be counted as recycling, while others do not. In the chart below, EPA has labeled the category measured as "recovery" instead of "recycling" in order to include materials that are recovered for other uses that do not fall under the definition of "recycling."

The weighted average recovery rate for the eight states for 2003 was 48%. While this number may not be fully representative of the entire country, it does provide an indicator of C&D materials recovery in the U.S. However, it is, at best, an approximation. For instance, it is known that the recovery numbers provided by some states likely include some concrete, asphalt pavement, and metals from non-building sources, while other states do not include those materials. Additionally, recovery efforts after disasters could be included in the reported numbers.[14] Thus, the recovery estimate of 48% for buildings may be high. On the other hand, the reported numbers for other states may not capture the entire amount of building-related C&D materials that are recovered in that state, either because the C&D materials were exported or because only certain types of C&D materials recycling facilities are required to report. As with comparing generation estimates, definitions of "recycling" and "C&D materials" can vary widely from state to state (see footnote on page 19). The EPA intends to continue working with state environmental agencies and other partners to develop better national recovery estimates for the future.

Unfortunately, looking overall at state data does not provide a breakdown of the recovery amounts for specific materials within the C&D recycling stream, so it is not possible to determine which sectors or which materials have the largest influence on the recovery rate.

[13] On the question of energy recovery, a major market for C&D wood is its use as "boiler fuel." Most recyclers include amounts of wood sold for boiler fuel in their reporting for recycling.

[14] For example, over seven million cubic yards (approximately 2 million tons) of vegetative debris was generated in the three most affected counties of Mississippi after Hurricane Katrina during 2005 and 2006. Such amounts can have large impacts on data reported as "recycled" and "disposed."

AR0070402

Additionally, it is not possible to estimate a material composition. If, through continued work with state environmental agencies and industry, such estimates are able to be derived, they may be included in future C&D materials estimations.

Table 3-1. Amount of C&D materials disposed and recovered by reporting state.

State	Amount of C&D Materials, 2003 (tons)		2003 Recovery Rate
	Disposed	Recovered	
Florida[27]	5,577,269	1,998,256	
Maryland	1,913,774	2,270,100	
Massachusetts	7,200,000	3,600,000	
New Jersey[28]	1,519,783	5,582,346	
North Carolina	1,814,401	210,002	
Utah	1,054,296	16,161	
Virginia	3,165,948	93,151	
Washington	1,780,356	2,610,900	
Total	**17,575,425**	**16,012,846**	**48%**

3.3 LANDFILL DISPOSAL

Based upon the recovery estimate above, 52% of the building-related C&D materials were discarded in 2003. Much of this material goes to specifically designated C&D landfills. However, C&D landfills are regulated by state and local governments, and the federal government does not collect disposal data for these landfills. Using a survey of states, Kaufman et al. (2004) reported the number of landfills to be over 1,900 in 2002. This number decreased to over 1,500 in 2004 (Simmons et al. 2006). The reasons for this decrease vary from state to state.

Similar to the recovery estimate, it is not possible to determine which sectors or materials have the largest influence on the national disposal rate. Some state and local environmental agencies have investigated the composition of the waste disposed in landfills within their state.[29] These reports should be consulted when examining regional C&D materials disposal.

C&D materials may also be disposed of in MSW landfills. The amount of C&D materials commingled with MSW and disposed of in MSW landfills or combusted in incinerators without energy recovery is not known, but could be significant. In some areas, disposal in MSW landfills is the most common management method for C&D materials. A portion of residential

AR0070403

renovation materials is also discarded by homeowners into the household trash and disposed of in MSW landfills or combusted in incinerators. Some C&D materials, typically those considered to be "inert," are used as fill in old quarries and other pits. Some states do not require permits for this use of C&D materials and, therefore, little is known about the total amount of materials used in this manner.

AR0070404

4 Conclusions

A methodology utilizing national statistical data on the amount of construction, renovation, and demolition activity in the U.S. and average amounts of waste generated at job sites was used to estimate that approximately 170 million tons of building-related C&D materials were generated in the U.S. during 2003. This is a 25% increase in generation from the 1996 estimate of 136 million tons. During the same time period, total construction spending increased 50% (USCB, 2007), however it was estimated that building construction increased only 32%. Construction spending increases can also reflect inflation, profit, and other factors that do not necessarily correlate to increased materials use.

Of the amount generated, approximately 48% was estimated to be recovered, based on state reported disposal and recovery data. This recovery rate may be an overestimate due to the inclusion of materials that are from non-building sources. This recovery estimate is a 23% increase from the 1996 estimate. Comparison of these estimates should be viewed with caution because data limitations created the need for different methodologies in 1996 and 2003.

The amount of available information varies from year to year as few entities collect consistent national data regarding C&D materials. Thus, various sources of data must be relied on to make national estimates of C&D generation and recovery. Decreasing available landfill space and interest in green building will all have a positive impact on the rates of recovery of C&D materials, until recently, the rise in commodity prices had a similar impact. EPA will continue to work in partnership with state environmental agencies, AGC, BNRA, CMRA, NAHB, and NDA to actively promote recovery and recycling of C&D materials.

APPENDIX A

BUILDING-RELATED C&D MATERIALS GENERATION AMOUNT CALCULATIONS

AR0070411

Table A-1. Residential Construction Materials Worksheet

Method Used:

(1) Start with total dollars of new construction from Census Bureau Current Construction Reports (C-30)

(2) Calculate sq ft of new construction from total dollars and $/sq ft construction cost

(3) From empirical waste assessment, estimate lb/sq ft of new construction

(4) Calculate tons generation

Calculation	2003
(1) C-30, Residential Construction	$352,252,000,000
Total dollar private new residential and public housing & nodev. depreciation	
(2) Table 925 of 2001 Statistical Abstract of the United States (Note: whole industry not included)	
Residential Construction	$282,070,000,000
Residential sq ft of new construction	3,072,000,000 sq ft
Cost of new construction	
($/residential construction sq ft Residential new construction	$ 91.80 per sq ft
2+3 Total sq ft of new construction = $352,252,000,000 / $91.80	3,837,000,000 sq ft
(3) See sampling waste assessment results Table 2-	
Average Generation	4.39 lb/sq ft
(4) Total estimated amount of residential construction materials generated in 2003	**16,100,000,000 tons**

Note: Data are rounded to the appropriate significant digit. Data may not add due to rounding shown.

Table A-2. Nonresidential Construction Materials Worksheet

Method Used:

(1) Start with total dollars of new construction from Census Bureau Current Construction Reports (C-30)

(2) Calculate sq ft of new construction from total dollars and $/sq ft construction cost

(3) From empirical waste assessment, estimate lb/sq ft of new construction.

(4) Calculate tons generation

Calculation	2003
(1) C-30, Nonresidential Construction*	$256,501,000,000
Total dollar value of new construction, additions, and alterations to buildings for industrial, commercial, educational, religious, public safety, and miscellaneous categories	
(2) Table 925 of 2001 Statistical Abstract of the United States (Note: whole industry not included)	
Nonresidential Construction	$153,501,000,000
Nonresidential sq ft of new construction	1,368,000,000 sq ft
Cost of new construction	
($/Nonresidential Construction sq ft Nonresidential new construction	$112.21 per sq ft
2+3 Total sq ft of new construction = 256,501,000,000 / 112.21	2,286,000,000 sq ft
(3) See sampling waste assessment results Table 4	
Average Generation	4.34 lb/sq ft
(4) Total estimated amount of nonresidential construction materials in 2003 =	**5,000,000,000 tons**

*Data downloaded from the Census Bureau website on July 2005

Note: Data are rounded to the appropriate significant digit. Data may not add due to rounding shown.

AR0070412

Table A-3. Residential Demolition Materials Worksheet

Model Used

(1) How many demolitions per year?

(2) What is the average size (square feet) of the demolished buildings?

(3) How many pounds per square foot are generated?

(4) What is the total generation?

Calculation

(1) Assume 2,000,000 residential demolitions per year [1]

(2) What is the average size (square feet) of the demolished buildings?

Single-family homes: 1,500 sq ft [2]

Multi-family homes: 1,000 sq ft [3]

(3) How many pounds per square foot are generated?

Single-family homes: 155 lbs/sq ft [4]

Multi-family homes: 155 lbs/sq ft [4]

(4) What is the total generation?

Single-family homes	310,000,000,000 lbs
Multi-family homes	155,000,000,000 lbs
Total	465,000,000,000 lbs

[1] Assumption. Based on 2015 housing stock, there are approximately 120 million housing units in the United States. Assuming an average lifespan of 60 years, approximately 2 million units are demolished each year.

[2] Assumption. Single-family homes are assumed to be 1,500 square feet on average, based on data from the U.S. Census Bureau's American Housing Survey.

[3] Assumption. Multi-family homes are assumed to be 1,000 square feet on average, based on data from the U.S. Census Bureau's American Housing Survey.

[4] Assumption. Based on the assumption that 50% of the demolished buildings are made of concrete and 50% are made of wood, with an average density of 155 lbs/sq ft for concrete and 50 lbs/sq ft for wood.

Note: Data not available for the specific year requested. Data may not be available for all states.

Single-family homes	100%	155	310,000,000	48,050,000,000
Multi-family homes	100%	155	155,000,000	24,025,000,000
Total			465,000,000	72,075,000,000

Total estimated amount of residential demolition materials generated in 2015: 72,075,000,000 tons

Table A-4. Residential Renovation Materials Worksheet

Method Used:

1) Estimate the amount of renovation debris (roofs, driveways, HVAC, kitchens, etc.) and the amount associated from each
2) Calculate total generation

Calculation:

1) Estimates for remodeling:

	Million Sq. Ft.	Demolished	Tons
Kitchen remodel	1.2	0.75	1,800,000
Kitchen, complete	0.38	1.5	2,660,000
Bath remodel	1.60	0.25	800,000
Bath complete	0.70	1.00	700,000
Additions	1.50	0.75	1,800,000

2) Replacements (new construction, following Appendix Tables A-5, A-7, A-8, & A-9):

Roofing (square feet of roofing)	20,000,000 (tear-off)
Asphalt roofs	7,000,000
Wood roofs	2,000,000
Siding & A/C replacement	2,500,000
Kitchen remodeling	3,000,000
Bathroom remodeling	1,000,000
Additions	1,500,000

Total estimated amount of residential renovation materials in 2005: 37,806,000 tons

a) *The Changing Structure of the Remodeling Industry*, Joint Center for Housing Studies of Harvard University

b) Year 1998

Note: Data are rounded to the appropriate significant digit. Data may not add to totals shown.

AR0070414

Table A-5. Nonresidential Renovation Materials Worksheet

Method Used

Estimate total nonresidential and residential improvement expenditures and assume that the amount of waste generated is proportional to dollars spent in these two sectors

- (1) Determine total expenditures of nonresidential construction projects from historical Census data*
- (2) Multiply quantity of residential renovation debris (Table A-4) by the ratio of nonresidential to residential improvement expenditures

Calculation

(1) Total estimated expenditures for nonresidential improvements in 2003**	155,386
This compares to 2003 residential improvement expenditures of	176,899
Total 2003 improvement expenditures	332,285

(2) Estimated generation of nonresidential renovation materials in the 2003

155,386 / 332,285 x 37,816,400 = 17,680,000 tons

---

* Obtain historical numbers by averaging the ratio of nonresidential dollars spent for the years 2003 and 1992. See the Methodology used for 1998 - 2003. No data available on nonresidential renovation debris generated in 2003.

** Assume same ratio of expenditures in 1992 ($100,400 nonresidential and $134,500 residential) which translates the current dollars spent of nonresidential renovation debris

(100,400/134,500 x 176,899 = 155,386)

Note: Data are rounded to the appropriate significant digits. Data may not add to totals shown.

Table A-6. Estimated Weight of Residential Concrete Driveways Replaced in the U.S. 2003

AR0070416

APPENDIX B

SOURCES OF C&D MATERIALS RECOVERY DATA

AR0070417

Sources of C&D Materials Recovery Data

Many sources compile information on C&D materials recovery, either for reuse, recycling, beneficial use, or energy. Industry associations are interested in the amount of materials that their members recover. Some federal agencies collect data on C&D materials recovery in studies that they perform. Since C&D materials are regulated at the state and local level, some state agencies track the amount that is disposed and/or the amount that is recycled in their state.

Surveys of C&D Materials Processors/Recyclers and Reuse Stores

Construction Materials Recycling Association (CMRA). The CMRA represents companies that process materials for recycling, beneficial use, or energy recovery markets. They surveyed their members in 2004 to determine the number of operating facilities and the amount of material that they are processing. Since not all C&D materials recyclers are members of the CMRA, they projected the member survey results onto the non-members. Sources of materials include all C&D generators, including building, road, and other structure sites.

The number of recycling facilities for C&D materials has been growing rapidly in the last few years. The CMRA estimated there were at least 2,800 operating C&D recycling facilities in 2004. That estimate included approximately 2,400 concrete and asphalt pavement crushing facilities, 250 mechanized mixed-waste C&D facilities, and 150 wood waste processors.

CMRA estimated that approximately 197 million tons of C&D materials were recovered in 2004, including 28 million tons at mixed[1] C&D materials processing facilities, 155 million tons at concrete and asphalt crushing facilities, and 14 million tons at wood waste processing facilities. These amounts do not include asphalt pavement recycled on-place or at hot-mix asphalt plants. These amounts, however, include materials from many sources beyond typical building construction, renovation, or demolition sites, such as concrete from transportation and utility projects, wood waste from land clearing, and wood waste in the form of pallets and wood spools. It also does not include any materials that were reused or recycled at the job site, without first processing the material at a recycling facility.

It can be assumed that most of the materials that mixed C&D materials processing facilities receive are from buildings. Some of the materials from buildings, however, go to concrete asphalt pavement facilities and wood waste processing facilities, but the majority does not. Thus, if this amount (28 million tons) is compared to the amount of C&D materials estimated as generated (164 million tons), the recycling rate would be 16%. This is much lower than the estimated 48% calculated using reported state data. This quick calculation demonstrates the uncertainty inherit in the estimates generated for this report.

Building Materials Reuse Association (BMRA). The BMRA is a non-profit educational organization whose mission is to facilitate building deconstruction and the reuse/recycling of recovered building materials. Members include owners of C&D materials reuse stores, deconstruction contractors, and manufacturers of reclaimed wood products. In 2006, the BMRA surveyed their members to determine the amount of C&D materials reused in the U.S. and

[1] Mixed C&D processing facilities are those that accept heterogeneous loads of C&D materials and do not require C&D materials loads to be segregated by material.

AR0070418

received a 17% response rate to the survey. If the results of this survey were projected to their entire membership, it can be estimated that approximately 200,000 tons of C&D materials are reused in the U.S. every year.

Surveys of Contractors

National Demolition Association (NDA). The NDA is a non-profit trade organization representing more than 1,000 U.S. and Canadian companies which offer standard demolition services, as well as a full range of demolition-related services and products. Its educational efforts help members stay abreast of regulatory and safety matters. The NDA also keeps regulators informed about issues facing their industry. In addition, the NDA is dedicated to increasing public awareness of the industry, as well as providing members with information on the latest technical advances in equipment and services. In 2005, the NDA surveyed their membership to gather data on the quantity of demolition materials recovered for recycling. They learned that demolition contractors recycle concrete, masonry, wood metals, and asphalt pavement.

Associated General Contractors (AGC) of America. The AGC is a national construction trade association representing all facets of commercial construction for both public and private entities. The AGC has approximately 32,000 member companies representing general contractors, specialty contractors, service providers, and suppliers. In 2004, the AGC sent an email survey to their members regarding C&D materials and received 328 responses. Of these responses, 58% reported that they recycle C&D materials, mostly asphalt pavement, concrete, steel, and wood.

Data Collected by State Agencies

A search of reuse, recycling, or diversion data collected by states was performed. Eight states collected data on C&D materials recycling for 2003. Although this information is labeled as tons "recycled," these numbers could also include C&D wood used as boiler fuel or other C&D materials that were not, by some definitions, "recycled." These data show that there is significant recovery of C&D materials for recycling in some locations. However, it is not known if these areas are fully representative of the United States as a whole.

Data Collected by Federal Agencies

U.S. Department of Agriculture (USDA). Deconstruction is the process of selective dismantling or removal of materials from buildings before or instead of demolition. A common practice in the United States is to remove materials of value from buildings prior to and during demolition for recycling or reuse. Reuse examples include electrical and plumbing fixtures that are reused; steel, copper, and lumber that are reused or recycled; wood flooring that is remilled; and doors and windows that are refinished for use in new construction. The USDA Forest Service has compiled a directory of companies that are involved in the deconstruction and reuse of materials from wood-framed buildings (USDA 2004). According to this directory, there are 420 companies involved in deconstructing buildings or selling reusable materials.

The USDA has also collected information on the amount of wood waste that is generated and recovered (McKeever 2004, McKeever and Falk 2004). They have estimated that approximately

AR0070419

39 million tons of C&D wood waste was generated in 2002. This represents approximately 24% of the total C&D estimate of 164 million tons reported in this study, which is consistent with past estimates that show that wood represents approximately 20-30% of building-related C&D materials (Sandler, 2003).

U.S. Geologic Survey (USGS). The USGS has been keeping track of the amount of minerals that the U.S. extracts, imports, and exports since the late 19th century. They publish the Minerals Yearbook annually, which reports the results of minerals and metals producer surveys. When surveying crushed stone, sand, and gravel producers, they have discovered that some of these producers have started recycling concrete to supplement their business. While it is assumed that these producers recycle a small portion of the total amount of concrete recycled in the U.S., these data demonstrate the increasing acceptance of and demand for recycled concrete aggregate.

U.S. Department of Energy (USDOE). The USDOE reports the amount of energy that is produced from various sources, including wood waste. It is unknown, however, the proportion of the wood waste used for energy that originated from C&D sources. Other sources of wood waste include paper production plants, saw mill, plants, retail stores, and other sources.

Construction & Demolition Materials Recycling – Measuring Success

Melinda L. Tomaino
The Associated General Contractors of America
Resource Conservation Challenge Workshop
Thursday, February 22, 2007

About AGC of America

- National trade association, est. 1918
- 98 chapters
- Approx. 32,000 member companies
  - 7,000 general contractors
  - 11,000 specialty contractors
  - 13,000 service providers and suppliers

About AGC Members

- Majority are small businesses
- Multiple types of construction
- Varied project delivery methods

AGC Environmental Services

- Compliance tools, educational programs, publications
- Storm water, wetlands (Section 404 permits), TMDL, air quality, diesel retrofit, endangered species, hazardous and non-hazardous waste, EMS, green construction, C&D debris recycling

AGC/EPA Joint Efforts

- Network Partner, EPA National Environmental Performance Track Program
- Partner, EPA Sector Strategies Program
- OECA – Compliance tools
- OAR – Reports, workgroups and collaboratives
- OSWER – _____

2004 C&D Debris Survey

- Gather data
  - Establish a baseline
- Understand the barriers
  - Facilitate recycling

AR0070421

2004 C&D Debris Survey

- Survey e-mail sent May 28, 2204 and closed June 26, 2004
- 811 members went to the online survey page from e-mail
- 328 completed the survey

Survey Results

- Size of company
  - 123 small businesses
  - 82 medium-sized businesses
  - 123 large businesses
- Does company recycle
  - 191 do recycle
  - 137 do not

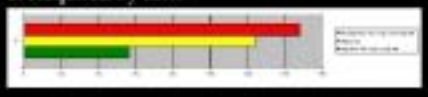
Survey Results

- What affects decision to recycle (or not to recycle)
  - a. Money.

Survey Results

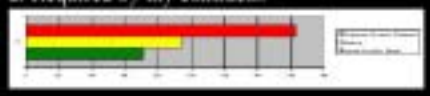
- b. Public image.

- c. Required by law.

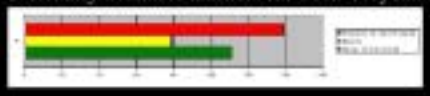


Survey Results

- d. Required by my contracts.

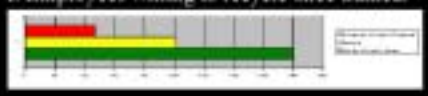


- e. Readily available markets for C&D recyclables.



Survey Results

- f. Employees willing to recycle once trained.



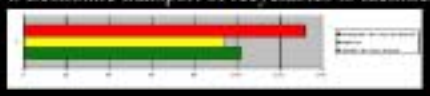
- g. Subcontractors willing to recycle once trained.

AR0070422

Survey Results

- h. Flexible disposal practices.

- i. Economic transport of recyclables to facilities.



Building Your Quality of Life

Survey Results

- Project-specific information and estimates
  - Respondents by project type—
    - 186 building, 59 highway, 29 demolition, 20 utility, 26 unspecified
  - Projects in 43 states
  - Projects varied in value ($1500 to $4 billion)
  - Focused on asphalt, concrete, steel, and wood

Building Your Quality of Life

Survey Results

- 68.0 percent of asphalt debris was recycled of the average 15,664 tons generated per site (91-93 recorded responses)
- 88.7 percent of concrete debris was recycled of the average 15,126 tons generated per site (148-151 recorded responses)
- 13.6 percent of wood debris was recycled of the average 1,708 tons generated per site (121-125 recorded responses)
- 87.3 percent of steel debris was recycled of the average 1,939 tons generated per site (123-128 recorded responses)

Building Your Quality of Life

AGC Conclusions

- Survey results suggest contractors are willing to recycling, where feasible.
- Survey results and other communications with contractors show an absence of cultural barriers to recycling.
- Choices to recycle depend on local issues, such as availability of recycling facilities and a market for recycled materials.

Building Your Quality of Life

Next Steps

- AGC's Environmental Agenda —
  - Objective 4: Facilitate members' efforts to recycle or reuse C&D debris
    - Develop resources for members
    - Investigate barriers to recycling

AR0070423

Trends in Building Deconstruction and Materials Reuse
Brad Guy 11/06/06

Introduction

This article is intended to provide an update on some of the trends in the deconstruction and reuse industry. One major aspect of the building materials reuse industry in North America is the HFH ReStore network. ReStores are retail outlets for donated and reclaimed building materials facilities operated by HFH affiliates as a fundraising mechanism for their home-building programs. The Habitat for Humanity (HFH) ReStore network is growing by leaps and bounds. As an example, in Canada in 2000 there were 16 ReStores with gross sales of $3.1 million. In 2005, there were 41 Canadian ReStores with gross sales of $14.5 million. This is a growth of 156% in the number of stores, and a growth of 368% in revenues in just 5 years (HFH Partnernet, 2006). The numbers for the US are similar. According to a study by Penn State University, the average ReStore age is 5 years, with the oldest is 18 years old. More than half of the ReStores have operated for less than 5 years (57.8%), while 28.8% have operated for more than 5 but less than 10 years, and 13.6% have operated for more than 10 years (Judd and Echols, 2005).

Survey

In a recent survey of deconstruction and reuse organizations, an attempt was made to ascertain the materials flows and economics of deconstruction and reuse in the US. An email survey was sent to 450 organizations identified in three categories, deconstruction services, reused materials retail sales and value added products manufacturing with reclaimed wood. A total of 76 responses was received or about a 17% response rate.

Of these 76 respondents, 41 were reuse stores only, and 28 combined both deconstruction services with retail reuse sales. Of the firms that were reuse stores only, 59% reported conducting some form of active salvage operations, with the remaining 41% relying solely on donations. The remaining 7 respondents focused on wood reuse only, through remanufacturing.

Employment

Firms combining deconstruction with a reuse store employ on average more full-time employees (FTE) per organization than those with a reuse store only, 5.8 to 4.6 FTE per firm respectively. It should be noted that many non-profit reuse stores especially the HFH ReStores may also have labor provided by volunteers that is not accounted for by a measure of FTE, while comprising a significant component of the total labor utilized by the organization. The large majority of organizations employed a small number of persons, with 12% of combined deconstruction and reuse firms reporting 16 or more employees. Firms that conduct reclaimed wood value-adding products manufacturing reported an average of 15 employees per firm. Clearly, the value-added aspect of the both front-end deconstruction and back-end remanufacturing provides much greater potential for employment than direct retail resale by itself.

AR0070424

Table 1. Firms with Deconstruction and Reused Materials Sales
1-5 employees - 69% of firms
6-10 employees - 14% of firms
11-15 employees - 5% of firms
16-20 employees - 10% of firms
More than 20 employees - 2% of firms

Revenues
Firms combining deconstruction and a reuse store reported greater average annual revenues per organization than organizations with a reuse store only. $430,796 to $383,849 per firm, respectively. The difference is about 12% average higher annual revenues per firm. Anecdotally, while there is some investment required for deconstruction and salvage services, a much greater investment is required for the facilities and equipment of a reuse store, such as the warehouse space, racking for materials, fork-lift, a truck for pick-ups, etc. Adding deconstruction to a reuse facility operation can add net revenue potential evidenced by higher average revenues for the combined firms. The investment is minimal in terms of equipment compared to demolition, but similar to demolition in terms of potential increased insurance requirements. Adding a reuse facility to an existing demolition or deconstruction firm is a greater investment than the deconstruction operational requirements alone. There is more capital investment in land, building(s), and equipment.

Not surprisingly, the firms engaged in reclaimed lumber value-adding reported average annual revenues of $2,089,286 per firm. With an average 3 times more employees, these firms also have 3-4 times greater annual revenues than the organizations engaged in the recovery of the materials and direct reused materials sales. Anecdotally, there is trend towards reuse firms adding a value-added component to their operations. Also anecdotally, there are considerable difficulties to the endeavor especially when the value-added product sales are located at the reuse facility. In many cases the markets are very different for a value-added higher cost remanufactured product and the reused building materials store's established clientele which are used to purchasing low-cost products.

Materials Flow
The average amount of materials reported handled annually by firms engaged in both deconstruction and retail reuse sales was 1,011,286 LBS per firm compared to 583,476 LBS per firms only engaged in reuse retail sales. The firms engaged in wood value-adding reported about 1,132,500 LBS of wood materials handled on average per firm per year. Most reuse retail sales firms that responded did not know the amount of materials they handled per year in mass. About 69% of the firms conducting only reuse sales reported not knowing the materials they handled other than by revenues. About 63% of the firms conducting both deconstruction and reuse sales reported not knowing the total amount of materials they handled by mass. Firms that remanufacture wood products all reported a board feet metric of the wood materials they processed. There seems to be a small correlation between the amount of materials handled and number of employees and the attention paid to tracking the materials handled.

AR0070425

While many non-profit reuse firms may rely more on volunteer labor and function with lower revenues, making it difficult to justify and implement quantity-based inventory systems, they might also be motivated to track materials flow in regards to environmental metrics for the purposes of donor reporting and demonstrating goals such as waste diversion.

Revenues per Employee and Mass of Materials

The average revenues per employee reported by firms engaged in combined deconstruction and reuse retail sales was $73,900 compared to $96,516 per firm for organizations engaged in reuse retail sales only. It is not clear if this relates to wage differences between deconstruction employees and retail store employees in general or other factors. An anecdotal factor, as mentioned above, is that there is less capital overhead involved in just a reuse retail operation by itself compared to a combined deconstruction and reuse retail sales operation.

Keeping this capital investment lower for reuse firms would certainly increase revenues per employee, but it can be noted that the combined deconstruction and reuse retails sales firms employ on average more persons per firm, move more materials by mass per firm (of which more will be commodity materials such as lumber and brick which are lower value per pound than many other building components such as doors, windows, cabinets and fixtures that are the predominant products in building materials reuse retail stores). Perhaps a trend towards larger facilities and more combined deconstruction and reuse firms will follow in the next few years. At this time we do not have sufficient information over time to make this claim.

The revenue per mass of material handled was also calculated from the firms that reported quantities handled per year. For firms engaged in both deconstruction and reuse retail sales the average revenue per mass of materials was $1.39 / LB of materials handled. For firms engaged in reuse retail sales only it was $0.91 / LB and for firms engaged in reclaimed wood value-adding it was $3.10 / LB of wood materials. Clearly there is a correlation between the amount of materials handled and the revenues generated on average and a 3-times greater economic return per LB by the firms engaged in reclaimed wood value-adding. The last significant factor gleaned from this survey is the growth in sales by the three types of firms that were categorized. As noted in Table 2, annual sales revenue growth by firms with combined deconstruction and reuse sales on average was 56%. As noted in Tables 4, annual sales revenue growth by firms with reuse retail sales only on average was 32%. As noted in Tables 5, annual sales revenue growth by firms with reclaimed wood remanufacturing on average was 28%.

Table 2. Combined Deconstruction and Reuse Sales Firms

	FTE	Revenues annual	Revenues/FTE	#s annually	Revenues/LB	% growth
Average	5.8	$430,796	$73,900	1,011,286	$1.39	56

Table 3. Deconstruction Component of Deconstruction and Reuse Sales Organizations

	Annual projects	Contract / project
Average	28	$12,655

AR0070426

Table 4. Retail Sales Reuse-Only Firms

	FTE	Revenues annual	Revenues/FTE	#s annually	Revenues/LB	% growth
Average	4.6	$383,849	$96,516	583,376	$0.91	32

Table 5. Reclaimed Wood Remanufacturing Firms

	FTE	Revenues annual	Revenues/FTE	#s annually	Revenues/LB	% growth
Average	15	$2,089,286	$132,604	1,132,500	$3.10	28

Reclaimed Materials Being Recovered and Sold

The last aspect of this review of the deconstruction and reuse industry was a focus group review of the most "popular" reclaimed materials. The focus group participants all engaged in recovery and reuse operations. An extensive list of 39 the most common reused materials categories was provided to each participant. They were asked to rank each product based on three criteria. The criteria were: highest resale value; ease of removal from an existing building; and ease of inventory. These rankings were combined, scored and averaged to produce an overall score for the materials deemed most easily recoverable, inventoried and sold. According to this focus group of six successful deconstruction and reuse store operations, the reclaimed products with highest value for resale were grouped into four tiers.

The top tier of reclaimed products based on value includes:

- Architectural elements
- Windows - decorative
- Cabinets - complete sets
- Lumber - wood finish flooring

The second tier of products based on value includes:

- Doors – interior and exterior
- Hardware – including door and plumbing fixtures
- Windows – double-glazed

The third tier of products based on value includes:

- Light fixtures
- Appliances – no more than 5 years old
- Lumber – 1 x sheathing materials

The fourth tier of products based on value includes:

- Brick and stone
- Lumber – floor joists and sub-flooring
- Electrical – hardware and fixtures

From the perspective of the ease of removal only, the products deemed easiest to remove by this group of experts include:

Easiest to remove for salvage:

- Doors – exterior and interior with associated hardware
- Fixtures – ceiling fans, lights, faucets, sinks, mirrors

AR0070427

The second tier of easy-to-remove components includes:

- Cabinets – tops and complete sets
- Electrical – hardware and fixtures
- Exterior – pavers
- Windows – decorative

The third tier of easiest-to-remove components includes:

- Architectural elements
- Windows – double-glazed

Most Desirable Overall (value, removal, inventory) Best to Less Desirable

1. Doors
2. Mantels
3. Architectural elements
4. Faucet - complete set
5. Cabinets - with doors and drawers
6. Windows - double-glazed

Least Desirable Overall (value, removal, inventory) Worst to More Desirable

1. Brick - three-hole
2. Lumber - porch roof framing
3. Lumber – exterior wall framing
4. Slate roofing
5. Lumber - non-load-bearing wall framing
6. Stone - building

Caveats:

Given that a non-profit reuse sales facility is much more amenable to volunteer labor than deconstruction activities, the reuse sales only organizations potentially make greater use of volunteer labor which is not accounted for in the FTE accounting. Adding in the volunteer labor used by non-profit organizations would produce a lower revenues / employee + volunteer number for both types but potentially more so for the organizations that conduct reuse sales only, widening this disparity.

Of important note is that the pre-ponderance of the deconstruction / salvage and reuse retail sales organizations that reported were non-profits versus for-profits, 87% to 13%, respectively. It should be noted that as non profit organizations their IRS reporting is legally required to be made available to the public, whereas this is not so for for-profit organizations. All of the wood remanufacturing firms that reported were for-profits. The proportion of non-profit to for-profit firms reporting is much greater than past surveys suggest is the proportion of non-profit to for-profit in the industry as whole, so this would clearly distort this information towards the non-profit Firm model.

AR0070430

Recycling Surveys Waste Wood Processing Plants

- Companies Reporting CY 2004 Activity:
  - Waste Wood Recyclers: 3
  - Total No. of Plants Included in the Survey Data: 4
- Range of Annual Capacity
  - Plants @ 1,000 TPY: 1 (Small)
  - Plants > 5,000 TPY: 3 (Med.-Large)

Throughput of Waste Wood Plants Returning the Survey

- Tons Processed (All): 148,000 TPY
- Size Range: 1,000 – 70,000
- Annual Throughput Reported:
  - Avg. Throughput (4-plants): 37,000 TPY
- Materials Recycled:
  - Avg. Recycled Quantity (All):36,500 TPY
  - Avg. Percent: 99.5%

Materials Reported as Recycled From Waste Wood Processing Plants

Material	Total Amount Recycled, TPY	Amount % Basis
Wood, Mulch, etc.	147,000	>99
All Other Marketed	1,000	<1
Total	**148,000**	100

Preliminary Estimate of C&D Using 1997 C&D Processing Plant Data

Facility Type	Est. No. of Plants in 1997	CMRA Survey Avg. Input, TPY	Est. of Annual C&D Waste Processed, Tons
Mixed C&D	224	110,500	25,000,000
Concrete Crushing, (Incl. Asphalt ,Brick and Block)	479	125,000 (adjusted for mobile and fixed)	60,000,000
Wood Waste Processing	360	30,000	11,000,000
Total	1,063	-	96,400,000

Estimate of Today's C&D Processed Using CMRA 2004 C&D Processing Plant Data

Facility Type	Est. No. of Plants in 2004	CMRA Survey Avg. Input, TPY	Est. of Annual C&D Waste Processed
Mixed C&D	250	110,500	28,000,000
Concrete Crushing, (Incl. Asphalt, Brick and Block)	1,300 units (700 Portable + 800 Fixed Units)	50,000 tpy (portable) + 150,000 tpy (fixed)	135,000,000
Wood Waste Processing	490	30,000	14,000,000
Total	2,200	-	197,000,000

Comment on 2004 Inerts Crushing Data…re: Asphalt Pavement

- Est. Baseline: 155 million Tons
- "Rough" Est. of Concrete vs. Asphalt:
  - Concrete 85-90% of total
  - Asphalt 10-15% of total
- Rough Estimate of Throughput:
  - Crushed Concrete: 130-140 million TPY
  - Crushed Asphalt: 15-25 million TPY
- Note: the above asphalt numbers do not include the highway millings and contractor's specific full –depth removal project work of which the "total" for these activities is estimated by the National Asphalt Pavement Association's (NAPA) to be an estimated 90 million TPY by their industry association, with greater than 80% or 72 TPY recycled.

AR0070431

But Is There Even More?

- 2500 Crushers x 70%= 1750
- 100 tons per hour
- 1600 hours per year
- Grand Total: 280,000,000 tons per year
- And that is only recycled, not generated

Thank You

September 24, 2005

1

Status of Survey Responses

- 555 NDA Members were sent the Survey
- 105 NDA Members in the USA returned their Survey (2 more from Canada)
- Almost 20% Level of Participation

2

Summary of Returned Surveys

- Re: inquiries about Company's decisions to Recycle
  - 100% of Surveys responded to at least part of the questions
  - Questions response & the GBB Rating:

Strongly Agree	= 1
Agree	= 2
Neutral	= 3
Disagree	= 4
Strongly Disagree	= 5

3

Company's Decision to Recycle

Average Rating of Survey Responses

What effects your Company Decisions	Avg. Rating
5a. Recycling Saves Money	1.8
5b. Recycling Improves Demo Company Image	1.8
5c. Recycling is Required by Law	3.0
5d. Recycling is Required by Contracts	3.2
5e. Readily available markets for C&D recyclables	2.9
5f. Employees willing to recycle C&D wastes once trained	2.2
5g. Subcontractors willing to recycle C&D once trained	2.6
5h. Established waste disposal practices can change w/o major difficulty to include C&D recycling	2.8
5i. C&D recyclables can be economically transported to recycling facilities	2.6

4

Methodology of GBB Allocation of Survey Data

- Example: Demo Generation Reported – 100 Tons per Year (TPY)
- Split of Work in CA – 90% = 90 Tons
- Split of Work in NM – 10% = 10 Tons

5

Summary of Members Survey Data

(Demo Generated in States > 400,000 TPY)

State (No. of Surveys)	Demo Generated (TPY)	% of Total, by State
CA (19)	4,578,251	29.0%
FL (7)	2,452,572	15.5%
TX (5)	1,506,304	9.5%
NJ (6)	1,340,453	8.5%
MN (5)	739,433	4.7%

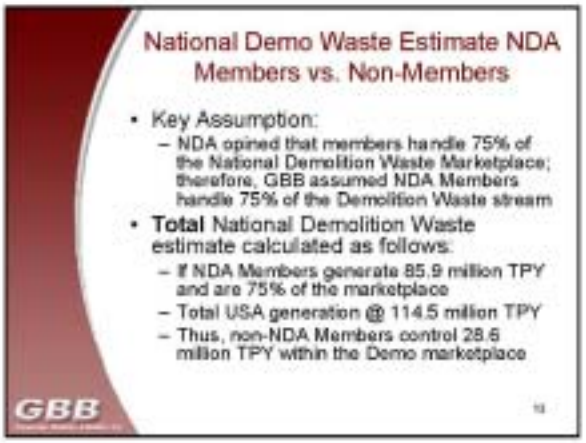
Est. Number of NDA Members, by Sales Range	Avg. Tons Generated, by Sales Range	Est. of TOTAL Demolition Waste, by Sales Range
222 (< $2 million)	48,083	10.7 million
139 (>$2mil <$5mil)	89,077	12.4 million
139 (>$5mil <$10mil)	200,843	27.9 million
55 (>$10 million)	634,412	34.9 million
Total		**85.9 million**

GBB

AR0070434



National Demo Waste Estimate NDA Members vs. Non-Members
• Key Assumption:
– NDA opined that members handle 75% of the National Demolition Waste Marketplace; therefore, GBB assumed NDA Members handle 75% of the Demolition Waste stream
• **Total** National Demolition Waste estimate calculated as follows:
– If NDA Members generate 85.9 million TPY and are 75% of the marketplace
– Total USA generation @ 114.5 million TPY
– Thus, non-NDA Members control 28.6 million TPY within the Demo marketplace

AR0070447

1. INTRODUCTION

As a society evolves technologically, the sources of noise grow in number and kind. Noise levels increase and the effects of noise on society become increasingly severe. Concomitantly, society continually requires more machinery, operating at higher speeds with greater power output. Aircraft, for example, have continued to grow in number and noise level, creating almost intolerable conditions for populations living, working, and playing in the vicinity of airports. Trucks and construction equipment require increasingly powerful engines to enable a single operator to move more goods, materials, or earth faster and more economically. The thunder of these engines not only degrades the quality of life in our communities but also causes the operators to incur substantial levels of permanent hearing loss. A profusion of appliances that provide the energy needed to do everything from brushing our teeth and cooling our houses, to washing our dishes, disposing of our garbage, and cutting our grass often generate noise levels that interfere with conversation and disturb neighbors. Even the wilderness, once a refuge from hectic urban life, is now disturbed by the noise of trail bikes, all-terrain vehicles, and snowmobiles.

Given that noise is a serious environmental problem, some appropriate questions one might ask in seeking a comprehensive noise-control objective are: Precisely what are the sources of noise pollution? How many people are exposed to these sources and how are they affected? What can be done to control the noise output of offending sources? This report attempts to answer these questions for the specific categories of construction, home appliances, and building equipment.

AR0070448

1.1 Source Characterization

The two principal objectives in characterizing sources are (1) evaluating noise levels in quantitative terms that may be used to determine the impact on people and (2) obtaining the information needed to assess the noise reduction that can be achieved. Relating measurable aspects of sound to human response is difficult at best. Such impact criteria as speech interference, sleep interruption, and annoyance depend not only on the physical nature of sound such as level, spectral content, and degree of fluctuation but also on the nonphysical aspects of noise such as the information content or implications of the sound. A rattling piece of equipment is often annoying not because of the noise level but primarily because it indicates a malfunction requiring attention.

Several attempts have been made to include various aspects of noise in a single number related to annoyance. Most of these methods try to account for the unequal sensitivity of the human hearing mechanisms to different frequencies and some try to account for fluctuations of level with time. A single number which accounts rather well for the human ear's relative insensitivity to low and very high frequency sound is the A-weighted scale. This weighting has been found to correlate about as well with annoyance as other indices [1]; it is quite widely accepted and can be read on a meter. In this report, we use A-weighting [dB(A)] to characterize noise insofar as impact evaluations are concerned.

Noise spectra are of far more use than single number ratings for assessing the contribution from various components to total noise levels. Pure tones associated with integer multiples of speeds of rotating machinery often appear as identifiable spectral peaks. Exhaust noise from an internal combustion engine

AR0070449

typically contributes the dominant low-frequency component, whereas engine structural radiation and turbocharger whine usually generate the high-frequency levels. Hence, where possible, we provide noise spectra in octave or one-third octave bands.

Once sources have been characterized, we evaluate the abatement potential associated with each. Our evaluation is based on a somewhat broad analysis of the component contributions and to a great extent on judgment developed from experience with similar sources. For example, prior work with internal combustion engines enables us to estimate the benefit achievable from state-of-the-art mufflers or engine enclosures. We estimate our predictions of achievable abatement potential to be within ±5 dB. A more accurate prediction of noise reduction would require detailed diagnosis of contributions from each source component and implementation of experimental noise-control treatment.

Because of the large number of sources evaluated (see Sec. 2), we place much detailed information (e.g., a number of noise spectra for sources whose impact is small) in Appendix A. Included in Appendix B is the background to the development of impact criteria and in Appendix D a discussion of existing standards.

1.2 Impact Evaluation

We evaluate the impact of noise on people, using two principal measures: intensity and extent. Clearly, it is important to know the levels to which a person may be exposed and the effects of this exposure. Thus, once the sources have been characterized and the relation of a listener to the source has been postulated, we estimate the physiological, psychological, and sociological effects of the noise. For example, permanent hearing damage is likely to occur for a significant percentage of the population

AR0070450

exposed to levels of 90 dB(A) for eight hours a day over an extended period of time. If the exposure time is short (e.g., 15 minutes a day), the noise may or may not contribute to hearing damage, but during exposure one cannot conduct an intelligible conversation. Exposure during evening hours to levels of noise that exceed approximately 70 dB(A) will usually lengthen the time one requires to go to sleep or will awaken someone who is already asleep - especially if the noise is intermittent and the background level is low.

The extent of noise impact is as important as the intensity in assessing the magnitude of noise pollution since this measure gives some perspective to the contribution from various sources. A truly comprehensive assessment would involve a detailed social survey with extensive noise measurements and statistically significant samples from every stratum of society. Such a program would no doubt cost millions of dollars and several calendar years. Clearly, this approach is not feasible in the three-month time period available for this study, nor would it represent an entirely justifiable allocation of resources. The goal of determining the impact of noise can be viewed only as an intermediate step to solving the actual problem: reducing the noise exposure of our population. Hence, an order-of-magnitude assessment of impact is probably an adequate guide to the development of a noise-abatement program. What matters, for example, is that approximately six million workers on night shifts and children under four cannot sleep because of construction noise. One's approach to construction-noise abatement would probably not be different if the figure were two million or ten million. We therefore provide this impact evaluation, not by social survey, but by estimating (1) the noise levels to which people are exposed, (2) the effects of noise on these people, and (3) the number of people

exposed. These estimates are based on measured values of equipment noise, data on human response to noise, statistics of equipment utilization, and statistics of population distributions. The impact of construction, appliances, and building equipment is discussed in Sec. 3.

1.3 Industry Assessment

To bring about control of environmental noise, the EPA must have information not only about the technology of abatement but also about the nature of the industry it may be called upon to influence. An understanding of the pressures for and against noise control is helpful in assessing the extent to which an industry is likely to institute noise control measures on its own and how the industry will be affected if it is compelled to produce quieter products. For example, the principal impact of construction noise, other than hearing-damage risk to operators (who have been unexpectedly vocal about their plight), is on the community rather than the purchaser. The community has been able to exert very little influence on the purchaser or the manufacturer, the result being that very little has been accomplished in quieting construction equipment. For example, diesel-powered equipment is sometimes advertised and sold without even mufflers. A small number of companies, however, have begun to produce quiet equipment; they attribute their recent success in the marketplace to certain local noise legislation and to the threat of such regulations spreading to other communities.

An example of the efforts that noise regulations may have on business comes from the home appliance industry. An air-conditioner manufacturer has indicated that certain marketplace pressures inhibit him from implementing additional noise control in bottom-of-the-line items. He argues that more noise control

AR0070452

would increase the price of an item, thereby harming his competitive position. If all manufacturers were required to make their products quieter (and therefore more costly), one could argue that a segment of the population at lower income levels could no longer afford air-conditioners and would be deprived of that comfort.

By interviewing manufacturers of construction equipment, home appliances, and building equipment, we obtained their views of the relevance of noise control to their business. We found a substantial difference between the attitudes of people who manufacture construction equipment and those who manufacture appliances. The former, who find practically no marketplace demand for quiet equipment, are faced with the prospect of a mélange of state and city ordinances; they almost welcome "reasonable" federal standards. The latter find an increasing marketplace demand for quiet appliances and prefer not to see the implementation of federal standards or labeling requirements. Chapter 4 of this report contains an analysis of the pressures on industry to reduce (or not to reduce) noise levels, its response to these pressures, its present achievements, and its potential.

AR0070453

2. SOURCE CHARACTERIZATION

2.1 Construction Equipment and Operation

Construction has become a major noise problem in many cities and towns. The trend toward urban renewal and more high-rise structures has created an almost perpetual din on city streets. Equipment associated with construction projects is more numerous, and the time span for construction at a given site has lengthened. Residents very near a construction site may well plan on two years of intolerable noise levels as a high-rise structure is being built.

In this section, we consider the construction noise problem as it relates to residential and nonresidential buildings, city streets, and public works, because these kinds of project usually take place in areas where the number of people likely to be exposed is very high. Heavy construction, such as highways and civil works, has been omitted from our study because the vast bulk of this activity occurs in thinly populated areas where the noise affects very few people. We view construction as a process that can be categorized according to type and that consists of separate and distinct phases.

2.1.1 The construction process

The basic unit of construction activity is the construction site, which exists in both space and time. The temporal dimension consists of various sequential phases which change the character of the site's noise output as work progresses. These phases are discussed further below. In the case of building construction, the spatial character of the site is self-evident; in the case of sewers and roads, the extent of a site is taken, for reasons explained in Sec. 3.2, to be one standard city block or

AR0070454

about 1/8 of a mile. (That is, if a city reports 40 miles of sewer construction, we consider that project as consisting of 320 separate sites.)

Construction sites are typically classified in the fifteen categories in which construction data is reported by the U.S. Bureau of Census and various state and municipal bodies. The categories are:

- Residential buildings:
  - one- to four-family
  - Five-family and larger
- Nonresidential buildings:
  - Office, bank, professional
  - Hotel, motel, etc.
  - Hospitals and other institutions
  - Schools
  - Public works buildings
  - Industrial
  - Parking garages
  - Religious
  - Recreational
  - Store, mercantile
  - Service, repair station
- Municipal streets
- Public works (e.g., sewers, water mains).

For purposes of allocating construction effort among the different types of sites, it is possible to group the nonresidential sites into four larger categories which are differentiated by the cost of the average building in each category, as well as by the distribution of effort among the various construction

AR0070455

phases. These four groups, in order of decreasing average cost per building, are:

- Office buildings, hospitals, hotels
- Schools, public works buildings
- Industrial buildings, parking garages
- Stores, service stations, recreational buildings, and religious buildings.

Construction is carried out in several reasonably discrete steps, each of which has its own mix of equipment and consequently its own noise characteristics. The phases (some of which can be subdivided) are:

- *Building Construction*
  1. a. Clearing
     b. Demolition
     c. Site preparation
  2. Excavation
  3. Placing foundations
  4. a. Frame erection
     b. Floors and roof
     c. Skin and windows
  5. a. Finishing
     b. Cleanup
- *City Streets*
  1. Clearing
  2. Removing old roadbed
  3. Reconditioning old roadbed
  4. Laying new subbase, paving
  5. Finishing and cleanup

AR0070456

- *Public Works*
  1. Clearing
  2. Excavation
  3. Compacting trench floor
  4. Pipe installation, filling trench
  5. Finishing and cleanup.

Defining the construction phases as above allows us to account for the variation in site noise output with time. By inventorying the equipment which is to be found at each site in each phase, we can derive a representative source level for each phase by the process described below.

2.1.2 Equipment noise characteristics

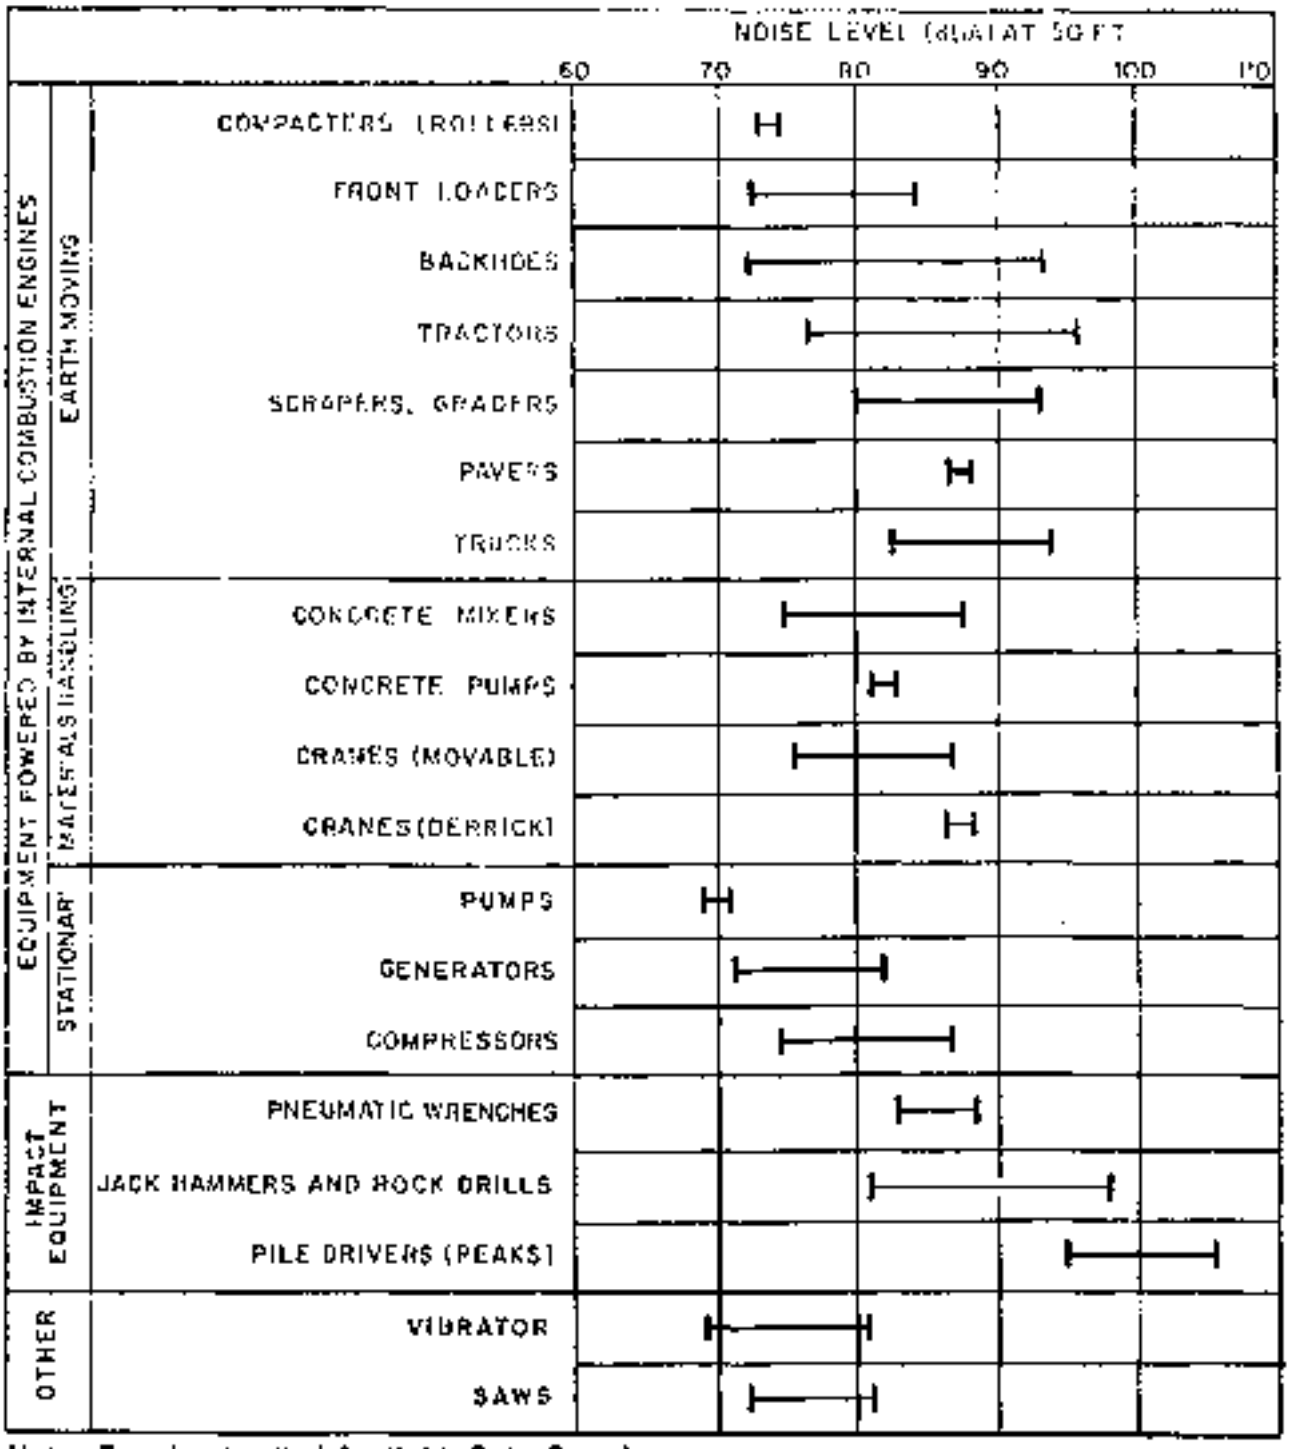
Despite the variety in type and size of construction equipment, similarities in the dominant noise sources and in patterns of operation permit one to assign all equipment to a very limited number of categories. These categories are described below and are indicated in Fig. 1, together with corresponding noise level data. Corresponding spectra and the sources of this data are given in Appendix A.

Equipment Powered by Internal Combustion Engines

The most prevalent noise source in construction equipment is the prime mover, i.e., the internal combustion engine (usually of the diesel type) used to provide motive and/or operating power. Engine-powered equipment may be categorized according to its mobility and operating characteristics, as (1) earthmoving equipment (highly mobile), (2) handling equipment (partly mobile), and (3) stationary equipment.

Earthmoving equipment includes excavating machinery (backhoes, bulldozers, shovels, front loaders, etc.) and highway

AR0070457



Note: Based on Limited Available Data Samples

FIG. 1. CONSTRUCTION EQUIPMENT NOISE RANGES.

AR0070458

building equipment (compactors, scrapers, graders, pavers, etc.). Internal combustion engines are used for propulsion (either on wheels or tracks) and for powering working mechanisms (buckets, arms, trenchers, etc.). Engine power varies from about 50 hp to over 600 hp. Engine noise typically predominates, with exhaust noise usually being most significant and with inlet noise and structural noise being of secondary importance. Other sources of noise in this equipment include the mechanical and hydraulic transmission and actuation systems, and cooling fans (often very significant). Typical operating cycles may involve one or two minutes of full-power operation, followed by three or four minutes at lower power.

Noise levels at 50 ft from earthmoving equipment range from about 73 to 96 dB(A). The greatest and most direct potential for noise abatement here lies in quieting the engine by use of improved mufflers.

Engine-powered materials-handling equipment such as cranes, derricks, concrete mixers, and concrete pumps, is used in a more-or-less fixed location; mobility of this equipment over the ground is not part of its major work cycle. Although noise from the working process (such as the clanking of aggregate in the concrete mixing bin) often is the most "identifiable" noise component, the dominant source of noise generally is the prime mover. Noise levels at 50 ft range from about 75 to 90 dB(A). The greatest potential abatement for noise again lies in engine quieting, with treatment of power transmission and working mechanisms being of secondary importance.

Stationary equipment, such as pumps, electric power generators and air compressors, generally runs continuously at relatively constant power and speed. Noise levels at 50 ft range

AR0070459

from about 70 to 80 dB(A), with pumps typically at the low end of this range. Stationary equipment, because of its fixed location and constant speed and/or load operation, may be quieted more easily than mobile equipment; engine mufflers can be more effective, and use of enclosures becomes feasible. [In fact, noise from some air compressors, has already been reduced by about 10 dB(A) by use of appropriate enclosures.]

The greatest near-term abatement potential for all current equipment powered by internal combustion engines lies in the use of better exhaust mufflers, intake silencers, and engine enclosures (in conjunction with appropriate cooling system and fan design). Reductions of 5 to 10 dB(A) appear to be achievable, usually without great difficulty. Practical long-term abatement [of about 15 to 20 dB(A)] can probably be achieved by basic engine design changes. Of course, replacement of the internal combustion engine by a quieter prime mover, such as a gas turbine or electric motor, would eliminate the reciprocating-engine noise source altogether.

Impact Equipment and Tools

Conventional pile drivers are either steam-powered or diesel-powered; in both types, the impact of the hammer dropping onto the pile is the dominant noise component. With steam drivers, noise is also generated by the power supply (a boiler) and the release of steam at the head; with diesel drivers, noise is also generated by the combustion explosion that actuates the hammer. Noise levels are difficult to measure or standardize, because they are affected by pile type and length, but peak levels tend to be about 100 dB(A) (or higher) at 50 ft.

AR0070460

Impact-noise is absent in the so-called "sonic" (or vibratory) pile drivers. These do not use a drop hammer, but vibrate the pile at resonance. The noise associated with pile vibrations typically occurs around 150 Hz and is barely audible. The power source, which generally consists of two gasoline engines, is the primary noise source.

Abatement can be accomplished best by substituting use of a sonic pile driver for an impact machine where possible. (Unfortunately, sonic pile drivers are useful only for some soils.) Impact noise reduction at the source generally is very difficult. Substitution of nonimpact tools offers the best practical abatement potential; otherwise, reductions of perhaps 5 dB(A) may be obtained by use of enclosures.

Most impact tools, such as jack hammers, pavement breakers, and rock drills are pneumatically powered, but there are also hydraulic and electric models. The dominant sources of noise in pneumatic tools are the high-pressure exhaust and the impact of the tool bit against the work. Noise levels at 50 ft typically range from 80 to 97 dB(A).

An exhaust muffler on the compressed air exhaust can lower noise levels from the exhaust by up to about 10 dB(A). Pneumatic exhaust noise, of course, is absent in hydraulic or electric impact tools. Reduction of the impact noise from within a tool can be accomplished by means of an external jacket, which can contribute perhaps a 5 dB(A) reduction. Reduction of the noise due to impact between the tool and material being worked upon generally is difficult and requires acoustic barriers enclosing the work area and its immediate vicinity. Depending on the impacted structures, such barriers may reduce noise by 3 to 10 dB(A).

AR0070461

Small hand-held pneumatic tools, such as pneumatic wrenches, generate noise of levels between 84 and 88 dB(A) at 50 ft. The exhaust and the impact are the dominant noise sources. Because of the obvious weight and size limitations to which hand tools are subject, only small and light mufflers can be used with them, limiting the achievable noise reduction to 5 dB(A) at best. The best practical means for reducing the noise from impact tools consists of using other types of tools to accomplish the same functions.

2.1.3 Site noise characteristics

To characterize the noisiness — i.e., the average noise annoyance potential — of the various types of construction sites during each phase of construction, a Noise Pollution Level (NPL) was calculated for each type of site and each construction phase. The NPL used here was taken as the same measure that was used for similar evaluation of traffic noise [2]. The NPL (in dB) is defined as the sum of the A-weighted average sound pressure level and 2.56 times the standard deviation of the A-weighted sound pressure level*; thus, NPL accounts for the effect of steady noise, plus the annoyance due to fluctuations.

Although a thorough study relating NPL to subjective descriptors of annoyance (e.g., acceptable, unacceptable) has not been accomplished, a provisional interpretation of NPL in such terms can be suggested. On the basis of an evaluation of domestic and

*A-weighting refers to a standard weighting of the various frequency components, approximating the behavior of human hearing. The average sound pressure level is computed on the basis of the time-average root-mean-square sound pressure, whereas the standard deviation is calculated from the time-variation of the dB(A) values.

AR0070462

Foreign social surveys and psycho-acoustic studies, the Department of Housing and Urban Development has adopted a set of "guideline criteria" [3] for outdoor noise levels in residential areas as shown in Fig. 2 [4]. According to this chart, the community noise situation is evaluated by comparing a measured distribution of A-weighted levels with the criteria curves. The situation is categorized by the region of least desirability penetrated by the actual noise distribution. Since this criterian is based on level distributions, the boundaries between regions of acceptability may be defined in terms of the NPL. Thus, the following descriptors of NPL values may be used in interpreting the site noise NPL levels used in the remainder of this report.

Clearly Acceptable: The noise exposure is such that both the indoor and outdoor environments are pleasant.	NPL less than 62 dB
Normally Acceptable: The noise exposure is great enough to be of some concern but common building constructions will make the indoor environment acceptable, even for sleeping quarters, and the outdoor environment will be reasonably pleasant for recreation and play.	NPL between 62 and 74 dB
Normally Unacceptable: The noise exposure is significantly more severe so that unusual and costly building constructions are necessary to ensure some tranquility indoors, and barriers must be erected between the site and prominent noise sources to make the outdoor environment tolerable.	NPL between 74 and 88 dB
Clearly Unacceptable: The noise exposure at the site is so severe that the construction costs to make the indoor environment acceptable would be prohibitive and the outdoor environment would still be intolerable.	NPL greater than 88 dB

AR0070463

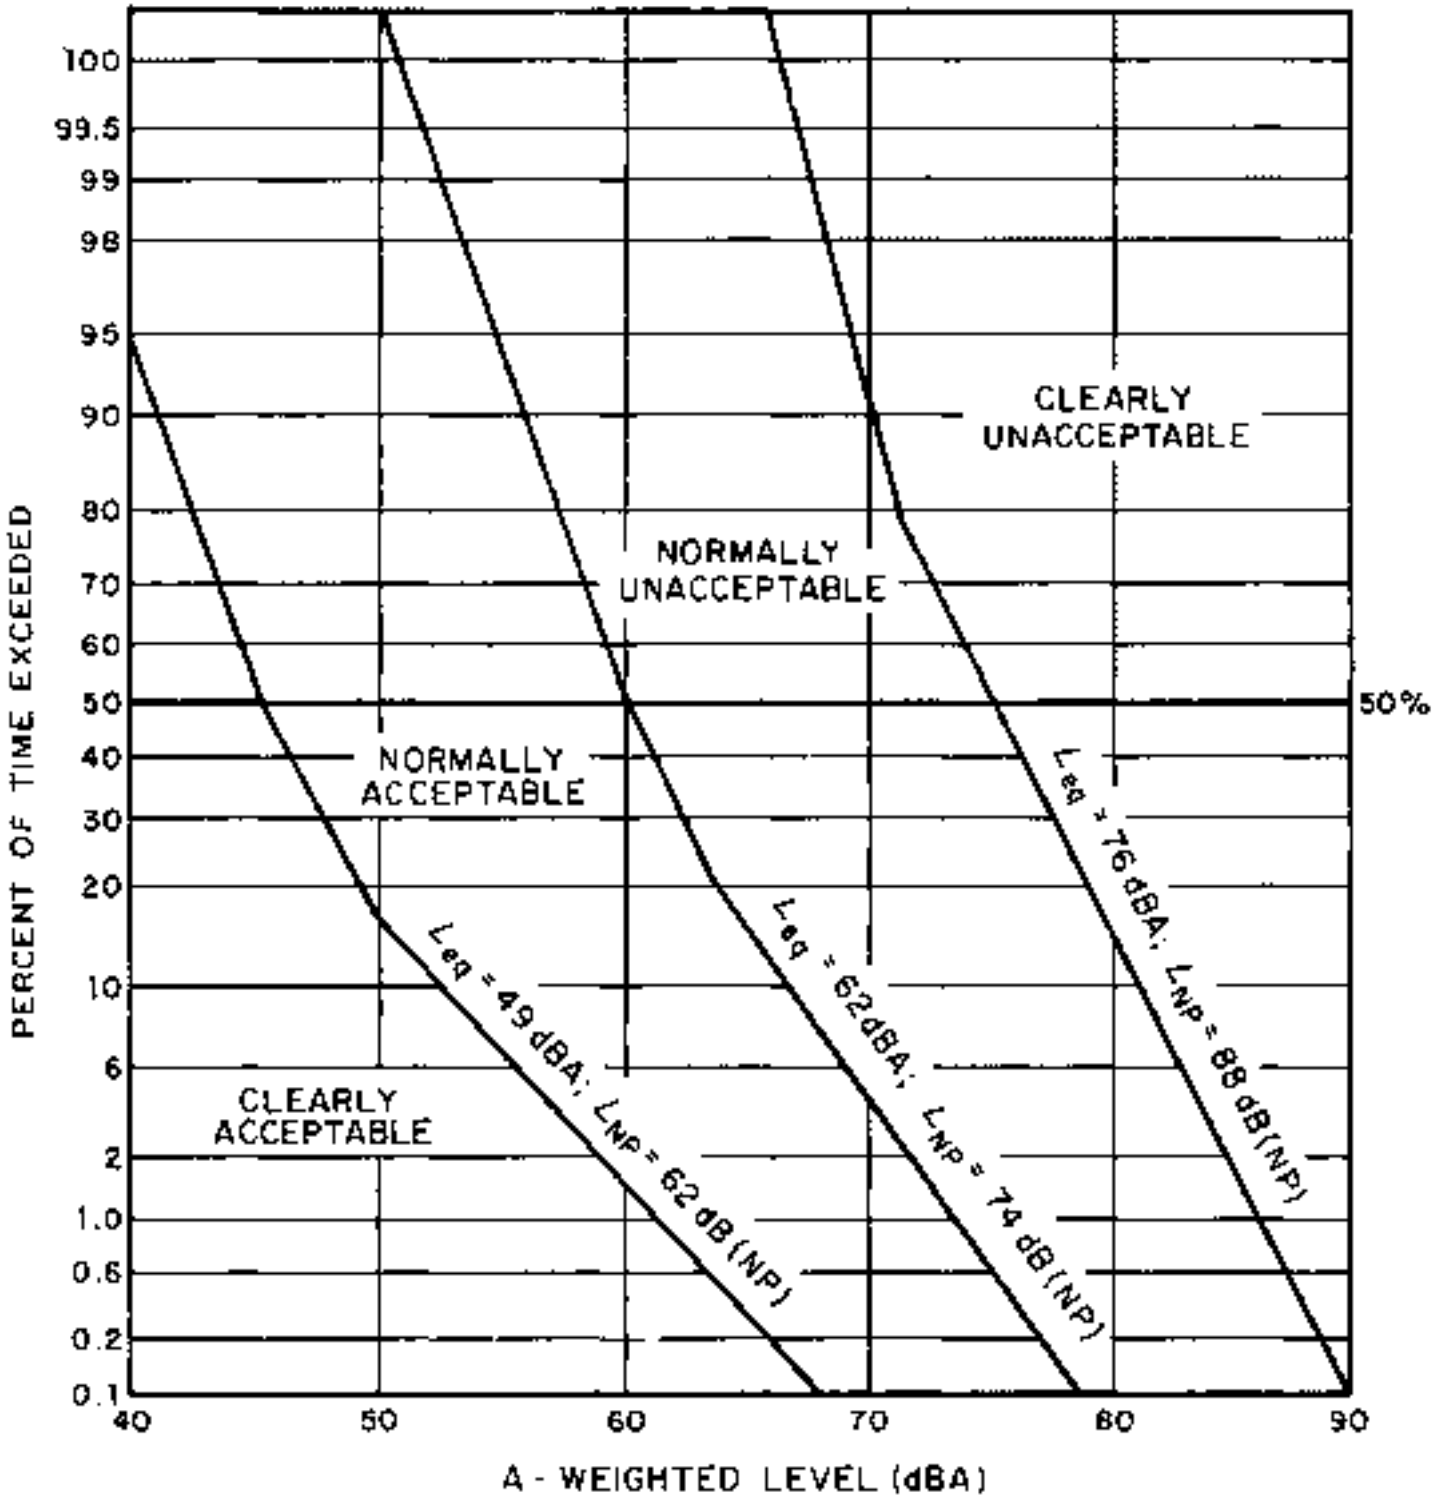


FIG. 2 PROVISIONAL CRITERIA RELATING NPL TO COMMUNITY NOISE ACCEPTABILITY

We must emphasize that these criteria have not been officially or unofficially adopted by HUD or any other government agency. They are presented here solely to enable the reader to interpret NPL values computed in this report.

The aforementioned averages of noise annoyance potential were calculated on the basis of information obtained on (1) the number of each item of equipment typically present at a site (in a given phase), (2) the length of the duty cycles of this equipment, and (3) the average noise levels during operation. For purposes of site characterization, the noisiest piece of equipment was assumed to be located at 50 ft from an observer, and all other equipment was assumed to be located at 200 ft from the observer; ambient noise, of levels depending on the surroundings of the site, was taken to be present in addition to the equipment noise. (Note that pile driver noise was not included in the NPL calculations, because its repetitive impact character makes its intrusion characteristics different from the more continuous noises for which the NPL concept was developed.) Clearly, this construction noise model is not entirely realistic; however, it may be expected to fulfill its intended purposes — that of yielding at least a relative measure of the noise annoyance associated with each type of site and phase for the most adverse conditions likely to be associated with each phase.

Table 1 shows NPLs calculated for each of five phases for each of four types of construction. For residential housing and public works construction, two NPL values are given in the table; one pertains to a noisy [70 dB(A)] background characteristic of urban conditions, the other to relatively quiet [50 dB(A)] ambient conditions found in suburban environments. As one may expect, the values indicated in the table reflect the fact that a given intruding noise is more annoying if it occurs in a quieter environment.

II – Minimum required equipment present at site.

AR0070467

The NPL values shown in Table I obviously depend on the previously described model of site noise. For this model, the average sound pressure level depends strongly on the one or two noisiest pieces of equipment, whereas the standard deviation depends largely on the numbers and duty cycles of the less noisy equipment and on the ambient noise level.

As evident from Table I, in building construction, the initial ground clearing and excavation phases tend to be the noisiest, the subsequent foundation and erection phases tend to be somewhat less noisy, and the final finishing phase again tends to be relatively noisy. In public works construction, on the other hand, NPLs are more nearly the same for all phases, except that the erection phase tends to be less noisy.

Table II lists the two noisiest types of equipment for each site type and phase, together with the average A-weighted noise levels (at 50 ft) for this equipment. Inspection of this table indicates that rock drills, which typically are the noisiest equipment, are prevalent in the excavation and finishing phases; trucks, on the other hand, are somewhat less noisy than rock drills or similar equipment but are present in nearly all phases.

Effect of Equipment Quieting

To assess the effect of some quieting strategies on the previously described site noise model, we recalculated the NPL for three "strategies" for each type of site and each phase:

Strategy 1:

- Only the noisiest piece of equipment being quieted by 10 dB(A), with this equipment remaining at the previously specified 50 ft distance from the observer.

AR0070468

TABLE II. NOISIEST EQUIPMENT TYPES OPERATING AT CONSTRUCTION SITES*

Construction Phase	Construction Type: Domestic Housing	Office Bldgs.	Industrial	Public Works
Ground Clearing	Truck (91)	Truck (91)	Truck (91)	Truck (91)
	Bulldozer (88)	Bulldozer (88)	Bulldozer (88)	Bulldozer (88)
Excavation	Rock Drill (98)	Rock Drill (98)	Rock Drill (98)	Rock Drill (98)
	Truck (91)	Truck (91)	Truck (91)	Truck (91)
Foundations	Concrete Mixer (85)	Jack Hammer (88)	Jack Hammer (88)	Truck (91)
	Pneumatic Tools (85)	Concrete Mixer (85)	Concrete Mixer (85)	Scraper (88)
Erection	Concrete Mixer (85)	Derrick Crane (88)	Derrick Crane (88)	Paver (89)
	Pneumatic Tools (85)	Jack Hammer (88)	Jack Hammer (88)	Bulldozer (88)
Finishing	Rock Drill (98)	Rock Drill (98)	Rock Drill (98)	Truck (91)
	Truck (91)	Truck (91)	Truck (91)	Paver (89)

*Numbers in parentheses represent typical dB(A) levels at 50 ft. See Table I for definition of construction types.

AR0070469

Strategy 2:

- Only the noisiest piece of equipment being quieted by 10 dB(A), with this equipment moved to 200 ft and with the next noisiest equipment (unquieted) moved to 50 ft from the observer position

Strategy A:

- All items of equipment quieted by 10 dB(A).

The results of these calculations are shown in Table III, together with the NPL values previously obtained without any quieting (Strategy 0). It appears that quieting only the noisiest piece of equipment generally reduces the site NPL relatively little, if other types of equipment can also operate near the observer (compare Strategies 0 and 2). On the other hand, quieting the noisiest equipment and letting no others operate near the observer may result in significant reductions (compare Strategies 0 and 1). Of course, quieting all equipment (Strategy A) results in the lowest NPL values; however, these values are often only slightly lower than those obtained by quieting only the noisiest item (Strategy 1).

The site noise model used here initially assumes the noisiest equipment to be located nearest the observer. It can happen that quieting the noisiest equipment, moving it away from the observer, and moving the second noisiest equipment near the observer (Strategy 2) results in an *increase* in the NPL, if the second noisiest equipment is used more frequently than the noisiest. This peculiarity of the noise model, where equipment quieting seemingly increases the noise, is evident at several places in Table III.

AR0070470

TABLE III. NOISE POLLUTION LEVELS IN dB(A) OF CONSTRUCTION SITES, VARIOUS EQUIPMENT QUIETING STRATEGIES*

* See text for site noise model; see Table I for construction type and ambient noise definitions.

** 0 — No quieting

1 — Noisiest equipment, at 50 ft from observer, quieted by 10 dB(A).

2 — Noisiest equipment quieted by 10 dB(A) and moved to 200 ft from observer; second-noisiest equipment (not quieted) moved to 50 ft from observer.

A — All equipment quieted by 10 dB(A).

AR0070471

Other Means for Site Noise Control

The NPL generated by a construction site also may be reduced by means other than quieting the equipment:

- Replacement of individual operations and techniques by less noisy ones — e.g., using welding instead of riveting, mixing concrete offsite instead of onsite, and employing prefabricated structures instead of assembling them on site.
- Selecting the quietest of alternate items of equipment — e.g., electric instead of diesel-powered equipment, hydraulic tools instead of pneumatic impact tools.
- Scheduling of equipment operations to keep average levels low, to have noisiest operations coincide with times of highest ambient levels, and to keep noise levels relatively uniform in time; also, turning off idling equipment.
- Keeping noisy equipment as far as possible from site boundaries.
- Providing enclosures for stationary items of equipment and barriers around particularly noisy areas on the site or around the entire site.

Equipment Noise Reduction Potential

Table IV lists the present average noise levels in dB(A) for the various types of construction equipment discussed previously; also listed are the noise levels expected to be achievable in a relatively short time, with limited cost and performance penalties. In addition, the table shows the most significant noise sources for each type of equipment and assigns a numerical "usage" factor to each item, on the basis of which one can assess the significance of quieting of the various individual items. From

AR0070473

this table, one may determine that control of engine noise, and particularly of engine exhaust noise, will affect many items of equipment with high usage factors and thus should be given high priority.

Table V presents a brief listing of the noise control techniques applicable to the sources indicated in Table IV, together with an estimate of the noise reductions that may readily be achieved by means of these techniques.

2.2 Home Appliances

The use of convenient and sometimes necessary appliances constitutes a growing noise problem within the home. Almost without exception, appliances could be significantly quieter. However, manufacturers offer three primary arguments for opposing quieter redesign; they believe

- that the public associates the noise generated by a device with its power;
- that quieter appliances would be marketed at a price disadvantage and since the public has not objected to noise, that the public, in general, is satisfied;
- that since appliances are generally controlled by the operator, the option, as with air conditioners, "to have quiet or to be cool" is "option enough".

Yet, in keeping with the public's growing awareness of noise, many appliances are advertised as being "noiseless", "quiet", "vibration-free".

Although many manufacturers have made detailed acoustic measurements of the noise output of their appliances, very little data has been reported in the open literature. Some of the

AR0070475

literature (especially "nonacoustic" reporting) presents insufficient information to enable utilization of the reported measurements in this study. For example, in one report [8], the noise levels are described as being "recorded at operator's or housewife's normal ear distance"; for those appliances not requiring continual operation, the distance from the exposed person to the appliance is not specified. In other examples drawn from newspapers, trade journals, and magazines measurements are not qualified as to distance from the source, type of instrumentation, and weighting network (if any) that was used. In the following sections, only the literature found to be well-documented and considered accurate will be used in appropriate discussions.

2.2.1 Measurements

Because of the scarcity of reliable data, we measured the noise from thirty types of home appliances and eleven types of home shop tools. Sound levels were measured in dB(A) at a distance of 3 ft from the appliance and a height of 5 ft; this measurement position approximates the location of the operator's ear for those appliances requiring an operator. For those appliances not requiring an operator, this position represents noise levels in the vicinity of the appliance. Noise levels in the reverberant field of the room in which the appliance is being operated may be on the order of 2 to 3 dB(A) less than the measurement at 3 ft.

Noise levels in adjacent rooms with the interconnecting door open may be as much as 10 dB(A) less than the levels at 3 ft or as much as several dB(A) greater than the 3 ft levels, depending upon the details of the installation. For the appliances that are used near the ear (e.g., an electric-shaver), the noise level at the ear may be as much as 10 dB(A) greater than the 3 ft mea-

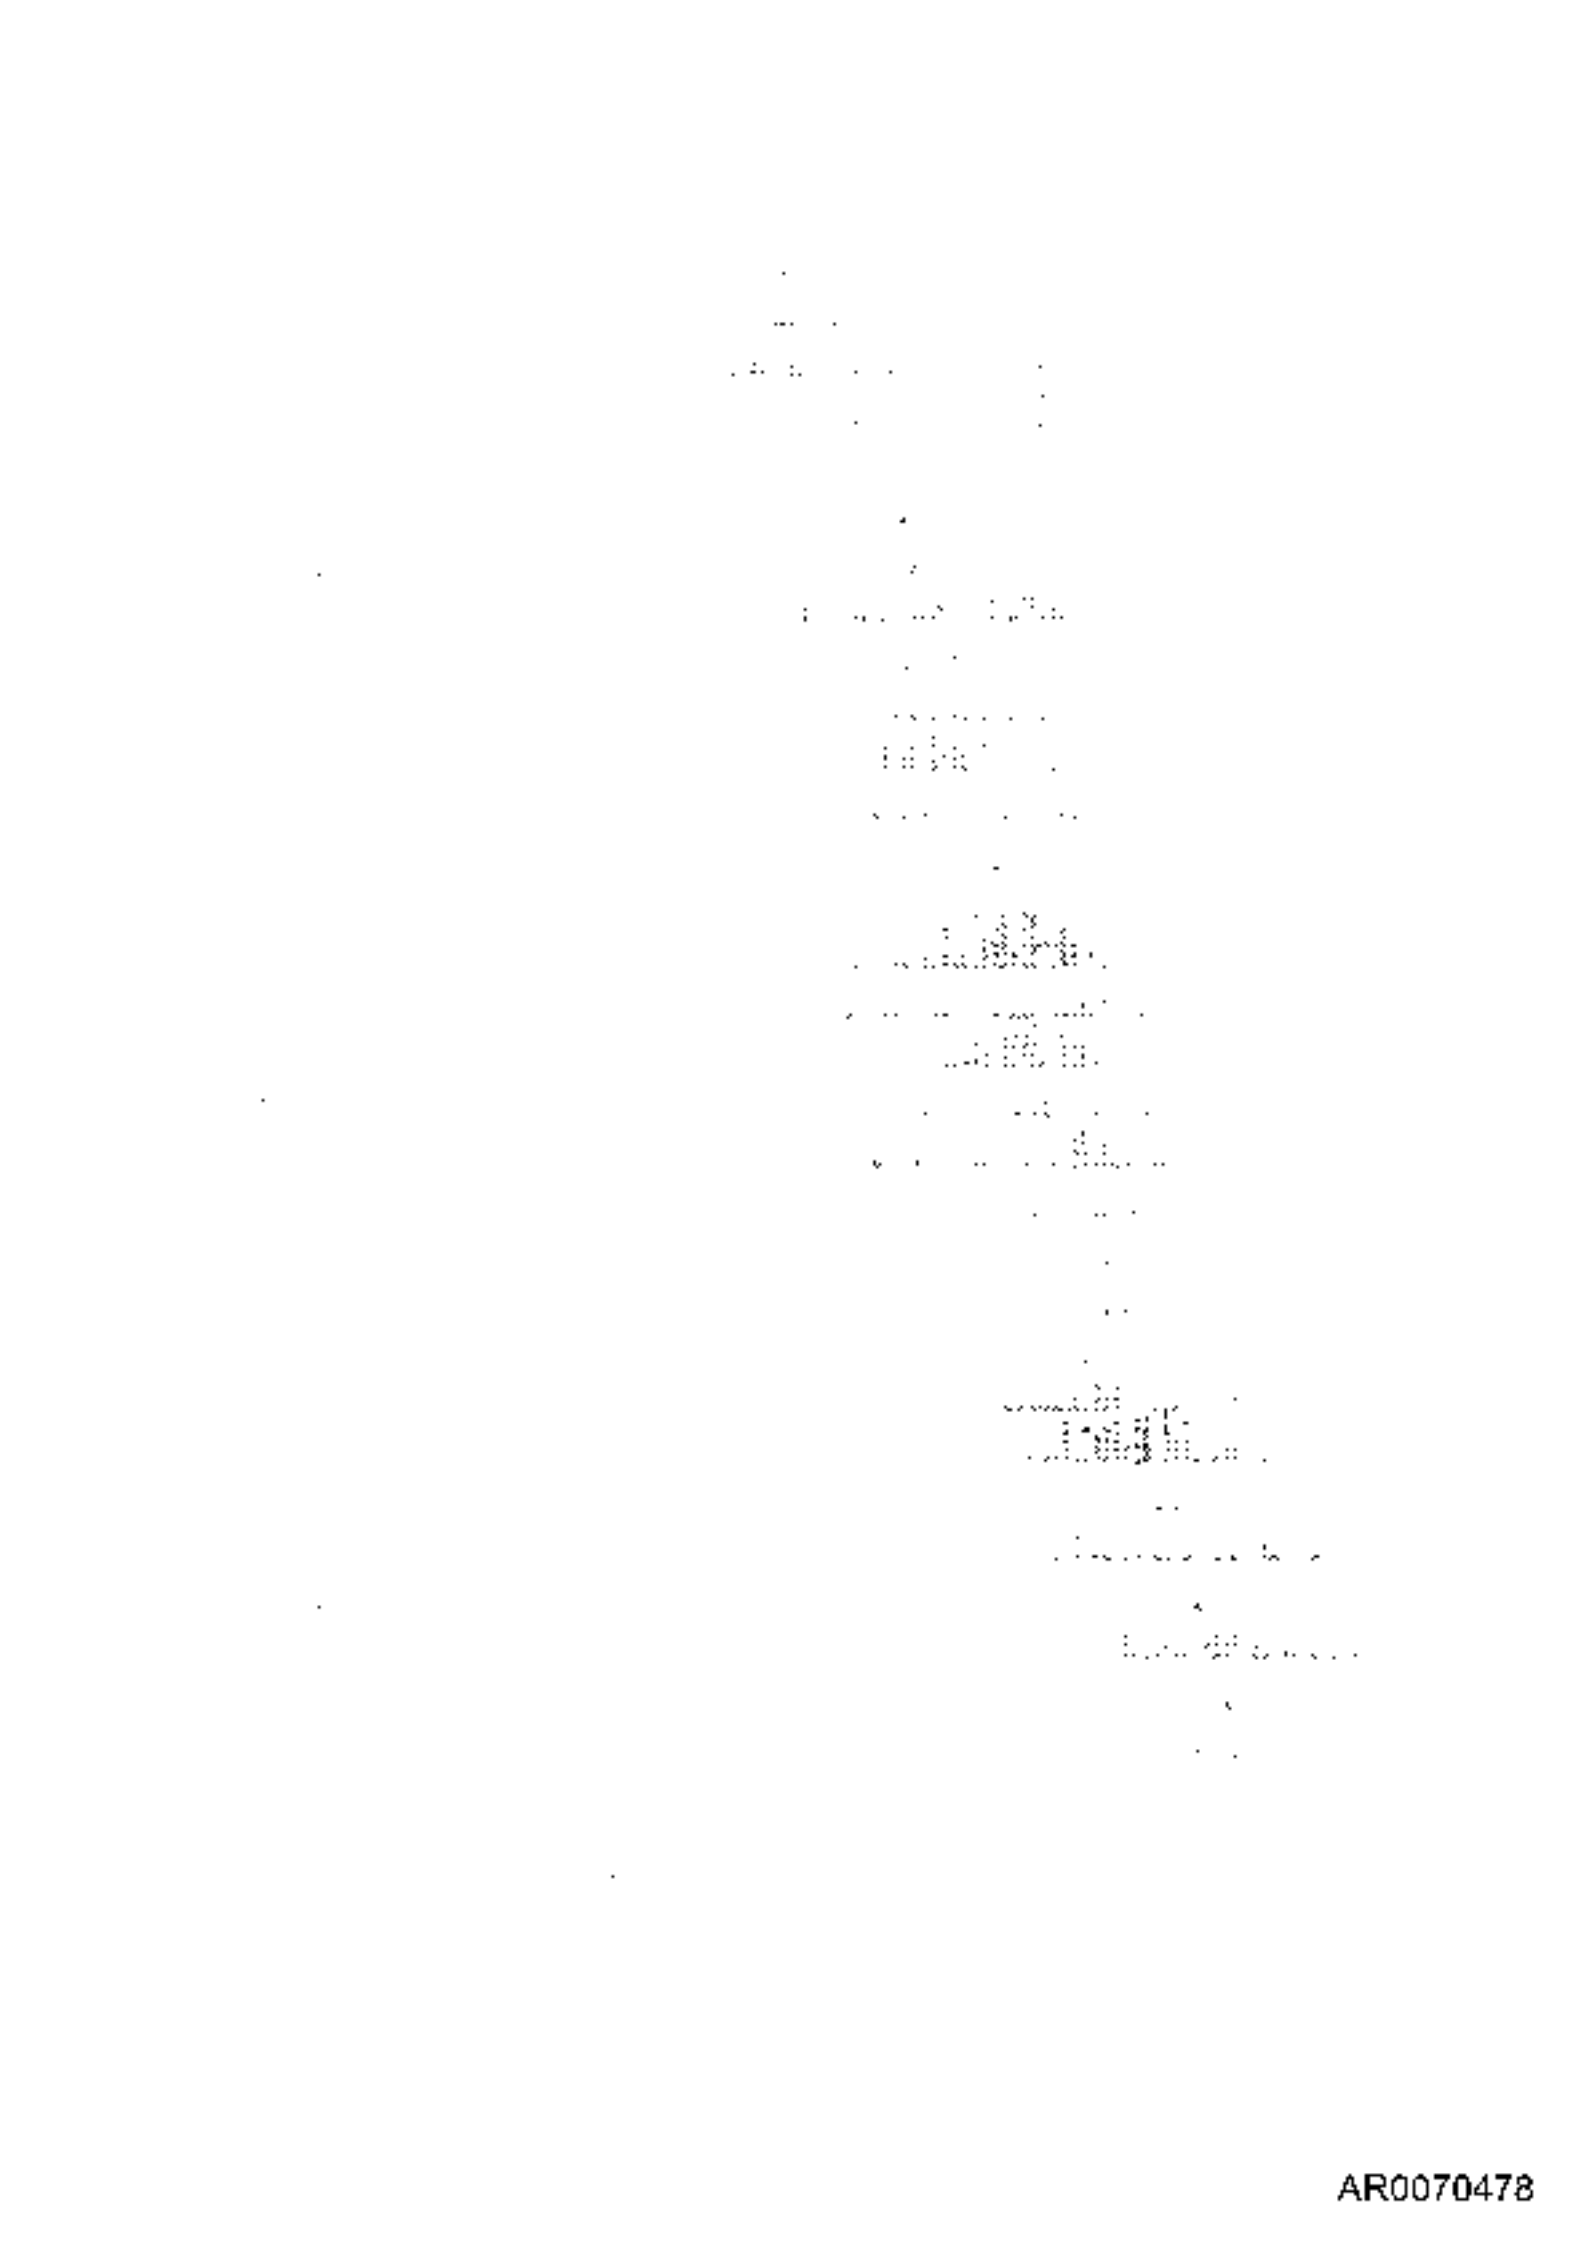
AR0070476

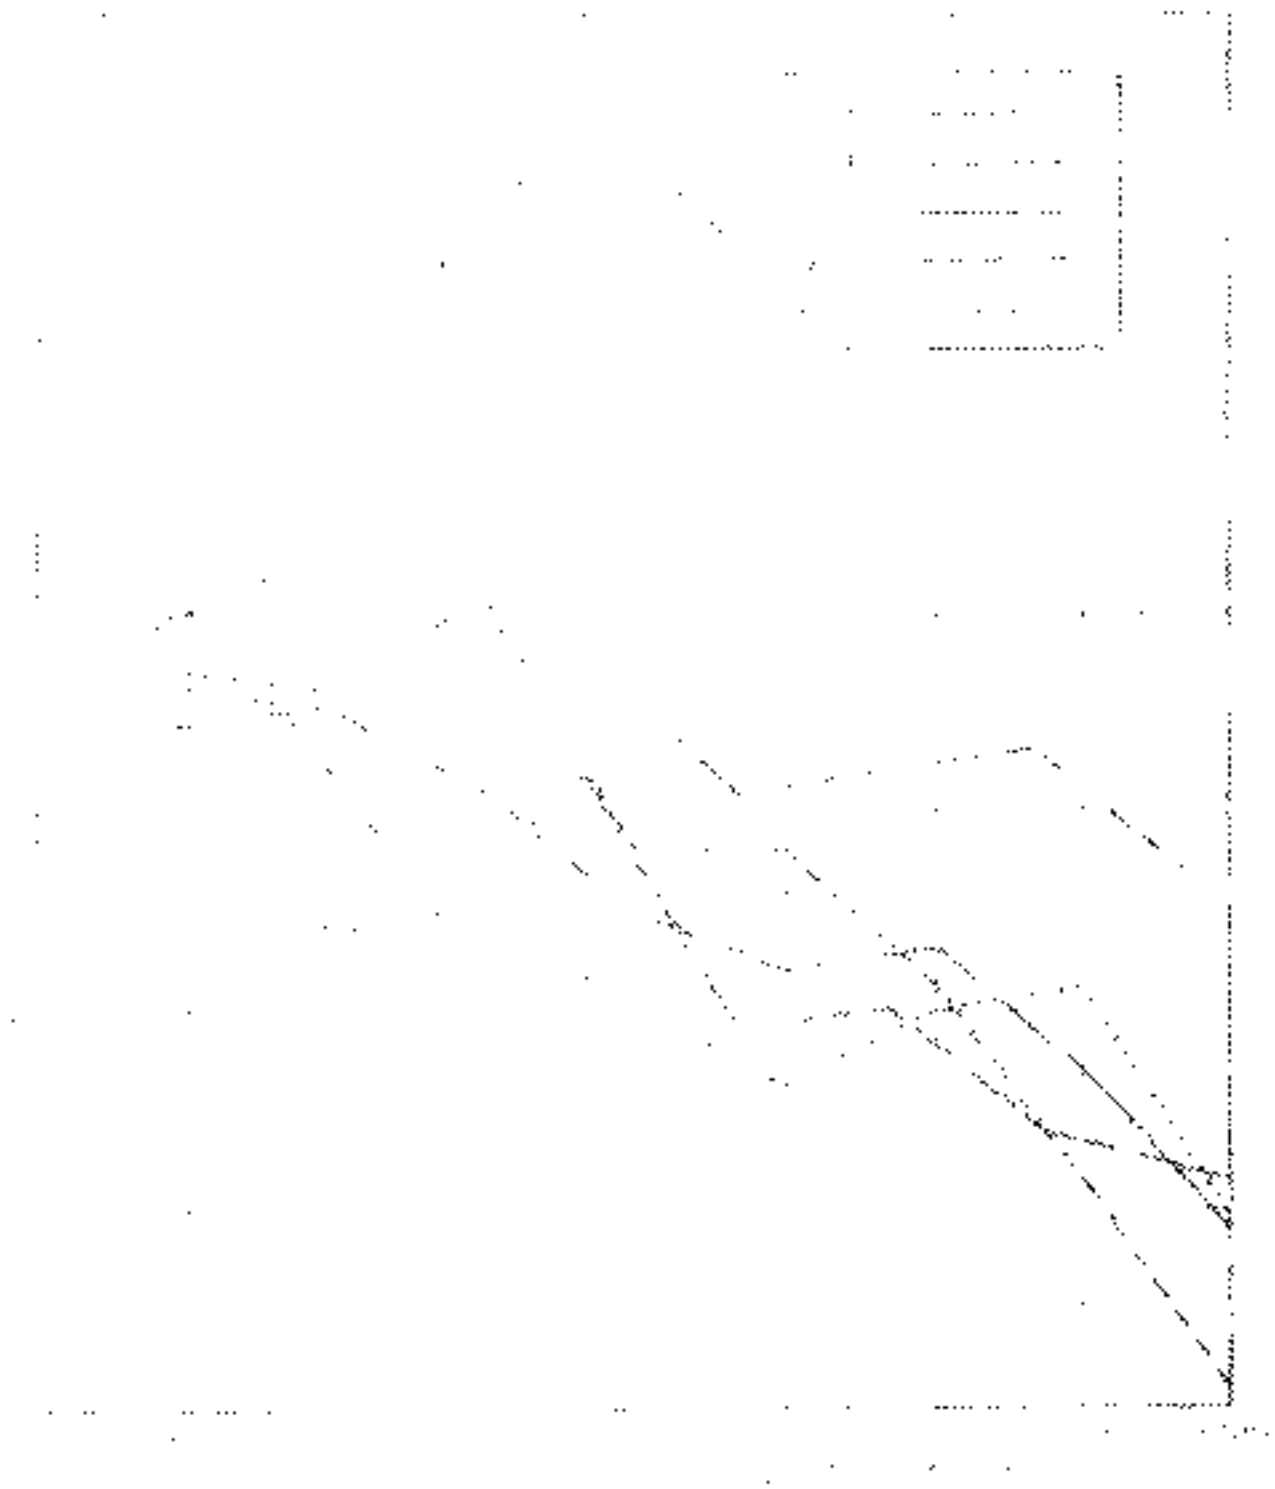
[illegible]. Figure 3 summarizes the noise measurements made by [illegible] and some of those reported in the literature. Each point represents a single measurement. Several measurements are given for a single appliance that operates in different modes. The solid circles represent noise levels generated by American manufacturers; foreign brands are represented by the squares. Problems arise in evaluating this data because the appliances were manufactured in different years by different companies, were sold with the [illegible] offered by the manufacturers, and may be [illegible] different features. For example, a recently built refrigerator may be frost-free and may have special devices such as [illegible] heaters; therefore it may generate more noise than earlier refrigerators. Figure 4 presents octave band spectra for refrigerators that were manufactured through 1968 [6] and in 1965, 1967, and 1970 [7]. Noise generated by this sample of refrigerators demonstrates the problem of data comparison: the unit that was old in 1968 was the noisiest, while the 1970 unit was second quietest. The quietest refrigerator is the 1965 model. However, there is considerable difference between the physical size of the units, and the newer models incorporate such features automatic defrost, ice-cube maker, water dispenser, and humidified compartment.

2.2.2 Noise abatement potential

The thirty appliances and eleven shop tools surveyed exhibited no apparent acoustical problems that could not be abated through the diligent application of noise control technology. Achieving a cost-effective solution that can be incorporated into the design of an appliance is more difficult but still possible. Standard noise control techniques are readily available; wrapping, damping, flexible connections, vibration isolation, better

AR0070477





balance, and smoother mechanical connections. Since many appliances have similar mechanisms, noise control techniques used on one appliance can often be applied to another.

After reviewing the operating characteristics and mechanical properties of appliances, we ranked the noise sources in order of their contribution to the total noise generated by an appliance (see Table VI). Definitive measurements are not available to enable a quantitative breakdown of the contribution of individual components. However, in general, motors, fans, knives (or other cutting blades), and air flow are the most frequent sources of noise. Noise radiated from the casing or panels of the appliances and noise radiated from walls, floors, cabinets, sinks (set into vibration by solid structural connections) are also of major importance.

We review here in some detail the noise generating mechanisms of several appliances that have high enough noise levels and exposure time to be considered annoying. Included in this review are air conditioners, dishwashers, food waste disposers, vacuum cleaners, and toilets. Other appliances are discussed in Appendix A.

Room Air Conditioners

Figure 5 is a schematic view of a typical room air conditioner. Basically, warm air in the room or from outside is drawn through a dust filter, blown across cold evaporator coils and distributed back into the room. Fluid in the evaporator, heated by this action, flows to the condenser coils. Outside air is blown across these coils by the propeller fan. The fluid is then compressed and flows back to the evaporator.

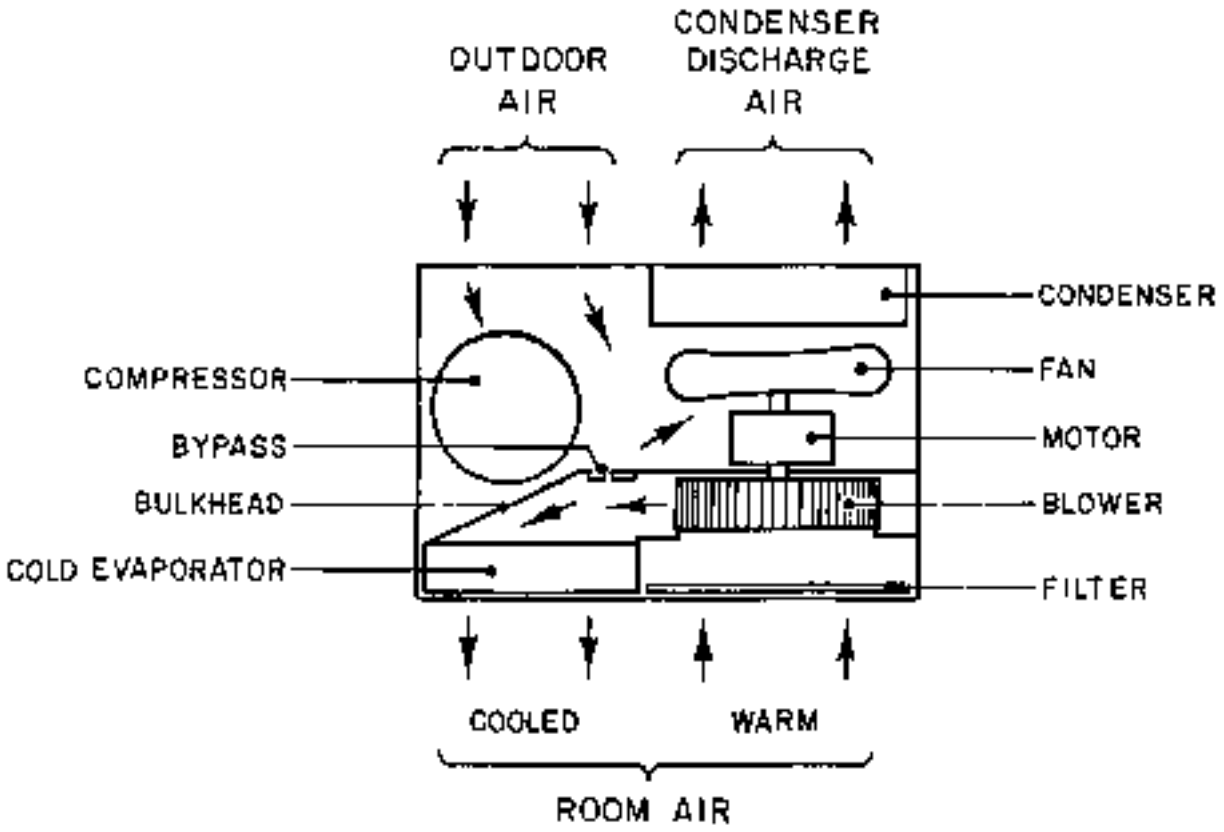

FIG. 5. SCHEMATIC VIEW OF A TYPICAL ROOM AIR CONDITIONER.

AR0070483

The major sources of noise in this process are the motor, the blower (evaporator fan), the propeller fan (condenser fan), the compressor, and the air flow across the evaporator coils. In addition, panels of the housing radiate noise, as does the structure upon which the air conditioning unit is mounted. The character of this noise is complex, consisting of pure tones, pulsating sounds, intermittent clicks, buzzes and rattles, all superimposed on broadband noise [8]. The tonal components and broadband noise represent the primary noises that require noise control treatment; for the most part, buzzes and rattles (often caused by loose parts), intermittent clicks (caused by spring activated thermostat controls and relays), and pulsating noises (generated by the capillary tube and evaporator valves) have been controlled in current models so that they do not dominate the total noise level.

Pure tones may be generated by (1) the motor at multiples of the rotation speed, (2) the compressor at multiples of the pumping fundamental frequency (the speed in revolutions per second times the number of pumping cycles per revolution), and (3) the propeller fan at blade-passage frequency (the speed in revolutions per second times the number of blades). Whether or not these pure tones appear in the spectrum heard indoors depends upon the structural connections between the components and the enclosure panels as well as on connections to supporting structures. In Fig. 6, noise levels measured on a particular unit with the fan on high speed, with and without the compressor, illustrate this concept; the increase in the one-third octave band centered at 63 Hz is due to a lack of sufficient vibration isolation of the compressor from its case and/or insufficient isolation of the casing from the wall supporting it.

AR0070484

Broadband noise is generated by the blower, the flow of air through the evaporator coils, and the deflection of the air into the room. Often the blower can operate at several speeds; the slower the speed, the lower the noise level from both the blower and the air flow (see Fig. 7).

Noise control means that can be applied to motor and compressor noise include better vibration isolation of the motor and fans from the housing through use of rubber or neoprene mounts. Compressors, usually hermetically-sealed, can be mounted on springs internally, and on rubber or neoprene pads externally. A more thorough isolation of the motor, fans, and compressor from the casing and of the complete unit from its support could result in a noise reduction of about 5 dB in the low-frequency region controlled by tonal sounds from these components.

The broadband noise generated by the centrifugal blower and the air flow can be reduced by

- reducing the air velocity by using the low-speed fan (if maximum cool is not required);
- reducing the air velocity by increasing the area of the evaporator coils (perhaps increasing the total size of the unit);
- incorporating sound absorbing material, such as open-cell polyurethane foam, between the evaporator coils and the deflection grids and in the duct passage between the blower and the evaporator coils and the blower and the dust filter; and
- tightening the gasketing system to eliminate rattles.

Broadband noise can be reduced by 10 to 15 dB through effective use of these techniques. Coupled with more effective isolation

AR0070486

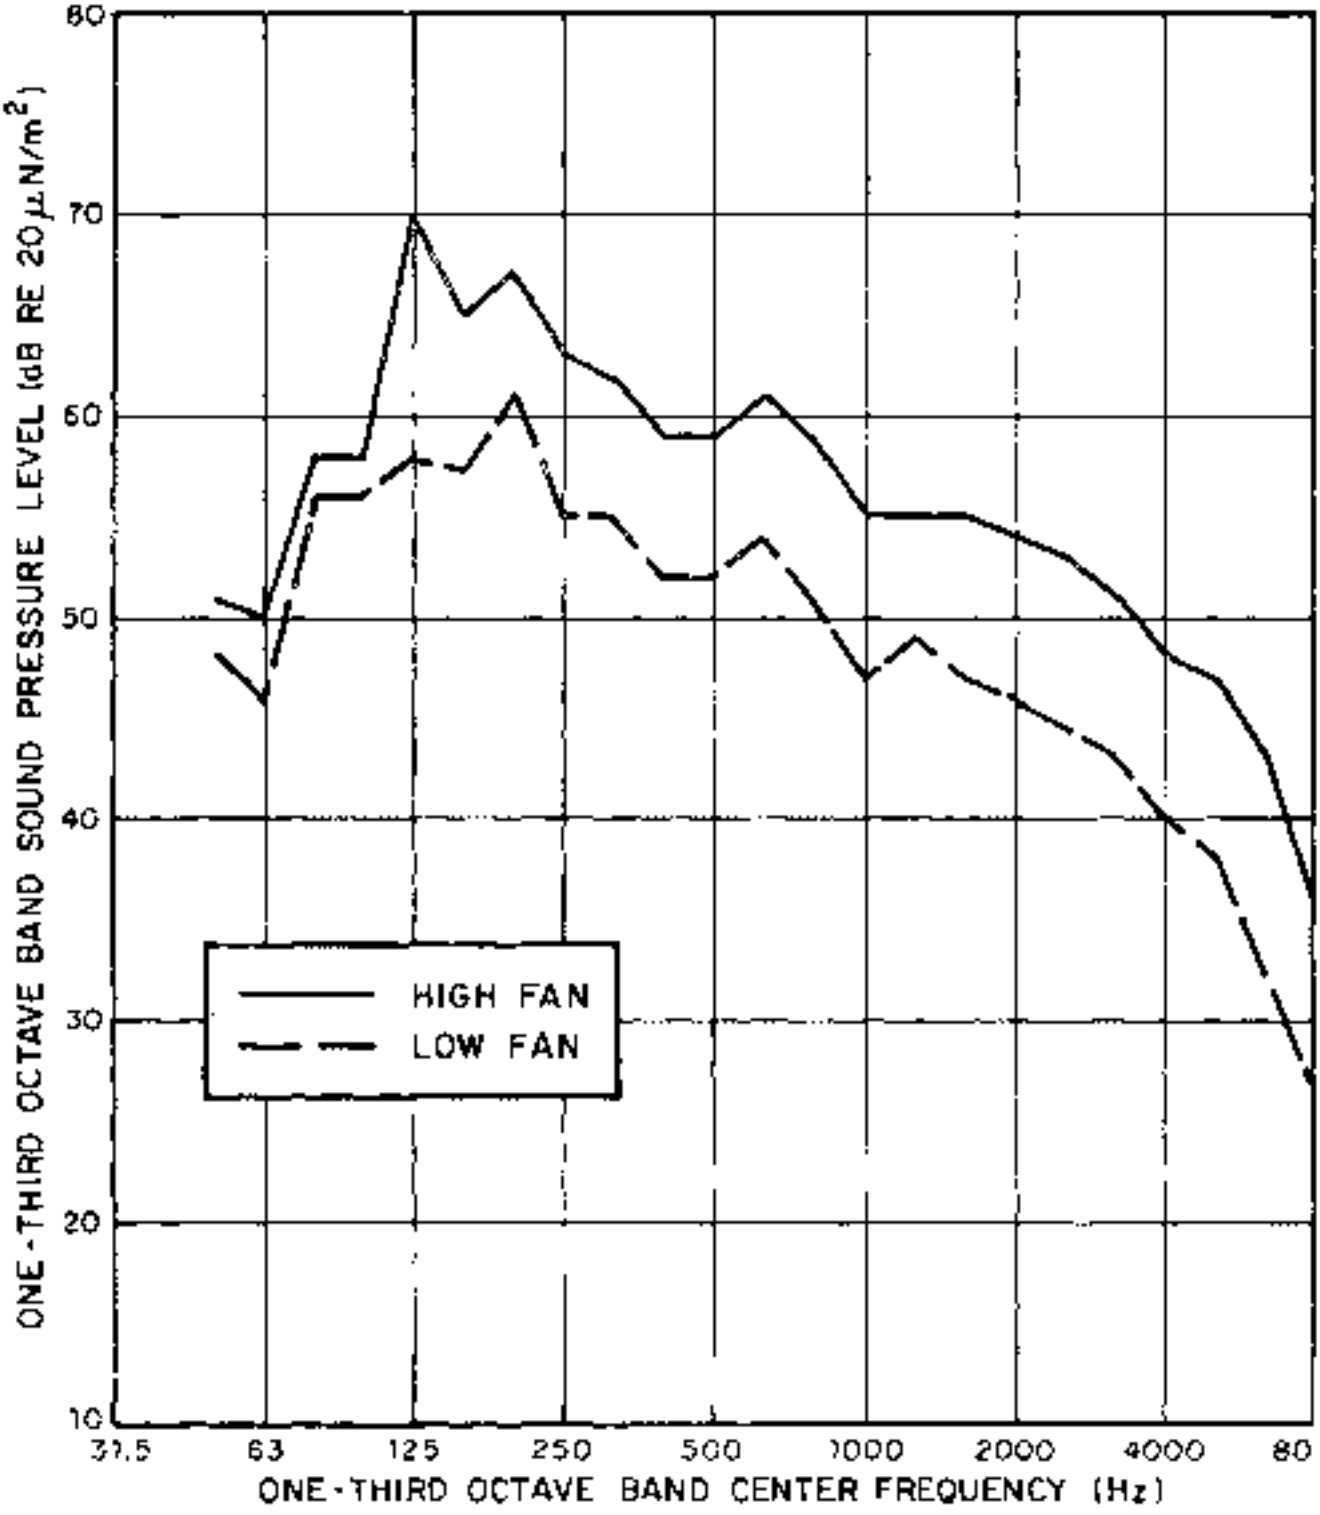

FIG. 7. SOUND PRESSURE LEVELS FROM AIR CONDITIONER AT FAN SETTINGS (MEASURED AT 3 ft)

of the compressor, motor, and [illegible], a total noise reduction of 10 to 15 dB(A) is not unreasonable. Perhaps an appropriate design goal for room cool operation is 45 dB(A) at 3 ft.

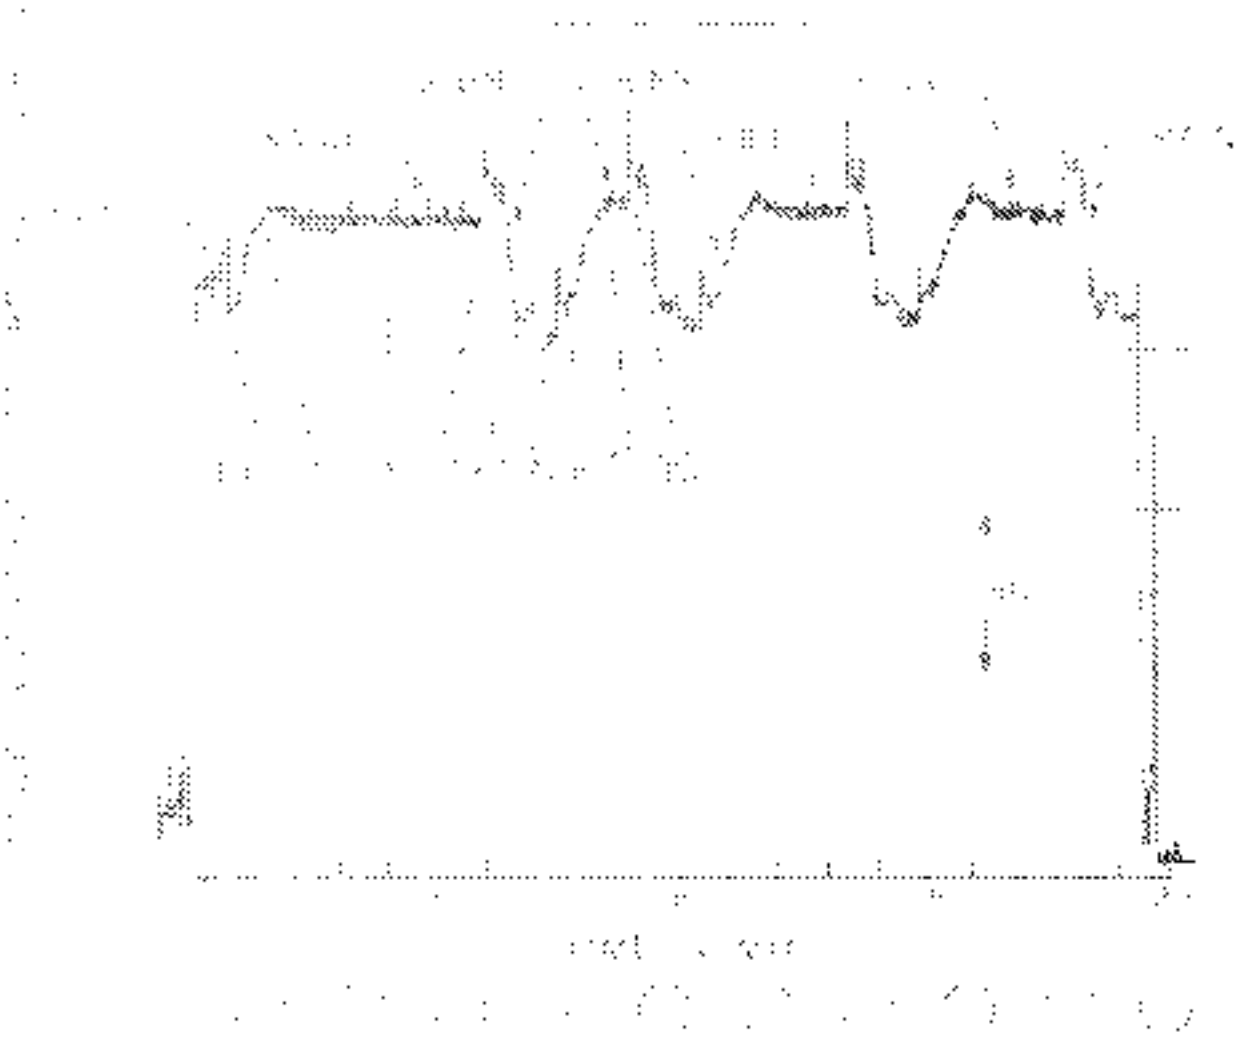
Dishwashers

A dishwasher is essentially a tub equipped with a water spray system that is driven by a motor-pump assembly. Heating coils and a blower are provided to assist in the drying operation. A complete wash may consist of as many as thirteen cycles: rinse, fill, wash, drain, fill, rinse, drain, fill, rinse drain, fill, rinse, drain. Figure 8 plots the noise level in dB(A) as a function of operation (e.g., In this example, the wash and rinse cycles are noisier than the drain and fill cycles by about 8 dB(A). Figure 9 presents octave band measurements made during the wash cycle on five different dishwashers. The data varies 5 to 20 dB between the quietest and noisiest dishwasher measured in 1971, depending on the frequency band of interest, representing about 10 dB(A) difference between the quietest and the noisiest. Although the data sample is small, this figure also illustrates, that some newer dishwashers are noisier than older ones.

The noise generating mechanisms in a dishwasher include the impingement of water against the sides and top of the tub, the motor, the pump, the excitation of panel casings, structural connections to water supply, water drain and cabinet, and the blower.

Broadband "water noise" is most important in the frequency range above 300 to 400 Hz; motor-induced noise, often pure tones at the motor rotation frequency and harmonics thereof, dominate the lower frequencies. The kick panel below the loading door on a dishwasher installed in a typical kitchen-cabinet also transmits noise from the motor enclosure into the room.

AR0070488



Through the use of experimental splash curtains, which prevent impingement of the water spray on the tub walls, water noise has been reduced by 6 to 8 dB(A) [11]. The motor-pump assembly is often isolated from the tub by rubber mounts; however, the effectiveness of these mounts can be reduced in the installation process by an insufficient clearance between the motor and the floor.

Often, the sides and top of a dishwasher are brought into contact with the cabinet. A clearance of 1/2 in. all around the machines, with neoprene isolation pads insuring the clearance, will reduce the noise radiated by the cabinet as well as the noise transmitted to other parts of the house. The use of rubber hoses for supply and drainage are an improvement over the copper tubing often provided. The incorporation of acoustic material in the motor-pump enclosure and a kick panel that is sealed (no air leaks) would also reduce the noise. It is anticipated that - if

- water noise were reduced (e.g., by installing splash curtains);
- effective vibration isolation of the motor-pump from the tub were ensured;
- effective vibration isolation of the dishwasher housing from the floor, cabinet walls and top were ensured;
- rubber hoses were used;
- acoustical absorption material were installed in the motor enclosure; and
- the kick panel were sealed air-tight -

the noise levels of a typical dishwasher could be reduced by some 10 to 15 dB(A), from a level in the mid sixties to one in the low

AR0070491

fixtures. Because of its intermittent operation, a goal of 45 to 50 dB(A) at 3 ft is probably acceptable.

Food Waste Disposers

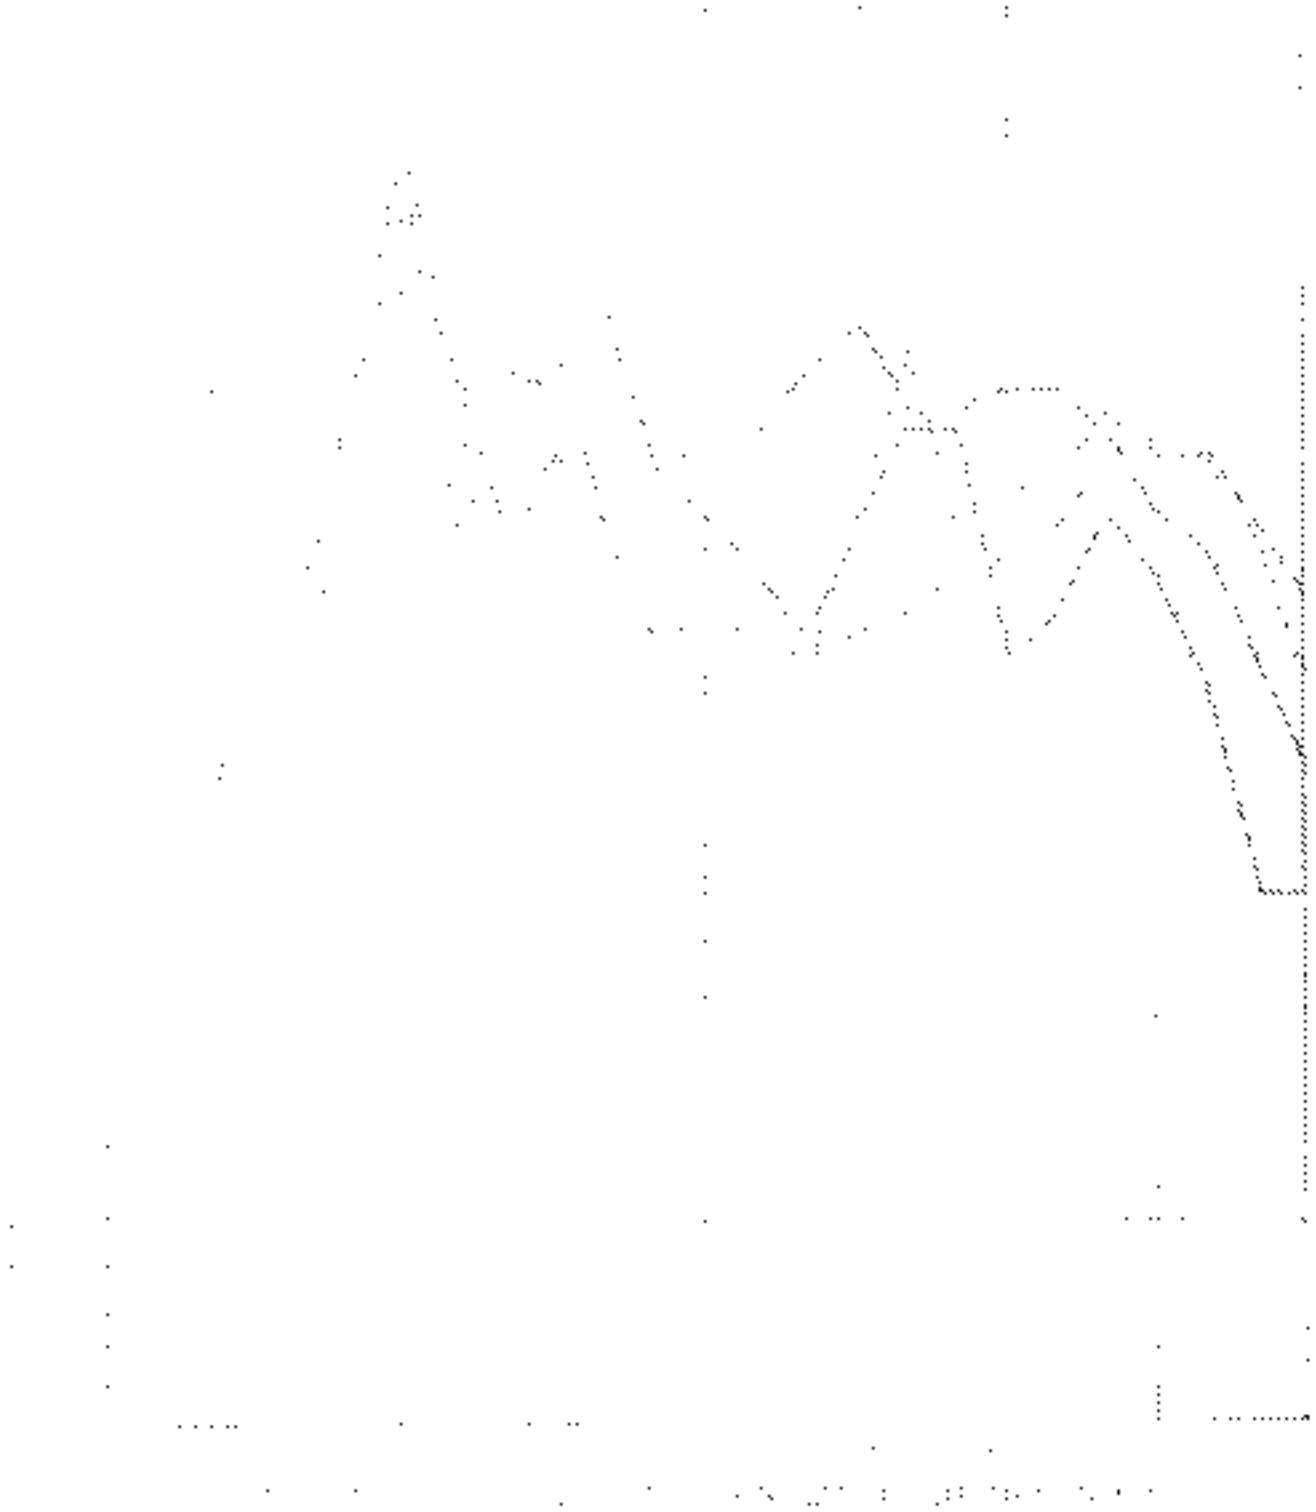
Continuous-feed and batch-feed disposers are chambers in which food waste is ground by a motor-driven wheel with cutting edges. Figure 10 presents one-third octave band sound pressure level data for four different disposers. Although the details of the spectra differ, each has a major peak at 125 Hz and several minor peaks at higher frequencies, all superimposed on broadband noise. The peak at 125 Hz is primarily motor noise. The minor peaks can be attributed to the blade-passage frequency of the grind wheel, multiples thereof, and resonances in the sink. The broadband noise is generated by the sloshing of water and waste against the housing of the chamber.

Noise is transmitted up through the mouth of the disposer. Batch-feed disposers, which require the sink cover to be in place before operation, have the potential for being quieter. Continuous-feed units sometimes have partial rubber closures at the mouth of the unit (primarily to prevent food waste from being expelled); for these closures to be effective in controlling noise, they must overlap to shut off the entire opening.

Basic noise control treatments that have been moderately successful include vibration isolation of the disposer from the sink and the enclosure of the chamber and motor with a double wall construction. It is estimated that the noise levels generated by disposers could be reduced by about 10 dB(A) with the following treatments:

- effective vibration isolation of the disposer from the sink;
- damping of the sink;

AR0070492



- flexible connections between the disposer and the drain pipe, which will also reduce the noise transmitted to other rooms and/or apartments;
- flexible electrical connection;
- enclosure of both the grinding chamber and motor, with appropriate ventilation; and
- effective closure of the mouth of the disposer.

Vacuum Cleaners

Canister vacuum cleaners consist of a tank (either horizontal or vertical) that provides suction, a connecting hose, and appropriate nozzles. Some recently manufactured canister units also have powered rotating brush attachments for cleaning carpets. Figure 11 presents sound pressure levels measured in one-third octave frequency bands for four canister units. As with other appliances, the peak at 125 Hz is motor-induced noise. The peaks in the 800 to 1600 Hz range are probably caused by the blade-passage frequency of the blower and/or resonances of the unit structure. Through the use of better blower design, more thorough vibration isolation of the motor and blower(s) from the structure, and damping and sealing of the canister structure, the noise generated by canister units could be reduced by 10 dB(A).

In addition to a motor-blower assembly, upright vacuum cleaners have a mechanism (either vibrating agitators or rolling brushes) that beats the carpet to bring dirt to the surface where it is sucked away. Figure 12 presents one-third octave band sound pressure level data for two upright vacuum cleaners -- a large unit with a beating mechanism and a small one without a beater. For the larger unit, the low frequency noise is again

AR0070494

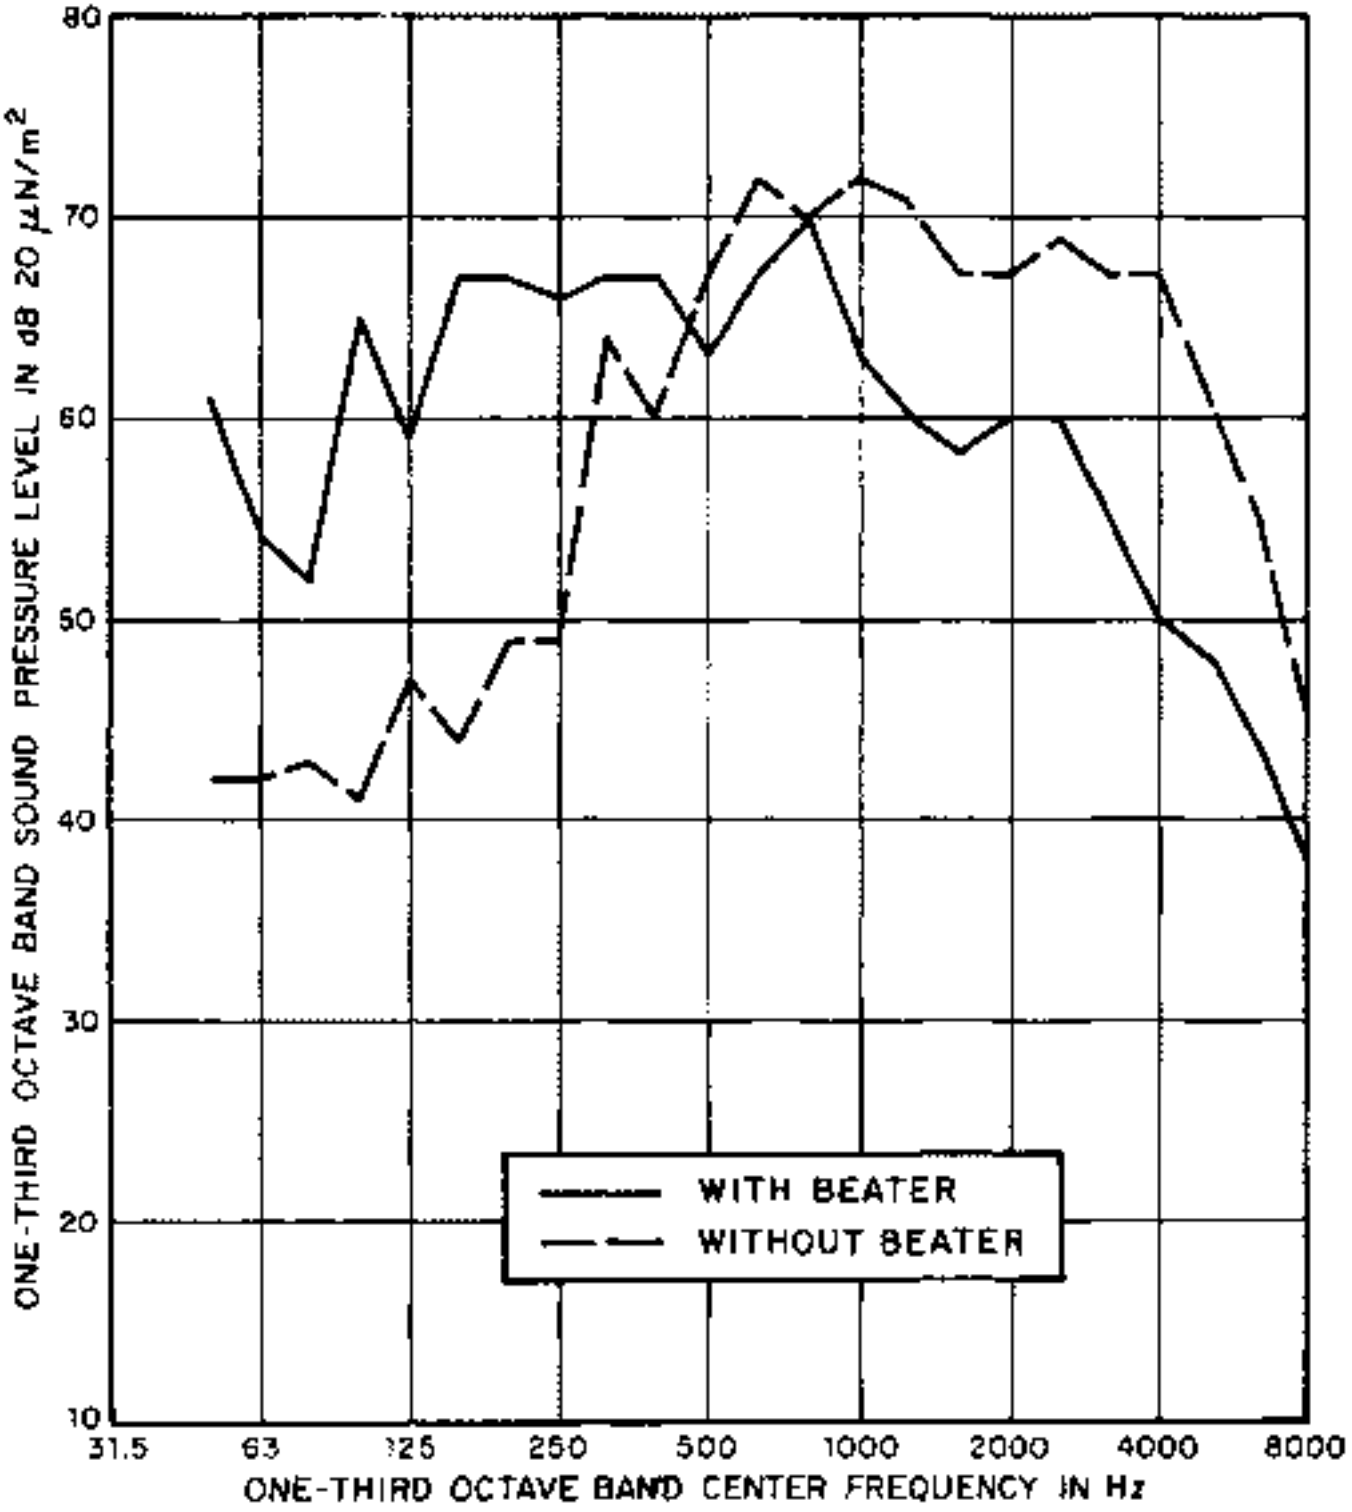


FIG. 12. SOUND PRESSURE LEVELS OF TWO UPRIGHT VACUUM CLEANERS (MEASURED AT 3 FT)

AR0070496

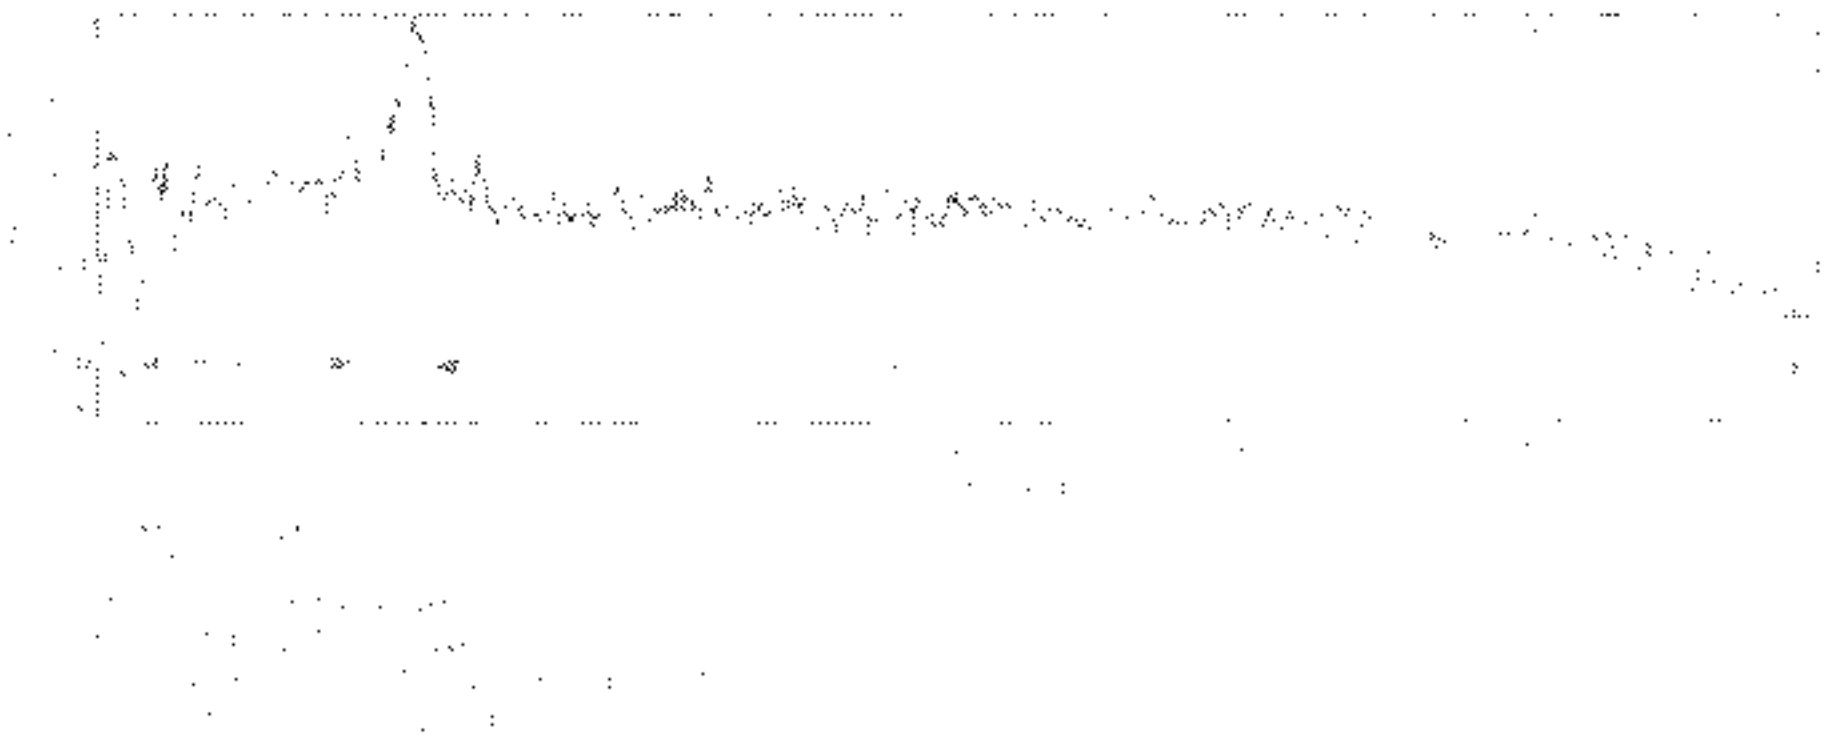
motor-induced. The peaks in the higher frequency range are caused by fan(s) and/or structural radiation. The difference between the two units in the low-frequency bands is due to the difference in capacity as well as to the lack of a heater on one model. Noise control for upright cleaners will be more difficult to achieve than for the canister units because of the location of the heater and the limitations on size. It is anticipated that a 5 dB(A) noise reduction could be achieved on the typical unit.

Water closets

Water closets are either of the tank type or the valve type and are either floor-mounted or wall-mounted. Figure 13 illustrates the time history of the sound pressure level in the 250 Hz octave band for operation of a tank water closet [12]. Time Period A represents the valve opening and releasing water in the tank to flow into the bowl through an opening in the base of the bowl. The water produces a swirling action in the lower half of the bowl (Time Period B). The valve closes (Time Period C) and the tank and bowl are refilled (Time Period D).

Figure 14 illustrates the time history of the sound pressure level in the 250 Hz octave band for a flush valve water closet [7A]. The valve opens (A); air and then water are forced out of the pipe supply (B); the valve closes (C) and the bowl is refilled (D). A comparison of these two figures suggests that flush valve water closets generate somewhat higher initial noise levels during an operating cycle but that the noise does not persist as long as with tank water closets. Since the character of the sounds is different, it is not clear at this time which would be more desirable.

AR0070497



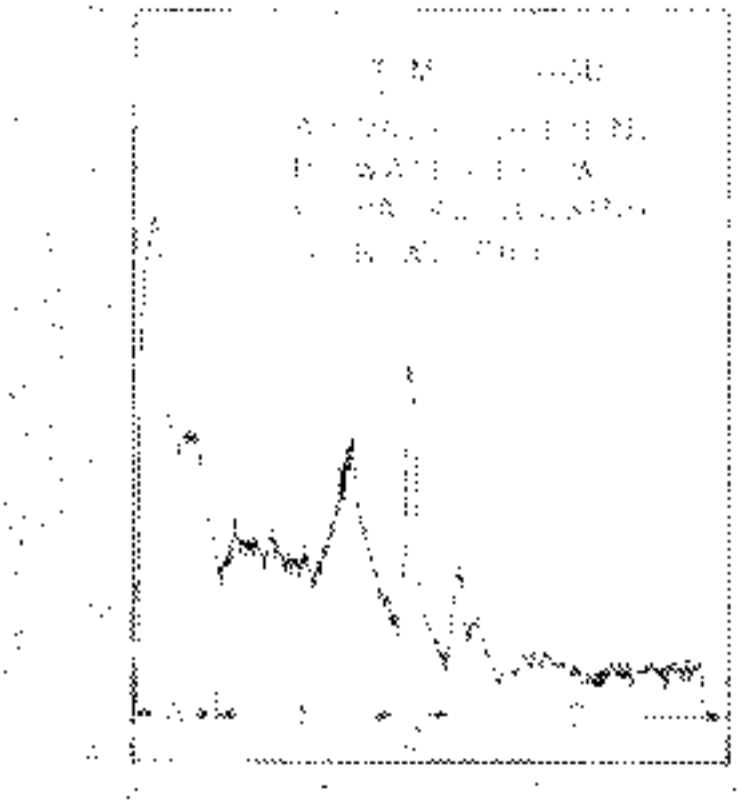


Figure 15 presents peak octave band data for a sampling of tank water closets and Fig. 16 for flush valve water closets. A comparison of these two figures shows that it is possible to have relatively noisy or quiet operation with either type of water closet provided. For tank water closets, water flow control and inlet water pressure are both important variables in the noise generated [12]. For flush valve closets, bowl design was found to be of major importance, with valve type (exposed flush vs recessed flush) and mounting (floor vs wall) of lesser importance. Resilient mounting of water closets and piping was found to be more important for some fixtures than for others - e.g., a range of several dB(A) to 15 dB(A) for valve-operated water closets.

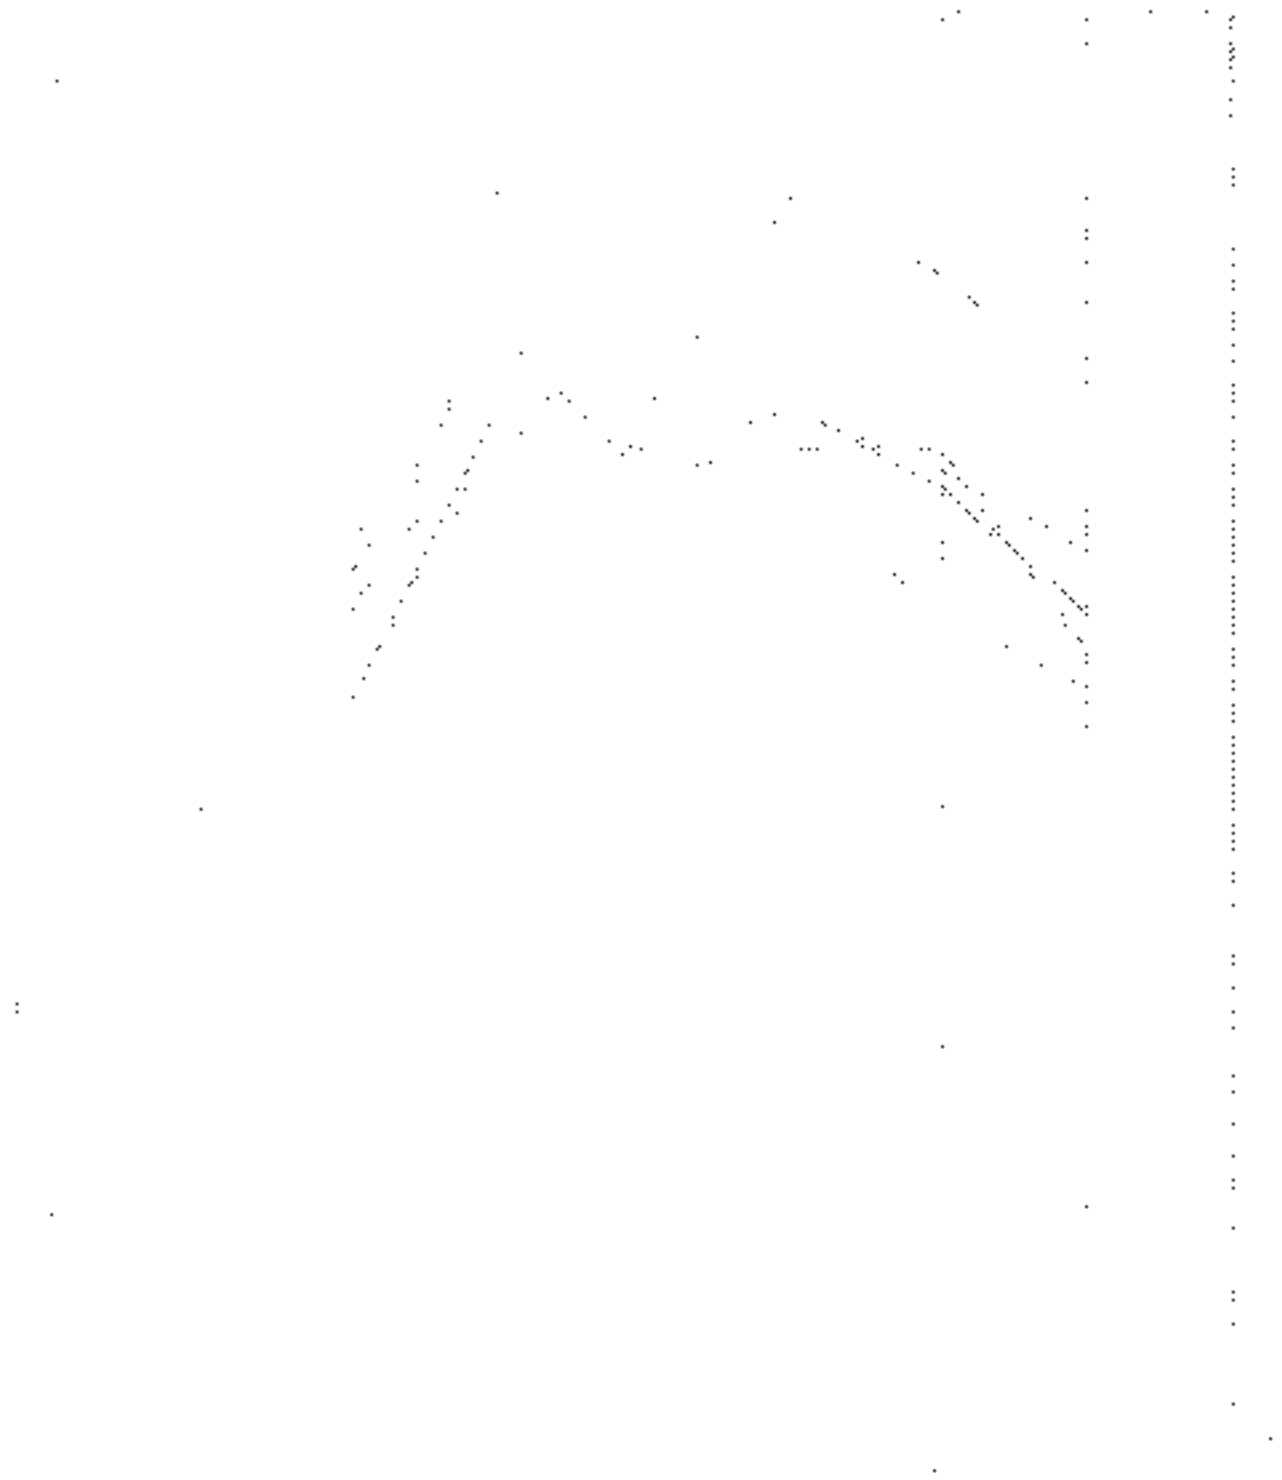
2.3 Building Equipment

The proper operation of large buildings requires a number of different types of electrical and mechanical equipment. In this section, we review the noise levels generated by electrical and mechanical equipment, present noise levels for a typical multi-story building, and discuss the possibilities of noise control through architectural modification. Detailed descriptions of additional building equipment types are given in Appendix A.

2.3.1 Types of equipment

The majority of electrical and mechanical equipment in buildings is used to supply the building occupants with a suitable quantity of air at a comfortable temperature and moisture content. In addition, pumping and piping systems are used for water and fluid circulation, elevators and escalators are used for movement of personnel, and various conveyence systems are used for moving material.

AR0070500



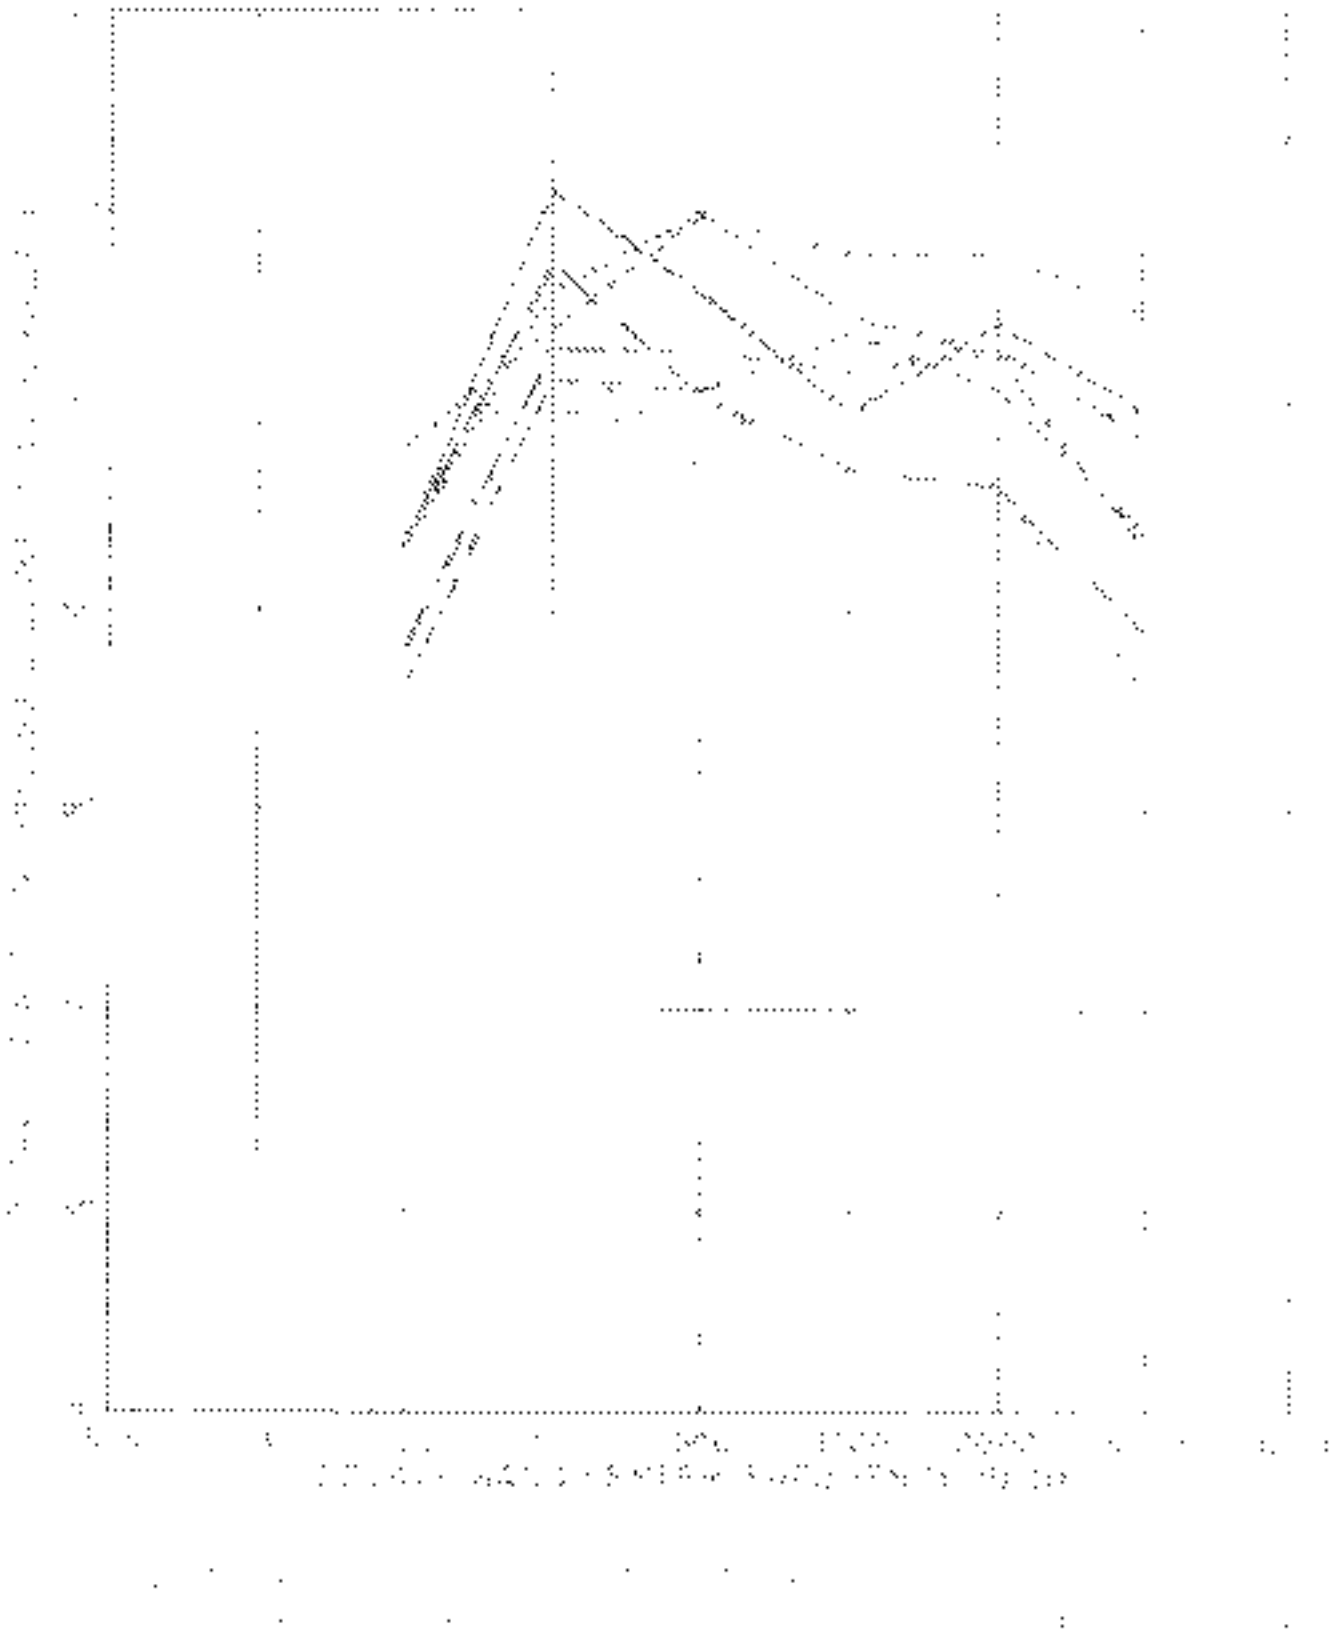


Figure 17 presents the typical range of sound levels in dB(A) at 3 ft for building equipment. Much of this equipment is hidden in mechanical equipment rooms, above ceilings, in walls, or behind cabinet type exterior enclosures. Table VII, which summarizes the exposure of occupants to the noise generated by building equipment, shows that occupants are *directly* exposed to the noise of only about eight different types of equipment. The noise generated by these units is thus of special interest since there are no intervening walls to provide attenuation. The noise generated by building equipment hidden from view can be sufficiently attenuated through the proper use of current architectural techniques. In practice, such techniques are not always implemented.

2.3.2 Noise levels within a typical multistory building

Although details of the frequency spectrum are of considerable importance in selecting noise control treatments, the model presented in this section is keyed, for simplification, to dB(A); it is not intended that this method be used for actual situations. Figure 18 presents a cross-section of a multistory building, locating a typical occupant with respect to building equipment. Figure 19 summarizes the noise exposure in dB(A) of an occupant to individual sources. The higher level in each case is representative of the sound level near the source — e.g., at 3 ft. The lower level is representative of the level to which the contribution from a particular source is reduced through proper implementation of noise control techniques. The treatments include:

E — enclosure of noise source

D — ductwork lined with acoustically absorbing material

W — wall

AR0070506

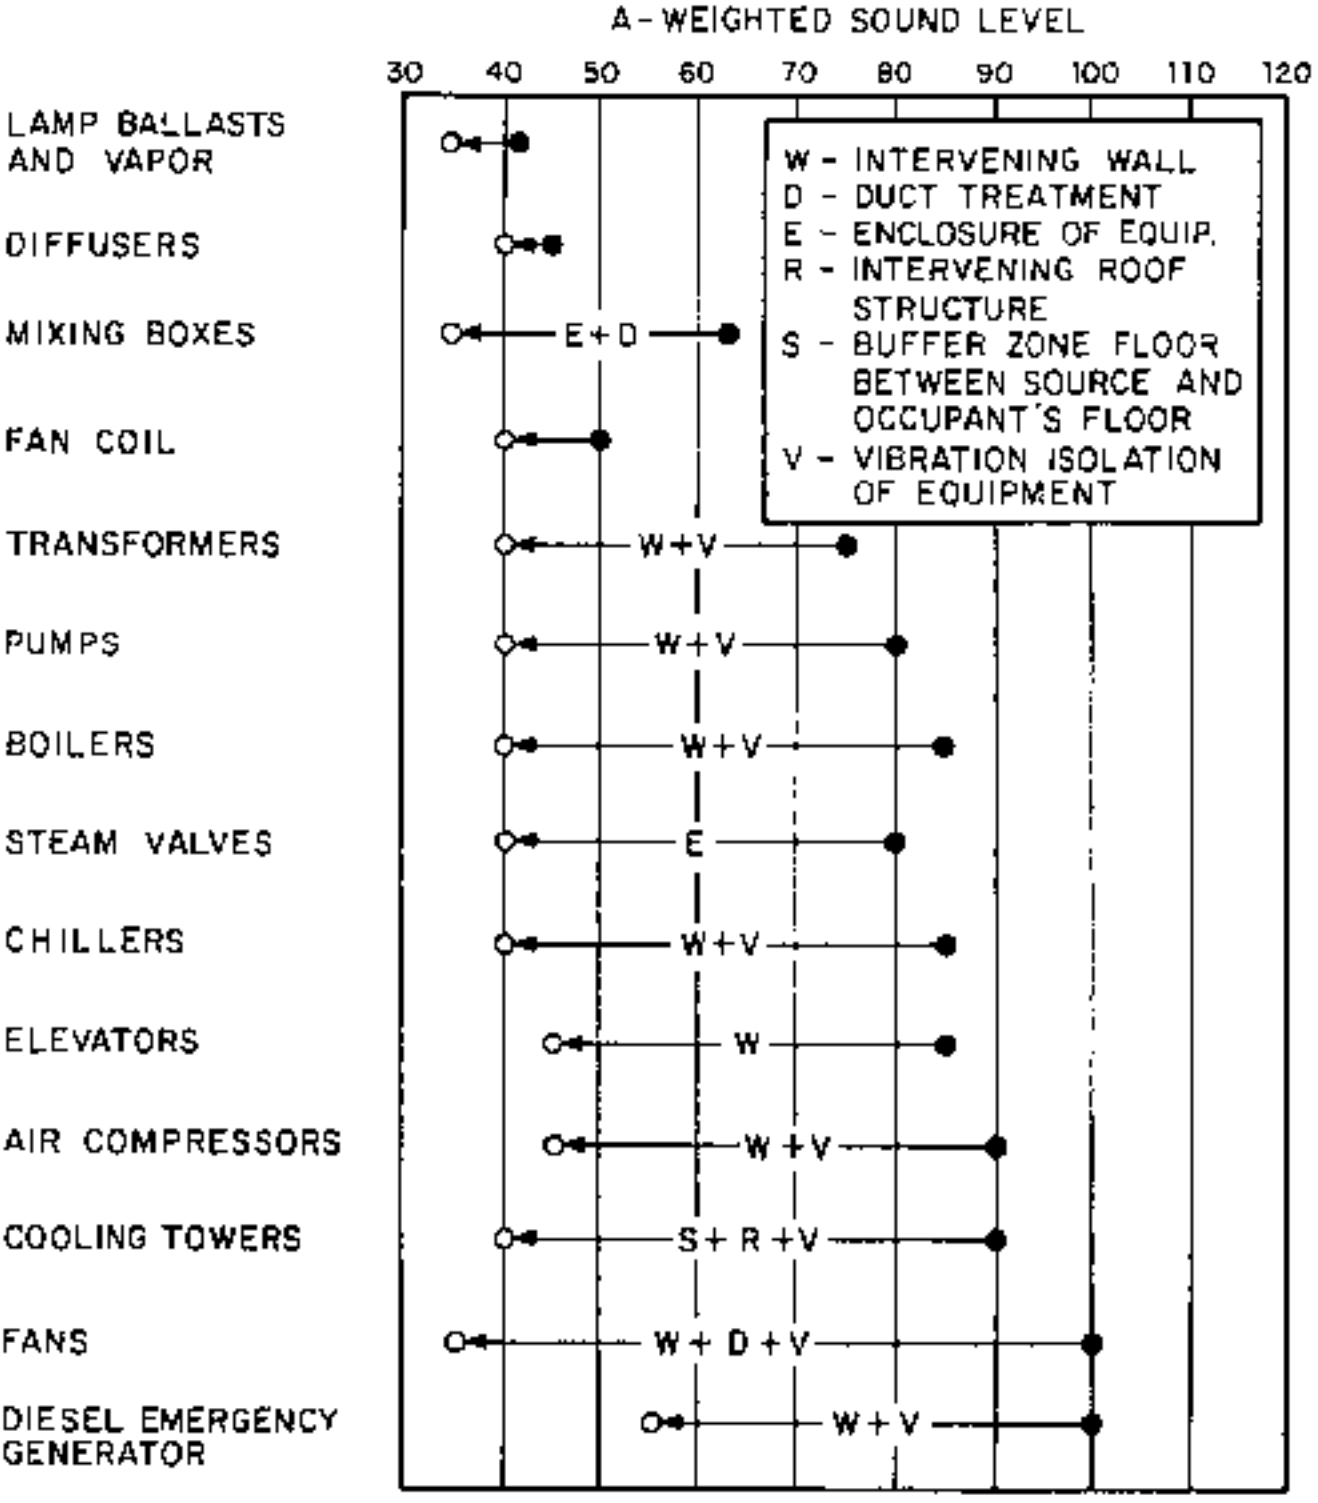

FIG. 19. RANGE OF BUILDING EQUIPMENT NOISE LEVELS TO WHICH PEOPLE ARE EXPOSED.

R -- roof slab

S -- intervening story -- e.g., the penthouse mechanical equipment floor

V - vibration isolation.

Goals for acceptable noise levels vary with the activities to be held in a space. If one is interested in increasing the speech privacy within an office, then a higher noise level of an appropriate spectral shape would be appropriate. On the other hand, if one is performing certain types of tests or listening to critical sounds, a quieter environment is required. Through the use of current technology, it is possible to achieve virtually any noise goal, if the owner of the building is willing to bear the cost and space requirements of the treatment. Of course, by specifying quiet equipment, the owner may minimize these requirements.

AR0070508

3. IMPACT

3.1 Noise Level Criteria for Impact Evaluation

In this report, the impact of noise exposure upon people is evaluated primarily in terms of three direct effects and secondarily in terms of a number of indirect consequences. The three major effects are speech interference, sleep interference, and annoyance. Two rationales for emphasizing these effects in particular. First, they are among the most salient and tangible consequences of noise exposure and thus can be most readily interpreted in societal terms. Evidence that they are widely understood by the public may be found in their frequent mention in noise complaints. Secondly, research on these three effects has been more extensive than on other noise effects; therefore, sharper predictions can be made with greater confidence.

Although the three primary effects are used to summarize the major impact of noise exposure, the indirect consequences of exposure also demand consideration. These effects include physiological stress, annoyance, startle, and task interference. They are termed "indirect" in that they are not produced exclusively by noise, nor are they simple functions of the physical magnitude of noise exposure. Further, relatively little systematic information about these effects is available; thus, specification of precise levels of noise exposure leading to particular levels of effect is a somewhat speculative matter. However, one may not assume that these secondary consequences are unimportant merely because they are difficult to quantify.

The following table presents the physical levels at which it is felt that each of the above-mentioned effects of noise exposure achieves (1) a moderate level of effect and (2) an appreciable level of effect. The decisions leading to these specifications are discussed below.

AR0070509

TABLE VIII. ESTIMATES OF MAGNITUDES OF NOISE EFFECTS
[IN dB(A)]

Effect	Moderate Level	Appreciable Level
Hearing Damage Risk	70	90
Speech Interference	45	60
Sleep Interference	40	70
Physiological Stress	*	90
Startle	*	110
Annoyance	40	60
Task Interference	55	75

3.1.1. Hearing-damage risk

The hearing-damage risk levels specified in Table VIII were selected on the basis of eight hours of daily exposure. Exposure durations of this order are chosen as representative of the amount of time usually spent in home and work environments. Since hearing-damage risk is cumulative over long periods of time [73], the recommendations are intended to account for prolonged noise exposure over a period of years.

The estimate of the level at which hearing-damage risk commences was determined on a rather stringent basis. The Walsh-Healey Public Contracts Act, as amended to include noise limits for hearing conservation, is based on a CHABA report [74], which permits permanent threshold shifts up to 10 dB at frequencies

---

*Effects at low levels are at best weak functions of the physical intensity of noise. They are determined far more strongly by factors such as the meaning associated with the acoustic signal, attitudes toward the source, rise time of the signal, unexpectedness of the signal, and so forth. It therefore makes little sense to specify discrete levels in these cases.

AR0070510

over 1000 Hz; up to 15 dB at 2000 Hz, and up to 20 dB at frequencies above 3000 Hz. Hearing losses of these magnitudes are considered inconsequential in the sense that they are ineligible for compensation under the terms of the [illegible] legislation. Even these surprisingly low limits are based on the questionable assumption of a sixteen-hour daily recovery period of little or no noise exposure [17]. Further, the OSHA regs. [74] is intended to afford this partial protection to only half of the population exposed to noise. Clearly, these criteria are neither applicable to individual circumstances nor capable of protecting many people from sizeable hearing losses.

Kryter's published redefinition of the hearing-damage risk criterion [75] maintains that no permanent threshold shift whatever is tolerable at 2 frequencies below 2000 Hz and that no more than a 10 dB shift is tolerable at other frequencies. Kryter also applies the protection afforded by his definition to 75% of the population rather than 50%. He states that the 'threshold' of hearing-damage risk for eight hours of daily exposure is 67 dB(A). Glorig et al [13] operating under similar assumptions specify 75 dB(A) as the level at which hearing-damage risk commences. Miller [16] believes that a level of 70 dB(A) represents a level of noise exposure above which hearing-damage risk becomes nonnegligible. In Miller's terminology, habitual exposure to levels between 70 and 90 dB(A) represents yellow (i.e., cautionary) risk of hearing damage; exposure to levels between 90 and 90 dB(A) entails "orange" risk; while exposure to levels in excess of 90 dB(A involves "red" (serious) risk.

The estimate of Table VIII for the onset of hearing-damage risk agrees with Miller's estimate. The estimate of the level at which appreciable risk of hearing damage occurs agrees both

AR0070511

with Miller's estimate and the provisions of the Walsh-Healey Act. The latter criteria, based on a report of the NAS-NRC Committee on Hearing, Bioacoustics, and Biomechanics [14], indicates that eight hours of daily exposure to levels in excess of 90 dB(A) constitutes a serious risk of hearing damage to one-half of the population.

3.1.2 Speech interference

The levels specified in Table VIII for speech interference are the most straightforward and readily defensible of all of the estimates. A criterion for adequate verbal communication in the home was taken to be comprehension of 98% of all sentences or an equivalent rate of comprehension of 85% of the words of a standard phonetically balanced (PB) list. In terms of nominal vocal effort [approximately 65 dB(A) at a distance of one meter], such a level of speech intelligibility would be sustained at a speaker-listener distance of approximately five meters in a noise background of 45 dB(A) [17]. Five meters was taken to be the maximal distance at which conversation in normal levels might reasonably be expected to be held in a quiet outdoor (nonreverberant) environment.* The level of appreciable effect specified in Table VIII was derived by assuming that noise-induced speech interference would be intolerable if conversation at nominal levels of vocal effort were precluded at speaker-listener distances greater than one meter. Such conditions prevail in noise environments in excess of 60 dB(A) [17].

---

*Greater speaker-listener distances would be possible indoors at the same levels of vocal effort and speech intelligibility, because sound pressure levels diminish more slowly than predicted by the inverse square law.

AR0070512

It should be pointed out that selection of the above criterion represents a belief that the 70% comprehension of PB words suggested by Webster [17] and Bormanx [18] does not provide for a reasonable standard of communication in the home. Webster's criterion was established for "barely adequate communication" and is inappropriately applied to the home environment. The levels recommended in this report are thus 5 dB lower than Webster's.

3.1.3 Sleep interference

Two principal ways in which noise exposure can interfere with sleep are to delay the onset of sleep and to shift sleep "stages". Scores of studies are available on the sleep-delaying and stage-shift effects of noise exposure. Although there is frequently broad agreement among studies, detailed agreement is lacking. Discrepancies among outcomes of similar studies are attributable to incomparable control conditions, differences in experimental design, and the host of individual differences which beset sleep research.

For example, it is universally observed that the initial time required for subjects to fall asleep increases monotonically with exposure to increasing noise levels. Unfortunately, different studies produce estimates of the sleep-delaying effects of noise that are more than 35 dB apart. Thus, two studies report delays in onset of sleep from 20 to 90 minutes [19,20], corresponding to exposure to continuous noise at levels of 35 dB(A) and 50 dB(A), respectively. Other studies, [21–23] however, report that subjects can fall asleep in as little as twelve minutes despite exposure to noise levels of 70 dB(A).

Further, prolonged exposure to high noise levels can produce tinnitus (ringing in the ears), which has been claimed to delay

AR0070513

the onset of sleep [24]. In other words, aftereffects of noise, even in the absence of *any* noise exposure at bedtime, can impede sleep. It is also claimed in the literature that levels as low as 35 dB(A) can either induce a shift from a "deeper" to a "lighter" level of sleep or awaken certain people [26]. Pronounced differences in sensitivity to noise during sleep have been observed as a function of age as well.

An absolute criterion for noise exposure levels in sleeping quarters is obviously unjustifiable on the basis of extant research. A conservative criterion for noise exposure (from the point of view of minimizing sleep interference) might be based on the lowest levels at which sleep interference have been reported. According to the Wilson Report [26], levels of 40 dB(A) have been known to awaken approximately 25% of the sleeping population, while levels of 45 dB(A) appear to keep about 20% of the population from falling asleep immediately. These considerations have led to the adoption of 40 dB(A) as a criterion level for the onset of sleep interference effects. According to the Wilson Report data, a little more than half of the population may be awakened by noise exposure to levels of 70 dB(A), while a little less than half of the population will find some difficulty in falling asleep when exposed to such levels. These data led to adoption of 70 dB(A) as the level at which sleep interference effects become considerable.

3.1.4 Physiological stress

The amount of stress produced by low-level acoustic signals is primarily determined by their meaning. A footfall in one's bedroom at night, or a growling animal, or one's boss's voice can excite stress mechanisms by virtue of their implications rather

AR0070514

than their physical attributes. Since it is the learned and instinctive associations to sounds which are largely responsible for their ability to create stress, no level of minimal effect has been specified.

At high noise levels a somewhat stronger case may be made for specification of a criterion. Studies of physiological correlates of noise-related stress in animals suggest that noise levels in the vicinity of 90 dB(A) produce strong effects [57]. Pupillary dilation, increased pulse pressure and heart rate, and pulse volume changes have been observed in humans exposed to noise levels of approximately 70 dB(A) [58]. There can be little argument that at even higher levels noise stimulation induces stress in and of itself, rather than as an exclusive function of its meaning. Extremely intense noise fields can cause auditory and bodily pain. Such intense fields commonly are associated with strong vibrational components, which can also be harmful.

3.1.5 Startle

The arguments above about the relative roles of meaning and levels of acoustic signals in determining stress also apply to startle. For the same reasons, therefore, no minimal level of effect can be specified.

A major obstacle to establishing a firm criterion for the startling effects of high level noise is the phenomenon of habituation. In general, humans display a marked decrease in sensitivity to repeated exposure to startling sounds. Expectedness, regularity, familiarity, arousal level, and numerous other factors strongly mediate startle effects. Even at high absolute noise levels, startle is as much affected by signal-to-noise ratio considerations as it is by the level of the startling signal.

AR0070515

Thus, an exploding paper bag would almost certainly produce more startle in a library than in a boiler factory.

The level recommended in Table VIII is therefore chosen to represent a noise level sufficiently rarely heard and of a signal-to-noise ratio sufficiently great to make a significant startle reaction highly probable.

3.1.6 Annoyance

The levels recommended in Table VIII for gauging annoyance effects are intended to reflect the lowest level at which any of the other tabled effects can occur. In other words, one is expected to be annoyed by a noise sufficiently intense to produce sleep interruption, speech interference, etc.

It is, of course, also true that long-term exposure to very low level noises can be annoying. A dripping faucet or a chalk squeak can be exceptionally irritating. Once again, however, it is the meaning of the acoustic signal rather than its level *per se* which plays a major role in determining the magnitude of annoyance. Also, the spectral composition and temporal density of noise heavily influences its annoyance value. Unfortunately, temporal and spectral factors cannot be adequately expressed in dB(A).

3.1.7 Task interference

The literature on the effects of noise on human performance contains numerous conflicting and inconclusive reports. By and large, high-intensity, aperiodic, intermittent noise is reported to impede efficient work to a greater extent than low-intensity, steady-state noise [29]. Nonetheless, numerous studies find no effects of noise on performance, while a few studies find

AR0070516

occasional improvements in performance attributable to noise exposure [30]. Of course, improvements in performance when an environment is changed (presumably worsened) are often due to changes in the level of attention perceived by the subject and their attendant reaction. The nature of the task at hand and the duration of noise exposure also influence the extent of task interference.

It is our feeling that the most sensitive and complex tasks (of the nature of brain surgery, diamond cutting, etc.) might be sensitive to interference from noise at levels as low as 65 dB(A). Although most published studies which report task interference give levels in the vicinity of 90 to 110 dB(A), it is felt that certain tasks might prove susceptible to appreciable interference at approximately 75 dB(A).

3.2 Construction Noise

3.2.1 Extent of exposure

Our determination of the impact of construction noise on the American public is based on information obtained about the number of people exposed to such noise and the extent of their exposure. This information was gathered in four steps:

- We determined the number of construction sites of various types in various geographical regions.
- We determined the density of people in the geographical regions (two classes of people were considered: stationary population such as workers and residents and transient population such as drivers and pedestrians).
- We postulated a model of sound propagation around a typical construction site.

AR0070517

- We combined the information obtained in the first three steps with the site source level data presented in Sec. 2.1 to determine the number of people exposed to given levels of noise.

For the purpose of gathering and analyzing population and construction site statistics, we divided the U.S. into five regions. These regions are based on those defined by the U.S. Bureaus of the Budget [31] and of the Census [32]. A key to understanding the rationale used for establishing these regions is the concept of Standard Metropolitan Statistical Area (SMSA). An SMSA is a group of contiguous counties which contains at least one central city of 50,000 inhabitants or more, or "twin cities" with a combined population of 50,000 or more. There are 233 SMSAs containing 65% of the nation's population and about 10% of the land area. The population density in the nonmetropolitan areas is too low to create much construction noise exposure or to allow meaningful computation of the exposure that does exist. This study, therefore, restricts itself to construction occurring within the SMSAs (see Table IX).

Classification of Construction Sites

As explained in Sec. 2.1, four major categories of construction were studied:

- Residential buildings
- Nonresidential buildings
- Municipal roads
- Public works

Certain heavy construction and large civil works, such as dams and bridges, were omitted because this type of construction

AR0070518

TABLE IX. METROPOLITAN REGIONS CONSIDERED IN CONSTRUCTION NOISE EXPOSURE ESTIMATE: STATISTICS AS OF 1970*

	Population (thousands)	Area (sq. mi.)	Population Density (people per sq. mi.)
Large High-Density Central Cities** (12)	22,299	1,462	15,160
Large Low-Density Central Cities (14)	10,539	2,382	4,410
All Other SMSA Central Cities (196)	15,990	6,981	3,710
Urban Fringe	49,080	14,797	3,320
Non-Urban Outside Urban Areas	92,349	739,276	125

*Population figures are extrapolated to 1970 from 1960 Census figures according to recent growth rates.

**Large cities are those whose metropolitan area population exceeded 1,000,000 in 1960.

High-Density: Baltimore, Boston, Buffalo, Chicago, Cleveland, Detroit, New York, Philadelphia, Pittsburgh, San Francisco, St. Louis, Washington.

Low-Density: Atlanta, Cincinnati, Dallas, Denver, Houston, Kansas City, Los Angeles, Milwaukee, Minneapolis-St. Paul, Miami-Ft. Lauderdale, New Orleans, St. Petersburg-Tampa, San Diego, Seattle-Tacoma.

AR0070519

rarely takes place in heavily populated areas. The residential and nonresidential building categories were further subdivided into specific types of buildings to account for variations in the duration of construction and the mix of machinery at different kinds of sites.

The Number of Construction Sites

Data on the annual number of building sites on which construction was begun in 1969 was collected from the U.S. Postal and Defense Services Administration [33] and from unpublished compilations made by the Bureau of the Census. Data for large central cities and for the nation as a whole were directly available; sites were ascribed to "other central cities", "urban fringe", and "nonurbanized metropolitan area" on the basis of population distribution. The number of residential and nonresidential building sites in the five metropolitan-area regions is shown in the first two columns of Table X, as well as the average cost of construction for each case. A more detailed breakdown by type of building is given in Appendix B.

Data on total municipal road construction [34] was apportioned among the various metropolitan regions by assuming a constant ratio of miles of road constructed to miles of road in place. The number of miles of such work performed in 1969 is shown in the third column of Table X.

Unlike the case with buildings and roads, data on construction and maintenance of public works such as sewers and water mains is not collected on a national basis. The extent of this construction, therefore, has been estimated first by determining the ratio of sewer construction to street construction for several cities in the Boston area and then by using this ratio to

AR0070520

TABLE X. ANNUAL CONSTRUCTION ACTIVITY — 1970*

Metropolitan Regions	Residential Buildings (no. of sites)	Nonresidential Buildings (no. of sites)	Municipal Streets (miles)	Public Works (miles)
Large high-density central cities	8,708	1,952	273	398
Large low-density central cities	21,578	4,303	2,150	3,140
Other central cities	102,559	12,321	6,000	8,700
Urban fringe	262,800	30,915	11,800	16,865
Met. area outside urban fringe	118,779	13,758	21,700	31,550
Total	514,424	62,549	41,923	60,653

* All figures are in thousands.

AR0070521

estimate the miles of sewer construction nationwide for 1970. These figures are contained in the fourth column of Table X. A more detailed description of this computation is contained in Appendix B.

Construction Phases

Construction of buildings and other works is carried out in discrete stages, each of which has its own characteristic mix of equipment. Because of the items of equipment on a site change as construction progresses, the noise output from the site also changes with time. As explained in Sec. 2.1, we have characterized the noise output from each site according to construction phase:

- Clearing and demolition
- Excavation
- Placement of foundations
- Erection of frame, floors, roof, and skin
- Finishing and cleanup.

These phase descriptions are used for road and sewer construction, even though the actual operations are different from those for buildings, so as to allow a consistent analysis of the various types of sites. (See Sec. 2.1 for a more complete description.) A list of the equipment commonly found in each phase is given in Table A-1.

Number of Individuals Exposed

We obtained the number of people exposed to various levels of noise from construction sites by combining information on

AR0070522

population density, the number of sites active per year, and the sound propagation model described below.

We revised the population figures in Table IX, which represent the residential distribution of the U.S. population, to reflect the net transfer [25] of people from suburbs to central city during the average working day, the period when most construction noise is produced. These revised density figures are given in Table XI in terms of people per square mile and people per one-eighth mile of street (assuming the entire metropolitan area to be divided into city blocks one-eighth of a mile long).

TABLE XI. GEOGRAPHICAL DISTRIBUTION OF WORKING-DAY POPULATIONS

	People per square mile	People per 1/8 mile of street (approximate)
Large high-density central cities	16,650	130
Large low-density central cities	4,860	40
All other central cities	4,070	32
Urban fringe	3,100	24
Met. area outside urban fringe	114	--

Note that the number of people per city block in the metropolitan area outside the urban fringe is negligible and therefore is disregarded in the following discussions.

AR0070523

In addition to the working-day population density estimate given in Table XI, we must also account for the number of passers-by who are exposed to construction noise. Since there are no data on typical driver and pedestrian distributions, a definitive estimate of this type of exposure is not possible. We have, however, made an order-of-magnitude estimate on the basis of some survey work performed by the Boston Traffic Department (1970). Although incomplete, these surveys report seemingly reasonable numbers, which are therefore offered in Table XII as preliminary estimates.

TABLE XII. NUMBER OF PEOPLE PER DAY PASSING A CONSTRUCTION SITE

	Drivers and Passengers	Pedestrians
Large high-density central cities	3000	1000
Large low-density central cities	3000	1000
Other central cities	1500	500
Urban fringe	500	100

Table XIII presents the total number of building construction sites active in 1970 (see Table X) for all metropolitan regions. In the case of roads and sewers, the definition of a "construction site" is somewhat obscure, since such projects extend linearly for some distance with construction usually occurring one section at a time. The area of influence of construction on one section is about one-eighth of a mile. We therefore consider each eighth-mile of street and sewer construction as an independent site.

AR0070524

TABLE XIII. LEVEL OF ANNUAL CONSTRUCTION ACTIVITY

Type of Site	Number of Sites (National Total)
Residential Building	514,424
Nonresidential	62,549
Municipal Streets	336,000
Public Works	485,000

The level of exposure to noise from a construction site depends on one's distance from the site and the nature of his immediate environment. In city streets, it has been found experimentally that sound intensity decreases as the inverse square of the distance from the source [36]. In logarithmic units, this amounts to a 6 dB reduction per distance doubled. This model has been adopted for open-air propagation, which is significant in the case of pedestrians. In addition, a factor of 20 dB(A) attenuation has been included for people who are inside buildings with closed windows and 15 dB(A) for people inside cars with closed windows [37]. Construction noise is assumed to propagate along the street adjacent to the site, but to be heavily attenuated in the direction transverse to the street; in effect, only the people along the street adjacent to the site are affected by the noise. A further assumption is that the sound is reduced 10 dB(A) when one crosses a street intersection [36].

Using these parameters, we illustrate in Fig. 20 a representative geometry for a building construction site and contours of attenuation for observers. Details of the computations involved in constructing this diagram are given in Appendix B. Assuming a uniform distribution of observers along the sides of

AR0070525

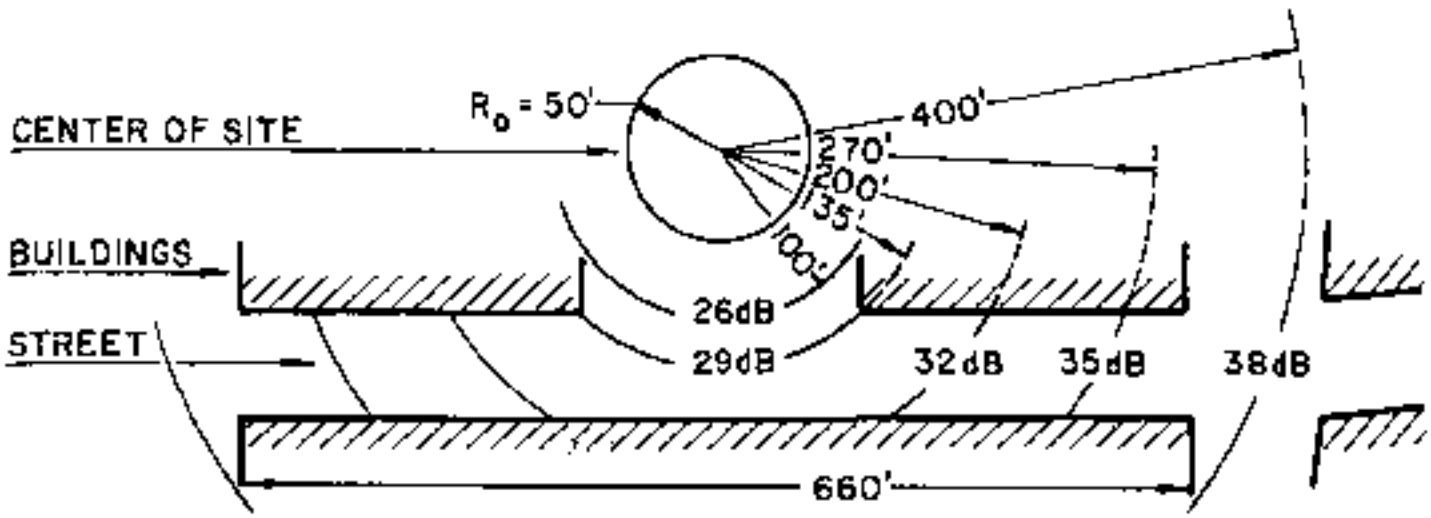

FIG. 20. CONSTRUCTION SITE GEOMETRY AND ATTENUATION CONTOURS FOR A STATIONARY POPULATION WITHIN BUILDINGS. (SEE APPENDIX 9 FOR METHOD OF COMPUTATION.)

AR0070526

the street, we can determine the fraction of people within each set of attenuation contours. These proportions, which are shown in Table XIV below, apply only to observers in buildings with closed windows adjacent to the street on which building construction is taking place; drivers and pedestrians move relative to the site, crossing contours as they go.

TABLE XIV. DISTRIBUTION OF STATIONARY OBSERVERS RELATIVE TO ATTENUATION CONTOURS

Attenuation Interval	Percent of Observers
26 – 29 dB	15%
29 – 32 dB	35%
32 – 35 dB	32%
35 – 40 dB	18%

All observers more than 40 dB away from the site have been disregarded, as they are assumed to be unaffected by the noise. The actual number of people within each pair of attenuation contours can be obtained by multiplying the percentages in Table XIV by the number of people per 1/8 mile of city street for the appropriate metropolitan area (as given in Table XI).

In the case of street and sewer construction, operation is typically distributed along the length of the street and cannot be modeled as a point source. Accordingly, all the people in the eighth-mile of city street adjoining the site are assumed to be exposed to the same noise level. This level is taken to be the source level of the site diminished 20 dB to account for attenuation within buildings with closed windows.

AR0070527

The noise exposure of pedestrians and drivers cannot be computed by the above model, since, as noted above, their distance from the site varies with time. In these cases, we consider the peak exposure experienced by the transient observer. For pedestrians, this exposure is 6 dB less than the site source level referenced to 50 ft; for drivers, it is 20 dB less.

Noise Exposure Estimates

The above figures on observer densities, number of sites, and attenuation have been combined with the data on average and peak site source levels presented in Sec. 2.1 to determine the number of people exposed to particular levels of noise. Table XV shows the national noise exposure of the stationary population due to residential building, nonresidential building, municipal street, and public works construction. The noise levels are broken down into the five phases of construction described above.

To compute exposure of drivers and pedestrians, one multiplies the number of people per day passing each site by the number of sites. This gives the number of passersby exposed per day of site operation. Multiplying this number by the average number of days each site is operated gives the total annual number of instances in which an individual passes a construction site and is thus exposed to noise. For this computation, we use the number of sites from Table X and the number of passersby from Table XII. The duration of construction on the average site is not available from survey data but the following figures are considered typical:

- Residential buildings (single-family only) — 27 days
- Nonresidential buildings and multifamily dwellings — 170 days
- Streets and Public Works — 7 days.

AR0070528

TABLE XV. AVERAGE AND PEAK EXPOSURE LEVELS TO CONSTRUCTION NOISE

Number of People	Average Levels, Construction Phase					Peak Levels, Construction Phase				
	I	II	III	IV	V	I	II	III	IV	V
				RESIDENTIAL BUILDING CONSTRUCTION

1,730,000										
				MUNICIPAL STREET AND PUBLIC WORKS CONSTRUCTION						
14,500,000*	63.0	65.0	60.0	56.0	64.0	71.0	78.0	71.0	69.0	71.0
				FEDERAL AND STATE HIGHWAY CONSTRUCTION						
7,000,000*	63.0	65.0	60.0	56.0	64.0	71.0	78.0	71.0	69.0	71.0

*Assuming homogeneous exposure of all people indoors with windows shut.

AR0070529

The estimated number of occasions per year in which a driver or pedestrian passes a site is shown in Table XVI below. These figures do *not* represent the number of people who pass construction sites, since one person may pass many sites, or one site many times. If one divides the grand total of Table XVI, 24.7 billion passings, by the total national metropolitan population of 137 million, it is seen that the average inhabitant of metropolitan areas passes a construction site approximately 180 times per year.

3.2.2. Impact assessment

Determining the impact of construction noise on people is a multistage process. The procedures by which estimates of levels and durations of noise exposures were derived are discussed in the preceding section (3.2.1). Development of the criteria by which the severity of noise effects are judged is discussed in Sec. 3.1. In this section, we explicitly combine the exposure data with the criteria; Appendix B contains a number of important comments on the inferences which may be prudently drawn from the findings reported here.

Table XV of Sec. 3.2.1 and Table XVII of this section provide an overview of the exposure data as they pertain to impact assessment. The tables contain information about the number of people who receive primary and secondary exposure to construction site noise and the levels of noise to which they are exposed *in their listening environments*. Estimates of the duration of noise exposures are also presented in the tables. The following discussion is organized according to strength of impact.

AR0070530

TABLE XVI. ESTIMATED ANNUAL PASSINGS OF CONSTRUCTION SITES — ALL METROPOLITAN REGIONS* (MILLIONS OF OCCURRENCES)

	Residential Buildings	Nonresidential Buildings	Municipal Streets and Public Works	Total
Drivers and Passengers	8,300	5,160	1,980	18,440
Pedestrians	2,760	2,700	882	6,342
			Grand Total	24,782

*A "passing" is defined as one person passing one site by car or foot.

AR0070531

Speech Interference

Perhaps the single most obvious effect of exposure to construction site noise is speech interference. Even cursory examination of Table XV reveals that in almost all phases of construction, noise levels associated with construction activity are capable of degrading speech communication. In many instances — specifically, those in which construction noise produces levels approaching or exceeding 80 dB(A) in the listening environment — degradation of speech communication is severe. When one considers that the "average" levels of Table XVII are energy averages, it is clear that peak levels of construction noise, although infrequent, can preclude speech communication completely.

It is apparent from Table XVII that for those people who live or work in the vicinity of construction sites (i.e., those who receive primary exposure to construction noise), the duration of speech interference effects can be considerable. It seems safe to state that approximately 34 million people suffer a total of several hundred hours of speech interference yearly as a result of exposure to construction site noise in the United States. Approximately 20 million of those people must communicate in noise environments which seriously degrade speech intelligibility and/or demand significantly increased vocal effort.

In contrast to those who must endure such speech interference on a relatively long term basis, there are many more people who suffer the same effects on a briefer time scale. These people are the passersby who are exposed to construction site noise for a matter of minutes daily. Although the actual number of different individuals who pass by construction sites on foot or in vehicles is difficult to estimate, there are probably on the order of 25 billion such brief encounters yearly. The prin-

AR0070532

TABLE XVII. ORDER OF MAGNITUDE ESTIMATES OF YEARLY DURATION OF CONSTRUCTION NOISE EXPOSURE

Source	Number of People	Hours of Exposure by Construction Phase				
		I	II	III	IV	V
Primary (Stationary) Exposure to Domestic Construction Noise	11,500,000	24	24	40	80	40
Primary (Stationary) Exposure to All Other Building Construction	1,500,000	80	320	320	480	160
Primary (Stationary) Exposure to All Other Construction in SMSA Areas	14,500,000	8	8	16	16	8
Municipal Public Works		12	12	24	24	12
Federal and State Highway	7,000,000	250	250	500	500	250
Subtotal						
Secondary (Passerby) Exposure of Pedestrians to Construction in All SMSA Areas	6,348,000,000*	Five minutes' exposure to levels approximately 30 dB higher than those of Table XV				
Secondary (Passerby) Exposure of Drivers and Passengers to All Construction in SMSA Areas	18,440,000,000*	Thirty seconds' exposure to levels approximately 15 dB higher than those of Table XV				
Subtotal						

*These figures represent the number of annual occurrences of exposure, defined as the product of the number of people exposed and the frequency of their exposure.

AR0070533

cipal effect of such transient exposure to construction noise is probably interruption of conversation.

Applying state-of-the-art noise reduction techniques to the major sources of construction noise could provide a meaningful reduction of both the severity of speech interference and the number of people exposed to speech interference effects. Quieting all construction equipment by 10 dB(A) would lower peak construction noise levels by an equivalent amount and average levels by a somewhat lesser amount (due to overlapping temporal patterns of use). Nonetheless, speech interference effects increase sharply in the range between 60 and 80 dB(A), so that a noise reduction of about 10 dB(A) would be highly beneficial. Interestingly enough, the advantages of reducing construction noise an additional 10 dB(A) might not be as great. Although 70 dB(A) reduction of construction noise would clearly result in even less speech interference than would a 10 dB(A) reduction, at the resulting levels construction noise might well be submerged in background noise a good part of the time. Additional reductions [beyond the first 10 dB(A)] might be necessary for the benefit of those who operate the equipment, however.

Sleep Interference

To the extent that construction activity and sleep do not commonly occur during the same hours, construction noise does not interfere with sleep. However, daytime sleeping needs of the very young, the aged, and people working irregular or night hours, and emergency and other nighttime construction work must be taken into account. The total number of adults so affected by construction is estimated to be about 3 million. Judging from the ratio of people exposed to construction noise to the total population of the country, approximately 1/7 of the children four years of

AR0070534

age or younger, or about 7.3 million, might also be exposed to sleep interference from construction noise.

The 5.5 million people attempting to sleep during exposure to construction noise are likely to encounter substantial interference. Even at relatively great distances from construction sites, levels in the vicinity of 50 dB(A) are encountered. Such levels are capable of significantly lengthening the time required to fall asleep and of awakening roughly 40% of sleeping persons.

Nonetheless, the usefulness of reducing average construction noise levels by 10 dB(A) (possible through state-of-the-art noise reduction procedures) appears marginal. The number of people whose sleep is disturbed by construction noise is relatively small, and the shallow slope of the function relating the number of people awakened to noise levels argues that construction noise would have to be reduced by much more than 10 dB(A) to effect a significant reduction of sleep interference.

Hearing-Damage Risk

The risk of hearing damage from construction noise for those not directly concerned with construction activity does not seem very great. In most cases the distance between the construction site and people exposed to its noise and the transmission loss of the buildings or vehicles are sufficiently great to minimize the probability of hearing damage. It is possible that peak noise levels from construction sites might present some risk to those who are frequently in close proximity to the site. The greater number of such people (presumably pedestrians), however, are subject only to short exposure durations.

If state-of-the-art noise reduction techniques were applied to the major sources of construction noise, exposure levels would

AR0070535

probably be sufficiently reduced to render hearing damage a remote risk. In short, construction noise does not pose a major hearing-damage risk for the public.

Other Indirect Effects

Without doubt, a major consequence of exposure to construction noise for many people is annoyance. Both those who are exposed to construction noise on a regular, long-term basis as well as those who are exposed to it on a transient basis are annoyed by their exposure. Annoyance is particularly great if the noise intrusion from the construction site is perceived as unnecessary or inappropriate. People who must endure weeks or months of construction noise exposure may exhibit some form of habituation to the noise, but despite the commonly expressed attitude toward noise of "you get used to it", it is doubtful that construction noise ever loses all of its annoyance value.

In relative terms, annoyance from construction noise probably represents less of a problem than annoyance produced by aircraft or traffic noise. Nonetheless, both individual complaint behavior and community action could conceivably result from the annoyance of exposure to construction noise.

One measure formulated to provide some degree of quantification for annoyance due to noise exposure is the Noise Pollution Level [8]. Table I contains NPL's encountered in the immediate vicinity of construction sites. Unfortunately, interpretation of NPL's is not a straightforward procedure. Relative interpretations of two or more noise situations are readily enough made through use of the NPL index. Few grounds exist, however, for absolute interpretations. It has been suggested that long-term exposure to noise levels characterized by an NPL value of 72

AR0070536

(computed from A-level measurements) is "acceptable" [2]. By this criterion, noise levels in the immediate vicinity of construction sites are clearly "unacceptable" on a long-term basis. However, the bulk of exposure to construction noise of such high levels is of a transitory nature. Residents or transients exposed to construction noise would be exposed to levels about 30 dB lower. Although it would be tempting to assert that such exposure (to NPL's in the range of 60–70) would be marginally acceptable, only meager evidence could be marshalled to support such a claim.

It is distinctly possible for exposure to construction noise to result in task interference. It seems plausible that among the approximately 20 million people exposed on a long-term basis to the highest levels of construction noise (Table XV), some might be engaged in exacting manual or mental work which could be sensitive to interference. Such tasks might include medical operations, library use, scholarly activities, and the like. Unfortunately, one cannot quantify the amount of task interference produced by construction noise by applying the usual procedures of estimation and assumption.

Similar comments apply to the potential startle and physiological stress produced by exposure to construction noise. Although startle does not seem to be a very common consequence of exposure to construction noise, it is nevertheless possible for startle to result from unexpectedly or intermittently high-level noise. The size of the standard deviations of distributions of construction noise levels discussed in Sec. 3.2.1 makes the occurrence of unusually high noise levels reasonably probable events.

As for the stressful consequences of exposure to construction noise, we can offer only informed conjecture. Noise-induced

AR0070537

physiological stress is known to be cumulative, and exposure to construction noise is only one determinant. Perhaps some of the people who are faced with exposure to construction noise at work every day for months must also face noisy home environments. For such people, exposure to construction noise could constitute a major source of stress.

Tables XVIII and XIX summarize the impact of construction noise on people. A composite quantity intended to reflect both the extent and duration of exposure to specific noise sources was developed to permit concise summation. The quantity is defined as the product of the estimated number of people exposed to noise from a particular source and the estimated duration of individual exposure to the same source. The statistic expressing the quantity is called (for lack of a better term) the "person-hour".

Extreme caution must be used in interpreting figures expressed in terms of person-hours. First, figures so expressed are intended only as order-of-magnitude estimates rather than as precise quantities. Second, inferences about the equivalence of number of people and duration of exposure in assessing psychological or physiological impact are completely unjustified. No compensatory model of number of people exposed and exposure duration is intended. Third, comparison of person-hour figures for exposure to noise from one source with person-hour figures for exposure to noise of another source is without theoretical foundation. Thus, comparisons of impact among different sources expressed in common terms of person-hours should be performed in a fashion similar to "addition" of apples and oranges. In other words, inferences about severity of impact may be drawn only withint person-hour estimates of similar origin.

AR0070538

TABLE XVIII. ORDER-OF-MAGNITUDE ESTIMATES OF CONSTRUCTION NOISE EXPOSURE IN MILLIONS OF PERSON-HOURS PER WEEK

Source	Millions of Person-Hours Per Week
Primary (Stationary) Exposure to Domestic Construction Noise	42
Primary (Stationary) Exposure to All Other Building Construction	39
Primary (Stationary) Exposure to All Other Construction in SMSA Areas	18
Subtotal	101

Secondary (Passerby) Exposure of Drivers and Passengers to All Construction in SMSA Areas	0.3

AR0070539

TABLE XIX. ORDER-OF-MAGNITUDE ESTIMATES OF IMPACT OF PRIMARY AND SECONDARY EXPOSURE TO CONSTRUCTION NOISE EXPRESSED IN MILLIONS OF PERSON-HOURS PER WEEK

Noise Source	Speech Interference*		Sleep Interference*		Hearing Damage Risk	
	Moderate (45–60)	Severe (>60)	Slight (35–50)	Moderate (50–70)	Slight (70–80)	Moderate (80–90)
Primary (Stationary) Exposure to Domestic Construction Noise	44			2	0	
Primary (Stationary) Exposure to All Other Building Construction	38			2	0	
Primary (Stationary) Exposure to All Other Construction in SMSA Areas	14			1	0	
Secondary (Passerby) Exposure of Pedestrians to Construction in All SMSA Areas		10	0			10
Secondary (Passerby) Exposure of Drivers and Passengers to all Construction in SMSA Areas		0.3	0			0.3

*Entries in these columns may not be interpreted directly as person-hours of direct speech or sleep interference (see text).

AR0070540

With these restrictions firmly in mind, the reader is referred to Tables XVIII and XIX for a concise summary of the impact of construction noise on people. Table XVIII expresses the impact of construction noise in terms of millions of person-hours per week. (It may be useful to bear in mind that a week in the United States contains approximately 35 billion person-hours.) Table XIX relates the impact of construction noise directly to the principal criteria of Sec. 3.1 in terms of person-hours per week. Entries for speech interference and sleep interference effects reflect the number of person-hours of potential impact, which may be interpreted as upper bounds.

3.3 Appliances

3.3.1 Extent of exposure

This section is concerned primarily with power tools and household appliances whose volume cannot be controlled by the user. Therefore, volume-controllable equipment such as televisions, radios, and stereos are not included, nor are gasoline-engine powered outdoor equipment and audible signaling mechanisms (bells, alarms, etc.). It should be noted, however, that non-controllable noise-producing devices often raise the background level of noise to such a degree that volume-controllable sound has to be increased in level to be heard and, hence, is more apt to affect neighbors. An estimate of the number of noncontrollable noise-producing devices being used in the United States in 1971 is given in Table XX.

To determine the extent of exposure to home appliance and tool noise, we gathered three kinds of data: The distribution of appliances and tools over family units, the time that the devices are typically in use, and the exposure of people who are

AR0070541

TABLE XX. NONCONTROLLABLE HOUSEHOLD NOISE SOURCES (1971) [31]

	Number (thousands)	Percent of Homes
Wired Refrigeration	69,400	100
Complete Plumbing	68,000	98

in the home. In collecting this information, we found that the variables, particularly with respect to personal behavior, covered a very large range. We therefore created a simplified model to cover the range of household values.

Data were obtained from a variety of sources. Statistical information was collected from government sources, such as the Bureau of the Census. Of particular help was information provided by Cornell University's College of Human Ecology on domestic living patterns. Industry information was obtained from various trade and business publications. Individual company materials were used in instances where the material was applicable to the whole industry and was available to the public. Various simulations representing consumer and home economists were conducted. We also conducted our own survey of appliance use in 40 households.

Appliances, Tools, and Building Equipment

The dimensions used by industry to analyze household appliance purchase and use patterns usually include home ownership, age of the head of the family, size of family, and family income. Since these dimensions are interrelated, we chose only one — family income level — for our analysis. We treat the time that appliances are used as a function of the age of the homemaker and of the number of school and pre-school children in the family. Figure 21 shows the trend toward greater use of home appliances and power tools. Figure 22 gives the distribution of some common appliances as a function of income level.

Noise-producing devices used in and around the home are usually classified as

AR0070543

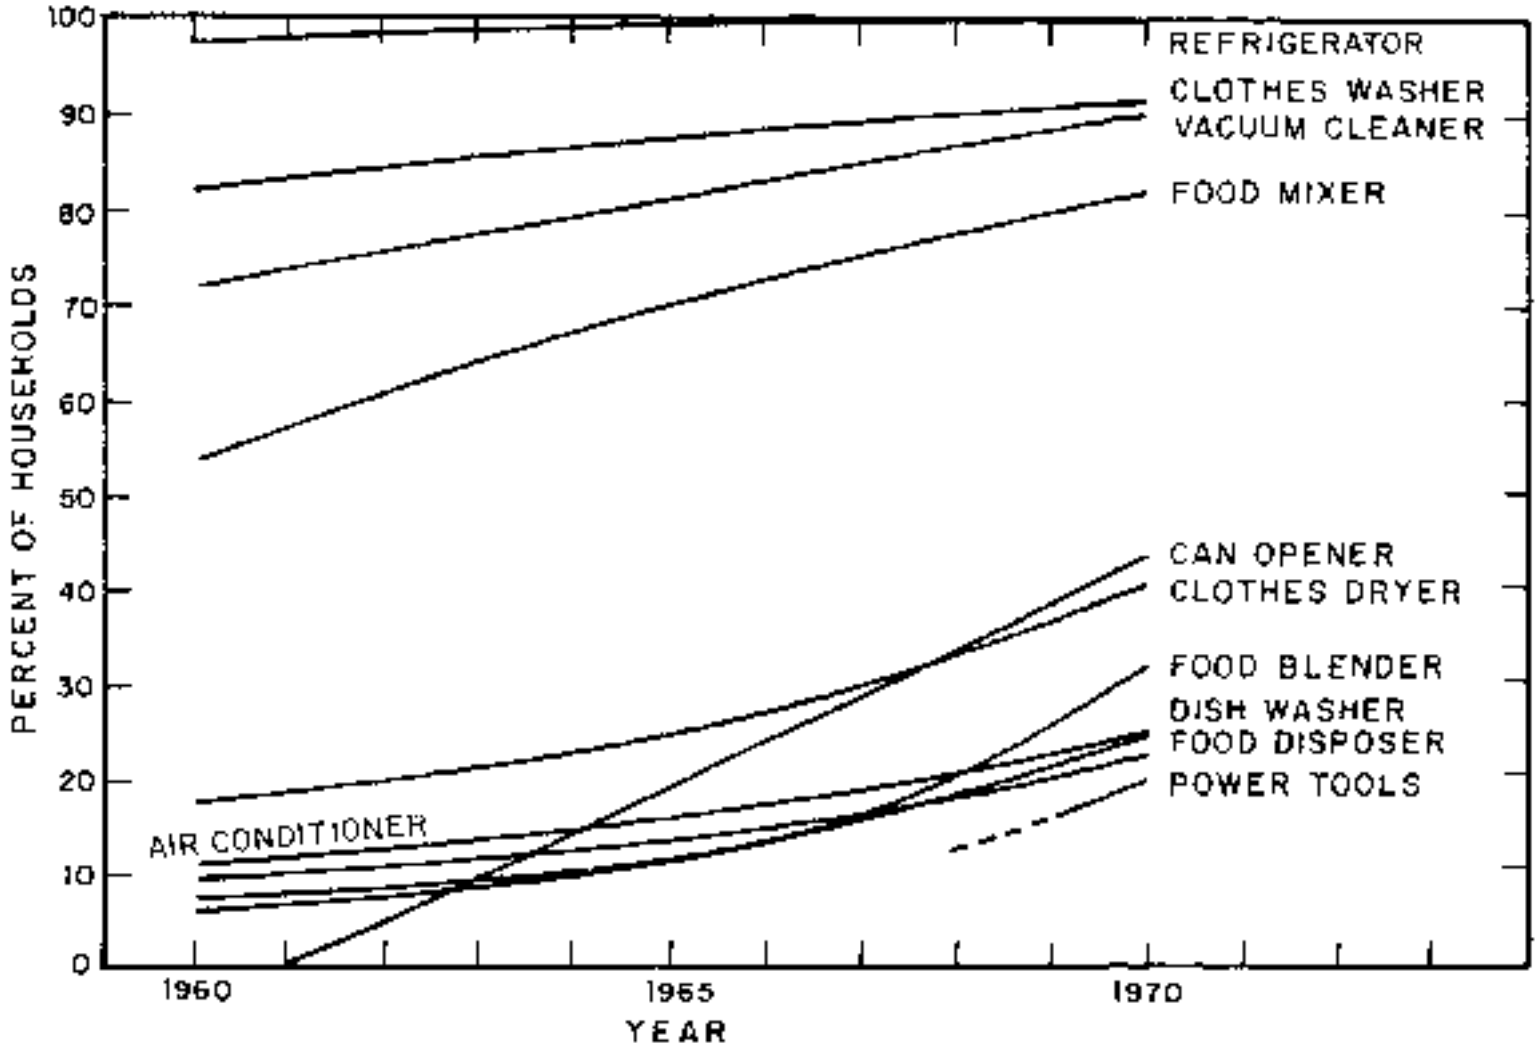

FIG. 21. PERCENT OF HOUSEHOLDS WITH SELECTED NOISE-PRODUCING APPLIANCES AND TOOLS.

AR0070544

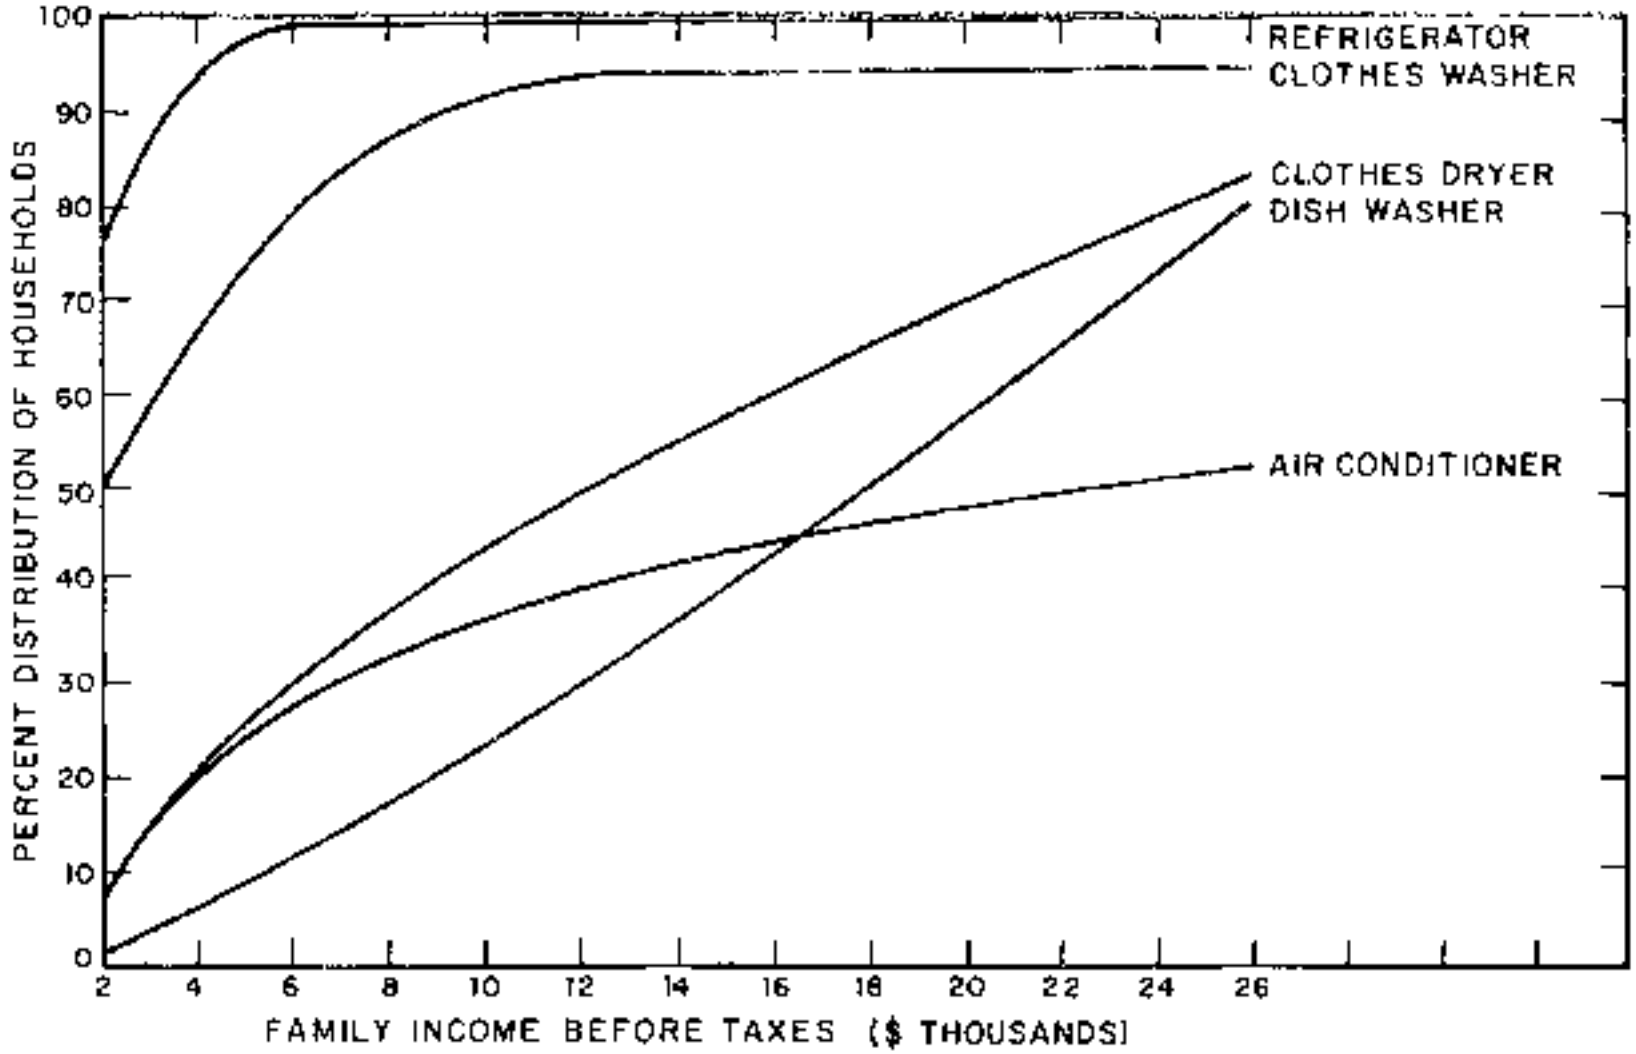

FIG. 28. ESTIMATED PLACEMENT DISTRIBUTION OF MAJOR APPLIANCES BY INCOME LEVEL.

AR0070545

- Major Appliances (including clothes washers, clothes dryers, refrigerators and freezers, air conditioners, dishwashers, vacuum cleaners, disposers, dehumidifiers, and compactors)
- Other Household Appliances
- Power Tools
- Outdoor Equipment
- Building Equipment

Other convenient classifications are based on time mode of operation (continuous or intermittent) and method of operation (manual or automatic).

Analysis of the noise-producing building equipment used in homes is complicated by interaction of the equipment with the structure of the house, by do-it-yourself modifications of equipment, and by differences in the adequacy of equipment maintenance. Size of housing is also a factor in noise level. Smaller housing units are apt to be noisier because of reverberant buildup of sound levels. Larger housing units on the other hand, frequently reflecting a higher standard of living, tend to have more appliances and more frequent exposure but lower noise levels for any particular appliance owing to the larger space and to the room separation from the various sources. Multiple-family housing units are subject to higher levels of noise from the building equipment.

In heating systems either the heating source or distribution system or both are common sources of noise; however, the number of factors involved is too great to allow a precise analysis of the extent of heating noise. Electric heating, which is essentially noiseless, is currently being used by 4.4 million customers.

AR0070546

(It should be noted, however, that electric heating customers are likely to be high users of electric appliances. Furthermore, humidity control, ventilating, and/or air cleaning, which are often used in conjunction with electric heating, require air circulation; therefore, fan noise is present where these additional functions are performed.) The more common heating systems generate burner noise, fan/duct noise (in hot-air systems), and pipe, valve, and pump noise (in hot water and steam systems).

Twenty-one percent of all households have one or more room air conditioners. Location of these air conditioners is distributed approximately [36]:

Living Room	35%	Kitchen	7%
Master Bedroom	27%	Playroom	4%
Other Bedroom	5%	Other	22%

All dehumidifiers and many humidifiers are substantial noise sources. Frequently, dehumidifiers are located in the basement and therefore direct exposure to the noise is small. Dehumidifiers are used in 6.7% of homes; humidifiers in 7.0% [30].

Living patterns, equipment installations, etc. are variables that make it difficult to estimate the extent of plumbing noise. The typical range of toilet flushes is 10 to 50 per day. Complete plumbing (hot and cold water, bath or shower, toilet) is found in 82% of all rental units and in 93% of all owner-occupied units in the United States.

The number of fans being used in this country far exceeds the total number of households. Many fans are part of other appliances, but many are used for immediate air circulation (i.e., cooling fans, kitchen fans, etc.).

AR0070547

Use of Domestic Appliances and Tools

The extent to which appliances are used is an important factor in assessing the total noise exposure. Statistical information is scarce, but we have found the following sources useful:

- BBN survey (in-depth study of noise levels and appliance use in 20 homes).
- New York State College of Human Ecology, Cornell University (both published and unpublished data gathered as part of a 1296-household survey of Syracuse, New York).
- Department of Agriculture information based on studies of home activities (a long-term interest, which is now being continued under the Agriculture Research Service Division of the Department of Agriculture).
- Potomac Electric Power Company (an informal survey conducted by their Home Services Department).
- Manufacturer's industry information.

Although many factors affect the range of appliance use, there is a tendency for people in the family-raising years to have increased incomes, own their homes, and possess more appliances. The time a homemaker spends in household activities is a strong function of age, number of children, and the presence of pre-school children, as shown in Table XXI. Table XXII presents the information on which we base our estimate of typical use of appliances; Table XXIII gives our estimate of appliance use in two typical households; appliance operating times are estimated from Table XXII. Using the values of appliance use (total minutes per week) and of average noise levels given in Table XXIII, we present in Fig. 23 a schematic illustration of the noise levels of the two typical households.

Level of Exposure

We have selected two criteria to show different measures of exposure. A *potential exposure* represents the number of people likely to be exposed to an appliance and depends solely on an average distribution of the population and the percentage of households that possess the particular appliance. A *primary exposure* is estimated by the normal mode of operation, the location

of the appliance, and the number of operators and observers likely to be exposed to noise when the appliance is operating. Table XXIV gives these two kinds of exposure for each appliance; Table XXV relates exposure to room level.

3.3.2 Impact assessment

The estimates of the extensiveness of distribution, duration of exposure, and noise levels of a variety of building equipment and home appliances are discussed here with a view toward assessing the impact of noise from these sources on people in the home environment. To approximate the environment in which noises are heard, we had to adjust the noise levels from the standardized values used in previous sections (i.e., levels recorded at a measurement position 3 ft from the source). Thus, 10 dB was added to the noise levels of hand-held appliances, such as electric shavers, to obtain a fair representation of noise levels at the user's ear. Similarly, 2 dB was subtracted from levels for exposure to noise in a highly reverberant field, such as a kitchen or bathroom; 3 dB from standardized measurements to account for noise exposure in less reverberant spaces, such as carpeted (living room) or open areas; 10 dB from the standard values to compensate for exposure in adjacent rooms connected by open doors; and 20 dB to represent the transmission loss of a typical frame house to noise from external sources (such as powered yard tools). Levels for about thirty typical home appliance and building noise sources adjusted in this manner appear in Table XXVI.

Table XXVII classifies the noise sources discussed in the previous section of this report into four categories: (1) Quiet Major Equipment and Appliances, characterized by operating levels lower than 60 dB(A); (2) Quiet Equipment and Small Appliances,

characterized by noise levels between 60 and 70 dB(A); (3) Noisy Small Appliances, characterized by noise levels between 70 and 80 dB(A); and (4) Noisy Electric Tools, characterized by noise levels in excess of 80 dB(A).

Group I: Quiet Major Equipment and Appliances

Group I contains the noise sources to which people are exposed for the greatest lengths of time in the home environment. Most building climate-control equipment, food-refrigeration appliances, and clothes dryers fall into this category. In view of the widespread distribution of equipment in Group I, it is indeed fortunate that this equipment is among the least noisy in the home.

In general, due to the low levels of noise produced by equipment and appliances in Group I, effects of exposure are either negligible or mild. Noise sources in Group I present no appreciable risk of hearing damage under conventional operating conditions. Under certain conditions, however, these noise sources can affect sleep. Of the noisier sources in Group I, only fans and air conditioners are likely to be present in sleeping quarters at night. These devices are characterized by nearly steady-state spectra because of their continuous operation. Differences in levels among operating cycles are small, so that peak noise levels are usually within a few dB of average levels. As such, these devices may delay the onset of sleep, but are unlikely to awaken many people. They may, in fact, facilitate sleep for those directly exposed to their noise, since they function as sources of masking noise which can suppress interference from other sources.

AR0070558

The major effect of exposure to noise from Group I equipment is speech interference. Conversations in the immediate vicinity of the noisier sources of Group I would have to be conducted in somewhat higher than normal levels, or at slightly shorter than normal speaking distances.

The annoyance value of exposure to noise from Group I appliances is also minimal. The steady-state nature of their amplitude and frequency spectra are highly conducive to rapid habituation. Only rarely does one become sufficiently aware of refrigerator noise, for example, to become annoyed by it. Indeed, it is the noise sources of Group I which define the background noise environment of many homes.

Exposure to Group I noise sources has little or no bearing on startle and stress. Very few people are startled by the noise of their air conditioners or feel menaced by the implications of their refrigerator's whirring.

Considering the mild nature of most of the effects of exposure to noise from Group I sources, noise reduction is not an urgent need. Many appliances in Group I already operate at or near the level of background noise in the home, so that submerging them further into the background noise environment would serve little purpose. Those few noise sources in Group I which do produce noise levels appreciably above background levels could probably profit greatly from approximately 10 dB(A) of quieting. Such noise reduction, well within the capabilities of existing technology, would alleviate the undesirable effects of noise exposure from this group of appliances.

AR0070559

Group II: Quiet Equipment and Small Appliances

Most of the noise sources of Group II are found in many American homes, although not all of the sources are as common as the major equipment and appliances of Group I. Noise levels in Group II are sufficiently elevated to render certain appreciable effects, particularly speech interference and annoyance. Fortunately, the typical pattern of exposure is an infrequent, brief encounter.

Of the three major effects by which noise impact is gauged in this report, noise sources in Group II produce only speech interference in significant measure. Hearing-damage risk is negligible, both for operators and for others who may experience secondary exposure. Since most of the appliances in this group require an operator, sleep interference is not a serious consequence of primary exposure. Secondary exposure probably affects daytime sleeping to some slight extent. Secondary exposure to plumbing noise in multi-unit residences could conceivably awaken as many as 35% of sleepers, although habituation probably reduces the percentage dramatically.

Operators of the appliances in Group II would find speech communication during operation quite difficult; conversations would have to be conducted with significantly greater than normal vocal effort or at very short ranges, and the intelligibility of fixed level speech (such as radio or television) would become marginal. The obvious mitigating circumstances, however, is the brevity of noise exposure typical of this group of appliances. In practical terms, the most likely consequence of exposure to this sort of short duration appliance noise is a temporary interruption of conversation.

AR0070560

Annoyance is the most significant of the indirect consequences of exposure to noise from Group II appliances. While the operator may be summarily annoyed by the brief speech interference effects, people experiencing secondary exposure may be equally, if not more, annoyed. The annoyance of these people (such as neighbors in multi-unit residences or other family members in different rooms) is conditioned in part by the intrusive nature of the exposure and in part by feelings of lack of control of the noise source. Feelings of helplessness, exasperation, or frustration are themselves unpleasant and can produce further annoyance. Should secondary exposure become unduly or unreasonably common, physiological stress from emotional arousal might develop.

Primary exposure to the noise of these appliances is not likely to result in much task interference. This is true simply because it is the undemanding and highly practiced task at hand that is generating the noise. Exposure to appliance noise for people other than the operator could interfere with certain highly sensitive tasks. Generally, however, considering the usual brevity of exposure, such task interference would be the exception rather than the rule.

A 10 dB(A) reduction of noise levels produced by appliances of Group II would be a useful and worthwhile endeavor. Many of the effects of secondary exposure would become negligible, while the speech interference effects for the operator would be considerably reduced. It is clear from Table XXVII that the single most common source of noise exposure in the home is plumbing. Better design of plumbing fixtures would have a gradual but significant effect in making multifamily residences less noisy. Sales resistance to less noisy products (including the much-discussed "quiet vacuum cleaner") may be expected to diminish as the public becomes more noise conscious.

AR0070561

Group III: Noisy Small Appliances

The distribution and exposure patterns of noise sources in Group III continue the trend observed in Group II. Group III appliances are found in fewer homes than the appliances of the preceding group. Exposure to their noise is for equally brief periods at long intervals. Both of these factors tend to moderate the impact of the relatively high-level noise developed by these appliances.

Hearing-damage risk can no longer be dismissed as of minor importance for this group of noise sources. While it is true that average exposure is measured in fractions of hours per week, it is very likely that certain elements of the population are exposed to one or another of Group III source for prolonged periods of time. Some seamstresses, for example, could easily be exposed to several hours of sewing machine noise daily. Yard care specialists might be exposed to equivalent amounts of lawn mower noise. Although even these exposure durations would not constitute an imminent hazard to hearing (in the sense that they would be unlikely to lead to sizeable permanent threshold shifts for many years), they would nevertheless hasten eventual hearing damage in the context of cumulative exposure from many sources. In Miller's [16] terminology, noise sources in Group III would be rated "yellow" (cautionary) with respect to hearing-damage risk.

Speech interference is severe. Operators receiving primary exposure to noise sources of Group III would not attempt conversation during the brief periods in which the appliances are used, although communication by shouting would still be possible. Secondary exposure to the noise of Group III sources would also interfere somewhat with verbal communication. The principal

AR0070562

form of interference, however, would be degradation of speech intelligibility rather than more severe disruptions of conversation.

Since appliances of Group III require operators, sleep interference effects of primary exposure to their noise are negligible. Sleep interference effects of secondary exposure to this set of appliance noises also tend to be low, both because the noise exposure often occurs during hours during which sleep is uncommon and because the very brief periods of exposure occur only infrequently. Of course, the tendency for more mothers to be employed outside the home during the day constrains their use of appliances to evening hours, when the attendant noise levels may interfere with family social activities and the sleep of young children.

Annoyance is once again the chief indirect effect of exposure to noise from Group III sources. The operator himself may find the noise signature of the appliance unpleasant, particularly if it contains pure tone components or a highly variable temporal distribution of levels. Secondary exposure to these noises is also likely to be annoying, particularly if the people exposed to the noise feel that they are deriving none of the benefits of the appliance's use.

Task interference, startle, and stress reactions are all plausible consequences of exposure to this sort of noise. As usual, however, difficulties in assessing the unexpectedness of the intruding signal or the nature of background activity make precise prediction of the magnitude of these effects impractical.

Reduction of noise produced by appliances of Group III could substantially reduce the levels of hearing-damage risk and speech interference. The operator's annoyance with the noise signature of an appliance could also be affected by noise reduc-

AR0070563

tion, but special attention would have to be paid to the spectral characteristics of the appliance. All of the effects of secondary exposure to noise from this appliance group would be significantly lessened by a 10 dB(A) reduction of noise output levels.

Group IV: Noisy Electric Tools

Group IV contains the appliances which produce the highest levels of noise exposure in the home environment. Considering the potentially serious effects of exposure to such levels, it is fortunate that the distribution of sources is quite restricted. As may be seen from Table XXVII, only about 250,000 electric yard care tools have been sold, and only about 12 million electric shop tools are in use. Further, the use of such tools is probably concentrated in nonurban areas where secondary exposure effects are not as widespread as they might be in multi-unit residences.

Hearing-damage risk can be great if exposure to the noise levels of Group IV sources is habitual or prolonged. Hobbyists who engage in regular use of power tools are likely to receive considerably more than the average six minutes per week exposure noted in Table XXVII. Many such tools (saws, drills, routers, etc.) are operated within a few feet of the user's ear, making hearing-damage risk even more probable. In Miller's (1971) terminology, such tools can produce "orange" or even "red" hearing damage risk if exposure is prolonged. It is doubtful that any major risk of hearing damage is encountered in secondary exposure, owing to the much lower levels experienced.

Speech interference effects of exposure to noise of Group IV sources can be of sufficient magnitude to preclude verbal communication in any form other than shouting directly into the

AR0070564

[illegible] be loud enough to require conversation to be conducted at high levels of vocal effort or at very short distances. As was pointed out earlier, however, relatively few people are affected by such secondary exposure, and those who are affected are exposed for only brief intervals.

Sleep interference effects of exposure to Group IV noises could be quite serious were the hours of use of Group IV appliances to coincide with hours of uninterrupted sleep. Primary exposure, of course, is not a problem here, but even secondary exposure can reach levels in the vicinity of 60 to 70 dB(A). Data from the Wilson report [58] may be interpreted as predicting that such levels will awaken one-half of all sleepers and about one-third of all people would find it difficult to fall asleep. Use of electric yard care tools at night is unlikely, but home shop tools are often used at night.

To the extent that noise exposure to such high levels is perceived as avoidable or unnecessary, annoyance effects are probably quite pronounced. A neighbor's noise, particularly at such high levels, is rarely welcome. The high noise levels produced by these tools may also interfere with the very tasks the operators are attempting to accomplish. If noise levels are sufficiently high to mask warning signals or other unexpected acoustic signs of danger, the safety of the operator and his efficiency may be compromised. Stress produced through prolonged exposure to noise levels characteristic of Group IV tools may be appreciable, particularly if exposure is involuntary.

Considering the seriousness of the effects of exposure to noise of appliances in Group IV, application of noise reduction techniques is urgently needed. Reduction of noise levels by as

AR0070565

little as 10 dB(A) would have immediate benefits in reducing the hearing-damage risk to the operator and reduction of the speech interference and annoyance-related effects for those receiving secondary exposure.

Summary of Effects of Appliance Noise on People

Tables XXVI and XXVII summarize the impact of appliance noise on people in concise terms. Table XXVII contains an account of the extent and duration of noise exposure from all four appliance groups in terms of millions of person-hours per week. The reader is reminded of the cautions expressed in the summary of Sec. 3.2.1 for the interpretations of figures expressed in person-hours. Table XXVIII relates person-hours of exposure directly to the major criteria of Sec. 3.1.

3.4 Projections of Construction and Appliance Noise to the Year 2000

Projecting conditions to the year 2000 involves a number of uncertainties. One of these is the exponential rate at which technology is evolving and affecting society. As pointed out by Sir Arthur Clark*, life in the year 2001 will be as different from the present as the present is from 1890. Who – in 1890 – could have realized the impact that electricity and the automobile would have both on life style and on the environment? Technological innovation, however, is not the only factor to be considered. One simply cannot account for future changes in social attitudes. Although a few far-sighted technologists may have predicted in 1940 the capability to transport passengers at

*Lecture to the Arlington Library Association, Arlington, Mass. (Sept. 1970).

AR0070566

TABLE XXVIII. ORDER-OF-MAGNITUDE ESTIMATES OF EXPOSURE TO HOME APPLIANCE AND BUILDING EQUIPMENT NOISE EXPRESSED IN MILLIONS OF PERSON-HOURS PER WEEK

Noise Source	Speech Interference*		Sleep Interference*		Hearing Damage Risk	
	Moderate (45–60)	Severe (>60)	Slight (35–50)	Moderate (50–70)	Slight (70–80)	Moderate (80–90)
Group I: Quiet Major Equipment and Appliances						
Fans	[illegible]		[illegible]		[illegible]	
Air Conditioner	[illegible]		[illegible]		[illegible]	
Clothes Dryer	[illegible]		[illegible]		[illegible]	
Humidifier	[illegible]		[illegible]		[illegible]	
Freezer	[illegible]		[illegible]		[illegible]	
Refrigerator	[illegible]		[illegible]		[illegible]	
Group II: Quiet Equipment and Small Appliances						
Plumbing (Faucets, Toilets)		[illegible]	[illegible]		[illegible]	
Dishwasher		[illegible]	[illegible]		[illegible]	
Vacuum Cleaner		[illegible]	[illegible]		[illegible]

Home Shop Tools		[illegible]		[illegible]		[illegible]
Electric Yard Care Tools		[illegible]		[illegible]		[illegible]

*These figures are not directly interpretable in terms of permanent loss of hearing or speech interference (see text).

AR0070567

supersonic speeds, it is doubtful that they could have predicted that such a technologically feasible system would be abandoned largely because it was expected to make too much noise.

Although any long-term predictions are fraught with such difficulties, one can still make educated guesses with a reasonable level of confidence. Rather than merely extrapolate existing conditions to the indefinite future, we try to be somewhat quantitative by projecting the impact of construction and appliance noise on the basis of existing forecasts of population, family size, gross national product, and trends toward urbanization. Construction activities will continue to follow such growth patterns, although the character of construction may change significantly with greater use of prefabricated materials and the introduction of new kinds of equipment. Similarly, ownership of appliances has been found to be a function of family income level, and we use their relationship to project the growth of appliance use in the generally more affluent households predicted for the year 2000. Also, rather than trying to account for conflicting trends and changing attitudes, we project the extent of exposure with the assumption of no change in noise level for a given equipment or appliance type and consider only major trends that can be easily identified.

We use the following data, taken from the U.S. Census Bureau, for projecting the increase in exposure to construction and appliance noise:

	1970	2000	Ratio
GNP (billions of 1958 dollars)	720	2240	3.2
Total Population (millions)	200	293	1.45
Total Number of Households (millions)	63	104	1.65
People per Household	3.17	2.8	0.9

AR0070568

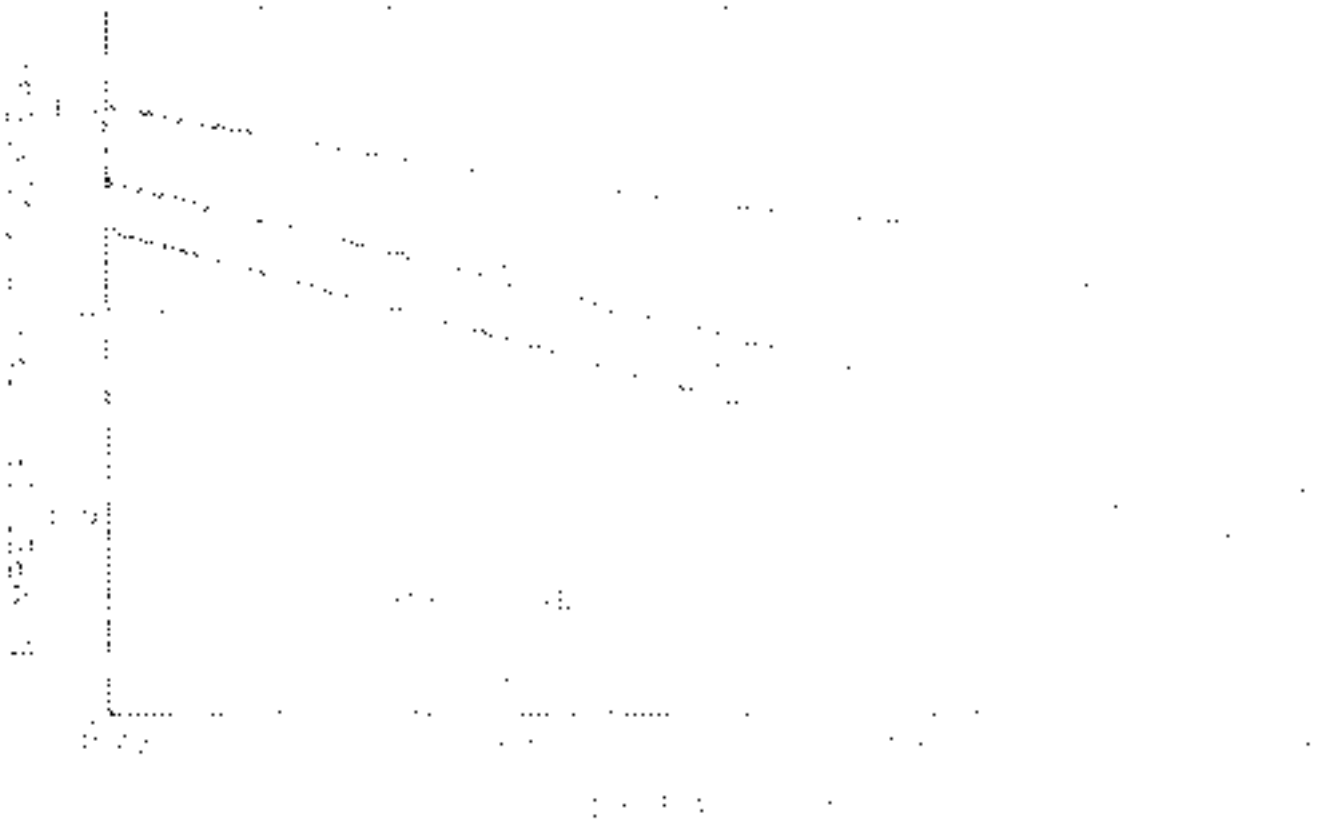
3.4.1 Construction activity

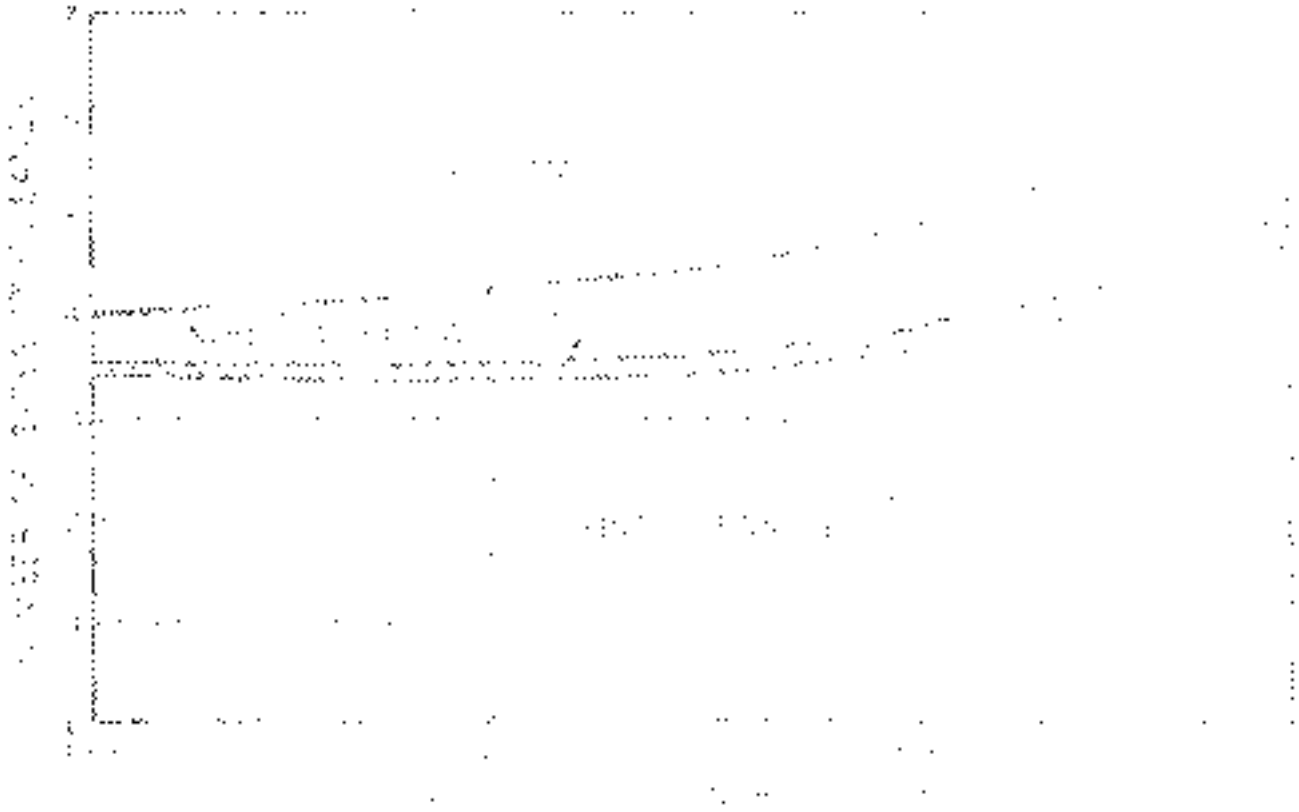
Given the predicted increase in population and in financial resources, one can expect fairly extensive building activity. However, the urban areas have limited space available for new building; thus, the trend is for areas outside those now identified as central cities to become urbanized. Figure 24 illustrates this trend for single-family, multi-family, and nonresidential construction activities. With available land becoming more and more scarce within the central city, the building of single-family and multi-family dwellings will continue to decrease sharply. In 2000, we can expect to find approximately one-third the number of residential construction sites as were active in 1970. Nonresidential building is expected to increase. In areas outside the central cities, both residential and nonresidential construction should increase significantly. Nonresidential building activity is expected to increase by over 50% as the present suburbs become urbanized. With this general trend in mind, we use the data given above to project the expected increase in exposure to noise from construction activities.

Nonresidential

We assume that the level of nonresidential construction activity in any given year is proportional to the real Gross National Product (GNP) for that year. To find the nonresidential construction activity for any particular year, the ratio of the GNP for that year to the 1970 GNP is multiplied by the number of nonresidential sites built in 1970 (Table X). The resulting total construction figures are apportioned between "central cities" and "other metropolitan areas" in the same proportions as occurred in 1970. Despite the expected decrease in total con-

AR0070569





struction site within the central city, nonresidential sites are expected to increase.

Residential

We assume that the population and population density of central cities will remain at their present levels until the year 2000, and that most residential construction in central cities will be for the purpose of replacing decayed units rather than for housing new population. The number of construction sites will decrease due to the established trend toward an increasing population of multi-family dwellings over single-family dwellings. (Two- to four-family houses, which represent a negligible fraction of total construction, are here included in the total for single-family housing.)

For metropolitan areas other than suburbs, the number of units constructed in any one year is assumed to be proportional to the population increase in the previous ten years. To estimate this increase, we project the total metropolitan population by multiplying the projected total national population by the estimated proportion of the population living in metropolitan areas. All the increase in metropolitan areas population for a particular year is ascribed to noncentral city areas.

Roads

A simple but plausible indication of road construction activity, is the population level. Clearly additional people will require additional roads, the capability of rapid transit being small at present. However, the urban areas have limited space for new roads, and urban residents are expressing increasing opposition to new road construction on grounds of aesthetics,

AR0070571

pollution, and the community dismemberment concomitant with the installation of limited access highways. Thus, it would seem unlikely that road construction will rise as fast as other measures such as the GNP. We therefore project the future level by multiplying the present level of activity by the ratio of the projected population divided by the current population.

The number of people affected by construction sites is computed in the manner described in Sec. 3.2.1. Population densities for all metropolitan areas are assumed to be constant with time – 4500 people/sq mi for central cities and 2400 people/sq mi for other metropolitan areas. At any one site, people are apportioned to specific transmission loss intervals according to the method shown in Fig. 20. The resulting exposure to construction noise is given in Fig. 25 in person-hours. In this figure, multifamily residential construction has been included with nonresidential construction, since these types of building activities are quite similar. Note that the number of people exposed to noise from single-family dwelling construction declines steadily with time. This trend is more than compensated for by the rapid increase in nonresidential and multi-family sites – for which the duration of construction is typically six times greater than the duration for single-family houses. Thus, the number of person-hours of exposure is expected to increase by about 50% in the next 30 years.

3.4.2 Appliance use

We assume that the probability of future appliance ownership as a function of income level will remain the same and that appliance costs will remain approximately the same in current dollars. With these assumptions in mind, we base our approximation of appliance use on projected population, family income,

AR0070572

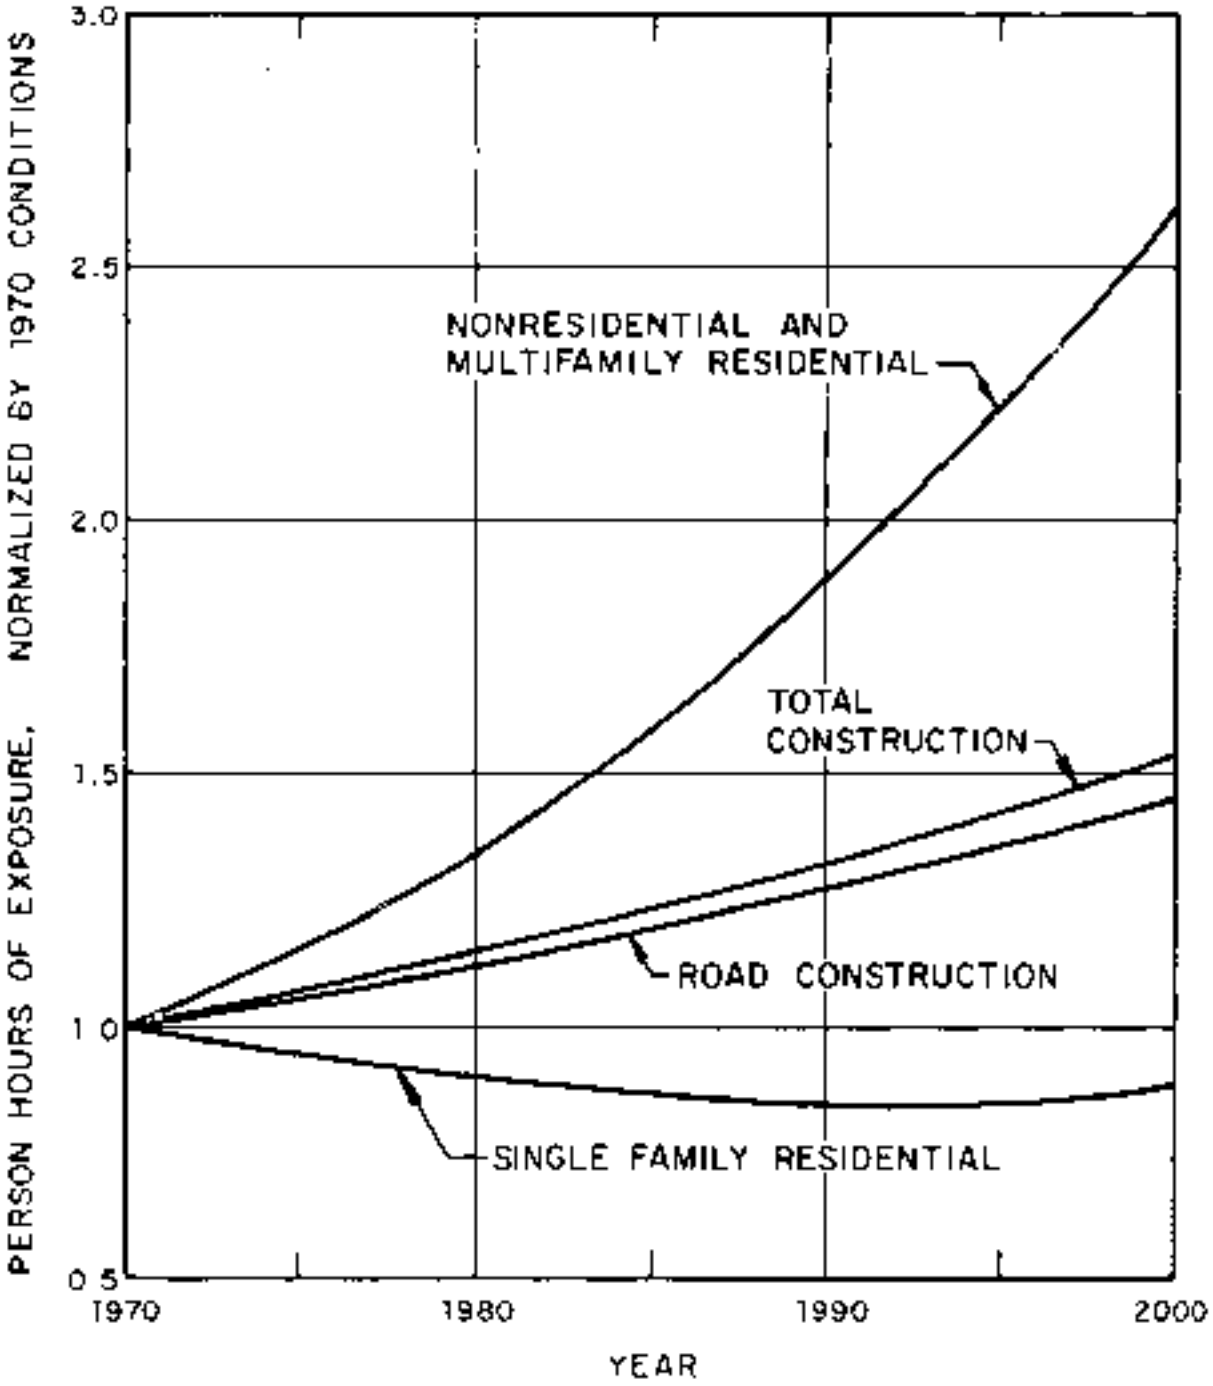


FIG. 25. PROJECTED CHANGE IN EXPOSURE TO CONSTRUCTION NOISE, ASSUMING NO CHANGE IN NOISE LEVELS.

and income distribution. This estimation is likely conservative as some appliances are continuing to increase their acceptance in all income levels, although their growth of acceptance is low at the higher income levels where some appliances have nearly saturated the market. For those appliances for which insufficient information is available on appliance possession at the various income levels to make the projection described above, we estimate future possession from current marketing information on percentage of replacement sales and on market penetration.

In projecting future impact, we estimate that the appliance usage will remain approximately at current levels. Supporting this assumption is the little deviation shown in average time spent by homemakers over the last forty years.

Figure 26 illustrates the increase in exposure to appliance noise by plotting hearing-damage risk and speech and sleep interference in person-hours of exposure. As explained in Sec. 3.1, these three effects are among the most salient and tangible consequencies of noise exposure and thus can be most readily interpreted in nontechnical terms. As can be seen on Fig. 26, we project that number of person hours during which people will be exposed to the risk of hearing damage will more than double in the next thirty years, as will the number of person-hours during which normal conversation will be difficult and people will be either awakened or prevented from falling asleep.

As explained previously, we have not taken into account certain trends, discussed in Sec. 4, which are having some effect on the noise levels produced by construction equipment and appliances. However, one should note, when reviewing these projections, that industries are becoming sensitive to a growing concern about noise pollution among the general population. For

AR0070574

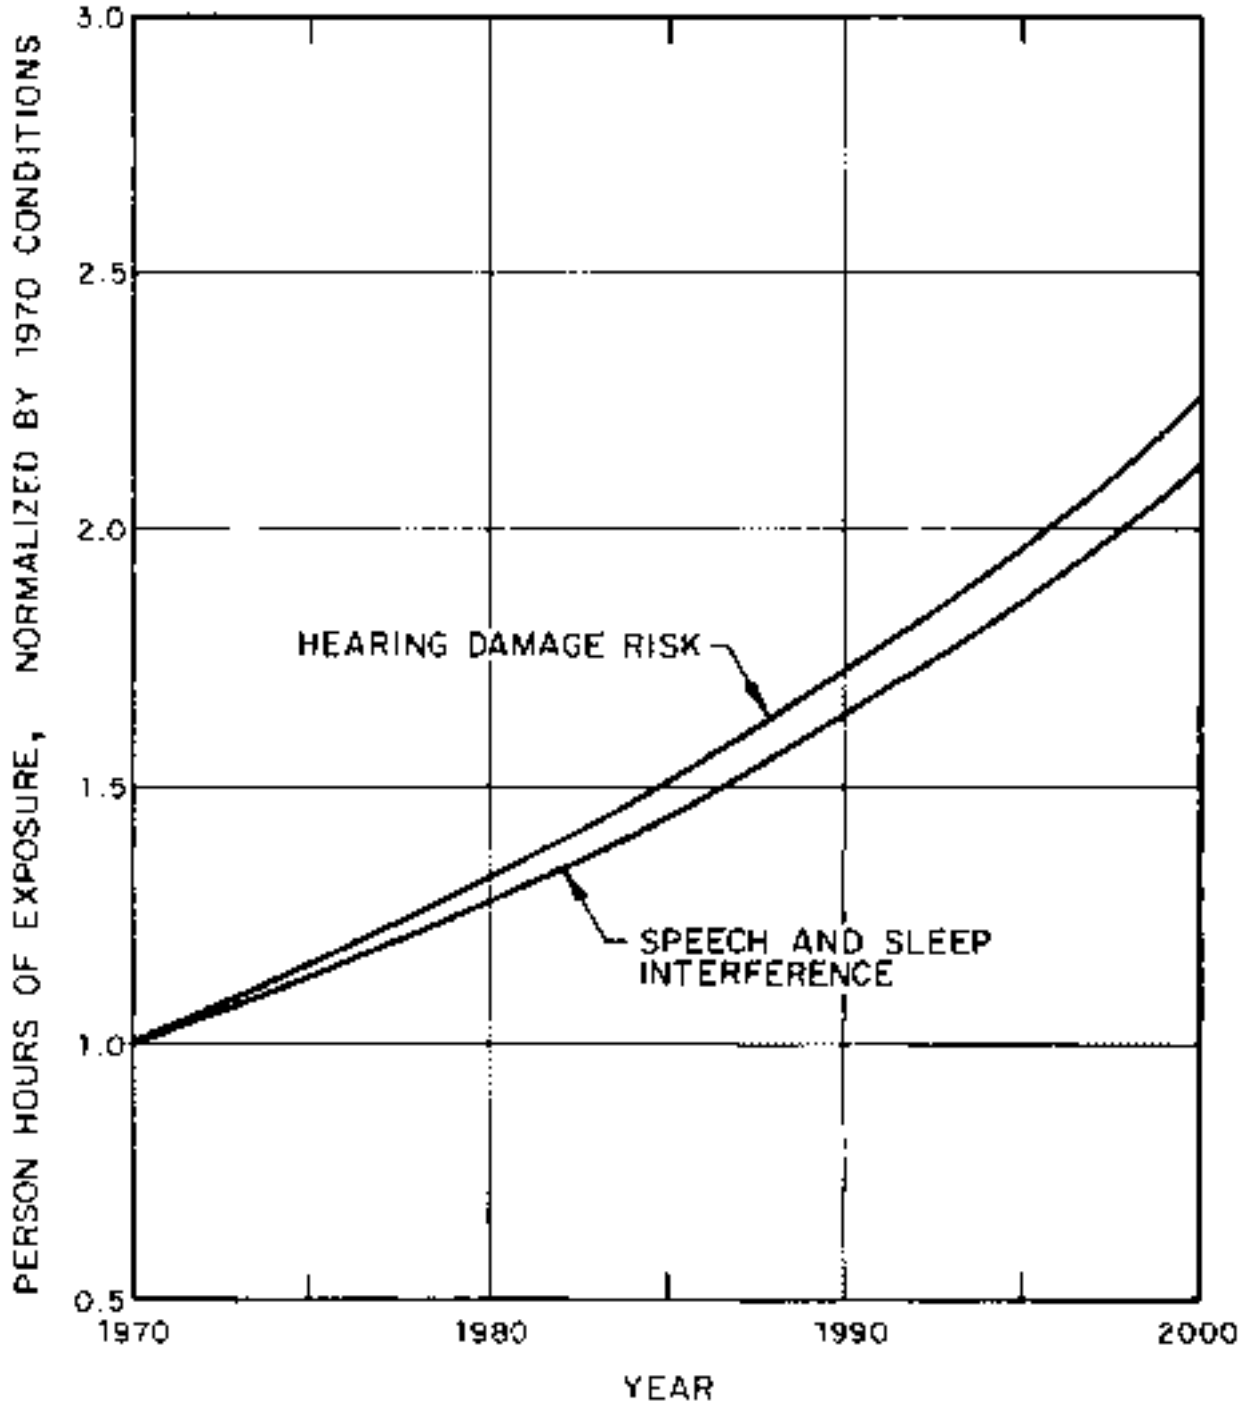

FIG. 26. PROJECTED CHANGE IN EXPOSURE TO APPLIANCE NOISE, ASSUMING NO CHANGE IN NOISE LEVELS.

example, construction equipment has become noisier as it has become more powerful; yet, one manufacturer has developed and is marketing a quiet air compressor. Conversely, refrigerators and air conditioners have become noisier as manufacturers have strived to meet market-place demands for extra features and smaller size. Thus, rather than try to account for an infinite number of variables, we have assumed no change in noise levels for both construction equipment and appliances. We feel that this method has resulted in reasonable near-term projections, if no noise control action is taken.

AR0070576

4. INDUSTRY EFFORTS

4.1 Introduction

Efforts by industry to quiet products are usually motivated by two factors: market place demand and government regulation. The consumer can exert pressure on industry by electing to buy or not to buy or by selecting a competitive brand that produces less annoying noise levels. This kind of "consumer regulation" can be very effective - particularly with regard to appliances — in that manufacturers are quick to respond to consumer tastes. However, consumer pressure can also subvert efforts a manufacturer may wish to make; for example, housewives often associate the noise produced by a vacuum cleaner with its ability to clean — the noisier the machine, the more satisfied a homemaker may be with its performance. In any event, the purchaser can apply direct pressure to the industry.

Public pressure, on the other hand, is usually very ineffective. The only recourse for people who do not own the noise sources to which they are exposed is to register a complaint. Such complaints have no effect whatsoever unless enough exposed people organize and concentrate their efforts on a particular source. This kind of community response may eventually result in government regulation.

Our analysis of industry efforts to quiet construction equipment, appliances, and building equipment was organized as follows:

- We constructed a matrix of common products and significant manufacturers.

AR0070577

- We rank-ordered products as to approximate magnitude of noise impact or need for quieting.
- We rank-ordered manufacturers as to their importance in the product area.
- We examined the resulting manufacturer/product "intersections" with a view toward organizing a number of interviews that would cover important products and leading firms and still be within the time and effort constraints of the study.
- We developed an extensive interview format both to guide the interview and to provide a standardized method of reporting. (Full use of this format was not possible within the constraints of this study; it could be useful, however, in the event that industry efforts are to be examined in more detail.)
- Under guidance of the format developed, we collected subjective data and objective observations; this information forms the basis for representative generalizations cited in this report.

As expected, the industry is concerned about releasing data which might disclose proprietary ideas or expose a competitively sensitive area of operations. Accordingly, identity of sources is carefully safeguarded herein. This need for corporate security has limited our collection of statistically meaningful data; the trends observed, however, are clear and, in themselves, undoubtedly represent the noise control environment in industry.

AR0070578

4.2 Construction Industry Efforts

We view the construction industry as consisting of two major sectors: equipment manufacturing and equipment operation (i.e., building construction). The functions of these two sectors of the industry are so different as to warrant separate discussion.

4.2.1 Equipment operation

Section 3.2 describes this sector of the construction industry in detail, identifying types and phases of site activity and describing the areas in which noise abatement can be achieved.

The industry has, in fact, done almost nothing to quiet site operations. Its attitude may be attributed in part to the fact that quiet equipment has not yet been made available on a cost-effective basis; however, a limited capability does exist for quieting a site by relocating or rescheduling equipment. This sector has not exercised its influence as a "consumer" to bring pressure to bear on the equipment manufacturers, nor has it responded to public complaints. Hence, regulatory measures may be the only solution to the problem of construction site noise, and such regulations are imminent.

4.2.2 Equipment manufacturers

There are approximately 2000 manufacturers* of construction equipment in the U.S. In total, these companies offer about 200 different products. For the purposes of assessing the state of noise control in this sector of the construction industry, we

*Defined by counting separately certain divisions of larger firms which have a highly identifiable product line.

AR0070579

categorized 48 general types of products that are potentially significant noise sources. We group these product types into three orders of classification: (1) class of noise problem anticipated, (2) relation of equipment to function at the site, and (3) specific equipment names.

I. Engines and power trains

A. Excavating equipment

1. backhoes
2. clamshells
3. dozers
4. draglines
5. loaders
6. rippers
7. (power) shovels

B. Highway equipment

1. compacters
2. graders
3. pavers
4. pipe layers
5. pulverizer/mixers
6. rollers
7. rotary borers and drills
8. scrapers
9. street sweepers
10. trenchers and backfillers

C. Equipment to handle finished materials

1. cranes
2. fork (and similar) lifts
3. travel lifts

D. Mobile units

1. tractors, crawler
2. tractors, wheel
3. trucks

E. Power supplies

1. compressors
2. electric-power generators

AR0070580

II. Interaction between equipment and materials (may include engines and power tools)

A. Equipment to handle bulk materials

1. bins (and hoppers)
2. concrete mixers
3. conveyors

B. Large impact tools

1. drop hammers
2. pile drivers

C. Medium impact tools

1. jack hammers
2. rock (vibrating) drills

D. Small impact tools (power)

1. impact hammers
2. impact wrenches
3. riveters
4. stud drivers

E. Rotary tools

1. bench drills
2. grinders
3. hand drills
4. hand saws
5. table saws

III. Miscellaneous (may include sources characteristic of I and II above)

A. Pumps

1. concrete pumps
2. stripping pumps
3. well-point pumps

B. Other

1. burners and heaters
2. sand blasters
3. screeds
4. concrete vibrators

AR0070581

Two assumptions underlie the terminology selected: (1) equipment in transit under its own power is a truck or tractor, even though when working it may be a dozer or a crane, and (2) classification by function at the site is arbitrary since many types of equipment have several uses.

Manufacturers of construction equipment can be classified according to size/type of equipment produced as

- large companies producing large volumes of essentially similar, large items of machinery;
- medium-size companies producing "customized" production runs of more limited numbers, usually of smaller machinery; and
- manufacturers of power hand tools and pneumatic equipment.

Our interview program was organized to cover the two major acoustic source types (prime-movers and power trains) and the forty-eight types of products and three classes of companies identified above. We concentrated our efforts on significant leaders in the industry and companies producing a wide variety of products that have high levels of noise output:

- Of the ten manufacturers intensively interviewed, about eighty product analyses resulted.
- Eight of the firms produced equipment in which the prime-mover or power train is a significant source of noise; two companies produced only power hand tools.

AR0070582

- Three companies were high-production manufacturers; seven manufactured customized equipment.
- Three-quarters of all the products where subjected to specific analysis, covering all significant noise sources except impact tools and pumps.
- The ten firms represent a significant part of the industry: Of the two thousand firms nominally in the industry, about twenty comprise the industry "core". Eight of the ten interviewed are part of this core.

Our overview of the equipment manufacturing industry showed that:

1. Large companies closely resemble the Detroit assembly-line manufacturing concept. They tend to have large engineering staffs and are quite advanced in their efforts toward developing quieter products. They are aware of the competitive advantage of quieting equipment but are also sensitive to price competition from smaller companies and foreign manufacturers.

2. Medium-size companies producing "customized" items tend to feel more keenly the competitive pressures of the market place. Competition comes not only from domestic and foreign companies but also from other types of equipment that can perform the same operation. Engineering staffs tend to be small and product-oriented, interested only in improvements that incorporate new technology (e.g., hydraulic vs mechanical drive). Little effort has been made toward quieting products, with pressures of current and planned noise control legislation being passed on to their suppliers. They generally have no plans or see no need for developing greater noise control technology.

AR0070583

3. Manufacturers of hand power tools and pneumatic equipment fall into two categories: large multiproduct companies which tend to mount considerable R&D efforts and smaller companies which are not so innovative but which do follow trends developed by the larger companies. Noise control has been pursued rather vigorously by these larger companies as part of their product improvement programs, but effective quieting of hand tools is difficult because of such practical constraints as size and weight.

Our in-depth interviews revealed that in the past the industry's concern with noise problems has been directed primarily to protection of the equipment operator. The impetus for this concern came largely from noise codes imposed by foreign countries, where some U.S. equipment has had to be "reworked" by foreign distributors. Three of the eight "large equipment" companies interviewed had previously quieted equipment to enter European markets. Switzerland and Belgium, for example, specify permissible noise levels for such machinery; in addition, foreign manufacturers make quieter machines and set a competitive pace in foreign markets. American manufacturers seem to have met this competition by custom-designing equipment for export. There is an implication here, of course, that many American machines marketed abroad have been quieter than counterparts that were marketed domestically; however, this implication has not been verified by this study.

Half the companies interviewed are currently undertaking programs to quiet their products for the domestic market for the first time. Many of the present programs have been started this past year and are aimed primarily at protecting operators, so as to conform to impending legislation/regulation regarding occupational health and safety. Only one of the companies indicated

AR0070584

that purchasers complain about protection for operators on their own initiative, and only one case emerged where a union had lodged a formal complaint. Six of the eight companies described pressures on behalf of operators that originated with existing or proposed governmental action.

Many manufacturers feel that the efforts they are now making on behalf of equipment operators will pay off in meeting future noise limits designed to protect the public. Perhaps, one of the most promising future approaches has been taken by one of the manufacturers of large equipment, who has charged design teams with the responsibility of integrating noise control into the overall design of his next generation of products and has set up review boards to evaluate new designs from all standpoints, including noise.

Four of the eight companies specifically mentioned the recently enacted Chicago noise ordinance as contributing to their specific future objectives. The industry generally anticipates EPA-administered federal control; the visits of our interviewers reinforced this feeling. Two companies believe that pressures for quieting will increase with time - apparently as a result of an increasing public awareness of noise as an environmental pollutant.

Although the industry has become increasingly aware of the pressures for noise control and has already made some efforts in this area, manufacturers must cope with economic pressures that argue against noise abatement. Some companies feel that the intensity of competition sets the limits on what price the market will bear. One of the industry's leaders was concerned that purchasers will continue using old equipment if prices rise significantly. Other industry leaders point out that foreign-made machines (some of them already quieted) will enter

AR0070585

the American market if prices rise appreciably. One company predicted that a small rise in the price of truck-mounted concrete mixers would lead to the introduction of alternative methods for handling concrete delivery and production.

Companies who feel that the demand for their products is great enough plan to pass quieting costs onto the consumer, although such threats as foreign competition and alternative methods put limits on this process. The question here is how fast the industry dares to move. One limit on rapid movement is price competition. One company may be able to beat its competitors to the market with a quiet machine, but it does not dare raise prices substantially in the face of competition. Different companies approach this problem differently. Most express the intention to meet or exceed the competition, but they feel that any great competitive advantage they gain through an all-out effort to quiet their products would be short-lived. One company sees its competition as being extremely severe, and fears that it may not be prepared for the next round of quieting, while another company has actively launched a program designed to produce quieter machines than its competitors at lower costs than the competitor will incur.

This company and some others expressed the concern that often accompanies any industry leadership; i.e., a company may invest large sums in quieting which will thus increase the cost of products, while another company that refuses to quiet products keeps it prices low and may successfully challenge noise regulation in the courts.

AR0070586

While all companies regard cost as an immediate — and perhaps as the ultimate — constraint, two other constraints become paramount if and as costs diminish: time and technology. Three companies, each in a different fashion, represented that costs can be traded for development time; i.e., more time for development would reduce the cost of competition, allowing quieting techniques to be integrated into planned engineering efforts and to be an integral part of the seasonal progression of models. The very company that is setting out to achieve the most quieting for the least cost is the one that feels that technology will eventually supercede cost as the principal factor that limits quieter equipment.

At another firm, the technical limitations are spelled out in terms of: (1) loss of equipment power through increased muffling; (2) increase in the difficulties and cost of maintenance; (3) fire hazards through using insulating materials that can become oil-soaked; (4) unsafe operation by suppressing or distorting the noise "signals" upon which operators depend for safety; and (5) ineffective operation, by disturbing these same "signals", thus hindering the ability of the operator to tell how effectively he is operating.

The industry also voiced concern over the feasibility of noise abatement where equipment and materials being worked interact to become prominent sources of noise; e.g., concrete mixers (where the structure may be the noise radiator); jack hammers (where the tool and its driving media may be the offender); riveters (where the structure of the building may be the primary source); and pile drivers (where both the structure and the media may be significant sources). This "interaction" type noise source may be very difficult to quiet.

AR0070587

However, no firm interviewed condemned noise limits out-of-hand, nor did they deny their inevitability. Six of the eight companies expressed the opinion that unless they quieted their products, their markets would disappear. Feelings varied from acceptance of inevitable reality to enthusiastic approval of the trend.

During the course of this study, members of the BBN team were actively engaged in the regulatory efforts of three cities and one state — Boston, Chicago, San Francisco, and Illinois. This work provided an insight into the mechanism of regulatory control from outside the construction industry. In addition, discussions were held with the Construction Industry Manufacturer's Association (CIMA) to obtain information about controls within the industry.

There are potentially four levels of regulatory bodies outside the industry: federal, state, city/town, and specialized local departments (city departments of health, air pollution control, zoning/building, etc.). The regulatory power exercised by these bodies is generally graduated into four steps: general standards (setting goals), enabling powers (granting power to a lower body), specific regulations (against which are judged infractions), and procedures (for measuring performance).

The target of the regulatory powers is either basic equipment performance (i.e., noise of new equipment as sold by manufacturer) or equipment operation (e.g., total noise emitted from a site). Regulations are usually aimed toward protecting (1) health (as in the hearing-protection section of the Federal Public Contracts Act) and (2) environmental quality (as in the construction site operating limits proposed for the city of Boston).

AR0070588

No fixed pattern has yet emerged which interrelates the regulatory bodies, nature of powers, targets, or degree of protection. Current activity at all levels, however, has alerted the industry that controls are imminent. One significant set of controls already in existence limits the noise from new construction equipment sold in Chicago; dual controls are being proposed in Boston, to limit site operation noise and to restrict noise from new equipment. Enabling legislation exists (as in the General Laws of the General Court of Massachusetts), and enabling powers have been passed on through city ordinance (again as in Boston). Even though the Federal Public Contracts Act does not apply to local construction, its philosophy is impressed on the industry, and its effect is increasingly noted in the carryover of standards into new federal occupational health and safety legislation.

In summary, the regulatory bodies outside the construction industry have begun to exercise some influence in the area of noise abatement.

CIMA and the national standards-setting bodies of ASTM/SAE are both actively addressing the problems of measuring equipment noise and recommending quieting standards. The equipment manufacturing industry would like to coordinate its activities with those of its closely related standards-setting bodies (see Appendix B for discussion of a paper prepared by CIMA). Self-regulation via industry-initiated standards is presumably somewhat hindered by federal anti-trust provisions.

As yet, no broad controls have been established. It is assumed that the example set by the City of Chicago equipment noise ordinance will stimulate other similar action, eventually resulting in a proliferation of standards put forth at the local

AR0070589

level. As an alternative, the industry would welcome one comprehensive overriding standard. However, some anxiety was expressed as to the reasonableness of future legislation, specifically that sufficient time would not be allowed to conform to such a standard. Typical new product lead-times are on the order of five years. Industry believes it could meet noise goals without excessive cost to the consumer, if given enough time.

In general, it appears that industry is aware that it will be forced to comply with ever-tightening noise standards. While this fact seems to worry everyone to some extent, most manufacturers are confident that they will meet the limits set by current and anticipated legislation/regulations/standards. In fact, all but one of the companies interviewed stated their noise control goals in terms of such limits, frequently specifying either the levels stated in the Walsh-Healey Public Contracts Act for operators or those set forth by the Chicago ordinance for public exposure.

Early abatement efforts made by the manufacturers have been highly successful; thus, the industry is somewhat optimistic about its ability to cope with pressures for noise control. However, it is important to note that the industry has begun with the most obvious and the easiest tasks it must accomplish. Future tasks are apt to be far more difficult and costly; therefore, future struggles to comply with more stringent standards could possibly influence company attitudes, making them less receptive to regulation.

AR0070590

4.3 Building Equipment and Appliance Industry Efforts

Throughout this study we have viewed the home appliance industry as consisting of two major sectors: owner-controlled appliances and major building equipment (such as heating and plumbing systems in multifamily dwellings). We continue this division, since (even though certain large companies produce both types of equipment) the nature of the marketing and of the pressures for noise control are quite different.

4.3.1 Building equipment

The quieting of building equipment involves the contributions and decisions of an interdependent chain that consists of owner, regulatory body, architect, engineer (both mechanical and structural), equipment, and manufacturer. For purposes of analyzing industry programs, three sectors of this network are significant: (1) the equipment manufacturing sector; (2) the design sector, and (3) the control sector.

Overall, quieting of the equipment in a building thus becomes a compromise between the elements of the chain on matters of design, budget and technical performance.

Manufacturing Sector

Manufacturers of building environmental control and services equipment are currently aware of the significance of quieting their products; they realize that they have a role to play in quieting at the source. The manufacturer does not have complete control over the quieting of the finished system; here, he is dependent on the architect and the mechanical/structural engineers as to location, local architectural treatment, and surrounding structural design.

AR0070591

Given this ambiguity, manufacturers in the past have been uncertain as to what to quiet, how much to quiet, and even how to measure progress in quieting. In a recent review of a wide variety of currently available equipment from a variety of manufacturers, several types of equipment showed spreads as large as 10 dB within the type. However, no line of equipment from a single manufacturer was characteristically noisy or quiet.

Currently, manufacturers are trying to solve problems of rating their equipment. This effort is being channeled largely through the trade associations and the technical societies. The fundamental aim of this effort is to furnish the architect and engineer with ratings that they can utilize in designing their equipment layouts and in specifying their equipment.

In the compressor industry this step has been substantially achieved. The result is that competitive criteria have become clearer and that the major technical barrier to quieting is common to the industry as a whole. (It is the blade-rate scream from the impeller.) It is apparent that if a manufacturer could make a technical breakthrough in this area, he would achieve a strong competitive advantage. There is some question, however, as to whether any single manufacturer can afford the development costs that such a breakthrough would entail.

When rating methods have been developed and when, as a result, the technical problems become better defined, manufacturers of building equipment will face three basic alternatives in reducing the noise from their products that reaches the building's occupant: (1) redesign of the equipment, (2) enclosure of the noise source by the manufacturer and (3) passing the problem along to the building designer.

AR0070592

Design Sector

The mechanical engineer is starting to add acoustic performance of equipment to the list of building specifications. These specifications are passed back to equipment manufacturers.

The mechanical and structural engineer interface with the equipment manufacturer in the area of containment of noise vs quieting at the source. Trade-off between the two approaches must be considered on both sides. Enclosures, if chosen often become a manufacturer's problem because of the need to bring proper controls and services through the enclosure.

The same two factors face each other regarding size of equipment. The design sector wants compact equipment in order to increase usable space as well as to be able to move through doors, while the manufacturer tends toward larger equipment to favor quieting.

The architect meets the manufacturer at another interface that concerns equipment location, local architectural treatment and selection of structural system. Acoustically remote spaces are often not possible to be allotted to house equipment in view of the high cost of building space and the attendant desire to maximize revenue-bearing space. Architectural taste for openness in design and novel structural systems can often make the isolation of equipment spaces more expensive.

The designer faces a unique combination of equipment for every structure he designs. These combinations create unique problems of design. They also create unique patterns of emission. Thus in one building, the designer may be able to afford a fairly noisy piece of equipment because it will operate by itself or because it will operate in relative isolation. In another

AR0070593

building he may require a very quiet piece of equipment to perform the same function because it may be operating among the other noisy machinery or in a location that makes the building users vulnerable.

Control Sector

Controls regarding building equipment acoustic performance emanate from four sources: (1) trade associations within the building equipment industry; (2) specialized technical societies also within that industry; (3) generalized professional technical societies (such as ASME, IEEE, etc.) serving all U.S. equipment industries; and (4) regulatory bodies (Federal, state and local).

The role of the trade associations is to set standards for rating the performance of equipment and to evolve guidelines for proper application of the equipment. Among the most active in dealing with noise control are:

- Air Conditioning and Refrigeration Institute
- Air Moving and Conditioning Association
- Air Diffusion Council
- Compressed Air and Gas Institute
- American Gear Manufacturers Association
- National Fluid Power Association
- Hydraulic Institute
- National Electrical Manufacturers Association

In contrast, the technical societies both within the building equipment industry and outside, serving all industries, are dedicated to developing measurement procedures and standardizing the

AR0070594

techniques for making measurements and reporting results. Most active in the measurement area are:

- American Society of Heating and Refrigerating and Air Conditioning Engineers
- Institute of Electrical and Electronics Engineers
- American Society of Mechanical Engineers
- American National Standards Institute
- American Society for Testing Materials

Government agencies exercise control in three ways: (1) as regulatory agencies concerned with occupational health; (2) again as regulatory bodies concerned with community noise; and (3) as significant purchasers of equipment for use in public buildings or publically financed projects. The occupational health and noise control aspects of the Walsh-Healey Public Contracts Act has served as a pace-setter for establishing targets for the building equipment industry, although the federal act itself generally has little direct applicability to most of equipment currently sold.

As state and local governments extend their protection against occupational health hazards, they are tending to adopt the Walsh-Healey criteria. These enactments tend to put pressure on manufacturers and designers alike. The most active current issue arises from the establishment of a stringent specification (80 dB(A) at three feet) by the General Services Administration for machine noise in federal buildings.

Manufacturers are having difficulty meeting the G.S.A. standards through quieting at source, but G.S.A. replies that containment will solve the problem. In one instance, however,

AR0070595

a substantial federal building project has not been able to attract qualified equipment bidders. Minimum property standards for FHA-assisted dwelling units have been in effect for a number of years. Some latitude regarding enforcement appears to be permitted to the directors of regional offices.

In total, the criteria for acoustic performance of building equipment are still in a state of evolution. More detailed discussion of standards is contained elsewhere in this report. Measurement procedures are still under development, and the current acoustic performance of standard equipment is still not fully understood within the various sectors of the industry. A system for rating equipment by category is seriously needed to give the control sector, designer and manufacturer a common language. The divergence of the city codes that do exist (15 dB spread) needs to be eliminated to reduce customizing requirements on the equipment manufacturers.

Summary of Pressures For/Against Quieting

a. For

- Quieting deemed a "necessity", no longer a "luxury"; tenants now in second or third generation of air conditioned buildings, and attitude toward quiet has matured to this point of view.
- Architectural desire for openness of design, new lightweight structural systems and economy of nonrevenue bearing space places premium on quieting of source.
- Mechanical engineers increasingly aware of need for quieting, hence now specifying acoustical performance.
- Occupational health and safety pressures spreading, following example set by Walsh-Healey Act.

AR0070596

- Codes at city level to enhance community quiet.
- Quieting generally becoming cost-beneficial in eyes of building owners.

b. Against

- Technical barriers make next step too expensive for single manufacturer to attempt by himself.
- Lightweight and small equipment desired to fit into small allocated spaces and remain tolerant of light foundations.
- Specific quieting goals are not clearly set, and codes and regulations are confusing and contradictory.

c. Trade-off Must be Examined

- Containment via enclosure vs quieting source — which is more cost effective?

4.3.2 Home appliances

There are approximately 70 to 80 important manufacturers* of home appliances in the U.S. These companies offer 30 to 40 different products that are potentially significant noise sources. For the purposes of assessing the state of noise control within this industry, we rank-ordered specific appliances according to their relative importance with regard to noise abatement in and around the home.

- air conditioners,
- dishwashers,
- water closets,

---

*Defined by observing company names and appliance categories in various well-established consumer journals.

AR0070597

- other major appliances (clothes washers, dryers, refrigerators), and
- appliances whose noise output is interpreted as a measure of its efficiency (vacuum cleaners, blenders).

The industry is characterized by four major company/product mix categories:

- large, multidivisional companies producing a broad range of products;
- medium-size companies formerly specializing in a well-known product but now branching out to take advantage of a good name in the consumer market;
- small and medium-size firms who maintain a certain leadership character through continued specialization; and
- companies manufacturing "private label" appliances to be sold by others, usually by large retailers who contract for and control the product policies of a large volume of home appliances.

Our interview program was organized to cover leading manufacturers of a range of equipment as well as retailers and industry associations. We interviewed eleven manufacturers (or manufacturing divisions of large companies), two major retailers, and two industry associations. Twenty-nine products and ninety-six product/manufacturers were covered by this survey.

AR0070598

Our overview of the industry's attitude toward noise control shows it to be so direct a function of market place pressure that noise control technology often exceeds application. Appliance manufacturers tend to maintain sophisticated R&D and product engineering staffs that are capable of delivering more noise reduction than market strategy can justify. In fact, some companies have tried — unsuccessfully — to market quiet products, such as air conditioners, vacuum cleaners, blenders, and hair dryers; others have developed a number of quiet prototypes that were not put into production.

Consumer research shows low noise levels are not highly valued by most customers. Several companies keep systematic track of customer correspondence, while the industry itself maintains a Major Appliance Consumer Action Panel (MACAP) that acts as a clearinghouse for complaints. These records, all of which concern major appliances, show relatively little complaint about noise. For example, only 9% of the letters to MACAP in the first eight months of 1971 were about noise.

The objectives for quieting household appliances seem to vary with the market pressures on particular products. With this observation in mind, we organize our discussion of noise control efforts around the "problem" appliances identified above.

Air Conditioners

There is probably more market pressure to quiet air conditioners than to quiet any other household appliance. Since air conditioners emit noise both indoors and out, they frequently affect not only the purchaser and his family, but also neighbors and passersby. Both kinds of emissions generate pressures for

AR0070599

noise reduction. Pressure from neighbors takes the form of local noise ordinances that specify maximum sound-emission levels at a property line; this pressure is passed on to the manufacturer, as one company pointed out, by dealers or marketing men who are aware of the ordinances.

Dollar sales of room air conditioners grew almost eight-fold in the decade of the 1960's; during that time, indoor quiet emerged as a competitive dimension. Several manufacturers are currently engaged in competitive advertising campaigns to sell the quietness of their room air conditioners and are giving their products brand or model names that imply the quietness. Two large appliance manufacturers independently volunteered the opinion that quiet is becoming more important to purchasers every year. One of these indicated that the fact that air conditioning allows one to close the house against outside noise may soon become a sales argument in air conditioner merchandising. However, one leader in the current "quiet" race indicated that their top-line model is not selling well.

Most quieting effort for air conditioners takes place in modest engineering laboratories that are attached to the local production facilities. One such laboratory reports spending three man-years per year on air conditioner noise control; one man-year per year was a more frequently mentioned level of effort. While the product policy people generally reported that they were making maximal use of available quieting technology, the study project acousticians who initiated the interviews felt that current state-of-the-art technology was not being universally applied.

AR0070600

Two estimates we received indicate that quieting room air conditioners adds 10 to 15% to their price. There may also be an inherent trade-off between quietness and efficiency (since one way to reduce air noise is to decrease air velocity). Sometimes, quieting results in increasing the air conditioner's physical dimensions, thus detracting from appearance as well as from convenience and ease of installation. There may also be a trend toward model lines differentiated by noise output — i.e., an expensive quiet air conditioner and a cheaper noisier model. One manager pointed out that there are anti-trust constraints against organizing industry consensus on noise levels.

Dishwashers and Food Disposers

The mechanical differences between dishwashers and disposers do not alter the fact that noise control pressures are similar and that the manufacturers' approach to quieting is similar. Thus our survey indicates that these two appliances logically group together.

Quiet is a saleable characteristic of dishwashers and disposers, although the pressures for quieting are not so great as for air conditioners. While we are aware of no advertising campaigns built exclusively on quiet, it is advertised with the same prominence given to power and reliability.

Noise levels from dishwashers and disposers are not currently under public regulation, hence the incentive for quiet comes almost exclusively from the purchaser. This gives rise to marked differences between models; if one wishes, one can buy an inexpensive, noisy dishwasher or disposer. Reports from the industry indicate that landlords frequently do just that.

AR0070601

Noise emissions from these two appliances are not so completely under the control of manufacturers as in the case of other appliances; the manner of installation greatly influences structureborne and plumbing-borne noises.

Dishwashers, however, present a promising example of industry's response to the purchaser's desire for lower noise levels. In a 1970 survey by the United States Steel Co., 43% of dishwasher owners had no complaints about their appliance, but of those who did, more complained about noise than about any other aspect of its operation. Both survey data and marketing "lore" indicate that the purchaser who has previously used these appliances puts a higher value on quietness than does the new user.

The costs of quieting were estimated by one dishwasher manufacturer to be 10% and by another to add $1 to $2 to manufacturing costs. A disposer manufacturer felt that quieting would add 12% to a product cost, whereas a retailer of disposers estimated 16%. Quieting these machines might deny their availability to those least able to pay.

In the case of dishwashers, one manufacturer indicated the possibility of trade-offs between noise and maintenance costs, and reliability. Another indicated a trade-off between water velocity and quiet but expressed the opinion that there are no serious technical restraints to quieting dishwashers.

In the case of disposers, industry claims inherent problems with water and grinding noise (especially with the noise of grinding bones). Some noise is considered necessary to the user's safety, so he will know when the disposer is operating and when it has finished grinding.

AR0070602

So far, a number of sophisticated techniques have been applied to dishwashers: isolation, damping, and parts re-design. Manufacturers of both dishwashers and disposers have tried to improve the quality of installation by providing carefully drawn instructions and flexible fittings. One company has reduced noise on its top-line dishwasher from 82 to 75 dB(A) (at an unspecified distance) since 1967 and plans a further reduction in the next few years. Another manufacturer expressed only the desire to keep abreast of the competition; this company tests each machine for noise, rejecting something under 1%.

None of the manufacturers interviewed intends to give up his noisier "economy" lines; goals did not seem to be appreciably influenced by the prospects of noise regulation.

The companies interviewed claimed to have adequate acoustic test facilities, although the efforts devoted to testing and to development varied widely in quantity and quality.

Water Closets

If evidence from mail order catalogues is reliable, quietness in water closets is a marketable attribute. Two top-line, "low profile" models prominently feature quiet in their advertising. One manufacturer indicated in an interview that placement of the height of the tank involves a trade-off between quiet and efficiency, and indicated that quiet designs may be less reliable, less efficient, and more expensive. Like dishwashers and food-waste disposers, economy-models are noisier than more expensive ones.

Currently, one company is trying to eliminate a water hiss that occurs when the tank is full.

AR0070603

Other Major Appliances

Quieter clothes washers, clothes dryers, and refrigerators tend to be by-products of engineering originally undertaken with other objectives in mind. The classic case is a washing machine model that was incidentally quieted when two gears were removed from the power train to save cost. In the context of product improvement, noise is generally treated as a secondary design goal, although manufacturers are concerned that engineering changes may produce noisier products. For example, refrigerators are becoming larger *and* noisier as manufacturers seek to meet the demand for special options such as ice makers; a spinner-type washing machine produced higher noise levels when spinner speed was increased to 2000 rpm.

Two of four manufacturers interviewed make quiet models of washing machines that sell at a $10 to $20 premium; sales for both lines are disappointing. None of the other models of these companies is marketed on the basis of quiet nor do the mail-order catalogues feature quiet. The single exception is a spinner-type washer in which "quiet operation" appears in the small-type description. There is, then, relatively little evidence of pressure for quieting appliances of this type.

Yet, despite the weakness of market pressures, considerable quieting effort has gone into the design of these appliances, especially washing machines. One manufacturer mentioned six different quieting projects that have recently been completed or are underway. A refrigerator manufacturer mentioned an effort to avoid strange or unidentifiable noise. No specific efforts to quiet dryers were uncovered.

AR0070604

Vacuum Cleaners

The manufacturers of vacuum cleaners believe that the market pressures are for noisy machines. The three manufacturers and one large retailer interviewed are all convinced that customers use noise as the basis for judging a machine's power. For example, after concentrated technical effort, a manufacturer had significantly reduced the noise from a canister model without reducing its cleaning capability. Housewives who participated in a marketing trial wanted to know "if the machines were really cleaning".

Neither of the large "private label" retailers we consulted mention quiet as a design goal. In fact, in advertising a nap adjuster, one company writes "... just slide the bar across until you hear the right cleaning purr". One company that carefully analyzes its correspondence from customers finds virtually no noise complaints about vacuum cleaners or any of its other portable appliances.

A reasonable level of engineering effort has produced feasible solutions to vacuum cleaner noise problems; according to all interviewed, however, these solutions are not being applied to products that are sold, because vacuum cleaner manufacturers and retailers do not sense a demand for quieter products. In fact, the sale of upright cleaners, whose beaters make them noisier, is growing at the expense of the sale of canister models. Apparently, the beater action of upright cleaners can better handle the new deep-pile weaves that make modern carpets harder to clean. There are technological limits to the quieting of upright vacuum cleaners, because of the interaction between the beater and the carpet, but the noise levels of production models seems to be determined by customer usage demand rather than by technological limitations.

AR0070605

The company that developed the quiet canister cleaner employs a physicist who works full-time on noise-control studies. The company calls in noise consultants about four times a year and samples its customers at six-month and two-year intervals. They have given considerable attention to the problem of heater noise and estimate that solutions that would not reduce a machine's efficiency would add 50% to its price.

Another large company made a study ten years ago (at a cost of about $30,000) in which they developed ways of reducing vacuum cleaner noise in middle and high frequencies by about 10 dB(A). They have just contracted for a study of their competitors' canister machines and of the effect of using alternate motors in their own machines. Although they have available technical staff and laboratory facilities in-house, they have never applied the results of their studies to the products they market because of customer attitude toward noise.

Small Appliances

During the interviews incidental information was gathered from five different companies concerning eleven small appliances: blenders, can openers, coffee mills, electric knives, fans, hair dryers, ice crushers, knife sharpeners, mixers, oral lavages, and electric tooth brushes. Manufacturers feel that there is public pressure for these appliances to sound as though they are "really doing their jobs". One manufacturer offered the generalization that, in the small appliance field, the quality of the sound is more important than the quantity. An appliance must sound "right". Some must sound powerful, some reliable, and none as though they are malfunctioning or undergoing excessive wear. This manufacturer expressed the belief that an accurate interpretation of the customers' desires in these areas is a condition for remaining in business.

AR0070606

This market pressure leads to diverse noise-control objectives, both among companies and between product lines produced by a single company. Customer complaints were reported about the noise from fans and hair dryers, and one marketing executive was quoted as believing that quiet is a salesable aspect of mixers. One company which does not manufacture the ice crushers that is sold under its label put a fairly high value on quietness in selecting the model it sells. Yet, none of these small appliances was described as quiet in either of the two mail-order catalogues that we examined. Blenders and electric can openers were specifically described by the managers interviewed as being appropriately noisy. A company which we did not interview was cited as having quieted a blender; in so doing, they slowed it down so that it became less efficient. At least one laboratory is seeking entirely new ways of comminuting foods that could be both quieter and cheaper than blenders. Another is designing a screw-type crushing tool that will substitute a growling sound for the raucous sound of the chipper that current ice crushers employ.

There is also a search for fan blade configurations that will eliminate certain predominant frequencies and produce a more pleasing sound. In addition to room fans, this experimentation includes hair dryers, where quieter designs for air passages are also being sought.

Rubber feet have been added to electric coffee mills to reduce vibration noise, but shielding is not being used because of its adverse effects on costs, size, and aesthetic design. Plastic beaters for mixers promise to reduce both noise and costs.

AR0070607

Many of these appliances are powered by universal-type motors, which are inexpensive, powerful for their size, but noisy. The size-power ratio considered important in such appliances as hand mixers, electric knives, can openers, and motor-in-the-bonnet hair dryers. Conventional hair dryers also embody a trade-off between speed and quiet; one hair dryer model that was marketed as "quiet" took 30 to 75 minutes longer to dry hair than faster, noisier models.

Speed or the potential power that speed permits was cited as important to electric knives, can openers, and blenders. In the case of blenders, one engineer argued that, if they were slowed down, the intensity of the noise would simply be traded for noise duration with no lessening of resulting impact. There is also reported to be a trade-off for electric tooth brushes between noise and cleansing effectiveness.

Cases of limitations on quieting were pointed out for knife sharpeners where there is grinder-blade interaction, as well as for blenders where rotating knives are essential and a glass casing is necessary if the housewife is to monitor the process visually. In the case of blenders, there is hesitation to experiment with consumer preferences since the already intense domestic competition is being raised by the entrance of Japanese products into the market.

Small appliance manufacturers make frequent use of subjective noise judgements in their developmental work. Their product laboratories tend to be less sophisticated than those for major appliances, although many have access to central acoustical laboratories of great sophistication. One small appliance manufacturer tests new products in his employees' homes. If employees object to the noise the new model makes

AR0070608

they are asked if they would be willing to pay for a quieter product. The general result of this approach is to make this manufacturer pessimistic about the economic pay-off from quieter products.

Although specific noise goals are hard to identify in the appliance industry and although some manufacturers seem discouraged with the return on their efforts to date, all those interviewed plan to persist in quieting efforts. Technological limits have not yet been reached. One manufacturer believes that the earlier competition which emphasized compactness has now been replaced with an emphasis on quiet. Accordingly, industry generally plans to hold the size of future models constant and to concentrate on producing quieter models, while presumably keeping prices within competitive limits.

AR0070609

5. CONCLUSIONS AND RECOMMENDATIONS

This report has presented a broad range of facets concerning the noise characteristics of construction, appliances, and building equipment, the influence of this noise on our lives, and the nature of the industries producing and using this machinery. In this section, we summarize our findings and recommend what we believe to be a balanced noise abatement program that may be pursued by EPA.

5.1 Conclusions

One of the most striking factors to emerge from this study is the monumental complexity of the physical, social, and industrial system that we have attempted to understand. There is a wide spectrum of noise-producing machinery types utilized for many different purposes in a nearly endless number of situations. This heterogeneity makes a characterization of even the average properties of the sources and transmission paths difficult at best. Of course, nobody is exposed to average conditions but rather to some part of a multi-variable distribution of circumstances, making some notion of the range of source/path/receiver situation desirable. Furthermore, human response to noise varies widely among individuals and depends not only on the readily measurable aspects of sound such as level and spectrum, but also on such factors as attitudes, predispositions, the information content of the sound, and concurrent nonauditory stimuli. The industrial situation is equally complex, the judgement of industrial leaders and their concommitant directives being influenced by marketplace and legislative demands, as well as by their own personal attitudes. In presenting what we feel are the salient features of this complex system, we claim to have observed no more than the top of the iceberg — and even that at some distance.

AR0070610

5.1.1 Sources

Despite the tremendous range of equipment, the noise-producing mechanisms are often similar and may be identified as part of a much smaller class. The principal source of noise in many types of construction equipment, for example, is the diesel engine. Exhaust noise is most readily identifiable with structural sound radiation and inlet noise is also of importance. Additionally, the hydraulics, fans, and transmissions of construction equipment generate loud and identifiable noise levels. Such heavy equipment often creates levels in excess of 90 dB(A) at 50 ft. Drilling and cutting machinery are also extremely noisy as are impact tools such as riveters, pavement breakers, certain powered wrenches, and most pile drivers. Noise from jack hammers and rock drills often lies between 80 and 100 dB(A) at 50 ft; pile driver noise can exceed 100 dB(A). Almost invariably, construction equipment, regardless of its size, is noisy.

In evaluating the control technology of construction noise, one finds that approximately 10 dB(A) of noise reduction are generally achievable using state-of-the-art techniques; 20 dB(A) could no doubt be achieved with a certain level of technology development. Of course, these are average values. For some equipment, such as that sold without exhaust mufflers, greater noise reduction would probably be easily achieved; for others, such as riveters, considerable effort would be required to meet these objectives.

The noise levels of home appliances span a much broader range than those of construction equipment. Certain appliances such as food freezers or refrigerators are rather quiet at 30 to 40 dB(A), measured at 3 ft; other items such as food blenders can be as noisy as 80 to 90 dB(A) depending on the type, speed,

AR0070611

and food being processed. Garbage disposers may even exceed 90 dB(A). By and large, the noisiest classes of home equipment are powered garden and shop tools. Noise from electric lawn mowers, hedge trimmers, and grass edgers all measured between 80 and 90 dB(A). Some shop tools generated nearly 100 dB(A).

Noise from appliances is attributable to electric motors and cooling fans, plus the components being driven by the motors. For refrigeration equipment, these components are compressors and blowers; for food-waste disposers, they are grinders; for shop tools they are typically cutting or grinding elements, often connected to the motor by noise-producing gears. As with construction equipment, noise reduction levels of 10 dB(A) are generally achievable with state-of-the-art techniques; 20 dB(A) often requires either extensive application of existing techniques or the development of new technology to obtain the same results at less cost.

Building equipment probably has as large a range of noise-making devices and noise levels as construction and appliances combined. Diesel engines, gas turbines, and large electric generators or motors are all utilized, especially in so-called "total energy systems" which supply both electric power and temperature control for buildings. Refrigeration and heating equipment, blowers, diffusers, and fluorescent light transformers all generate noise. Fortunately, the noisiest sources of building equipment are usually remotely located, typically in mechanical equipment rooms. Isolating people from this noise is mainly done through architectural treatment.

AR0070612

5.1.2 Impact

To have tried to measure the impact of noise on people in terms of the levels to which they are exposed, the duration, and the number of people. In a one year period approximately 30 million Americans will find themselves living or working near a construction site. The noise from this site will be sufficiently high to interfere with their conversation most of the day. Three million workers with eight children and 7.5 million children under five who may require naps live near these sites. Many will either find it more difficult to fall asleep or be awakened during their sleep because of construction noise. On the average, a metropolitan-area resident or worker passes a construction site every other day. Pedestrians can be exposed to noise levels in excess of 90 dB(A). Automobile drivers and passengers will often close their windows, thereby reducing the exposure to approximately 80 dB(A). Although many operators of heavy construction equipment are losing their hearing because of noise [99], hearing damage to persons in the environs of construction sites does not appear to be a substantial problem. Most people residing or working in buildings neighboring construction sites are exposed to less than 70 dB(A) most of the time. Some pedestrians are exposed to levels that could contribute to hearing loss particularly if these people are exposed to high noise levels during other times of the day.

One of the most significant aspects of construction noise is that, in any year, 15% of the population are exposed roughly eight hours a day, five days a week for many weeks or months. They have no control over the noise nor do they have much respite from it. The argument that construction is temporary has little appeal to people living near a several year project or one series of projects after another lowers all around them - after all, they argue, life itself is temporary.

AR0070613

Appliances have an impact on people in a rather different way. Most appliances affect only the people using them and only for a relatively brief time while they are in operation. For example, a food blender may generate 80 dB(A), but only for 30 seconds, at the end of which the user has a desired product. This leads to quite different attitudes toward appliances *vis a vis* construction equipment as bothersome noise sources. Of course, not all appliances affect only the user and his family. Appliances which affect neighbors are typically those which are built in to the home structure or plumbing and those which are used outside. Thus, food-waste disposers, dishwashers, water valves, and toilets are found to annoy and sometimes interfere with the sleep of people in multifamily dwellings. Powered garden tools such as lawn mowers, hedge clippers, and edge trimmers as well as power tools used outdoors (e.g., circular saws, drills, sanders) also generate sufficiently high noise levels to awaken or annoy neighbors.

One of the most striking aspect of appliances is their number. Roughly one billion appliances now are used in homes throughout the U.S. Virtually everyone owns at least some; e.g., 99.8% of homes are equipped with a refrigerator, over 90% have vacuum cleaners. By and large, people in the upper socio-economic stratum have more appliances. However, the generally increasing affluence of the nation coupled with the relatively constant price of appliances over the past 15 years (despite the inflationary growth of most other consumer items) has stimulated the profusion of appliances into homes at every economic level. This large number of appliances and their year-round use (with certain obvious exceptions) has made the exposure to appliance noise very large indeed. In fact, appliances account for more person-hours of speech interference, sleep interruption, and hearing damage than construction.

AR0070614

However, the impact in terms of annoyance is probably not so great, owing in large part to the controllability of many appliance operation times. For example, one does not have to run the dishwasher while listening to T.V., but it is difficult to ask the pile driver operator outside to cease work until a program of interest is over.

5.1.3 Industry programs

Industry activities in product quieting can best be understood by first considering the pressures they perceive. Demand for quiet appliances reaches manufacturers directly from the purchasers in the marketplace. The people who are exposed to noise, for the most part, are also those who purchase the appliance, or at least influence its selection. Demand for quiet construction equipment is also made by people living or working near construction sites. They generally have no economic influence on the building contractor or equipment manufacturer. Hence, their demands have largely gone unheeded and have been redirected through legislative bodies. A few successes in this arena have begun to create a marketplace demand for quiet equipment by contractors who "see the handwriting on the wall" and are willing to pay something of a premium for equipment that will not be illegal to operate in a few years when anticipated wider-ranging legislative controls are enacted.

The response to pressure for quiet has varied within and across the appliance and construction industries. Some appliance manufacturers have made a credible effort to develop capabilities to deal with noise-control problems and to design appropriate noise-control measures into their products. This has been especially true in the major appliance industry where air conditioners

AR0070615

and, more recently, dish-washers and food-waste disposers are being treated. As one might expect, the objective of disposer treatment is to reduce noise within the kitchen containing the unit. We know of no disposer designed to reduce transmission of noise through plumbing and into adjacent apartments. The disposers that incorporate airborne sound suppression are top-of-the-line items designed for use by the purchaser. Bottom-of-the-line disposers often have no noise treatment whatsoever and are usually installed in multifamily dwellings. Generally speaking, when noise control is introduced in appliances, it is in top-of-the-line items. There, it serves partly as an added luxury and partly as a test of market acceptability. If successful, it will often be introduced in other line items; if unsuccessful (for whatever reason) the notion will often develop and persist that consumers simply do not care about noise.

The construction equipment industry also shows a spectrum of levels of response to pressure for product quieting. A very few companies have foreseen the demand for quiet equipment and have begun a line of products that are significantly quieter than competitive models. Some companies have conducted experimental noise control projects, often with only a modicum of success. Several companies appear to have given noise-control very little effort (e.g., some heavy construction equipment does not even use exhaust mufflers for diesel engines). On the whole, noise has only begun to become a serious factor in the construction industry, which lacks much of the expertise required to deal successfully with it.

AR0070616

5.2 Recommendations

Most of the work presented in this report is of the nature of background material that must be applied to the problem of noise reduction to be of real value. Our recommendations therefore relate to the application of this information and the steps that we feel ought to proceed from it.

There appear to be two primary means by which the EPA can influence industry to bring about noise control. The first is to regulate the maximum allowable noise levels that can be produced by new equipment. The second is by instituting a mechanism for disseminating information to the consumer: namely, requiring the labeling of noisy products. In situations where the party exposed to noise is not the purchaser of the noisy equipment and is not in a position to influence the noise level or operation of the equipment, it appears that noise standards must be generated and applied to bring about noise reduction. This is largely the case in the construction industry, where the principal recourse to construction noise control by the community has been through local legislation. On the other hand, when the purchaser is, for all practical purposes, the only party affected by a noisy source and that source is not likely to contribute seriously to hearing damage, then standards appear to constrain unnecessarily one's freedom of choice. Rather it would seem appropriate to ensure that the purchaser is informed of the levels to which he will be exposed, but that he be allowed the freedom to weigh noise against other factors (e.g., price, size, durability) in reaching a decision among alternative products.

Setting standards and labeling requirements is no mean task. There are technical issues that must be resolved involving the conditions under which noise is to be measured. For example,

AR0070617

the type of sink in which a garbage disposer is installed and the character of food waste being disposed of, must be carefully specified to obtain meaningful and uniform results. Somewhat more difficult is the task of determining the maximum allowable levels for different kinds of equipment. In a sense, these levels invariably represent a compromise between desired values and values that are economically acceptable. This concept may be illustrated qualitatively by Fig. 27 in which we plot cost vs noise reduction. Cost is used to include capital, operation, and maintenance expenditures owing to the application of noise control treatment and whatever performance degradation might occur because of such treatment. Automobile mufflers are a good example; they increase the price of an automobile, often require replacement during the life of an automobile, and slightly degrade engine performance. Results achievable by application of state-of-the-art noise-control techniques are represented by an exponentially increasing curve. The first few dB of noise reduction are typically achieved at low cost; costs gain substantially as greater levels of quieting are sought. Also shown in the Fig. 27 is a cost vs noise reduction curve that might be achievable subsequent to noise-control research and development. In fact, it can probably be said that the sole objective of R&D should be to lower the state-of-the-art curve. The third curve in Fig. 27 shows a relation between cost and noise reduction deemed acceptable by the decision-makers. The curve is concave downward illustrating the notion that as a machine is made quieter, each increment of noise reduction is worth less and less. The intersection of the state-of-the-art curve with the acceptable cost vs noise reduction curve determines the noise reduction one is willing to specify. If this level of reduction is inadequate,

AR0070618

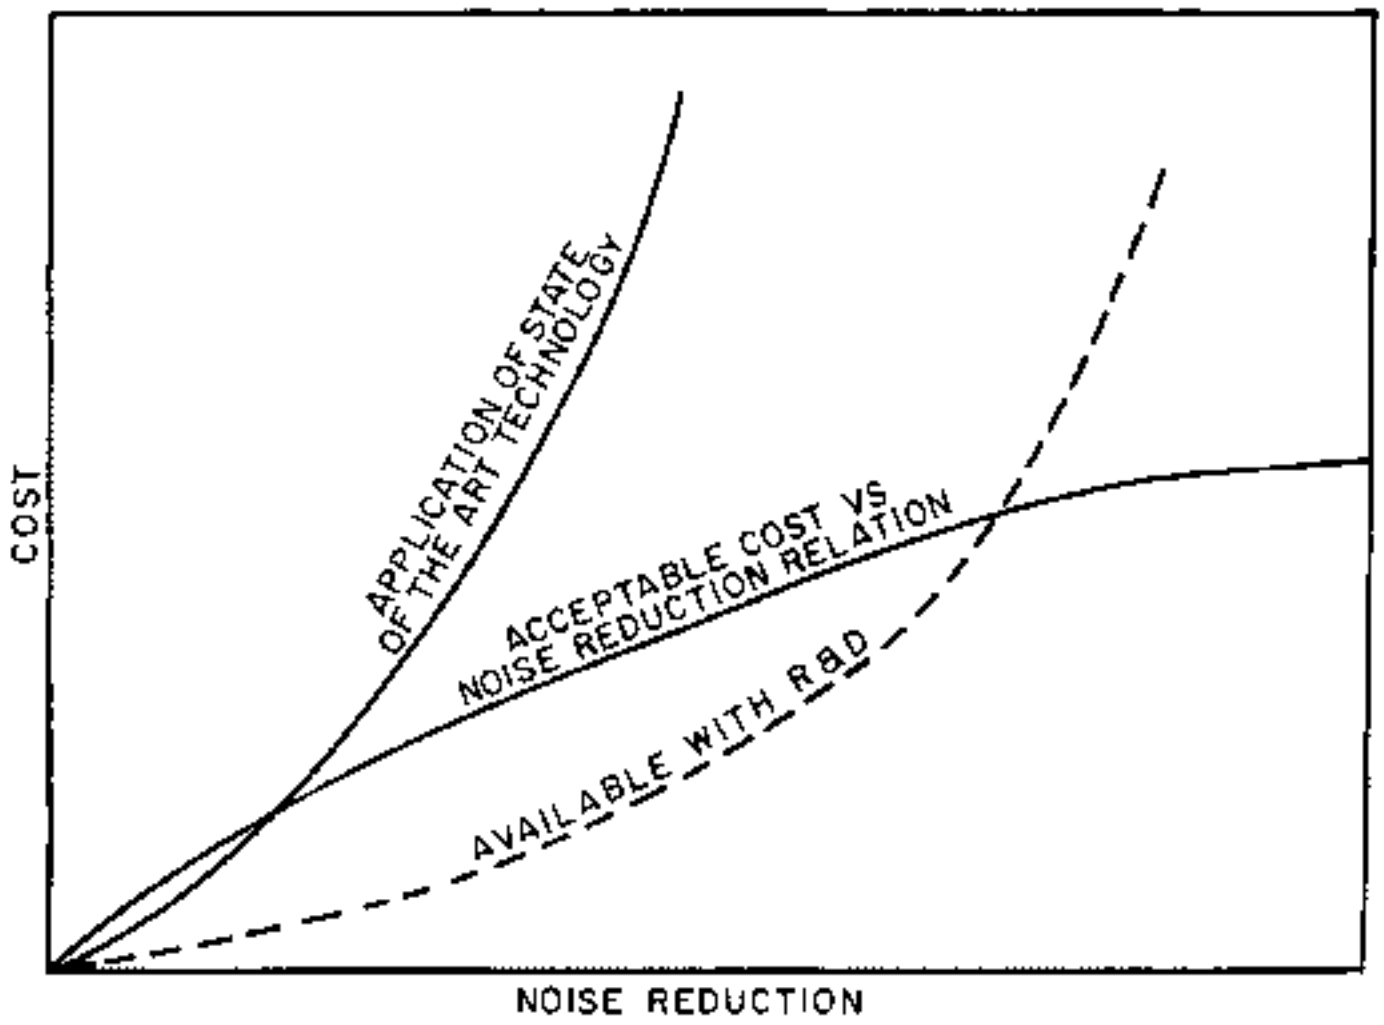

FIG. 27. COST OF NOISE CONTROL VS NOISE REDUCTION

AR0070619

it is necessary to conduct R&D to achieve a lower state-of-the-art curve and increase the level of noise reduction that can be justified economically.

Each party has its own view of the level of the acceptable cost vs noise reduction curve. For equipment manufacturers who find little marketplace demand for quiet products, the curve is low. People living or working near noisy equipment would naturally draw the curve at a higher level, especially if they did not have to bear a significant part of the cost for quieting the machinery. One of the problems that EPA will have to face is to develop an acceptability curve that is, in some sense, fair to all parties. Although it is difficult, if not impossible, to develop such curves quantitatively, it will be necessary for a decision maker to be aware of the pertinent relations between cost and noise reduction and to account for them in selecting the levels to be achieved. To assist in this process, we recommend here studies of the technology and economics of noise abatement, the economic impact of noise control, the type of improved noise criteria that ought to be developed, and social-indicator studies to measure the attitudes of the public to noise and noise control. First, let us consider which equipment ought to be regulated by standards and which by labeling.

5.2.1 Standards and labeling

We recommend that noise sources having a significant impact on parties who derive little direct benefit from the source ought to be controlled by the establishment of maximum allowable noise levels. This would include most construction equipment, construction sites, and certain types of appliances. Among the items of construction equipment requiring standards are all machinery powered by internal combustion engines as well as tools

AR0070620

utilizing impact or cutting mechanisms, such as drills, pavement breakers, and saws. Construction site noise levels ought to be regulated to ensure that the contractor deploy and utilize his machinery in a way that minimizes community noise exposure. Typical appliances requiring regulation are electric garden tools (e.g., lawn mowers, hedge clippers, edge trimmers), food-waste disposers, dishwashers, air conditioners, and shop tools. Because the noise of hazardous tools also serves to inform the user of their operation, minimum as well as maximum levels out to be set.

For standards to be applied in a way that may reasonably be met by industry and yet are sufficient to have an impact, we recommend the establishment of a three-phase program. A decreasing sequence of levels would be established and would go into effect approximately, one, four, and seven years subsequent to the time at which the levels are publicly announced.

One Year

The purpose of the first phase is to ensure that highly effective off-the-shelf noise control equipment is utilized on all new machinery. Thus, all machinery powered by internal combustion engines would be required to be equipped with high-quality mufflers, for example. (This contrasts with the current situation in which some construction equipment is advertised and sold without any muffling whatsoever.) One year appears adequate for manufacturers to order, receive, and install such equipment.

Four Years

The second phase would become effective approximately four years after announcement of levels. These levels would be selected to ensure that state-of-the-art noise control techniques are

AR0070621

incorporated in equipment. To achieve these levels, the manufacturer might have to use sound-absorptive engine enclosures, for example. Appliances might have to incorporate vibration isolators for all motors and pumps. Since the type of treatment envisioned here requires minor changes to equipment, four years appears adequate for manufacturers to design noise treatment and retool selected items of their production lines.

Seven Years

The levels to become effective after a period of seven years should largely represent state-of-the-art advances and should have a significant impact on the level generated by the noise source. Twenty dB(A) of noise reduction for the most offensive construction equipment and appliances would seem reasonable. Seven years allows sufficient time for the research and development needed for state-of-the-art advances and the incorporation of the fruits of this work in production items.

We also recommend labeling of appliances generating significant noise levels affecting primarily the user. Included in a list of items to be labeled are all items controlled by standards, as well as shop tools, vacuum cleaners, food blenders, fans, and hair dryers. Our rationale for labeling rather than standard setting is that a person should be informed of the noise to which he will expose himself and then be free to consider noise as but one of a number of factors accounting for his selection of a particular brand. Noise-control standards would no doubt raise appliance prices, unnecessarily restricting the consumer's range of choice.

AR0070622

5.2.2 Technology evaluation, demonstration, and development

We recommend the expenditure of appropriate levels of effort to evaluate, demonstrate, and develop technology in support of the establishment of standards. These studies are as follows:

Labeling

To make labeling meaningful, a consistent set of test procedures should be developed for each type of appliance or item of building equipment. This is especially important for appliances whose noise characteristics depend heavily on the installation. Prominent among these are food-waste disposers, dishwashers, plumbing fixtures, and vacuum cleaners (which may rest on a rug or a hard floor).

Standards — Phase I

The first recommended phase of standard setting establishes noise levels that can be met if highly effective off-the-shelf noise control devices are used on all equipment. Prior to the establishment of such standards, a program to measure the noise generated by selected machinery samples targeted for incorporation of such devices would seem appropriate.

Standards — Phase II

The second phase of standards would specify levels requiring the application of noise-control treatment. We recommend that EPA conduct noise-control demonstration projects on selected items for three reasons. First, achievable levels of noise reduction can be accurately evaluated, and accordingly specified, only by means of such programs. Without actually implementing noise-reduction techniques there would probably be an unacceptable

AR0070623

level of uncertainty associated with predictions. Furthermore, practical implementation problems are often not uncovered until treatment is actually put into practice. Second, such demonstration of results achievable by means of state-of-the-art noise treatment would put to rest any objections raised by the affected industry concerning the technological feasibility of achieving specified levels. Finally, the technical information generated by a demonstration program would be valuable across the affected industry, especially to small companies who often lack the requisite technical capability in noise control.

Standards — Phase III

The third recommended phase of standards is designed to have a significant impact on noise levels and will probably be achievable only through state-of-the-art advances in noise-control technology. To ensure that the state-of-the-art is appropriately advanced in sufficient time for implementation in new machinery we recommend the immediate commencement of R&D programs dealing with the following important aspects of construction and appliance noise (in approximate order of priority):

- diesel engines
- mufflers
- hydraulic systems
- cooling systems
- impact and cutting tools
- other power plants:
  - gas turbines (for nonaircraft use)
  - electric motors

AR0070624

- Transmissions (gears)
- Water valves

5.3 Economic Impact Studies

Determining the optimum balance between public's desire for quiet and the distributed costs required to achieve it by means of rigorous systems analysis effort would require a large-scale simulation of the economics of the construction industry and its place in the U.S. economy. Such a study is not feasible if usable results are required in a short time or if expenditure of funds is limited. It is possible, however, to make some choices as to what to quiet and how to quiet it, by doing some fairly unsophisticated investigation of how the quieting costs get distributed through the industry and the economy. We recommend treatment of:

- The impact of noise on various segments of the population. (This has largely been performed under the existing EPA contract and needs but a little expansion.)
- Estimated costs of quieting selected pieces of equipment as a function of degree of quieting. (This would be an order-of-magnitude estimate. Data can be obtained from price information on existing mufflers, heavy casings, absorptive materials, etc., as well as a study of price differentials between existing quieted and unquieted machinery — not just construction equipment. Costs of nonhardware guiding techniques, such as scheduling site operations to avoid using many prices of equipment at once, would be estimated by constructing typical scenarios and consulting with industry representatives to determine increases in construction cost increases (or decreases). Allowance should be made for uses

AR0070625

in which a change in equipment design or operation results in greater productivity, reliability, etc. The effect of such an occurrence could be a net *negative* quieting cost.)

- The distribution of increased equipment cost among producers, purchasers and the purchaser's customers. (Part of the cost will be absorbed by each, depending on the demand elasticity of the commodity. This information exists in published studies of the economics of the construction industry.)
- Allocation of increased equipment costs/rentals among various types of construction. (The resulting increase in construction costs are a strong function of what is being built. Equipment rental typically makes up 20% of the cost of civil works constructions, 10% of the cost of highways, but only 2% in the case of buildings.)

The above data would be used to compute the economic effect of quieting equipment on the public. The outputs would be:

- The expected increase in costs and rentals of housing, offices, industrial space, etc., as a function of the degree and method of site quieting. Also of interest is the degree of intersection of the sets of: (1) surrounding inhabitants, who get the benefits of quiet sites, and (2) building users, who pay the cost, or part of it.
- Expected increase in state, municipal, and federal taxes as a result of increased cost of public works construction, etc.

The net result of the study would be recommendations for an orderly construction quieting program based on the information developed above. The criteria by which specific techniques or regulations would be judged are:

AR0070626

- Cost-effectiveness (the degree of quieting achieved per dollar expended).
- Cost-benefits (the reduction in community noise exposure as a function of quieting cost).
- Equitability (the degree to which the beneficiaries of a quieting program bear the expense of that program).

5.4 A Program of Public Support Development

Our contact with managers of construction equipment and home appliance manufacturing companies has convinced us that their perspective on and attitudes toward noise control programs will strongly influence the efforts they make to quiet their products. This is even more true of the values they hold regarding the legitimacy and worth of quiet environments. Indeed, we regard the public support of noise abatement efforts as a crucial variable in the success of these efforts.

We would, therefore, recommend a continuous program to diagnose and develop public support for noise abatement. Such a program would embrace five activities:

Exploration of Programs in Other Areas

We visualize this as an inquiry both into the theory of public opinion, attitude change, and shifts in basic values and into the actual techniques of public support development that have been employed in other contexts.

A Continuous Inventory of Opinion-Leader Attitudes

This would be a program of interviews with opinion leaders who are dealing with noise abatement. It would include leaders

AR0070627

in government, business, relevant professions, and consumer- and ecology-advocate groups.

A Continuous Inventory of Public Awareness, Attitudes, and Values

These should be measured on a well-designed material sample on a continuous basis so that trends over time could be assessed concerning public knowledge, attitudes, and values.

Program Development

A program, based on information obtained from the three activities above, should be developed (1) to optimize the kind and degree of regulation which can be supported by the public opinion that exists, (2) to prescribe a public information program that will improve the quality of public opinion, and (3) to identify profitable areas for demonstration programs.

The Development and Administration of Pilot Programs of Noise Abatement

These pilot programs should test the relation of regulation to various levels of public support in the same sense that pilot programs that test innovative technological prototypes are developed.

We should like to say a word regarding the usefulness and feasibility of the continuous inventories of leader opinion and public opinion — activities 2 and 3 above.

Field research in the behavioral sciences has now reached the point that useful social indicators can often be developed if their development is undertaken on a pragmatic basis. We do

AR0070628

not visualize that these survey activities will be conducted at the level of public opinion polls. Again, the behavioral sciences have matured to the point that much more useful kinds of information can be gathered. We know from previous noise surveys that local economic status and attitudes toward noise makers influence noise annoyance and noise complaints. A recent study of noise variance noise that we have conducted indicates that the necessity of the noise, and the degree to which one perceives the noise as an intrusion, influences the level of annoyance. The survey efforts envisaged would map factors that would assist in the formulation of noise criteria. Are people willing to put up with "tolerable" levels of noise or do they now demand reduction to "comfortable" levels? Of greatest importance may be attitudes toward the regulating process itself. By now it is well-established in social psychology that basic orientations towards the exercise of influence alter behavior. With respect to the product manufacturer who promises to become an object of regulation, theory would predict that one's enforcement problems would be quite different if the manufacturers complied to regulation because of fear, because compliance was expected by his reference groups, or because his own values indicated compliance. These psychological orientations can be measured through interviews.

5.5 Social Impact

The following recommendations are made to evaluate the impact of noise not only from the sources under consideration in the current report but also from other sources.

1. The most fundamental action that can be taken to further the assessment of noise impact is to initiate research leading

AR0070629

to development of an absolute scale of annoyance for all noise exposure. The first stage of such a research program would obviously be a planning effort to structure the task and prepare detailed plans for its execution.

The need for such research is immediate. Existing methods for estimating annoyance are relative rather than absolute, limited in scope and application, not widely accepted, and of dubious utility. The intended research would entail simultaneous measurement of both complaint behavior and the offending acoustic signals producing complaints, *at the time of annoyance*. A continuous survey of residential noise annoyance over a considerable period of time is needed, as are surveys of noise annoyance in other environments. Until a well-founded research program of this sort is undertaken, one must continue to rely upon personal experience or the distortions of the popular press for estimates of the true magnitude of the annoyance problem.

2. Since speech interference proved to be such a widespread consequence of exposure to the noise sources considered in this report, research should be conducted to determine how accurately speech interference predictions made on the basis of laboratory data may be extended to real-life situations. Almost all current knowledge of speech interference effects has been produced by studies employing steady-state noise as the interfering signal. No research has been conducted on potentially crucial effects of temporal parameters of noise distributions (including frequency, duration, and periodicity of interference) on verbal communication. Further, little if anything is known of the annoyance value of speech interference. Trade-offs governing the relative annoyance of frequent but short interruptions vs infrequent but long interruptions of verbal communication have not been investigated. It therefore remains impossible to predict whether people would

AR0070630

suffer more speech interference from one type of appliance than another; whether redesign of machinery for longer duration but lower level noise output would be helpful; whether scheduling changes in the operation of construction machinery would reduce speech interference; and so forth.

3. Noise education programs should be designed to provide the public with the information needed to make decisions about the desirability of noise exposure. A noise-conscious public can exercise a modicum of control over its noise exposure through its purchasing power and its demands for noise control legislation. Consideration should be given to preparation of public information pamphlets, recordings, or other means of increasing public awareness of noise exposure.

APPENDIX A — DETAILED SOURCE CHARACTERIZATION

A.1 Construction Equipment

Of the considerable body of data on the noise of construction equipment, most pertains to the operator position; the available data on noise radiated by this equipment to its surroundings is very limited. The data presented in Fig. 1 (main text) and in this appendix were obtained from

- The open literature [3-4].
- Reports, including those submitted by various manufacturers at the EPA hearings on construction equipment held in Atlanta, Georgia, July 6 and 9, 1971.
- Field measurements conducted for this project at a number of construction sites in the vicinity of Boston.*

A.1.1 Noise spectra

Much of the equipment used at construction sites is powered by diesel engines, which generally constitute the predominant noise sources. Figure A.1 shows the envelope of the 1/3-octave band spectra of noise from 23 different items of diesel-powered construction equipment, rated from 45 to 770 hp and operating at between 1100 and 2700 rpm, at a variety of conditions (i.e., with various degrees of loading, ranging from none to heavy). These spectra were obtained at various locations around the equipment items, which also varied in the degree of exhaust muffling present.

*These measurements were made with a 1-in. Bruel and Kjaer type 4131 condenser microphone, coupled to a Bruel and Kjaer type 2203 sound level meter. The signals were recorded on a Kudelski Nagra type III tape recorder, and later analyzed in the laboratory by means of a General Radio Corp. "Real-Time Analyzer". Calibration was accomplished with the aid of a Bruel and Kjaer type 4220 piston phone.

AR0070636

Figures A.5, A.6, and A.7 show the noise spectra from some typical engine-powered items of equipment. The low-frequency peaks typically correspond to the firing frequency (the number of power strokes per unit time — which depends on the engine rpm, number of cylinders, and on the number of power strokes per revolution) and its harmonics. Figure A.2 illustrates the noise made by the tracked bulldozer under various working conditions. These spectra reflect not only the diesel noise but also the noise made by the tracks, rollers, and sprocket of metal on metal and soil.

The other equipment items listed above also operate over the similar kinds of diesel engines. In addition, equipment, however, should include here a wide range of low to higher power applications, with spark-ignition engines relegated to the lower power equipment. Spectra corresponding to two types of gasoline-engine powered equipment are shown in Fig. A.5.

Noise spectra for two air compressors - one diesel, one gasoline-engine powered - incorporating no special noise control provisions are shown in Fig. A.6. Figure A.6 shows the noise spectra associated with several pumps and generators; Fig. A.6 shows noise levels produced by a vibrator acting on a plywood framework and by various drum cutting work. Noise spectra produced by various pneumatic tools are shown in Fig. A.7.

The noise from conventional pile drivers is characterized by intense peaks associated with the impacts of the hammer against the pile. The peak levels associated with these spectra are indicated in Fig. A.8 for two conventional pile drivers, together with the noise levels produced by a sonic (vibratory, nonimpact) pile driver.

AR0070637

A.1.2 Average construction site noise pollution levels

Based on an analysis of the activities that occur during each phase of construction at the various types of sites, a listing of the equipment active during each phase was developed. This listing, together with an estimate of the fractional number of sites that involve each equipment item, appears in Table A-1.

For site noise analysis, this large table was simplified by averaging equipment usage over similar sites and by grouping together equipment items with similar noise characteristics. For the calculations, equipment with noise characteristics that were not known directly was replaced by equipment expected to have similar (known) noise characteristics (e.g., back fillers and trenchers were replaced by backhoes and loaders). Equipment known to be extremely quiet (e.g., electric cranes, electric fork lifts) was totally omitted from the calculations.

Since a given item of equipment is present at only a fraction of all sites and only during part of each phase, and since it only operates part of the time that it is present, a usage factor was assigned to each equipment item. This factor was calculated as the product of three factors: (1) the fractional number of sites at which the equipment is used (based on Table A-1), (2) the estimated fraction of the phase duration during which the equipment is on site and (3) the duty cycle, i.e., the fractional time that this equipment is operating while on site [5]. The resulting usage factors are summarized in Table A-2.

In order to calculate the site NPL, defined as the sum of the energy-average SPL in dB(A) and 2.56 times the Standard Deviation of A-scale SPL [6], one needs to know not only the average sound

AR0070643

pressure, but also enough about its time-variation so that one can determine its standard deviation. In addition, the background noise levels enter in the evaluation of both of these quantities. Accordingly, representative background noise levels were selected as 50 dB(A) for residential, suburban, and rural sites and 70 dB(A) for commercial and industrial (urban) sites, on the basis of data for various U.S. and foreign locations [7].

Representative time-variations of noise were generated by dividing each construction phase into 50 equal time intervals. The start (or "turn-on") times for each individual item listed in Table A-2 were determined at random (by means of a computer random number generator), and the fractional "on-time" duration for each item was taken as its usage factor (Table A-2). From the noise level for each item of equipment, the total noise level in each time interval was then calculated, and from this ensemble of values the desired average and standard deviations were evaluated. For test purposes, the calculations for several sites/phases were repeated several times, with different randomly selected start times; the resulting NPL values were always found to lie within a 3 dB(A) interval. Although such repetitive calculations were not carried out for all sites/phases, the reported site NPL values may be considered as valid within ±2 dB(A).

A.2 Appliances

In the following sections, brief discussions are presented of appliances not covered in the body of the report. We measured the noise levels of many of these appliances; these measurements are presented here as 1/3-octave band sound pressure data.

AR0070644

A.2.1 Can opener, electric

Noise of electric can openers is generated by the reducing gears, the electric motor, and the grating of the clamp against the moving lip of the can. Additional noise is radiated from the rivets or metal panels of the unit. Can openers are usually supported on small rubber feet which partially isolate the vibration from the work surface; however, wall mounting of the opener can short-circuit this isolation. The A-weighted sound level at a distance of 3 ft was measured for seven electric can openers; the mean level was 66 dB(A).

Figure A.9 shows 1/3-octave band plots of the sound pressure levels measured at a distance of 3 ft for two different can openers. The peaks at 53 and 125 Hz are probably motor-induced while the higher frequency peaks are probably related to the number of teeth in the reducing gears.

A.2.2 Clothes dryer

Clothes dryers are relatively quiet appliances which consist of a rotating drum within a metal enclosure; heat is supplied by either electric coils or a gas flame. The constant noise of the motor and the rumble of the drum, plus the combustion roar in a gas dryer, are punctuated by the noise of buttons or zippers impacting with the metal chamber. A range of sound levels from 51 dB(A) to 66 dB(A), with a mean level of 58 dB(A), was measured at a distance of 3 ft for eleven gas and electric dryers. Figure A.10 shows 1/3-octave band sound pressure level data for five different dryers.

AR0070645

A.2.3 Clothes washer

The noise generating components of clothes washers include:

- water noise during the filling, agitation, and spinning cycles
- unbalanced loads, which cause excessive vibration to be transmitted into piping and floor
- motor
- pump

Figure A.11 presents the noise levels for the wash cycle of five different machines; Fig. A.12 shows noise levels for the spin cycle of four of these five machines. The peaks in the low-frequency bands probably represent motor-induced noise while those in the mid-frequency bands may be related to spinning of the tub.

A.2.4 Coffee mill

A coffee mill consists of a grinding mechanism that is driven by a motor to produce fine to coarse ground coffee. Motor-induced noise is radiated from the casing and the coffee bean enclosure. Rubber feet are provided for vibration isolation. Measurements were made at a 3 ft distance on two coffee mills: the two sound levels were 75 dB(A) and 78 dB(A).

A.2.5 Dehumidifier

In a home humidifier, a small fan draws air across condensing coils, collecting the moisture in a removable pan. Noise measurements were made of four dehumidifiers; the noise varied from 52 dB(A) to 62 dB(A).

AR0070646

Figure A.13 present 1/3-octave band data for the quietest of these units. The broad peak in the vicinity of 120 Hz is motor induced; mid-frequency noise is dominated by the fan. Although compressors may be vibration isolated, the casing of a unit is likely an important radiator.

A.2.6 Edger and trimmer

An edger and trimmer consists of a high-speed motor directly driving a two-bladed knife. This lawn tool is used to trim the grass along walkways and the brush along garden paths.

Figure A.14 presents 1/3-octave band data on one unit; the sound level was 81 dB(A). The peaks in the frequency spectrum seem to be the 1st, 2nd, 3rd, 6th, and 20th harmonics of 400 Hz. It is anticipated that narrower band analysis would reveal more tonal components that are related to the blade passage of the cutting edge.

A.2.7 Fan

There are three general categories of fans found in the home: window fans, floor fans, and stove hood and bathroom exhaust fans.

- Window fans are usually standardized to a 14-in. or 22-in. size (12-in. and 20-in. diameter blades respectively). Features on deluxe models include thermostatic control and reversible direction of air flow. Twelve noise measurements of window fans ranged from 47 dB(A) to 66 dB(A); the mean was 57 dB(A). Low-speed to high-speed mean values showed a spread of 17 dB(A).

AR0070647

Figure A.15 presents 1/3-octave band noise measurements for three window fans for both low and high speed. The tonal components are likely related to the blade passage frequency of the fan, the motor, the blade tip velocity, and the blade design.

- Floor fans or table fans usually consist of a base, a small electric motor, and a blade with protective cage. They often rotate back and forth to spread air movement around an arc of 90° or so and are usually designed to run at various operating speeds. Twenty-two measurements at a 3 ft distance yielded a range of sound levels from 38 dB(A) to 67 dB(A); the mean level was 54 dB(A).

Figure A.16 presents 1/3-octave band data for three floor fans for both low and high speed. The noise sources are very similar to those of window fans.

- Stove hood exhaust fans and bathroom exhausts are typically small axial flow fans mounted directly above the stove to exhaust cooking odors or in the bathroom ceiling to exhaust hot air. The mean dB(A) level of ten measurements at a 3 ft distance was 53 dB(A).

Figure A.17 presents narrowband data for four speeds for one particular stove hood exhaust fan. Again, the tones are related to motor noise and blade passage fan noise. Through the use of appropriate lining it should be possible to reduce the noise of stove hood exhaust fans and bathroom exhaust fans by up to 15 dB(A).

AR0070648

A.2.8 Food blender

The electrical motor control system on food blenders is designed to drive the cutting blades (located at the bottom of a removable container) at a wide range of speeds in order to perform various food blending tasks. Speed control may be achieved by using a variable-speed motor or solid state electronic networks. The primary sources of noise are the motor, the whirling of the blades causing radiated noise, structureborne noise, and agitating noise of the fluid. From measurements of the noise generated by foreign and domestic food blenders, the sound level ranged from 82 to 88 dB(A) with a mean level of 75 dB(A). The container was half full of water during most of these measurements. Figure A.18 presents a series of narrowband measurements representing the noise levels generated by one food blender running at each of nine different speeds. The peaks in the spectrum shift upward in frequency with increased speed, suggesting a dependence on the blade passage frequency of the cutting edges. Figure A.19 shows the variation in noise level for a maximum speed setting for five food blenders of different manufacture.

A.2.9 Food mixer

Food mixers are available in both portable and table model styles. Portable mixers are lightweight versions of table models - they have no base but consist of the same basic mechanisms: a set of beaters and a variable-speed motor or a single-speed motor with reduction gears. Twenty-five sound level measurements were made at a 3 ft distance on domestic and foreign, portable and table model food mixers. The mixer was operated in a bowl half-full of water for most of the measurements. The sound level ranged from 49 dB(A) to 79 dB(A) with a mean level of 67 dB(A). Figure A.20 shows narrowband analysis of mixer noise at low speed and at high speed.

AR0070649

A.2.10 Freezer

The mechanical components of a freezer are a compressor, evaporative coils, condensing coils, and one or two fans, as in a refrigerator. Small freezers have the condensing coils spread over the back of the machine. On larger units, with their requirement for forced cooling, the condenser coils are grouped at the bottom and cooled by a fan that also cools the compressor. With the compressor in operation, the sound levels generated by three home freezers were measured; the mean level was 51 dB(A) with a range of 39 to 59 dB(A) at a 3-ft distance. Figure A.21 shows narrowband data for two of the three freezers. The primary noise generators are the motor, fans, and compressor, with some radiation from the casing.

A.2.11 Hair clipper

A measurement of the noise generated by a hair clipper was made at a distance of 3 ft; the sound level was 59 dB(A). The noise is generated by the motor and gears which enable the clipping blades to vibrate.

A.2.12 Hair dryer

Different models of hair dryers all share the design objective of forcing warmed air over wet hair. Table models have a hard-shelled enclosure like that of a professional hairdressers machine. Portable dryers have plastic bonnets connected to the fan and heater by a flexible hose. Noise is generated by the fan, motor and air flow. A faster drying rate is achieved by greater air flow and higher temperatures; this, however, means increased noise from the fan. The latest development of a totally portable unit – with motor and blower attached directly to the bonnet – is the noisiest arrangement because it puts the noise source directly by the ear of the user. Six hair

AR0070650

dryers were measured at a 3-ft distance; the mean level was 61 dB(A). Figure A.22 shows 1/3-octave band sound pressure levels measured at a distance of 3 ft from three units. The low-frequency tonal components are probably motor related, while the high-frequency peaks may relate to the blade passage of the blower.

A.2.13 Heater, electric

Electric heaters used to heat a single room typically have small single-speed fans that blow air past electric coils into the room. The noise generated by these heaters is due to the electric motors, the fans, air flow, and, often, rattling metallic parts. A noise level of 47 dB(A) was measured at 3 ft from an electric heater.

A.2.14 Hedge clippers

The noise of hedge clippers, in which an electric motor runs one or two cutter bars, is mainly generated by the motor and reciprocating gear action. On some models, one bar moves back and forth against a stationary bar; on other models, two cutters reciprocate. Since the latter is a more balanced action, vibration to the user is reduced. We measured a noise level of 84 dB(A) at 3 ft from one unit.

A.2.15 Home shop tools

Electrically-powered shop tools such as drills, saws, sanders, grinders, lathes, and routers have similar noise generating mechanisms. In general, portable shop tools, due to their requirement to be lightweight and high-powered, require forced cooling of the motor and use high-speed universal motors which are often noisy

AR0070651

even when running free. Table model shop tools generally use induction motors which are relatively low speed and quiet when running free.

The portable straight-line or vibration sander is relatively quiet when running free [63 dB(A) at 3 ft] because it has a lower power requirement than most power tools and requires no forced cooling. Figure A.23 shows narrowband data for two operations of a belt sander: running free [82 dB(A)] and sanding wood [86 dB(A)]. The primary noise is the vibrating action of the sander foot.

In drills the gears add to the noise – the more sets of gears required, the noisier the operation. The noise generated by four 1/4-in. drills with a single set of gears measured 76 to 80 dB(A), the noise of two 3/8-in. drills with two sets of gears measured 83 dB(A), and the noise of two 1/2-in. drills with three sets of gears measured 84 and 87 dB(A). Figure A.24 presents noise levels measured near a 1/4-in., a 3/8-in., and a 1/2-in. drill; the peaks in the spectrum are probably related to the speed and the teeth ratios of the gears. Figure A.25 presents narrowband data on two different drill presses, one working metal, the other wood.

Noise levels generated by three different grinders working metal [87 to 97 dB(A)] are shown in Fig. A.26. In Fig. A.27 the noise levels generated by a router running free [81 dB(A)] are compared with the levels when it is working wood [88 dB(A)]. Noise levels of a small metal lathe are shown in Fig. A.28 for a running free condition and for cutting metal. Figure A.29 shows the narrowband data for a sabre saw running free and cutting wood.

AR0070652

Noise levels associated with the cutting of wood by a jig saw, a radial saw, a table saw, and a band saw are shown in Fig. A.30. The tone at 3150 Hz for the table saw may correspond to the frequency of teeth passing a given point [8].

Tools such as a table grinder, lathe, table jig saw, and table band saw generate noise levels in the mid-sixty to mid-seventy dB(A) range at a 3-ft distance while running free. The larger portable tools especially drills and grinders, generate noise levels of 80 to over 90 dB(A) running free.

A.2.16 Humidifier

Room size humidifiers are relatively simple mechanical devices in which a fan forces air through a wetted pad. Humidifiers exemplify the recurring noise problem from air circulation caused by fan, motor, and air movement noise. Figure A.31 shows narrowband data - 41, 51, and 65 dB(A) - for three settings of one humidifier. The higher levels are associated with higher fan speeds and thereby increased flow noise.

A.2.17 Knife, electric

For easy handling in the home, electric knives are designed to be small and lightweight. Therefore, the electric motor and gears for reciprocating blade action are encased in lightweight plastic. While the noise of an electric knife [with a range of 65 to 75 dB(A) and a mean level of 70 dB(A) at 3 ft] can be annoying, it also acts as a signal that the knife is in operation. Figure A.32 shows narrowband data for two of the three samples.

AR0070653

A.2.18 Knife sharpener

Electric knife sharpeners are often attached to electric can openers as well as being seperate appliances. The rotation of sharpening stones alone is very quiet since just the motor and shaft rotate; however, the interaction between the stone and the knife during the sharpening process makes an unavoidable grating noise. A single measurement was made at a 3-ft distance; while the noise levels vary depending on the pressure of the knife against the stone, 72 db(A) is representative of a typical sharpening operation.

A.2.19 Lawn mower, electric

The gears and the A.C. or battery powered engine of the rotary type electric lawn mower are the main sources of noise. The rattling of the engine housing and other metal parts plus the whirling sound of the blade are also identifiable. Although an electric lawn mower is often quieter than a gasoline-powered lawn mower, the two electric ones that were measured registered 81 and 89 dB(A) at a 3-ft distance. The larger the lawn mower, the more powerful an engine is needed to rotate the blade, and thus the noisier the device. Certain possibilities appear feasible for quieting the electric lawn mower such as changes in blade design and speed to reduce vortex noise, tighter construction of the tool, and sound damping for the motor housing and blade covering.

A.2.20 Oral lavage

An oral lavage is a device that uses the squirting force of water to cleanse the mouth. The motor drives a reciprocating pump, connected to a water supply, which forces a tiny stream of water out the end of a tube. Two measurements gave values of 70 and 72 dB(A).

AR0070654

A.2.21 Refrigerator

The majority of the refrigerators sold today are automatically defrosting. Cooling coils are located outside the freezer storage area and cold air is circulated through the freezer unit by a fan. The automatic defrost mechanism periodically melts the ice which forms on the coils. The trend in recent years has been to larger refrigerators with features such as automatic ice cube tray filling, ice cube making, and defrosting. Refrigerators with such features require more power and thus larger compressors with resulting higher noise levels. Better sound isolation around the machinery compartment, sound absorbing material in the machinery compartment, and resilient mounting of the motor and compressor have prevented the noise of the newer machines from greatly increasing. Twelve refrigerators were measured at a distance of 3 ft from the front. The levels ranged from 35 dB(A) to 52 dB(A) with a mean level of 42 dB(A). Figure A.33 presents narrowband data for two refrigerators.

A.2.22 Sewing machine

Sewing machines from the simplest to the most sophisticated and complex ones all have variable-speed electric motors, necessary gear and drive mechanisms, and auxiliary accessories. There is a wide range of controls available such as stitch tension, variable stitch length and width, zig-zag stitching, forward-reverse action, needle orientation, etc. The more versatile sewing machines have insertable cams which can be changed for different stitching patterns. Measurements on two sewing machines in operation gave values of 70 dB(A) and 74 dB(A) measured 3 ft from the machine. Figure A.34 shows narrowband data for these two machines.

AR0070655

possible noise control measures are to reduce noise from the motor, linkages, gears, and clutch by use of different materials and more effective enclosures. Resilient mounting of vibrating parts to reduce structureborne vibration noise is presently used.

A.2.23 Shaver, electric

Electric shavers are run by a compact but powerful electric motor, powered from house current or a rechargeable battery. While shaving mechanisms may vary — using either rotary blades or oscillatory cutting action — the noise is generated by the motor and gears. The mean sound level for men's and women's shavers was 60 dB(A) at a 3 ft distance; the range was 47 to 69 dB(A). Figure A.35 shows narrowband data for four men's shavers and Fig. A.36 presents data for two women's shavers.

A.2.24 Toothbrush, electric

A small, lightweight high-speed motor run by either A.C. power or rechargeable batteries drives the detachable toothbrush. The less expensive models allow rotation in only one plane perpendicular to the axis of the toothbrush. With additional gearing, the more expensive models simultaneously rotate and move laterally to provide better cleaning action.

The main noise sources of an electric toothbrush are the motor and the gears. Typically, the devices with more gears are noisier. The mean sound level of three different electric toothbrushes at a 3 ft distance in bathrooms was 52 dB(A) with a range of 48 to 55 dB(A). At the user distance of about 3 in. from the device, the sound level is about 10 dB(A) higher. Figure A.37 shows narrowband data for an electric toothbrush.

AR0070656

Due to the overriding requirements for small size and light weight, noise control techniques such as improving the sound transmission loss of the casing or adding sound absorptive material are impractical. The most promising noise reduction possibilities will likely come from the development of quieter gear operations through the use of different materials or through designing the gears with closer tolerances or a different configuration.

A.2.25 Water faucets

Noise from water faucets includes water hammer, turbulence and cavitation noise. For particular values of pressure drop, a valve can be designed to minimize cavitation and its resulting noise; however, no valve configuration has been developed to minimize the noise for the full range of pressures that a valve experiences. The measured sound level at a distance of 3 ft for two water faucets was 61 dB(A). If die-casted brass fittings could replace sand-casted ones, there would be a smoother interior finish which would result in less turbulent flow and quieter operation.

A.3 Typical Equipment in Buildings

Many different types of electrical and mechanical equipment are required for the proper operation of modern large buildings. Much of this equipment is hidden in equipment rooms, behind ceilings, in walls, or behind cabinet type exterior enclosures, but the total cost and volume associated with such equipment represents a significant part of the cost and utility of a successful building. The majority of the equipment (including most of the basic heating and cooling system components) is for supplying the building occupants with a suitable amount of air at a comfortable temperature and moisture content. In addition, pumping and piping systems are

AR0070657

used for water and fluid circulation, elevators and escalators are used for movement of persons, and various conveyance systems are used for movement of material. In this section, the use and function of building equipment are briefly described. Where available, typical noise levels are presented for the equipment. For detailed information and procedures, the reader is referred to Refs. 9, 10, 11, and 18 at the end of this Appendix.

A.3.1 Prime movers

The function of prime movers is to transform energy — in the form of electric power or combustible fuel — into rotational movement for use in driving other equipment.

Electric Motors are the most widely used of the prime mover devices. They range in capacity from fractional hp up to several thousand hp; most motors fall in the speed range of about 450-3600 rpm. Motor noise is generated by aerodynamic, mechanical, and electrical forces. Aerodynamic noise, often the most prominent noise source, is generated by air turbulence due to movement of the blades of the cooling fan and the slots in the rotor. Recent designs have used higher cooling air velocities, thereby increasing the noise level.

Mechanical noise is due to bearings and shaft unbalance. Although mechanical noise can be identified in rotating machinery, low-frequency vibration rather than noise *per se* is the usual problem. Bearing noise is due to the sliding contact of sleeve bearings and the rolling contact of ball and roller bearings. When new, precision ball bearings are often quieter than sleeve bearings; however, after much use, they are much noisier. In new equipment, unbalance forces are usually small. Wear or build-up of dirt on the rotating component often increases the unbalance in a motor,

AR0070658

resulting in the generation of vibration at the rotational frequency and its integral multiples; e.g., since the shaft of a 3600 rpm motor turns at 3600 rpm $= 60 \frac{\text{rev}}{\text{min}} = 60 \frac{\text{rev}}{\text{sec}}$, energy will be concentrated at 60, 120, 180 Hz, etc. with the 60-Hz component being the strongest.

Electrical noise is generated by magnetostriction — where a component (iron laminations) contracts and expands in response to an alternating magnetic field. Such effects are particularly noticeable when D.C. or variable-speed motors are supplied rectified A.C. current. The wave-form of the rectified current contains high-frequency components that generate noise in the more audible frequency ranges. The primary excitation frequency for magnetostriction is twice the main power frequency, e.g., in the USA, 2×60 Hz or 120 Hz.

In the past, motor noise was generally less than the noise produced by the driven component. However, motors designed for high-temperature rises or powered by rectified current may now be the controlling noise sources. Even in the case of relatively quiet motors, motor noise often becomes predominant when the driven component is quieted. Figure A.38 presents a range of noise levels typical of a 3 ft measurement position for the many different sizes of motors used in buildings.

Diesel and Natural or LP (Liquified Propane) Gas Internal Combustion Engines are sometimes used when special conditions make them economically feasible. They are often used in emergency power systems, in total energy systems, and for driving large machines such as chillers. Noise generated by internal combustion engines consists of contributions from the intake and the exhaust and radiation from the casing. Although improperly muffled exhaust may be a source of community concern, the intake and radiation from

AR0070659

the casing are typically greater problems for buildings and considerable detail must be given to controlling the noise. Figure A.39 shows a range of noise levels measured at 3 ft from internal combustion engines found in buildings.

Gas Turbines are used almost exclusively in emergency power and "total energy" systems. A total energy system makes use of the fact that only about 20-30% of the heat energy of most fuels can be turned into mechanical power; the rest is rejected in the form of heat to cooling water and exhaust gases. A total energy system salvages some of the energy which is usually lost and uses it to heat water, etc. The advantages of turbines over equivalent internal combustion engines are their light weight, smaller size, and lower vibration, which can be governing factors for upper story installations. Figure A.40 presents noise levels representative of the noise generated by gas turbines.

Steam Turbines are sometimes used as high horsepower (over 50 hp) prime movers when high-pressure steam is available as a public utility service. Figure A.41 shows the range of noise levels typically found near steam turbines.

Transformers, although their function differs from that of the prime movers listed above, supply primary electrical input power; their output is an altered form of electrical power (higher amperage and lower voltage) rather than motion. The use of transformers permits large amounts of electrical energy to be supplied to a building with relatively small supply cables. Noise generated by transformers is due primarily to the magnetostrictive effect in the transformer cores. Thus, the noise consists of a harmonic series of component tones with a fundamental frequency equal to

AR0070660

twice the main power frequency. The range of noise levels generated by transformers typically housed in buildings is presented in Fig. A.4.

Generators or Motors are used to produce local electricity in emergencies when electrical power is unavailable from outside sources, to produce direct current electricity, or to convert power from one frequency to another. The noise generating characteristics and noise levels of generators are similar to those of electrical motors.

A.3.2 Fluid handling units

Pumps may be the common centrifugal type that uses an electric motor drive, or the diaphragm or piston or gear-rotor types that are positive displacement units. Many of the pumps in a building are part of the overall air-conditioning system. They convey water to and from cooling towers, chillers, boilers, and coil banks in airconditioners, humidifiers, unit heaters, unit ventilators, and induction units. Pumps may also be used to supply fuel oil to boilers, domestic water to upper floors, emergency fire-fighting water, hot water for various uses such as convectors, ice melting, radiant heating, etc., and for sewerage ejection from low levels.

Noise problems due to pumps are usually caused by mechanical forces and turbulence. Noise is radiated by the casing of the pump and associated piping. In order to prevent the tonal components at the impeller passage frequency (the impeller speed in revolutions per second multiplied by the number of impellers) from being detectable at remote locations, a vibration break of flexible connections in the piping is sometimes provided. However, sound

AR0070661

energy in the fluid may flank this flexible connection so that the pipe walls are excited downstream of the pipe break. Figure A.43 shows a range of noise levels typical of many pumps used in buildings.

Steam valves may be used either to control volume flow or to reduce the pressure from the main supply system. A steam valve, like any valve, is noisiest when there is a large pressure differential between the upstream and downstream of the valve. A typical spectrum for steam valve noise is presented in Fig. A.44.

A.3.3 Air handling

Fans are the driving mechanism for moving air about a building. Propeller-type fans may be used to distribute large quantities of air at little pressure drop across the fan; centrifugal and axial-flow type fans may build up relatively large static pressures in an air handling system and thus are used mostly in ducted ventilation systems in large buildings. In a ducted system, the air will tend to flow toward regions of lesser static pressure, eventually to be released at ambient pressure in the building proper.

Fan noise is generated by mechanical and aerodynamic sources. Bearings and unbalanced shafts are the primary mechanical sources; with proper construction and maintenance, fan noise from these sources can be minimized. Aerodynamic noise may be divided into components due to rotation and due to vortex shedding. Since an impluse is imparted to the air each time a fan blade passes a given point, the rotational component consists of a series of tones at multiples of the blade passage frequency (rotational speed in revolutions per second times the number of blades). The vortex

AR0070662

component is primarily the result of the shedding of vortices from the fan blades; it is an example of broadband random noise. Depending upon the type, size, and geometry of a particular fan, the total noise generated will have varying contributions from vortex and rotational noise.

The horsepower, volume flow, and static pressure, and thus the mechanical efficiency, are important indicators of the noise that will be generated by a particular type of fan. Figure A.45 shows estimated levels for a range of fans utilized in buildings. The noise problems that do occur are usually due to either a failure by the mechanical or acoustical system designer to consider an important source or path, or a failure of the builder to incorporate properly the designed noise control features in the building.

Air Control Units and Mixing Boxes comprise a family of supply air control and treatment devices that provide air at the proper volume, pressure, and temperature to a room. These devices include: constant volume control (CVCs), terminal reheat units (TRs), variable volume controls (VVCs), and dual duct mixing boxes. Their function, in many instances, is analogous to steam valves — they take air which has passed through a small duct at high velocity and pressure and reduce its pressure and control its volume flow. A constant volume control takes in air at varying pressure (caused by changing demands elsewhere in the system) and discharges a constant volume of air at a constant pressure. A terminal reheat unit adds the capability of heating the air by passing it over an electric or hot water coil before it is discharged. A variable volume control meters out an amount of heating or cooling air as demanded by a local thermostat and reduces the static pressure of the air to obtain the desired volume. Each of these units is usually located toward the end of supply ducts

AR0070663

near the space it serves. Noise generated by air control units and mixing boxes is a function of the pressure drop across the device and the volume of air flow. Figure A.46 presents a range of noise levels typical of a 3 ft distance from these units.

Diffusers, Grilles, Registers, and Louvers. After a supply of air at the correct pressure, temperature, and volume has been provided to the vicinity of a room, it must be introduced and distributed into the room without causing drafts. Portions of the air should be directed toward windows and other exterior surfaces that are too cold in the winter and too hot in the summer, while all the air should be distributed so as to provide ventilation to all parts of the space. This is done with various diffusing or direction-controlling devices, usually fabricated from sheet metal, consisting of fins, blades, vanes, etc., that are located at the end of the duct. Perforated grilles, registers, or other similar devices are used to receive the air to be returned to the distribution system. The noise generated by terminal devices, such as diffusers, is dependent on the pressure drop across the device, the volume of air flow, the cross-sectional area, and the spacing between vanes. Figure A.47 illustrates the range of noise levels possible with various diffusers, grilles, etc.

Air Compressors are the source of high-pressure air which is used by many large buildings as an energy source for pneumatic control devices throughout the ventilation system. Such controllers include fresh air intake dampers, zone control dampers, induction units, unit ventilators, mixing valves in mixing boxes, and control valves in CVC and VVC units. The high-pressure air provided by the compressor must be piped throughout the building, first to thermostats and then to the pneumatic operators. Buildings which

AR0070664

have laboratory or workshop facilities usually supply compressed air to those spaces. Air compressors are most often of the piston type and, depending upon the size of the unit, the reciprocating action of this type of compressor may make satisfactory vibration isolation difficult. Figure A.48 is an example of noise levels generated by reciprocating compressors.

A.3.4 Airconditioners

The usual functions of an airconditioner are to filter particulate matter and odors from the air, to regulate air temperature and humidity, and to propel the conditioned air to its destination. The fan in the airconditioner serves two purposes: 1) to move the air through the filters and heating and cooling coils, and 2) to provide enough static pressure to push the air throughout the duct system to the desired spaces. The heating and cooling coils are liquid-to-air heat exchangers, receiving warm or cold water or refrigerant from other machines and transferring warmth to or from the air carried past them.

Central Station. Strictly speaking, "central station" refers to the entire collection of equipment that has a part in conditioning the air that is ultimately distributed to the building. In its more limited use here, "central station" refers to the fan plenum equipment of the airconditioner. The equipment includes controllers and filters on the inlet side and heating and cooling coils, and temperature controllers and, possibly, zone controllers on the discharge side. The cooling coils act as dehumidifiers in that warm, moisture-laden air condenses on them. Occasionally, a humidifier is incorporated to add humidity for special needs. Central station units are most common in large multistory buildings. The size of a particular unit will depend upon the service that it is supplying. Noise levels for units typically found in buildings are presented in Fig. A.49.

AR0070665

Unitary Rooftop Units are usually found on one- or two-story buildings. They perform the same function as the larger central station units but do not rely on other machines to provice hot or cold fluid to their heating and cooling coils; in other words, these units include their own compressors, condensers, etc. In a large one-story building or building complex, this can represent a savings on the heating and cooling water piping which would be needed if the units were dependent on other machines. Figure A.50 presents noise levels measured near both small (the lower curve) and large units.

Unitary Split System Units are usually found in small buildings. They are almost identical in function to rooftop units, but they are located on occupied floors in the building. Thus, a remote heat exchanger (either a condenser or cooling tower) must be provided to reject waste heat when the units are cooling. The refrigerant compressor may be located remote from the unit together with the condenser.

Fan Coil Units are rather like miniature central station air-conditioners in that they draw in fresh air and rely on outside sources for hot water, cold water, or steam for their heating and cooling coils. They are small units, usually enclosed within a cabinet and placed under or near windows. Some units, rather than relying on hot water, use electric heating coils. Typical noise levels for fan coil units are presented in Fig. A.51.

Induction Units are similar in appearance and location to fan coil units but receive air from a central station unit at a rather high pressure, 1 to 4-in. static pressure, as compared to less than 1-in. operating static pressure for unit ventilators. This

AR0070666

air is used to induce circulation of the room air. Such units are also provided with heating and cooling coils to temper the air which they receive from the central supply. A range of noise levels for typical induction units are shown in Fig. A-52.

Humidifiers, Dehumidifiers, Heaters and Furnaces, although grouped under the heading of air conditioners, have only one function: to increase or decrease humidity, or to heat.

- *Humidifiers* are of two general types: 1) those that add steam to the air, and 2) those that blow the air through or over moist surfaces to add water to the air. Both types can be built into ductwork or can stand alone to serve a particular space. The steam type consists of a steam nozzle, a control valve, and possibly a fan. The moist surface type consists of a fan (if not located in ductwork), a water pump, and a moving porous belt or disk which passes through the water and then through the moving air.

- *Dehumidifiers*, if required, may be located in the ductwork where air flow is provided by the system fan. The primary element is a cooling coil which condenses moisture out of the passing air. In such an installation, a heating coil may be provided to temper the excessively cooled air that leaves the cooling coil. A self-contained unit will include a fan but usually not a heating coil.

Unit Heaters consist of a remote fan and heating coil, which may be either electric or mechanical, and receive hot water or steam from an external source. Such units are often used in little-occupied spaces such as mechanical equipment rooms, storage spaces, garages, stairways, etc.

AR0070667

- *Warm Air Furnaces* burn gaseous or oil fuel and use an integral air-to-air heat exchanger to heat the air. They usually have two built-in-fans, one to circulate the air, the other to provide air for combustion. They are often used in small buildings which do not have access to large quantities of hot water or steam.

A.3.5 Boilers

For supplying warm air to a building, most air conditioning systems use hot water or steam supplied by a boiler that may be located either nearby or remote from the building. (In total energy systems, waste heat from the engines may be captured to heat water in place of or in addition to a boiler.) Boilers heat water or generate steam by burning a fuel and passing the water through or around the fire in a gas-to-liquid heat exchanger. There are two principal types of boilers: water tube and fire tube. In the water tube boiler the tubes are filled with water and pass through the fire. In the fire tube boiler, the boiler is filled with water and combustion takes place in tubes that pass through the water. Steam boilers are usually of the water tube type, while hot water boilers may be either type. Figure A-53 shows a range of noise levels typical of boiler operations; fire tube boilers are represented by the upper part of this range and water tube boilers by the lower parts. Gas-fired burners in boilers are much quieter than oil-fired burners.

A.3.6 Refrigeration machines or chillers

Refrigeration machines or chillers use various methods to remove heat from water supplied to cooling coils (the "chilled water") and transfer that heat to other water for eventual rejection.

AR0070668

Absorption/Cycle Machines use heat energy and a salt solution to transfer heat from the chilled water system to the reject heat system. The machine is composed of tanks, condensers, evaporators, heat exchangers, pumps, and controls. On a per ton capacity basis, they are larger than vapor compression cycle machines. Figure A-54 presents value levels typical of these machines for estimating use.

Vapor Compression Cycle Machines, which are commonly called chillers, use a compressor to compress the refrigerant; the resulting hot compressed gas passes through a condenser where it is cooled and changed to a liquid. The refrigerant is then allowed to expand, further cooling it. The "chilled water" is then passed through a heat exchanger with the cooled gas and is cooled. The resulting heated refrigerant is again compressed and the cycle repeated. Chillers use various types of compressors: the positive displacement (piston and rotary screw) and the centrifugal types; value levels representative of these types are presented in Figs. A-55, A-56, and A-57 respectively.

Small Hermetic Refrigerant Compressors are used in small airconditioners in conjunction with integral or remote air-cooled condensers. These units function exactly the same as the compressors in vapor compression cycle machines except that the refrigerant is cooled in an air-cooled condenser rather than by a reject-heat water-circuit condenser.

A.3.7 Heat rejectors

In most refrigeration machines, rejected heat is transferred to water, which may be used once, e.g., river water, or repeatedly, in which case it must be cooled for re-use. Cooling towers, spray ponds, and air-cooled condensers are used to cool the water.

AR0070669

Cooling Towers receive large volumes of warm (typically 85° to 75°F) water and cool it a few degrees. In the process, the incoming warm water is sprayed onto the cooling tower "fill," a stack of wood, plastic planks or sheets, or ceramic blocks which have a large surface area. Typically, a fan is used to force air through the fill, cooling the water by evaporation. The air is expelled in a saturated or near-saturated condition and is usually a few degrees warmer. Noise is generated by the fan and by the water falling into the basin. Centrifugal cooling towers (using centrifugal fans) are quieter than propeller-fan towers. Figure A-58 presents a range of noise levels typical for both centrifugal and propeller towers.

Condensers of the liquid-cooled type are used in all large refrigeration machines; smaller machines use directly air-cooled condensers. In a condenser, the entering gaseous refrigerant is cooled as it passes through the gas-to-air exchanger, where the gas condenses to its liquid form, and the resulting liquid is returned to the refrigeration machine. A fan is frequently used to force air flow through the heat exchanger. Figure A-59 presents a range of noise levels representative of air-cooled condenser noise.

A.3.8 Conveyance systems

In multistory buildings, it is necessary to transport large numbers of people quickly. It is also desirable to transport heavy objects from one floor to another, and in hotels, hospitals, and apartments, to transport trash and soiled laundry to their respective collection areas from many locations in the buildings. Elevators, escalators, and pneumatic transport systems are examples of the conveyance systems used in buildings.

AR0070670

Elevators consist of three major components: the cab, hoist cables and counterweights, and the hoist motors or hydraulic ram piston. The weight of the cab is partially balanced by the counterweights which are located at the cab is rear. The hoist motors are DC-powered, which is best suited to the frequent starting, acceleration, and stopping operations of elevators. Supply current is controlled by accompanying motor-generator sets (using Ward-Leonard motor drive) or large rectifiers. The hoist motors are located directly over the elevator shaft, usually on the roof of a building, or at various upper floor levels. Hydraulic power is sometimes used for distances of under 60 ft. A hydraulic ram provides the raising force. Figure A-60 presents noise levels typically found in elevator machinery rooms.

Escalators are composed of two major components: the stairs with treads and the drive motors. The motors are usually located beneath the lowest flight, the upper flights being driven by those below.

Pneumatic Transport Systems use low-pressure differentials exerted over large or small areas to move comparable sized loads. The chief components are a high-pressure fan, a duct system, loading and unloading stations, and control devices. In a typical system, the fan is run at an idle speed (say 1/2 full speed which requires only 1/8 of the full-speed hp) until the loading station signals for full-speed operation. The load is then conveyed through the duct system to the desired unloading station. At the unloading station, the passage of the load signals the blower which then drops to idle speed.

AR0070671

A.3.9 Ballasts

Fluorescent and mercury and light requires higher voltage power than the normal 120 line current. Ballasts are essentially small transformers which alter the voltage to suit this need. Ballasts are usually mounted right to light sheet metal panels in order to provide the required cooling area. These panels often serve as very effective radiators of sound; thus, the noise levels may vary considerably. Figure A-61 presents measured data for one installation. Noise levels in other installations with different ballasts and fixtures may be as much as 10 dB quieter or noisier than the curve presented.

APPENDIX B - IMPACT CONSIDERATIONS

B.1 Interpretation of Impact Estimates

Sections 3.2.2 and 3.3.2 of this report have provided detailed breakdowns of the impact on people of exposure to a variety of noise sources. This section of the report is intended to permit the reader to gain an appreciation for the significance of these estimates. It therefore consists primarily of caveats.

First, it must be stressed that both the physical levels of the noise sources and the levels at which effects on people are specified are, at best, imperfect estimates. Every attempt has been made to obtain unbiased and statistically sufficient estimates. Nonetheless, the actual levels mentioned in the text cannot be regarded as exact. Variability is inherent not only in the measurement process, but also in the noise sources, the propagation paths by which their sounds are transmitted to people, and of course in the responses of people. Thus, individual instances of extreme sensitivity to noise effects are to be expected, as are cases of excessively noisy and quiet sources. In some situations the total amount of variability may be so great as to transform assessment of noise impact, *a priori*, into an imponderable issue. It is important to acknowledge that the impact estimation of Sections 3.2.2 and 3.3.2 can pertain only to the general, rather than the specific, instance.

It must also be understood that research on the effects of noise on people has been conducted for the most part under controlled and simplified conditions. The application of knowledge gained from such experimentation to heterogeneous populations living in complex environments necessarily entails

AR0070735

a fair amount of interpretation and approximation. Disagreement among experts on matters of detail is probably unavoidable.

Yet another important consideration to bear in mind when reading the sections on the impact of home appliance, building equipment, and construction noise on people is that these noises comprise only a fraction of most people's daily noise exposure. Since many noise effects are cumulative in nature, discussion of the impact of exposure to restricted classes of noise is both artificial and potentially misleading. It is not safe to assume, for example, that hearing damage is not a substantial risk to the public at large merely because the risk from construction noise exposure is negligible.

In short, it has been necessary to make a large number of assumptions in preparing most sections of this report. Assumptions are the coin with which conclusions are purchased. The reader must understand the assumptions before he can decide for himself whether the conclusions are worth the price.

The final caution is perhaps the most basic. Stated simply, it is that no attempt has been made in this report to address the crucial issues of societal desirability and costs of noise impacts. Such issues were purposely avoided as inappropriate and far beyond the scope of the current report. Value judgments about how much noise exposure is tolerable must inevitably be made, however, if this report is to be fully useful. Administrative or legislative bodies must eventually decide how much hearing loss workers must suffer to maintain industrial productivity; how much annoyance, stress, and task interference the public must endure; how much sleep interference is too much; and so forth. The authors hope that this report will provide the data and conclusions essential for intelligent actions on these issues.

AR0070736

B.2 Discussion of Construction Data

Table B-1 tabulates nonresidential building construction in 1970 by the nature of metropolitan region in which eleven major categories of buildings were constructed. Construction effort in each building category is characterized both by the number of sites and the total construction cost in each region. The average cost of each type of building in each region is also presented in Table B-1. The cost estimates are necessary for accurate estimation of the number of machine-hours of equipment operation at each site. The wide variability of building costs deserves special note. Office buildings in large, high-density central cities cost an average of $1.6 million while the same type of building costs an average of only $.47 million in low-density central cities.

The sources of the data in Table B-1 include the following:

- Columns 1 and 2: Unpublished tabulation by U.S. Bureau of the Census of all nonresidential building permits for 1970,
- Columns 3, 4, 5 and 6: Estimates based on population ratios, construction level ratios (where known), and assumptions about probable unit costs; and
- Column 7: *Construction Review*, except for lines 2, 5, and 7, which were estimated on the basis of known ratios of large city to national construction ratios.

Two categories of nonresidential building are recognized by the Bureau of the Census but are not discussed in this report. One is "residential garages and carports", of which 150,585 were authorized in 1970, at an average cost of $1600. Carport construction was judged to contribute negligibly to construction noise problems. The second category of buildings recognized by

*See Sec. 3.2.1.2, Table 1X, for definitions of large high-density and large low-density central cities.

AR0070739

to "other" but not discussed in the current report is "all other nonresidential buildings", of which 296,814 were authorized at an average cost of $7,700. The latter category of construction was considered too heterogeneous in nature to permit reasonable estimation of the nature of construction noise at a "typical" site.

Table B-2 presents data on the construction effort involved in erecting residential buildings as a function of the type of metropolitan region in which the construction occurs. The data in Table B-2 were obtained from unpublished Bureau of the Census tabulations and from the Census publication *Construction Reports: Housing Authorized by Building Permits and Public Contracts, 1970*

B.3 Estimating the Extent of Public Works Construction Noise

The public is exposed to construction noise not only from operations of erecting buildings of various sorts, but also from operations arising from public works construction. Such operations include road, highway, street, and sidewalk construction and maintenance, as well as sewerage, water works, and utilities installation and maintenance. The noise created by these construction activities is frequently prolonged and intense. Even small repair jobs on water works create considerable noise as sections of pavement are ripped up to gain access to buried pipes.

Estimation of the amount of noise created by such activities required that a number of assumptions be made about the distribution of construction noise from public works sites. The most important assumption was that federal and state public works activity could be neglected for the purposes of this study since it occurs primarily in rural regions of low population density. Attention was therefore concentrated on municipal public works activities within SMSAs.

AR0070740

Although summary reports contain ample information on federal and state public works activities, comparable municipal data are available only for individual municipalities. We have been able to obtain fairly complete data on municipal public works construction and maintenance for two large, high-density cities: the central city, Boston, Massachusetts, and the adjacent city of Cambridge. We have used this information, together with the figure of 42,000 miles for municipal street construction throughout the country in 1969, published by the Federal Highway Administration, to estimate total sewerage and water works activity (in terms of miles of pipe and mains laid) for the country.

In carrying out these calculations, we assumed average values of 1.0 miles each of water and of sewer main per mile of new street. We further assumed that on the average, water and sewer main additions per year would be 2% and 1.5% of existing footage, respectively, as opposed to 7.5% for the annual increase in length of municipal street systems. This gave estimated country-wide values of some 11,000 miles of water mains and 8,000 miles of sewage mains. These estimates are considered reasonable in that they are about half as great as would be obtained if the respective annual U.S. expenditure for water works and sewer construction were allocated solely to the installation of mains. Moreover, some mains would be installed concurrently with street construction and, as a consequence, not constitute separate sources of noise pollution.

Inherent in our approach to the estimation of exposure of the population to municipal construction noise is the assumption that the locus of both municipal construction and of population exposed is the street system of a municipality. We have therefore focused on the numbers of inhabitants distributed in permanent residence along the streets of a municipality as an index of the impact of

AR0070741

...ress-associated municipal construction noise. In order to facilitate the use of this approach, we developed a correlation (see Fig. B-1) between population density and the quantities, miles of street per square mile and inhabitants per mile of street for several dozen cities, towns and counties in Massachusetts and Tennessee for which we had data available.

Using the above correlation, together with the amounts of municipal public works construction estimated earlier, we arrived at the figures for these presented in Table B-3. The indicated exposures of residents along streets where municipal public works construction is taking place are 10 million and 4.4 million individuals, for street and water works and sewer construction, respectively, making a total of 14.4 million individuals exposed to public works construction noise.

B.4 Propagation Loss Model For Building Construction Sites in Metropolitan Areas

Two classes of people are exposed to construction noise: the stationary population which inhabits the region around the construction site (workers and residents) and the transient population which passes by the site (drivers, passengers, and pedestrians.) Two models were constructed to estimate the extent to which site noise is attenuated for each class of observers.

Stationary Population

The entire stationary population around a construction site was assumed to be indoors with closed windows. Acoustic propagation loss was modeled by postulating a representative site geometry and applying the formula

$$N = 20 \log \frac{R}{R_0} + 20 \text{ dB}$$

AR0070742

TABLE B-3. ANNUAL EXPOSURE OF PERSONS IN METROPOLITAN AREAS TO MUNICIPAL CONSTRUCTION NOISE

LENGTH OF MUNICIPAL CONSTRUCTION (MILES)

Activity	Large, High-Density Central Cities	Large, Low-Density Central Cities	All Other Central Cities	Urban Fringes	Met. Areas Outside Urban Fringes	Total
Street, Highway	273	2,150	6,300	11,300	21,700	[illegible]
Sewerage & Water	125	990	2,700	5,065	9,850	18,730
	398	3,140	9,700	16,365	31,550	60,653
Population Density (people/sq. mi.)	15,160	4,410	3,720	3,380	195	
Area (sq. mi.)	1,468	2,389	6,381	14,757	179,276	
Street Distribution (miles of street/ sq. mi.)	21	10.2	9.5	8.9	1.45	
Linear Distribution of Population (people/mile of street)	720	430	390	380	93	

PERSONS EXPOSED TO MUNICIPAL CONSTRUCTION NOISE ($X10^{-3}$)

Activity	Large High-Density Central Cities	Large, Low-Density Central Cities	All Other Central Cities	Urban Fringes	Met. Areas Outside Urban Fringes	Total
Street, Highway	196	925	2,340	4,479	[illegible]	[illegible]
Sewerage & Water	90	425	1,050	1,920	[illegible]	[illegible]
	286	1,350	3,390	6,399	[illegible]	14,350

1/ About 14.3 million people exposed to municipal construction noise.

AR0070743

where H = total propagation loss

R = range from source to observer

R_0 = reference range at which site source level was measured (50 ft).

Twenty dB was added to account for the loss through building walls with closed windows. The resulting transmission loss contours are shown in Figure 19 of the main text.

Transient Population

People passing by a construction site continuously vary their distance from the site. A model such as the above is not directly applicable. The peak noise level to which passersby are exposed, however, can be computed from the propagation loss at the passerby's closest point of approach (CPA) to the site. This propagation loss is computed from the formula

$$H = 20 \log \frac{R_1}{R_0} + H'$$

where H = total propagation loss

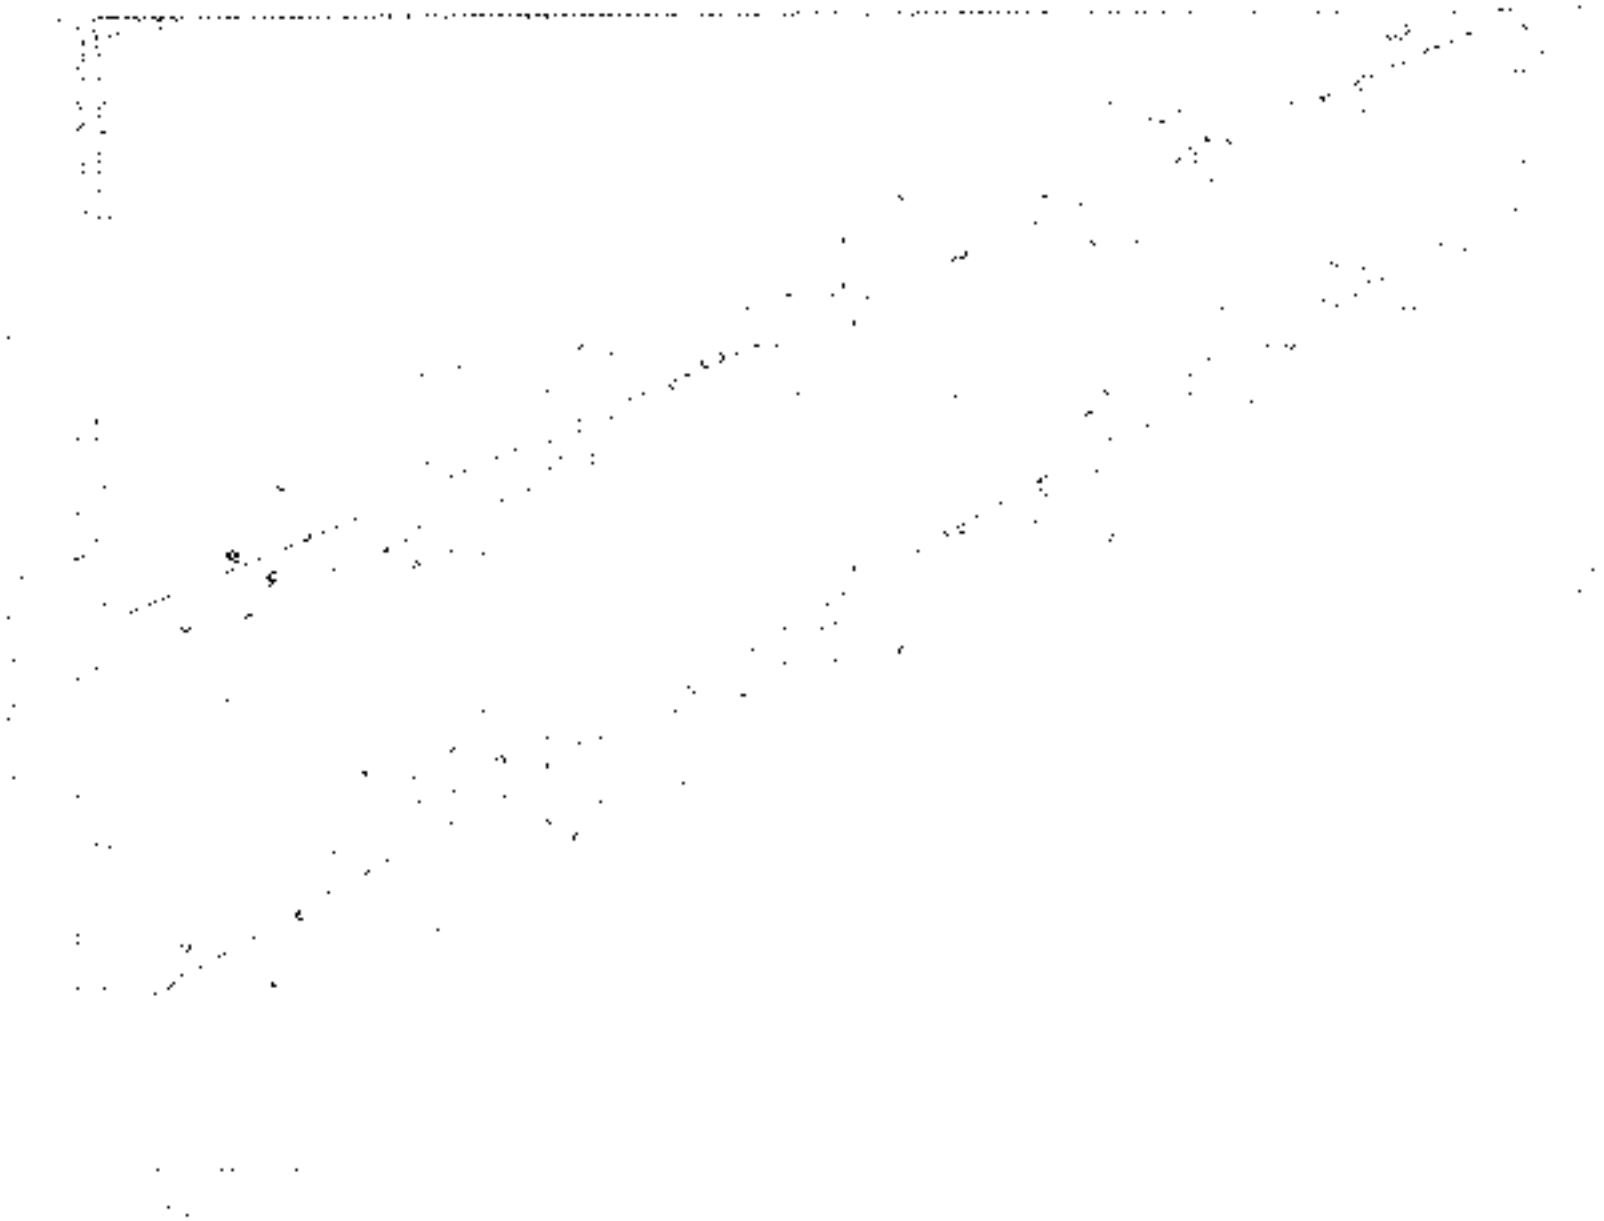
R_1 = range at CPA

R_0 = reference range at which site source level was measured (50 ft)

H' = is a term included to account for baffling or obstructions between source and observer

In the case of pedestrians, we assume that R_1 = 100 feet and H' is zero. H is therefore 6 dB. For drivers, we have assumed R_1 = 100 feet and H' = 15 dB to account for attenuation caused by the transmission loss of an automobile. For this case, H = 21 dB, which was rounded to 20 dB to emphasize that the figure is only an estimate.

AR0070744



APPENDIX C — SOUND LEVEL CONSIDERATIONS BY AMERICAN CONSTRUCTION MACHINERY MANUFACTURERS

by

H.T. Larmore
Deputy Director for Technical & Safety Services
Construction Industry Manufacturers Association
Milwaukee, Wisconsin

Presented at
The American Industrial Hygiene Association Conference
Toronto, Ontario
May 24, 1971

This presentation will attempt to place the problem of noise into its proper perspective relative to construction and construction machines — both as a potential cause of hearing loss for workers and as an air pollutant for the nearby community at construction sites.

NOISE — THE PROBLEM STATED

Unwanted sound — is not new to the construction industry. Construction sites are noisy. Likewise, it is not new to heavy machines used in the construction of buildings, highways, sewer and water systems, airports and the like. Indeed, it has been a criterion by which some machines have been operated. A skilled operator often relies upon the sound of his equipment for proper operation. Also, noise is often associated with power in the purchase of machines.

These philosophical concepts and the public demand for lower construction costs do not excuse construction machinery from being noisy, but they have contributed to the major emphasis by manufacturers over the past decade to design for greater productivity

AR0070746

motivation to build quieter machines. The transitory and temporary nature of construction has also allowed a lack of concern for noise. While any particular contract is underway, the workers and neighbors might well be annoyed by the noise. But relief comes when the job is completed and the big machines move on. Next job site - there are new workers; new neighbors.

During the past few decades, the public demand has been for more production with less labor and less cost. This prompted the development of today's remarkable machines with more power, automation and speed than ever before. But machine "improvements" to affect this demand generally tended to increase noise levels. Larger engines produced more noise both internally and from the exhaust. More automation was accomplished through more use of hydraulic power which also is a noise generator. Larger engines and more hydraulic power increased the heat which must be dissipated through larger quantities of air being driven by noisier fans through larger radiators. Increased speed means increased vibration frequencies which tend to concentrate in the audible hearing range.

THE CONCERN FOR NOISE

The concern for noise, only recently voiced by the public and expressed now in actual or proposed legislation at all levels of government would seem to have created a major shift from the "productive Sixties" to the "silent Seventies". Fortunately, our industry is geared to respond to our customer requirements and, hopefully, to recognize changing requirements soon enough to accommodate the necessary lead times for research and development, testing, tooling, manufacturing and distribution. Noise abatement, although recognized by manufacturers of construction

AR0070747

machines as a legitimate environmental concern, has been and still is difficult to define in precise engineering and machine requirements — how much — how fast — what costs and trade-offs are acceptable — cost/effectiveness ratios — all tend to remain fuzzy with even man/noise effects far from being accurately determined.

The manufacturers of construction machines, without waiting for all the answers, recognized in the late sixties the need for the basic tools for all change and/or regulation — Measurement Standards. Without such tools, base lines cannot be established or progress measured.

Through the Construction Industry Manufacturers Association (CIMA) — the necessary machinery and policies were established some four years ago to recognize needs for Performance or Safety Standards and to promote development of such Standards by nationally recognized technical and Standards writing bodies. Among these were the basic noise measurement Standards as voluntary guidelines for both industry and government authors. These were accepted for development by the Society of Automotive Engineers (SAE). They include for construction machines:

1. Noise measurement at operator station
2. Noise measurement at 50 foot radius
3. Construction job site noise measurement
4. Cumulative operator noise exposure measurement along with standardized reporting methods

Substantial progress has been made by SAE with completion and publication of some of these Standards expected in the near future.

AR0070748

The measurement of noise levels either at the operator's station or at a distance from the machine is no simple matter. A machine can be subjected to many operational variables. Engine at rated speed, acceleration, full power drawbar load, power take-off load, hydraulic load, idling engine, idling transmission, transport, addition of a cab, roll-over protective structures, windows open — these are some of the variables which affect noise levels. For that reason, a uniform procedure for noise measurement is most important.

There are currently under consideration at least four Federal Bills and twenty State legislative Bills which can regulate noise on construction machinery. Consequently, there is a real need for uniformity not only in measurement methods but in noise limit levels. It can be appreciated that legislators are concerned with protecting operators and others from hearing damage and the nuisance of excessive noise. However, a mass of legislation and regulations which are nonuniform are more of a liability than an asset in reducing noise levels on construction machines. Nonuniformity with little or no lead time for making the changes is leading to stop-gap measures which have unpredictable durability and effectiveness, and which perhaps introduce unwanted trade-offs and compromises through overheating, fire hazards, maintenance interference and reduced output.

WHAT ARE MANUFACTURERS DOING ABOUT NOISE?

So - what are construction machinery manufacturers doing individually and as an industry?

Individually they are:

1. Evaluating the many noise sources peculiar to each machine.

AR0070749

2. Developing operator enclosures for current products.

3. Developing procedures for customizing current products off the production lines.

4. Developing quieter components and systems for quieter machines in the future.

Through CIDA they are:

1. Seeking new and updated SAE Standards and Recommended Practices for operator and exterior noise levels.

2. Organizing a cooperative effort among governments, noise specialists, contractors and machinery manufacturers to accumulate the great masses of actual on-the-job noise data required by industrial hygienists in their evaluation of the man/noise effects in the construction environment.

3. Creating information on construction machine noise for use by regulatory bodies, consumers, and information media.

4. Investigating a means to express machinery noise sources in a uniform, usable and reliable manner.

THE COMPLEX ANSWERS

These individual and collective efforts are not simple nor do results come easily or cheaply. As a beginning, component noise sources are rapidly being isolated and evaluated. Oversimplification of the problem frequently leads many to believe that engine exhaust noises are the culprit and that larger mufflers would turn the trick. To be sure, this is part of the problem. However, noise reduction of the exhaust permits other machine

AR0070750

noises to become dominant. Larger mufflers also create a visibility problem since they usually end up directly in front of or behind the operator.

There are several other noise sources which are the same order of magnitude as exhaust noises, depending on the machine and its configuration.

These are:

1. Internal engine noises exclusive of the combustion itself.
2. Engine air inlet
3. Transmission and other gear noises.
4. Hydraulic system noises including the pump, tubes, valves, cylinders and hydraulic motors.
5. Air noise from the fan and radiator.
6. Various moving mechanical elements such as crawler tracks, or scraper elevators.

It is very likely that on a large machine today, each of these noises is individually in excess of 90 dB(A) (decibels on "A" rating scale). In the case of two equal noise source levels, the sum is about 3 dBA higher than either source alone. For four equal noise sources, the sum is about 6 dBA higher. And this in reverse acts much the same way. Suppose the total noise of a machine is 100 dBA composed of four equal noise sources. Let's say the exhaust, engine noises, gear and hydraulic noises and fan noises are these four. If by some magic the exhaust and internal engine noises could be reduced to zero, the machine would still have a noise level of 97 dBA. So, this is the

AR0070751

challenge to the engineers who are studying each noise source and striving for noise reduction of each component.

QUIETING CURRENT PRODUCTS

For quieting current production machines, some manufacturers are starting to use off-line, extra cost customizing. This may consist of one or more of the following: An isolation mounted cab; larger muffler; sound deadening material around noisy components; and vibration isolation of noise components. These methods are expensive and can have only minimal effect on the total problem. Also, the sound absorbing insulation causes some components to run hotter and can possibly absorb spilled petroleum products. This can be a fire hazard. One would not normally expect to replace such insulation during a machine's expected useful lifetime but durability of such materials and installation techniques are not broadly known.

FUTURE MACHINE QUIETNESS

For future machines, larger capacity cooling fans with non-resonant frequencies are being developed. These would utilize larger volumes of air at lower velocities, new radiator fin designs and more efficient shrouds.

Some gears must be changed from one form to another and perhaps made with more precision. Much noise is generated from variable gear loadings and from gear idling. Gears are designed to transmit a given power level at a required speed. Variations of these will set up vibrations which cause noise. Here again, isolation and insulation seem like possible temporary solutions but heat and flexibility can lead to premature failure and other new problems.

AR0070752

Hydraulic pumps, transmission lines, valves, cylinders and motors are all noise generators. Oil flowing in a smooth, uniform path should be one of the quietest methods of generating, transmitting and utilizing energy. However, each component has complicated restrictions which induce vibration. If all of the hydraulically performed functions were uniform and continuous, the noise would be minimal. But ease and flexibility of control are reasons for the many applications. Noise reduction programs for hydraulics are underway, but they will take time for development, testing and adopting.

Mechanical components such as the tracks of crawler tractors are noisy but fortunately are of lower frequencies. These types of mechanisms are just not readily quieted and do not lend themselves to encapsulation treatment. The long range, practical solution for all these problems may well dictate future machines of entirely new configurations.

NOISE STANDARDS AND REGULATIONS

Because of the many noise sources which add up to a single composite noise at an individual's ear, a unique but uniform measurement is necessary. For this purpose the SAE Standards are a very practical solution. The development of these Standards requires inputs from a broad spectrum of individuals with various areas of interest. One company cannot develop such Standards nor can just the machine manufacturers' industry. But, through CIMA, the industry is promoting and lending its support to the development of meaningful noise Standards by independent Standards writing bodies which include experts from manufacturers, government, public, users and labor.

AR0070753

As previously stated, these are noise measurement and reporting Standards being developed by engineers and other highly knowledgeable people in the construction field. Obviously, their efforts must be teamed with practical and effective noise limit Standards developed by the experts in the field of Industrial Hygiene. Such limits should be in keeping with the peculiar type of exposure found in the construction environment. Only when these two tasks are completed can effective and practical noise control programs and regulations be designed and implemented.

For Community Noise Control we visualize total construction job site limits geared to the particular needs of the surrounding community. This would create a natural demand for quieter machines yet still allow contractors and users to utilize their well demonstrated versatility and ingenuity to get the job done in compliance with realistic job site noise limits even with existing machines by using new job layout and operational techniques.

For control of hearing damage risk we would urge that the current Walsh-Healey noise exposure tables might be modified for construction workers to more accurately reflect their unique exposure to intermittent, variable intensity noise and the large seasonable fluctuations in noise dosages. These factors are covered in some detail in a CIMA sponsored study published by SAE, December 1969, as Technical Report — SAE Research Project R-4 and titled "A Study of Noise Induced Hearing Damage Risk, for Operators of Farm and Construction Equipment". This report is available from the Society of Automotive Engineers, Inc., Two Pennsylvania Plaza, New York, New York.

AR0070754

In summary, we have attempted to briefly review the background of construction machinery and the relatively recent public concern for noise.

We have outlined the complex and sophisticated industry problems involved and our concern that the public may be moving from apathy to overkill in one easy lesson.

We have indicated an industry recognition of the responsibility to help shape noise abatement legislation and regulation into reasonable and responsible instruments; also, our past and continuing active participation, through CIMA, to effectively utilize our industry expertise in major and necessary Standards activities.

We spoke of the industry efforts, both from individual manufacturers and collectively through CIMA to create quieter machines except as a stop gap, high cost measure.

We outlined the need for new noise limit criteria designed in consideration of the unique types of noise exposure and dosage for construction workers.

It is obvious that construction machine designers and industrial hygienists in both the government and private sectors are operating at the threshold of the art relative to noise. We believe there is real and urgent need for a combining of these two groups into a teamwork effort. Through such a combined grouping of expertise can come the tools and procedures to effectively reach our common noise abatement objectives — and to do so with full consideration of the total needs of our society and at costs and compromises satisfactory to the public.

AR0070755

APPENDIX D — NOISE CONTROL: REGULATION AND STANDARDS

D.1 Introduction

Control of the noise produced by construction activity, building equipment, and home appliances cannot be expected to proceed in an orderly fashion without supporting guidance in the form of noise criteria, noise standards, and noise limits. This section of the report presents information on the status of currently available guidance for noise control. Trends in development of criteria, standards, and limits are discussed. Where possible, future requirements for noise control guidance are anticipated.

A fundamental distinction must be made among the three basic forms of guidance necessary for systematic noise control. Noise criteria are defined as statements of the effects produced by various levels of noise exposure. Criteria are based on the effects of noise on people, as discussed in Section 3.1 of this report. Noise standards describe the properties of noise environments that are considered desirable. Standards are usually presented as long-term goals that a regulatory program may be designed to attain. Noise limits are in effect regulatory documents intended to limit public exposure to individual noise sources. The limits entail not only a knowledge of the existing noise environment, but also technological and economic constraints on noise abatement. It is intended by writers of noise limits that the noise environment should approach the goals of noise standards in a systematic fashion.

The next section will discuss the elements involved in the development and support of regulatory noise limits for construction equipment; the third section of this appendix will discuss those elements appropriate to building equipment and appliances.

AR0070756

D.2 Construction Equipment

The body of this report has included discussion of criteria in the estimation and evaluation of the impact of construction equipment noise. The criteria appropriate to construction equipment noise are not unique to such noise sources, of course. The selection of standards for noise exposure must take into account the characteristics of the combined impact of the many noise sources that pollute our environment, and most importantly, must be keyed to the business and recreational activities and situations in society that are to be protected from noise. Thus, the development of a set of standards for the protection of human activity from noise pollution is beyond the scope of the present project and report; indeed, the ultimate selection will be based on further legislation incorporating decisions of national policy. It is our intention here to describe the relationship between the various elements in an environmental regulatory scheme, and to identify their present state of development by scientific and engineering groups, and by State and local governments.

The third of these elements is the noise limit itself, which provides quantitative restriction of noise emissions through incorporation in legally enforceable rules, regulations, and laws. Quantitative limits must be directed at an identifiable legal entity (such as manufacturer, vendor or user), and must be accompanied by specific test and measurement procedures. Although no nationwide noise regulations for construction or other powered outdoor equipment now exist, several states are considering such noise limits, and a number of larger cities have recently enacted or proposed limits for construction equipment.

The next section of this Appendix will review the recent regulatory activities at the State and local levels that apply. Since procedures for construction equipment noise measurement are so important to the successful implementation of source limitations, the last section will discuss these in more detail.

AR0070757

State and Local Regulations

In the last two years, considerable activity has taken place at the State and local level with regard to reducing the noise of outdoor construction, maintenance, and repair activities.

Both the State of Illinois and the State of Hawaii enacted statutes in 1970 which grant broad regulatory powers over noise to specific state agencies. At this time neither the Illinois Pollution Control Board nor the Hawaii Dept. of Health have adopted any rules or regulations to control construction noise. The Illinois Institute for Environmental Quality has initiated a study of noise sources (including construction and other outdoor powered equipment) that could be covered by State regulations, and proposed limits for such equipment are being studied.

In the State of California, a report to the 1971 Legislature on the Subject of Noise was prepared by the State Dept. of Public Health. This report includes in its recommendations the establishment of noise emission standards for all noise-producing objects now in use as well as to be admitted in the future to California. The construction noise sources identified in the report include all diesel-engine powered equipment, such as generators, compressors, off-highway trucks, bulldozers, loaders, scrapers, power shovels and other excavating equipment, as well as piledrivers, riveting machines, jack hammers, elevators, cement mixers, hammers, power saws, drills, and nailers. Other State legislatures have or will consider a variety of proposed construction noise bills; a bill submitted to the New York State Legislature in 1968 would have limited construction noise as measured at the nearest multiple dwelling.

Because construction-equipment noise is especially severe in urban areas, limits have been proposed or adopted in several larger cities. New York City has proposed coverage of construction sites by permit, and limits for air-compressor and paving-breaker

AR0070758

equipment in a new noise code; public hearings are scheduled to begin in the City Council Committee on Environmental Protection on 9 September 1971. The City of Boston Air Pollution Control Commission has recently completed a study of community noise and, as part of its plan for noise control, will begin hearings 27 September 1971 on proposed regulations which include limitations on noise of both construction/outdoor powered equipment and on the operation of a construction site. The latter limits, in brief, apply at any nearby area open to the public except public ways, or at a 1000-ft radius from the site, whichever is nearer.

The City of Chicago adopted a comprehensive noise ordinance, effective 1 July 1971. Section 17-4.5 provides that "No person shall sell or lease,...any powered equipment or powered hand tool that produces a maximum noise level exceeding the following noise limits at a distance of 50 ft, under test procedures established by...this chapter." and there follows a table of limits in dB(A) for four categories of equipment. Two categories "Construction and Industrial Machinery" (#1) and "Commercial Service Machinery" (#3) cover the bulk of construction equipment.

"Construction and Industrial Machinery" includes powered outdoor equipment, mobile or stationary, associated with construction sites or industrial operations. Such equipment includes crawler-tractors, dozers, rotary drills, and augers, loaders, power shovels, cranes, derricks, motor graders, paving machines, off-highway trucks, ditchers, trenchers, compactors, scrapers, wagons, compressors, pavement breakers, pneumatic-powered equipment, etc. Specifically excluded are pile drivers.

AR0070759

"Commercial Service Machinery" includes powered equipment of 20 hp or less intended for infrequent service in residential areas, typically requiring commercial or skilled operators. Such equipment includes chain saws, light pavement breakers, log chippers, powered hand tools, etc.

The limits that apply to these categories are keyed to the date of manufacture of the equipment and provide a timetable for noise reduction as follows:

Manufactured after	Construction and Industrial Machinery	Commercial Service Machinery
1 Jan. 1972	94 dB(A)	88 dB(A)
1 Jan. 1973	90 dB(A)	84 dB(A)
1 Jan. 1975	86 dB(A)	--
1 Jan. 1978	--	--
1 Jan. 1980	80 dB(A)	80 dB(A)

The application of the limits to equipment for lease is most appropriate in the case of construction machinery; such equipment is usually leased rather than sold. Since the limits only apply to equipment manufactured after 1 January 1972, it is too early to look for compiled results, but several contractors in the Chicago area are now asking for "quieted" equipment that will meet these limits, and intend to use such equipment, insofar as possible, to reduce or eliminate community noise complaints. This provides very desirable pressure in the market place for such "quiet" equipment, encouraging manufacturers to offer noise control packages on their construction equipment before the required date.

AR0070760

Measurement Procedures

Since quantitative limits must be applied to the noise source, most test codes and recommended practices for measurement apply to the operation of an individual item of construction equipment. The following noise measurement procedures are of this form:

SAE Standard J88a Sound Levels for Engine Powered Equipment*

Scope: For engine powered equipment including mobile construction and industrial machinery, but not covering machinery designed for operation on highways, or within factories and building areas.

Test Type: Outdoor free-field measurement on level ground. Measurement distance 50 ft. Equipment operation at speed and load producing maximum sound level.

Data: A-weighted sound level.

City of Chicago Environmental Control Ordinance, Article IV†*
Test Procedures for Noise Emitted by Engine-Powered Equipment and Powered Hand Tools

Scope: For engine-powered equipment, including construction and industrial machinery (not including pile drivers) agricultural tractors and equipment, powered commercial equipment of 20 hp or less, and powered equipment for use in residential areas.

*Society of Automotive Engineers, Inc., NYC, N.Y. 10001

†Sec. 17-4.26 and corresponding section of DEC Code of Recommended Practice. Chicago Department of Environmental Control, Chicago, Ill. 60610.

AR0070761

Test Type: Outdoor free-field measurement on level surface. Measurement distance 50 ft. Both stationary test and acceleration test (for rubber-tired mobile equipment) at load and speed producing maximum sound level. Pneumatic equipment operated as specified in CAGI-PNEUROP Test Code.

Data: A-weighted sound level.

ANSI S1.13/193 (Proposed) Test-Site Measurement of Noise Emitted by Engine Powered Equipment*

Scope: For determining maximum noise emitted by construction and industrial machinery, transportation and recreation vehicles, and other engine-powered equipment.

Test Type: Outdoor free-field or reflecting ground. Measurement distance 15 meters (50 ft). Moving and stationary tests for construction equipment (Sec. 4.4).

Data: A-weighted sound level

CAGI-PNEUROP† Test Code for the Measurement of Sound from Pneumatic Equipment

Scope: Applies to compressors, percussive and nonpercussive pneumatic equipment. Specifies procedures and operating conditions, not always including process noise.

*American National Standards Institute, NYC, N.Y. 10018
†Compressed Air and Gas Institute, NYC, N.Y. 10017

AR0070762

Test Type: Indoor or outdoor, measurements in direct field at five positions at 1 meter from equipment. Secondary measurement at 7 meters distance. Non-percussive tools measured running free and with "quiet" work process.

Data: A-weighted and Octave-band sound pressure levels for each measurement point.

The procedures adopted by the City of Chicago are based on the SAE J352 standard and the revisions now under consideration by the SAE Agricultural and Construction Machinery Sound Level Subcommittee. Substantially the same measurement procedures have been proposed by the City of Boston Air Pollution Control Commission in their *Test Procedure for Measurement of Noise from Powered Devices*.

While SAE J952a contained specific noise limits, these are being separated in a later revision now under consideration, and the test procedure will appear separately. This procedure recommends an additional 2 dB tolerance for such noise measurements; this provision has been deliberately omitted in both the Chicago and Boston test procedures, and left to administrative decision. This is more appropriate, and not unlike the enforcement measurement procedures for vehicular speed limits.

Another approach to construction equipment noise measurement is to apply the measurement to the combined operators of all construction equipment at a single test site. At the request of CIMA (Construction Industry Manufacturers' Association) the SAE is developing such a test procedure.

AR0070763

SAE Recommended Practice (Proposed) Construction Site Sound Level Measurements

Scope: For sites where construction machinery is operated. Measures noise radiated off-site.

Test Type: Field measurement of radiated sound levels at four nearest inhabited locations to any centerpoint of construction activity. If no inhabited locations closer than 1000 ft to a centerpoint, measurements made at 4 locations spaced 90° on 1000 ft radius circle.

Data: A-weighted sound levels at each measurement point define "Construction Site Operational Sound Levels". Provision for a record of "Construction Site Baseline Sound Levels" allows limits to be expressed as change in ambient as well as absolute terms.

The combined-operations measurement procedure is presently being proposed for use by the City of Boston, and the City of Chicago plans a test of the latest SAE draft procedure as part of a feasibility study of noise limitations on construction sites. The Federal Highway Administration is considering this procedure as a basis for regulation of noise from Federal-aid highway construction.

AR0070764

D.3 Noise Standards for Indoor and Outdoor Equipment for Home and Office Use

The impetus for development of standards for measuring and rating the noise produced by many types of equipment has come from the manufacturers of noise sources. For example, the manufacturers of air conditioning and ventilation appliances are by far the most conscious of the impact of their equipment on the noise environment of the home and office. Within the past decade at least ten different "standard" procedures have been formulated for measuring and rating the noise of various types of air conditioning and ventilating equipment. The automotive and airframe industries have been similarly conscious of the noise impact of their equipment and sophisticated noise standards exist for these sources. By contrast, only one standard has appeared to deal with the noise of rotating electrical machinery; one to deal with gas turbines; one for gear noise; one standard of a general nature, produced by official American National Standards Institute (ANSI), intended to guide noise measurement of practically any piece of machinery; and a draft procedure is under consideration by ANSI to rate the noise of all engine-powered equipment.

Such standards are of two types. Measurement standards specify the manner in which meaningful and reliable acoustical data may be obtained. Rating standards apply these acoustical data to produce ratings, usually single-numbered, that are supposed to correlate with subjective response to equipment noise, thus permitting at least rank-ordering of equipment noise on a justifiable basis.

Both sorts of standards are necessary and form the basis for yet a third class of standards (applications standards) that are used by architects, consultants, building codes, noise

AR0070765

ordinances and similar organizations. Factors which are considered in developing application standards include the economic, social, and political. Applications standards represent an equilibrium between the costs of reducing noise exposure and the feasible noise reduction made possible by acoustic technology.

The following summaries indicate the general nature of existing U.S. noise measurement and rating standards for domestic and office equipment.

ASHRAE 36-62 Measurement of Sound Power Radiated from Heating, Refrigerating and Air-Conditioning Equipment*

Scope: For unitary, unducted equipment, large or small, for indoor or outdoor use.

Test Type: Reverberation room, substitution method.

Data: Total radiated sound power level in octave or 1/3-octave bands.

ASHRAE 36A-63 Method of Determining Sound Power Levels of Room Air Conditioners and Other Ductless, Through-the-Wall Equipment*

Scope: For room air conditioners, window or attic fans, and other ductless wall- or ceiling-mounted equipment that radiate sound directly both to the conditioned space and the outdoors.

Test Type: Reverberation room, substitution method (2 rooms needed).

Data: Total sound power level radiated to indoors and outdoors, separately, in 1/3-octave bands.

---

* American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc., 345 East 47th Street, New York, N.Y. 10017.

AR0070766

ASHRAE 36B-63 Method of Testing for Rating the Acoustic Performance of Air Control and Terminal Devices and Similar Equipment

Scope: For air control and terminal devices normally mounted in or connected to duct systems.

Test Type: Reverberation room, substitution method.

Data: Total sound power level radiated into the room served by the device, in octave bands.

AMCA 300-67 Test Code for Sound Rating Air Moving Devices*

Scope: For central station air conditioning and heating and ventilating units, for centrifugal fans, axial and propeller fans, power roof and wall ventilators, steam and hot water unit heaters (but not unit ventilators, room fan-coil units, room air induction units and air cooled refrigerant condensers).

Test Type: Reverberation room, substitution method, based on ASHRAE 36-62.

Data: Total radiated sound power level, in octave bands (including the sound radiated into the ducts, for ducted equipment).

AMCA 301-65 Method of Publishing Sound Ratings for Air Moving Devices*

Ratings for Centrifugal Fans, Axial and Propeller Fans, Power Roof and Wall Ventilators, Steam and Hot Water Unit Heaters; not yet suitable for central station A/C or H/V units.

Ratings: based on octave-band sound power levels, per AMCA 300-67:

For ducted devices, the eight octave-band sound power levels;

AR0070767

For unducted devices, the loudness in sones at a reference distence of 5 ft, as calculated from the sound power level data.

AMCA 302 "Application of Sone Loudness Ratings for Nonducted Air-Moving Devices"

Reference material covering applications of the loudness rating in sones (examplea, combinations of sources, prediction of sound loudness indoors and outdoors, variation with fan speed.

AMCA 303 "Application of Sound Power Level Ratings for Ducted Air Moving Devices"

Reference material covering significance and accuracy of sound power level ratings, particularly their relation to sound as heard.

*ANSI*S1.2 - 1962 "American Standard Method for the Physical Measurement of Sound"*

Scope: For all devices, machines or apparatus. Several test procedures are described:

Test Type: Free-field; free-field above reflecting plane; semi-reverberant field; or reverberation room. The semi-reverberant field procedure is similar to that of ASHRAE 36-62.

Data: Sound pressure levels at specific locations, or total sound power levels in octave bands (1/2-octave or 1/3-octave analysis optional); and directivity of the source.

---

* American National Standards Institute, 10 East 40th Street, New York, N.Y. 10016

AR0070768

IEEE #85 "Airborne Noise Measurements on Rotating Electric Machinery"*

Scope: For rotating electrical machinery of all sizes
Several test procedures are described:

Test Type: Free field; free field above reflecting plane; semi-reverberant field; or reverberation room. (Similar to ANSI S1.2-1962, but more detailed.)

Data: Sound levels or sound pressure levels in frequency bands (octave, 1/3-octave, or "narrow") at specified locations or total sound power level, overall or analyzed into frequency bands, and directivity of source.

ANSI S1.19/193 "Test-Site Measurement of Noise Emitted by Engine-Powered Equipment" (Draft only.)

Scope: For residential equipment (Section 4.5) [Other sections deal with automobiles, motorcycles, construction and industrial machinery and recreational equipment]

Test Type: Sound levels measured on flat test site with hard ground surface, free of large reflecting obstacles within 30 meters of equipment under test.

Data: A-weighted sound level measured at a point 50 ft from center of equipment and 4 ft above ground, for noisiest direction and noisiest operating conditions.

ARI+ 443-66 "Standard for Sound Rating of Room Fan-Coil Air-Conditioners"

Scope: For room fan-coil air conditioners.

---

* Institute of Electrical and Electronic Engineers, 345 East 47th Street, New York, N.Y. 10017

+ Air-Conditioning and Refrigeration Instutute, 1815 North Fort Meyer Drive, Arlington, Virginia 22209

AR0070769

Test Type: Reverberation room, substitution method, in accordance with ASHRAE 36-62

Data: Octave-band sound power levels, computed from 1/3-octave band data corrected for presence of pure tones.

ARI 270-67 Standard for Sound Rating of Outdoor Unitary Equipment

Scope: Outdoor sections of factory-made equipment, such as unitary air-conditioners or heat pumps.

Test Type: Reverberation room, substitution method, in accordance with ASHRAE 36-62 or ASHRAE 36A-63.

Data: Sound power levels in 1/3-octave bands.

Rating: Single-number rating based on the 1/3-octave band sound power levels (corrected for the presence of pure tones), by a calculation like the ANSI Standard S3.4, "Computation of Loudness of Noise".

ARI 275-68 Standard for Application of Sound Rated Outdoor Unitary Equipment

Reference material (related to ARI 270-67) establishing a method for predicting annoyance due to operation of outdoor unitary equipment, and providing recommendations for application of such equipment.

Calculation of annoyance level (ANL), taking into account distance, reflections, location of equipment, shielding by barriers, location of observer, multiple units, etc.

AR0070770

AHAM Room Air-Conditioner Sound Rating*

Scope: Room air conditioners

Test Type: Reverberation room, substitution method, in accordance with ASHRAE 36A-63

Data: Single number (or letter) ratings based on the 1/3-octave band sound power levels (corrected for the presence of pure tones), by a calculation like the ANSI Standard S3.4 "Computation of Loudness of Noise"; the calculations are different for the indoor side and the outdoor side of the unit, such that the two sound ratings would be the same if the sound power levels radiated indoors were all 15 dB less than the levels in corresponding frequency bands radiated to the outdoors. The outdoor calcuation is the same as that of ARI 270-67. The indoor sound rating (a number) is converted to a letter rating (11=A, 12=B, 13=C, etc.) for publication purposes.

HVI+#1966-1 Sound Test Procedure

Scope: For home ventilating equipment.

Test Type: Reverberation room, substitution method, similar to ASHRAE 36-62

Data: Octave band sound power levels, calculated from 1/3-octave band sound pressure levels, are used to compute octave-band free-field sound pressure levels at a reference 5-foot distance.

Rating: The nominal free-field octave-band SPL's at 5 foot are used to calculate loudness in sones, a single number,

\+ Home Ventilating Institute

AR0070771

according to ANSI S3.4 - 1968, "Computation of Loudness of Noise."

ADC Test Code 1062.R1 Equipment Test Code*

Scope: For air distribution and control devices (high pressure units).

Test Type: Reverberation room, substitution method, in accordance with ASHRAE 36B-63 (except that the ASHRAE test for attenuation of terminal devices is not used).

Data: Total sound power level radiated into room, in octave bands.

* * * *

In addition to these standards for measuring and rating noise from various kinds of ventilation equipment, both the Home Ventilating Institute and the Air Conditioning and Refrigeration Institute have published directories of equipment, giving noise ratings for each model tested (a large proportion of the manufactured models); and both the Air Conditioning and Refrigeration Institute and the Association of Home Appliance Manufacturers offer guidance for the writers of noise ordinances dealing with their equipment types, to indicate achievable goals and the necessary wording in terms of existing standards, to make the model ordinances enforceable.

At the present time, the existence of several different measurement and rating standards in the ventilating/air-conditioning field is something of an embarrassment, since they are not

---

* Air Diffusion Council, 435 North Michigan Ave., Chicago, Ill. 60611

AR0070772

mutually consistent nor even compatible, but are competing for general acceptance. In an attempt to deal with this situation, an ad hoc working group of ANSI is currently trying to draft a standard for both measurement and rating of equipment noise that exhibits the best features of the already existing standards and that, it is hoped, will be found acceptable by the various organizations that have pioneered in the standardization effort in the United States. It is still too early to predict whether this action will be successful.

In spite of the slightly chaotic present situation, it is clear that a great deal of careful thinking has been done about how to measure equipment noise in the United States; indeed, in this area the U. S. is somewhat in advance of the European practice.

IPCC Fourth Assessment Report: Climate Change 2007

Climate Change 2007: Working Group I: The Physical Science Basis

2.10.2 Direct Global Warming Potentials

< >

All GWPs depend on the AGWP for CO_2 (the denominator in the definition of the GWP). The AGWP of CO_2 again depends on the radiative efficiency for a small perturbation of CO_2 from the current level of about 380 ppm. The radiative efficiency per kilogram of CO_2 has been calculated using the same expression as for the CO_2 RF in Section 2.3.1, with an updated background CO_2 mixing ratio of 378 ppm. For a small perturbation from 378 ppm, the RF is 0.01413 W m^{-2} ppm^{-1} (8.7% lower than the TAR value). The CO_2 response function (see Table 2.14) is based on an updated version of the Bern carbon cycle model (Bern2.5CC; Joos et al. 2001), using a background CO_2 concentration of 378 ppm. The increased background concentration of CO_2 means that the airborne fraction of emitted CO_2 (Section 7.3) is enhanced, contributing to an increase in the AGWP for CO_2. The AGWP values for CO_2 for 20, 100, and 500 year time horizons are 2.47×10^{-14}, 8.69×10^{-14}, and 28.6×10^{-14} W m^{-2} yr (kg CO_2)$^{-1}$, respectively. The uncertainty in the AGWP for CO_2 is estimated to be ±15%, with equal contributions from the CO_2 response function and the RF calculation.

Updated radiative efficiencies for well-mixed greenhouse gases are given in Table 2.14. Since the TAR, radiative efficiencies have been reviewed by Mantzka et al. (2003) and Velders et al. (2005). Gohar et al. (2004) and Forster et al. (2005) investigated HFC compounds, with up to 40% differences from earlier published results. Based on a variety of radiative transfer codes, they found that uncertainties could be reduced to around 12% with well-constrained experiments. The HFCs studied were HFC-23, HFC-32, HFC-134a and HFC-227ea. Hurley et al. (2005) studied the infrared spectrum and RF of perfluoromethane (CF_4) and derived a 30% higher GWP value than given in the TAR. The RF calculations for the GWPs for CH_4, N_2O and halogen-containing well-mixed greenhouse gases employ the simplified formulas given in Ramaswamy et al. (2001; see Table 6.2 of the TAR). Table 2.14 gives GWP values for time horizons of 20, 100 and 500 years. The species in Table 2.14 are those for which either significant concentrations or large trends in concentrations have been observed or a clear potential for future emissions has been identified. The uncertainties of these direct GWPs are taken to be ±35% for the 5 to 95% (90%) confidence range.

Table 2.14. Lifetimes, radiative efficiencies and direct (except for CH_4) GWPs relative to CO_2. For ozone-depleting substances and their replacements, data are taken from IPCC/TEAP (2005) unless otherwise indicated.

Notes:

[a] The CO_2 response function used in this report is based on the revised version of the Bern Carbon cycle model used in Chapter 10 of this report (Bern2.5CC; Joos et al. 2001) using a background CO_2 concentration value of 378 ppm. The decay of a pulse of CO_2 with time t is given by

$$a_0 + \sum_{i=1}^{3} a_i \cdot e^{-t/\tau_i}$$

Where $a_0 = 0.217$, $a_1 = 0.259$, $a_2 = 0.338$, $a_3 = 0.186$, $\tau_1 = 172.9$ years, $\tau_2 = 18.51$ years, and $\tau_3 = 1.186$ years.

[b] The radiative efficiency of CO_2 is calculated using the IPCC (1990) simplified expression as revised in the TAR, with an updated background concentration value of 378 ppm and a perturbation of +1 ppm (see Section 2.10.2).

[c] The perturbation lifetime for methane is 12 years as in the TAR (see also Section 7.4). The GWP for methane includes indirect effects from enhancements of ozone and stratospheric water vapour (see Section 2.10.3.1).

[d] Shine et al. (2005c), updated by the revised AGWP for CO_2. The assumed lifetime of 1,000 years is a lower limit.

[e] Hurley et al. (2005)

[f] Robson et al. (2006)

[g] Young et al. (2005)

DEPARTMENT OF WATER AND POWER

DRAFT 2010 URBAN WATER MANAGEMENT PLAN

JANUARY 14, 2011

The Draft 2010 UWMP is available for review at www.ladwp.com.

Written comments are due by March 15, 2011 to:
LADWP – Water System
111 N. Hope St, Room 1460
Los Angeles, CA 90012
Attn: Simon Hsu
or
simon.hsu@ladwp.com

** The report is not in the final format.

Draft Table of Contents for LADWP 2010 UWMP

Executive Summary ES-1

Chapter 1: Introduction 1-1

Purpose 1-1

UWMP Requirements and Checklist 1-1

Water Supply Action Plan 1-2

Service Area 1-3

Land Use 1-3

Demographics 1-4

Climate 1-7

Water Demand and Supply Overview 1-8

Chapter 2: Water Demands 2-1

Historical Water Use 2-1

Water Use By Sector 2-2

Indoor and Outdoor Use 2-3

Quantification of Historical Water Conservation 2-5

Water Demand Forecast 2-6

Demand Forecast Methodology 2-6

Applying the Methodology 2-7

Water Demand Forecast Results 2-9

Water Demand Forecast with Average Weather Variability 2-10

Low-Income Water Demand Projections 2-11

Chapter 3: Water Conservation 3-1

Water Conservation Goals 3-4

Water Supply Action Plan Conservation Goal 3-4

Water Conservation Act of 2009 3-4

Existing Programs, Practices, and Technology to Achieve Water Conservation 3-6

State Laws and City Ordinances 3-6

Conservation Pricing 3-10

CUWCC Best Management Practices 3-11

LADWP Conservation Programs 3-13

Future Programs, Practices, and Technology to Achieve Water Conservation 3-26

Graywater 3-26

Demand Hardening 3-30

Projected Water Conservation Savings 3-31

Cost & Funding 3-34

Chapter 4: Recycled Water **4-1**

Regulatory Requirements 4-2

Non-Potable Reuse Regulations 4-2

Groundwater Replenishment Regulatory Requirements 4-6

Wastewater Treatment Plants 4-7

Donald C. Tillman Water Reclamation Plant 4-8

Los Angeles – Glendale Water Reclamation Plant 4-8

Terminal Island Water Reclamation Plant 4-9

Hyperion Treatment Plant 4-9

Projected Wastewater Volume 4-9

Existing Recycled Water Deliveries 4-10

Harbor Area 4-11

Metro Area 4-12

San Fernando Valley Area 4-13

Westside Area 4-15

Comparison of 2010 Projections Versus Actual Use 4-17

Recycled Water Master Planning Documents 4-18

Near-Term Planned Projects Through 2015 4-20

Non-Potable Reuse Projects to be completed between 2015 - 2025 4-23

Groundwater Replenishment 4-24

Efforts Beyond 50,000 AFY 4-26

Recycled Water Master Plan Cost and Funding 4-27

Stakeholder Process and Agency Coordination 4-28

Recycled Water Quality 4-29

Chapter 5: Los Angeles Aqueduct System 5-1

Historical Deliveries 5-1

Mono Basin and Owens Valley Supplies 5-4

Water Rights 5-5

Environmental Issues and Mitigation 5-5

Mono Basin 5-6

Lower Owens River Project 5-8

Owens Lake Dust Mitigation 5-10

Water Quality 5-12

Projected Deliveries 5-13

Los Angeles Aqueduct Delivery Cost 5-15

Chapter 6: Local Groundwater 6-1

Groundwater Rights 6-1

OLARA Groundwater Basin Adjudication 6-2

Historical Groundwater Production 6-2

San Fernando Basin 6-3

Groundwater Rights 6-3

Water Quality 6-4

Agency Cooperation of SFB Remediation 6-5

SFB Contamination Clean-up Programs 6-6

Sylmar and Eagle Rock Basins 6-8

Groundwater Rights 6-8

Water Quality 6-9
Central Basin 6-9
Groundwater Rights 6-9
Water Quality 6-10
West Coast Basin 6-10
Groundwater Rights 6-10
Water Quality 6-11
Water Quality Goals and Management 6-11
Groundwater Monitoring 6-11
Operating Goals 6-11
Managing Emerging Contaminants of Concern 6-12
Groundwater Pumping Costs 6-13
Groundwater Production Projections 6-14

Chapter 7: Watershed Management **7-1**
Importance of Watershed Management to Groundwater Supplies 7-1
Additional Benefits of Watershed Management 7-3
Stormwater Capture Master Plan 7-5
Tree People – Memorandum of Agreement 7-6
Centralized Stormwater Capture Projects 7-6
Distributed Stormwater Capture 7-10
Watershed Council – Water Augmentation Study 7-10
Integrated Water Resources Plan Analysis 7-13
Distributed Stormwater Capture Projects 7-18
Low Impact Development (LID) and Best Management Practices (BMP's) 7-21
Future Programs 7-21
Integrated Regional Water Management Plan (IRWMP) Program 7-22
Cost Analysis 7-23

Chapter 8: Metropolitan Water District Supplies **8-1**

Supply Sources 8-1

The Colorado River *8-4*

The State Water Project *8-12*

In Basin Storage *8-21*

Groundwater Storage and Water Transfers *8-24*

MWD Supply Reliability and Projected LADWP Purchase 8-27

MWD Rate Structure and LADWP's Purchase Water Costs 8-29

MWD Rate Structure *8-29*

LADWP's Purchase Water Costs *8-30*

Chapter 9: Other Potential Water Supplies **9-1**

Water Transfers and Banking 9-1

LADWP Opportunities *9-2*

MWD Opportunities *9-3*

Seawater Desalination 9-5

Desalination Technology *9-5*

DWR Desalination Efforts *9-6*

MWD Desalination Efforts *9-7*

LADWP Seawater Desalination Efforts *9-8*

Potential Water Supply Yield and Cost 9-9

Chapter 10: Integrated Resources Planning **10-1**

City of Los Angeles Integrated Water Resources Plan 10-1

Description and Purpose *10-1*

Integrated Watershed Approach *10-2*

Stakeholder Involvement *10-2*

IRP Alternatives *10-2*

Implementation Status *10-3*

Agency Coordination 10-7

IRP Implications for LADWP's Urban Water Management Plan 10-7

Greater Los Angeles Integrated Regional Water Management Plan (IRWMP) 10-7

Description and Purpose 10-7

Stakeholder Involvement 10-9

Recommended Projects 10-9

Implications of IRWMP for LADWP's Urban Water Management Plan 10-12

MWD's Integrated Resources Plan 10-13

MWD IRP 2004 Update 10-13

MWD IRP 2010 Update 10-14

Stakeholder Participation 10-15

Agency Coordination 10-15

IRP Implications for LADWP's Urban Water Management Plan 10-16

Chapter 11: Water Supply Reliability and Financial Integrity **11-1**

Unit Cost and Funding of Supplies 11-1

Unit Cost Summary of Supplies 11-1

Funding of Supplies 11-2

Reliability Assessment Under Different Hydrologic Conditions 11-3

Los Angeles Aqueducts 11-3

Groundwater 11-3

Conservation 11-3

Recycled Water 11-4

Water Transfers 11-4

MWD Imported Supplies 11-4

Potential Supplies 11-5

Service Area Reliability Assessment 11-6

Water Shortage Contingency Plan 11-15

Stages of Action 10632 (a) 11-15

AR0070793

Driest Three-Year Supply – 10632 (b) 11-16

Catastrophic Supply Interruption Plan 10632 (c) 11-18

Mandatory Water Use Prohibitions 10632 (d) 11-18

Consumption Reduction Methods during Water Shortages 10632 (e) 11-19

Penalties for Excessive Use (Non-Compliance to Prohibited Use) 10632 (f) 11-20

Analysis and Effects on Revenues and Expenditures of Reduced Sales During Shortages – 10632 (g) 11-21

Water Shortage Contingency Resolution or Ordinance – 10632 (h) 11-21

Methodology to Determine Actual Water Use Reductions During Shortages – 10632 (i) 11-23

Water Supply Assessments 11-24

Chapter 12: Climate Change **12-1**

Potential Impacts of Climate Change on Water Service Reliability 12-1

Local Impacts 12-2

Los Angeles Aqueduct Impacts 12-4

State Water Project Impacts 12-8

Colorado River Aqueduct Impacts 12-9

Water and Energy Nexus 12-9

Executive Summary

Executive summary will be included following public review.

Presentation at February 2011 public workshops provides an overview of the Urban Water Management Plan findings.

DRAFT

AR0070796

AR0070797

DRAFT Chapter One
Introduction

1.0 Overview

The availability of water has significantly contributed towards the tremendous growth and development of the City of Los Angeles (City). Since 1902, when the City's population was approximately 102,000, the Los Angeles Department of Water and Power (LADWP) has supported the City's transformation into the nation's second largest city with over 4 million residents, encompassing a 464 square mile area, and comprising the world's sixteenth largest economy. The largest municipal utility in the nation, LADWP was established in 1902 to deliver safe and reliable water and electricity supplies at an affordable price to the residents and businesses of Los Angeles.

With increasing demands for additional water supplies, LADWP along with all other water agencies in Southern California, are faced with the challenge of providing a reliable water supply for a growing population. LADWP will meet the City's water needs through the following actions:

- Pursue cost-effective water conservation, stormwater capture and recycling projects to increase supply reliability.
- Ensure continued reliability of the City's supplemental water supplies from the Metropolitan Water District of Southern California (MWD) through active representation of City interests on the MWD Board
- Protect existing groundwater supplies from contamination and provide treatment to optimize their use
- Maintain the operational integrity of the Los Angeles Aqueduct and in-City water distribution systems
- Meet or exceed all Federal and State standards for drinking water quality

1.1 Purpose

The LADWP 2010 Urban Water Management Plan (UWMP) serves two purposes: (1) achieving compliance with requirements of California's Urban Water Management Planning Act (Act); and (2) serving as a master plan for water supply and resources management consistent with the City's goals and policy objectives.

1.1.1 UWMP Requirements and Checklist

This 2010 Urban Water Management Plan (UWMP) complies with Sections 10610 and 10657 of the California Water Code, Urban Water Management Planning Act (Act), and details how LADWP plans to meet all of the City's customer water needs. The Act became effective on January 1, 1984 and requires that every urban water supplier that provides municipal and industrial water to more than 3,000 customers (or supplies more than 3,000 acre-feet per year) prepare and adopt an Urban Water Management Plan, in accordance with prescribed requirements, every five years. Appendix A contains the Act.

The Act was originally developed due to concerns for potential water supply shortages throughout the State. Therefore, it required information that focused primarily on water supply reliability and water use efficiency measures. Since its original passage in 1983, there have been several amendments added, the most recent adopted in 2009. Some of the recent amendments include: providing assessment of present and proposed future demands to achieve per capita water use reductions by 20 percent by 2020, projecting water use for low-income single family and multi-family residential housing, and the addition of "indirect potable reuse" to the list of recycled water uses. A copy of the 2010 UWMP Act requirements is

AR0070798

provided in Appendix B. A checklist of the Urban Water Management Plan cross-referencing Act requirements to applicable pages in this UWMP is provided in Appendix C.

With the passage of Senate Bills 610 and 221 in 2001, Urban Water Management Plans took on even more importance. SB 610 and 221 require that counties and cities consider the availability of adequate water supplies for certain new large developments. These statutes require written verification of sufficient water supply to serve these new developments, and Urban Water Management Plans are identified as key source documents for this verification. Based on this statute the LADWP prepares individual Water Supply Assessments for these new large developments.

LADWP's 2010 Urban Water Management Plan is not only designed to meet the current requirements of the Act, but also serves as the City's master plan for water supply and resource management. The UWMP is not only intended for officials in Sacramento, but also helps guide policy makers in the City and the Metropolitan Water District of Southern California (MWD), as well as providing information to the citizens of Los Angeles. The UWMP provides the basic policy principles that guide LADWP's decision-making process to secure a sustainable water supply for Los Angeles.

1.1.2 Water Supply Action Plan

LADWP has a long history of working to ensure that its customers have enough water. These efforts go back to the early 20th century with the building of the Los Angeles Aqueduct. Investments in water rights, aqueducts, reservoirs, conservation and more recently recycled water and stormwater capture have allowed Angelinos to enjoy a water supply that they can rely on. Sound planning and timely investments in water have played a critical role in meeting the water needs of the City despite the fact that Southern California is a semi-arid region

In May of 2008, LADWP's Water Supply Action Plan (Plan), "Securing L.A.'s Water Supply", was released to address a number of critical water supply reliability issues. These water supply issues included: (1) the lowest snowpack on record in the Eastern Sierras in 2007, where Los Angeles historically received the greatest share of its water supply; (2) the driest year on record in 2007 for the Los Angeles basin; (3) anticipated regional water allocations by MWD in response to reductions in imported water available from the San Francisco Bay Delta due to drought and regulatory restrictions; (4) local groundwater contamination in the San Fernando basin, restricting the ability to fully utilize this local resource; (5) Los Angeles Aqueduct delivery reductions due to environmental mitigation and enhancements in the Owen's Valley and Mono Lake Basins, representing nearly one-half of historic water supplies from the Eastern Sierra watershed; and (6) uncertain climate change impacts which threaten traditional water supply sources.

The convergence of these critical issues has far-reaching implications for the City of Los Angeles' water supply that requires long-range planning to sustain a reliable supply of water to meet current and future demand. The Plan was a blueprint for creating sustainable water resources to serve the future needs of the City, and outlined responsible water management and long-term planning. By 2028, the Plan envisioned a six-fold increase in recycled water supplies to a total of 50,000 AFY. Similarly, by 2030, an increase of 50,000 AFY was planned for conservation. As described in the Plan, this aggressive approach included: investments in state-of-the-art technology; a combination of rebates and incentives; efficient clothes washers, and urinals; and long-term measures such as expansion of water recycling and remediating contaminated groundwater supplies. A multi-faceted approach to developing a locally sustainable water supply was developed incorporating the following key short-term and long-term strategies:

AR0070799

Short-Term Conservation Strategies

- Enforcing prohibited uses of water
- Expanding prohibited uses of water
- Extending outreach efforts
- Encouraging regional conservation measures

Long-Term Strategies

- Increasing water conservation through reduction of outdoor water use and new technology
- Maximizing water recycling
- Enhancing stormwater capture
- Accelerating groundwater basin clean-up
- Expanding groundwater storage
- Green Building Initiatives (added subsequent to the release of the Plan)

As an integral part of the UWMP, the Water Supply Action Plan is incorporated into the associated chapters of the UWMP. The UWMP outlines how the strategies contained in the Water Supply Action Plan will be implemented and how these strategies will increase the reliability of LADWP's water supplies through 2035.

1.2 Service Area

In order to properly plan for water supply, it is important to understand the factors that influence water demands over time. These factors include land use, demographics, and climate.

1.2.1 Land Use

The City of Los Angeles is comprised of approximately 302,165 acres. Residential development constitutes over 51percent of the total land use within the City. Within the residential land use category, single-family residential is the largest at approximately 121,500 acres or 40 percent of the total land use within the City. Multi-family residential is approximately 34,000 acres or 11 percent of the total land use within the City. Open space/parks is the second largest land use within the City occupying approximately 13 percent of the total land use. Commercial and manufacturing land uses combined account for approximately 18 percent of total. Commercial land uses are inclusive of public facilities, such as libraries, public schools, and other government facilities. Exhibit 1A provides a breakdown of the land uses within the City of Los Angeles. The "Other" category includes specific plans, transportation, freeways, rights of way, and other miscellaneous uses that are not zoned.

1.2.2 Demographics

With over 4 million people residing in the LADWP service area, it is slightly larger than the legal boundary of the City of Los Angeles. LADWP provides water service to portions of West Hollywood, Culver City, Universal City, and small parts of the County of Los Angeles.

The population within LADWP's service area increased from 2.97 million in 1980 to 4.1 million in 2009, representing an average annual growth rate of 1.3 percent. The total number of housing units increased from 1.10 million in 1980 to 1.38 million in 2009, representing an average annual growth rate of 0.9 percent. During this time, average household size increased from 2.7 persons in 1980 to 2.9 persons in 2009. Employment grew by about 1.0 percent annually from 1980 to 1990, but declined from 1990 to 2000 as a result of an economic recession that started in 1991. Another decline began in 2008 reflecting the recent economic recession. Overall, employment increased by about 0.3 percent annually from 1990 to 2009. Exhibit 1B summarizes the historical demographics for the LADWP service area.

AR0070801

Exhibit 1B
Historical Demographics for LADWP Service Area

	Population	Housing	Employment
1980	2,970,000	1,100,000	1,692,000
1990	3,501,602	1,243,022	1,813,615
2000	3,732,579	1,290,440	1,773,895
2009	4,051,438	1,376,013	1,812,926

Demographic projections were obtained for the LADWP service area from the MWD utilizing a land-use based planning tool that allocates projected demographic data from the Southern California Association of Governments (SCAG) into water service areas for their member agencies. MWD's demographic projections use data reported in SCAG's 2008 Regional Transportation Plan (RTP). Exhibit 1C summarizes these demographic projections for the LADWP service area.

LADWP's service area population is expected to continue to grow over the next 25 years at a rate of 0.4 percent annually. While this is substantially less than the historical 1.3 percent annual growth rate from 1980 to 2009, it will still lead to approximately 367,300 new residents over the next 25 years. According to SCAG's 2008 RTP, housing is expected to grow faster than population over the next 25 years at 0.7 percent annual growth versus 0.4 percent annual growth for population, and it is anticipated that household size will continue to decline over the projection period.

The 2008 RTP projects that by 2035 the average household size will decrease to 2.65 persons per household. Throughout the projection period, multi-family housing units are expected to increase at slightly less than twice the rate of single-family housing units (0.93 percent annual growth vs. 0.47 percent annual growth).

Employment is expected to increase by 0.4 percent annually throughout the projection period. This growth is primarily driven by the current and long-term opportunities available from the economic base within the five-county metropolitan region of Southern California. The economic base is wide-ranging and includes services, wholesale and retail trade, manufacturing, government, financial service industries, transportation, utilities, construction, education, and tourism. Over the 25 year

AR0070802

forecast period, industrial growth is expected to decline and experience a subtle annual negative growth of -0.4 percent, while commercial employment is expected to increase by about 0.5 percent annually.

Exhibit 1C
Demographic Projections for LADWP Service Area

Demographic	2010	2015	2020	2025	2030	2035
Population	4,100,260	4,172,760	4,250,861	4,326,012	4,398,408	4,467,560
Housing						
Single-Family	627,395	646,067	665,261	678,956	691,703	701,101
Multi-Family	764,402	804,013	846,257	880,580	914,125	942,846
Total Housing	1,391,797	1,450,080	1,511,518	1,559,536	1,605,828	1,643,947
Persons per Household	2.88	2.81	2.75	2.71	2.67	2.65
Employment						
Commercial	1,674,032	1,724,106	1,754,998	1,790,798	1,828,765	1,865,156
Industrial	163,382	157,652	155,012	152,426	150,009	147,508
Total Employment	1,837,415	1,881,758	1,910,010	1,943,224	1,978,773	2,012,664

Source: SCAG Regional Transportation Plan (2008), modified using MWD's land use planning to represent LADWP's service area.

The SCAG demographic projections for population, households, and employment included in their 2008 RTP, and presented in LADWP's 2010 UWMP, vary from what was presented in LADWP's 2005 UWMP. The demographic projections in the 2005 UWMP were based on SCAG's 2004 RTP. The current 2008 projections incorporate the latest population, households, and employment data from multiple local, state and federal agencies. Projected 2008 RTP data reflect adjustments in future population growth related to declining fertility, mortality, labor force participation, and household headship rates; leveling in net migration; fluctuating net domestic migration in response to economic cycles; and an employment shift from the manufacturing sector to the service sector. The SCAG 2008 RTP was adopted in May 2008 prior to the recent recession beginning in 2008. Additionally, MWD has further adjusted the service area boundaries based on LADWP input. Exhibit 1D shows the differences between the SCAG demographic projections for the RTP in 2004 and 2008.

For the forecast year 2030 population was projected to be 4.30 million under the SCAG 2004 RTP and 4.40 million under the 2008 RTP, a difference of about 100,000. Housing was projected to be 1.60 million in 2030 under SCAG 2004 RTP and slightly more under the SCAG 2008 RTP at 1.61 million. Employment was forecast to be less in 2030 under the newest RTP. It is projected to be 2.20 million under the SCAG 2004 RTP versus 1.98 million with the 2008 RTP. It is important to recognize that projected total employment under both the 2004 RTP and 2008 RTP continue to increase from 2010 to 2035. The 2008 RTP simply projects a lower *rate* of increase than does the 2004 RTP. Conversely, the *rate* at which the population increases is expected to be higher with the 2008 RTP as compared with the 2004 RTP.

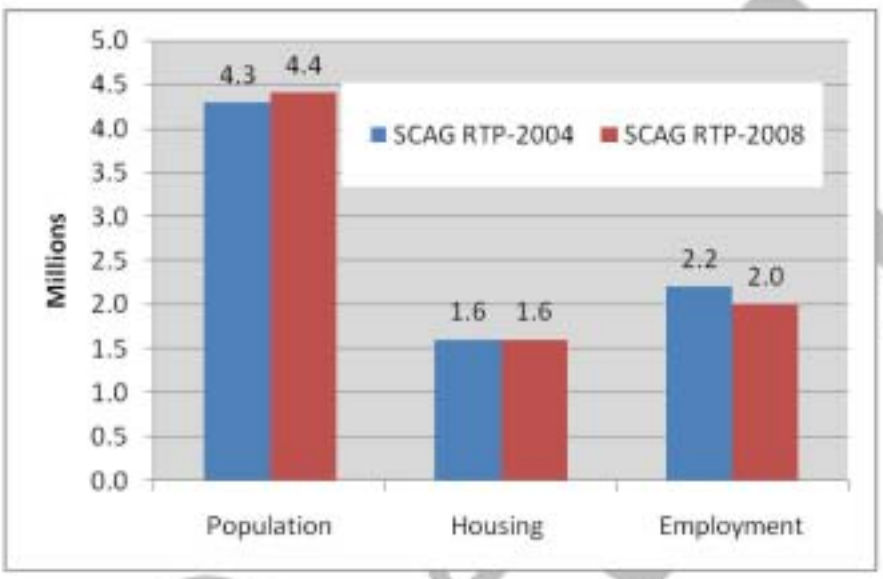
Comparison of SCAG Demographic Projections for LADWP Service Area Between 2004 and 2008 RTP Forecasts for Year 2030



1.2.3 Climate

Weather in Los Angeles is considered mild, which is a major attribute that attracts businesses, residents, and tourists to the City. The City experiences a sizable and popular portion of sunshine throughout the year. Because of its relative dryness, Los Angeles' climate has been characterized as Mediterranean. Exhibit 1E provides a summary of average monthly rainfall, maximum temperatures, and evapotranspiration readings.

The City's average monthly maximum temperature is 76 degrees Fahrenheit based on the period of 1990-2010. This is based on data from the Los Angeles Downtown weather station. The standard annual average evapotranspiration rate (ETo) for the Los Angeles area is 50.29 inches per year. ETo measures the loss of water to the atmosphere by evaporation from soil and plant surfaces and transpiration from plants. ETo serves as an indicator of how much water plants need for healthy growth. Total precipitation averages 14.8 inches per year, with over 90 percent of the total amount typically falling during the period of November through April.

1.2.4 Water Demand and Supply Overview

Primary sources of water for the LADWP service area are the Los Angeles Aqueducts (LAA), local groundwater, and imported supplemental water purchased from MWD. An additional fourth source, recycled water, is increasingly becoming a larger source in the overall supply portfolio. Two of the supply sources, LAA and water purchased from MWD, are classified as imported as they are obtained from outside LADWP's service area. Groundwater is local and is obtained within the service area. Historical supply sources are increasingly under multiple constraints including potential impacts of climate change, groundwater contamination, and reallocation of water for environmental concerns. To mitigate these impacts on supply sources, LADWP is modifying its water supply portfolio through conservation, water recycling, and stormwater capture.

The primary water supply sources are vital to maintaining LADWP's water system reliability. Pressure on one resource, such as little snowfall in the eastern Sierra Nevada Mountains, will result in an increased reliance on another resource, such as MWD. Supplies available from each source are determined using various computer models in an attempt to balance total projected supplies with projected demands. Exhibit 1F illustrates historical water supplies from 1980 to 2010. As a result of supply shortages, overall demands decreased by over 124,000 AFY in 2009-10 as compared to 2006-07. In 2009-10, approximately 36 percent of the water supply was from the LAA, 14 percent from local groundwater, 48 percent from MWD, and 1 percent from recycled water. From 2005-06 to 2009-10, the five–year average of the water supply portfolio was divided into the following percentages: 36 percent LAA, 11 percent local groundwater, 52 percent MWD, and less than 1 percent recycled water. The imported water (LAA water plus MWD water) supplied on average approximately 88 percent of demands.

Chapter Two
Water Demand

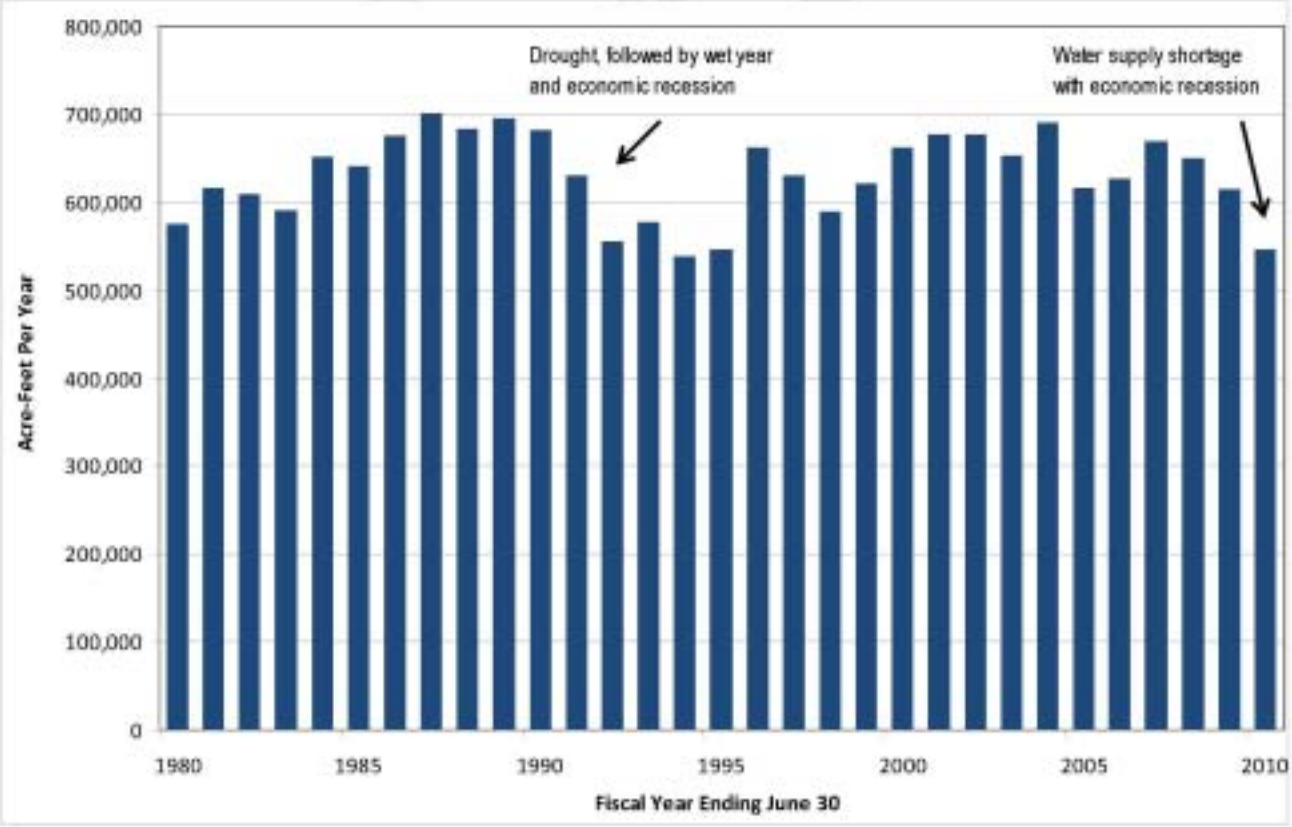
2.0 Overview

In order to properly plan for water supply, it is important to understand water demands and the factors that influence demands over time. LADWP maintains historical water use data separated into the following categories: single-family residential, multifamily residential, commercial, industrial, government, and non-revenue water. This categorization of demands allows better evaluation of trends in water use over time and more precise targeting of water conservation measures.

2.1 Historical Water Use

Exhibit 2A presents the historical water demand for LADWP. As seen in this exhibit, total water demand varies from year to year and is influenced by a number of factors such as population growth, weather, water conservation, drought, and economic activity. In 1991 mandatory conservation imposed on LADWP's customers in response to a six year drought resulted in water use dropping by 8 percent. An economic recession and wet weather in 1992 caused water use to continue to decrease another 12 percent. In 2009 a 3-year water supply shortage coinciding with an economic recession required LADWP to impose mandatory conservation. In 2010 mandatory conservation continued and the economic recession became more severe. This resulted in 2009-10 water use decreasing by 19 percent from 2006-07 levels.

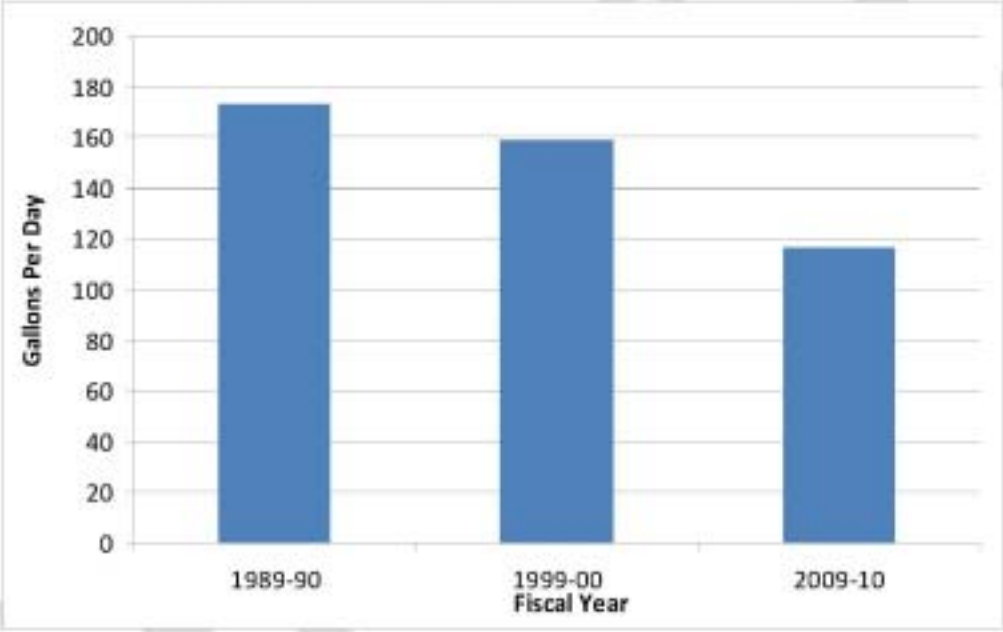
Exhibit 2A
Historical Total Water Demand in LADWP's Service Area



AR0070808

Prior to 1990, population growth in Los Angeles was a good indicator of total demands. From 1980 to 1990, population in the City grew at 1.7 percent annually. Water demands during this same ten year period also grew at 1.7 percent annually. However, after 1991, LADWP began implementing water conservation measures which prevented water demands from returning to pre-1990 levels. Average water demands in the last five years from 2004-05 to 2009-10 are about the same as they were in 1980-81 despite the fact that over 1.1 million additional people now live in Los Angeles. This is evidenced by examining per person (or per capita) water use since 1980 (see Exhibit 2B). In 1989-90, per capita water use was 173 gallons per day (gpd). By 1999-00, per capita water use fell to 159 gpd (or a 10 percent reduction from 1990). In 2009-10, per capita water use is estimated to be 117 gpd – but it is important to note that mandatory conservation and a severe economic recession were occurring at this time.

Exhibit 2B
Historical Per Capita Water Use in LADWP's Service Area



Water Use by Sector

Exhibit 2C shows the breakdown in average total water use between LADWP's major billing categories and non-revenue water in five-year interval for the past 25 years. Non-revenue water, which is the difference between total water use and billed water use, includes water for fire fighting, reservoir evaporation, mainline flushing, system losses, and theft. Single-family residential water use comprises the largest category of demand in LADWP's service area, representing about 36 percent of the total. Multifamily residential water use is the next largest category of demand, representing about 29 percent of the total. Industrial use is the smallest category, representing only 4 percent of the total demand. Although total water use has varied substantially from year to year, the breakdown between the major billing categories of use has not.

Non-revenue water has significantly decreased in recent years. Historically, non-revenue water has averaged 7 percent of total water demand. Since 2005, non-revenue water levels have averaged 5 percent. This may be attributed to a number of steps that LADWP has taken to improve its water system. In 2001, LADWP began replacing its large and intermediate meters. Work was focused on improving accuracy of the meters as well as their strategic placement. In fiscal year 2007-08, an

AR0070809

accelerated mainline replacement program was launched to repair and replace deteriorating pipelines. In addition, work to replace smaller customer meters was finally completed in fiscal year 2009-10 which also contributes to water loss control. Furthermore, LADWP's ongoing program to remove or cover large open-air reservoirs reduces water loss due to evaporation and infiltration.

Exhibit 2C
Breakdown in Historical Water Demand for LADWP's Service Area

Fiscal Year Ending	Single-Family		Multifamily		Commercial		Industrial		Government		Non-Revenue		Total

Indoor and Outdoor Water Use

In order to assess the potential for water use efficiency and target conservation programs, it is important to characterize water use in terms of indoor and outdoor demands. As with most water utilities, LADWP does not have separate irrigation meters for most of its customers. Only a small fraction of LADWP's customers, mostly parks and golf course, have designated irrigation meters. Therefore, measuring indoor vs. outdoor water demands involves the use of other data and assumptions.

There are two methods that LADWP uses to estimate total outdoor water use: (1) estimation of supplemental water needed for landscape irrigation in accordance with the California Model Water Efficient Landscape Ordinance; and (2) comparing wastewater flows to total water consumption. The first method uses the following formula to estimate the water needed to supplement outdoor landscape irrigation beyond the effect of natural precipitation:

$$LW = (Eto - Eppt) \times 0.62 \times A \times ETAF$$

Where:
LW = Estimated total supplemental water needed for landscape irrigation;
Eto = Reference evapotranspiration for the City of Los Angeles;
Eppt = Effective precipitation (25% of monthly precipitation);
0.62 = Conversion factor to gallons;
A = Total greenscape area; and
ETAF = Et adjustment factor

In 2007, an infrared analysis of the City was conducted as part of the City's Million Trees Program to determine tree canopy and landscape coverage. The infrared analysis methodology used two types of remotely sensed data, infrared imagery and aerial imagery, to determine the total greenscape areas within the City. Results of this effort indicated there is approximately 83,699 acres of greenscape area in Los Angeles. The ETAF (or Et adjustment factor) of 0.8 for the City was derived from types of plants to be irrigated and an assumed irrigation efficiency. It is consistent with the ETAF for non-rehabilitated landscapes as defined in the California Model Water Efficient Landscape Ordinance. The 2004-2007 average total water demand was selected as the basis for calculating outdoor water use percentage. This period was considered to be about average in terms of weather for Los Angeles and had no water restriction implemented by the City. Using the formula described previously, the supplemental water for outdoor landscaping in the City was estimated to be 249,000 AFY. During

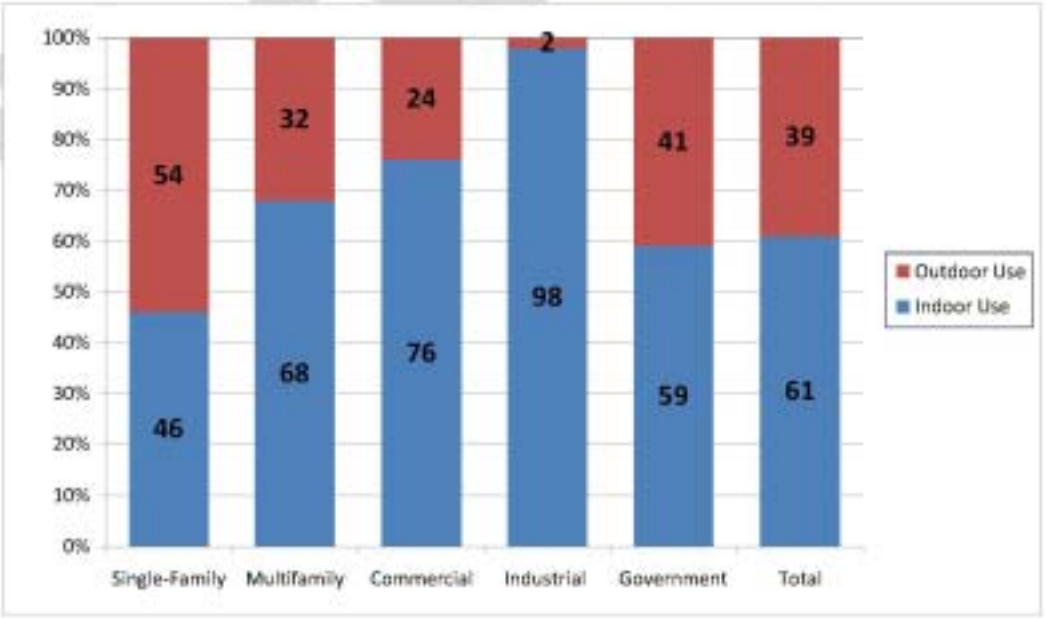
AR0070810

this same period, total water demand averaged 647,000 AFY. Therefore, the City's total outdoor water use represents approximately 39 percent of the total demand.

Comparing wastewater flows to total water consumption is another useful method to assess overall outdoor water use. Since wastewater flow represents indoor water use that flows into the sanitary sewer system, the difference between total water consumption and wastewater flows represents outdoor water use. However, groundwater infiltration and wet weather runoff may enter sanitary sewer systems through cracks and/or leaks in the sanitary sewer pipes or manholes and results in overestimation of the indoor water use. To reduce their impact, only summer months were used to estimate average monthly wastewater attributable to indoor water use. In Los Angeles, the summer months typically have little or no measurable rainfall. Using the same pre-water restriction period of 2004-2007 selected in the first method, the average monthly wastewater flow (only the months of June through September) yields approximately 365 million gallons per day (MGD) or 403,000 AFY of estimated indoor water use. Subtracting this estimated indoor water use from the total water consumption of 647,000 AFY results in an estimated total outdoor demand of 244,000 AFY or 38 percent, which is similar to the 39 percent obtained with the landscape irrigation method. Therefore, two entirely different methods produced very similar results in estimating the total outdoor water use for the City.

To obtain an estimate of indoor vs. outdoor water use for each major billing category, a minimum-month method was used. Monthly water use for single-family, multifamily, commercial, industrial and government was obtained for 2004-2007. The water use in the minimum month, usually one of the cool/wet winter months, is assumed to be mostly indoor use. The difference between any month and the minimum month is all attributed to outdoor water use. But based on the two prior methods, a certain amount of outdoor water use occurs even in the minimum month for some customers. Estimates of the outdoor water use that occurs in the minimum month were developed for each major billing category. Then the outdoor use of each major billing category was summed up to compare with the total outdoor water use obtained from the previous two methods. Exhibit 2D presents the estimated indoor and outdoor water use for the City using all three methods.

Exhibit 2D
Indoor vs. Outdoor Water Use in LADWP's Service Area

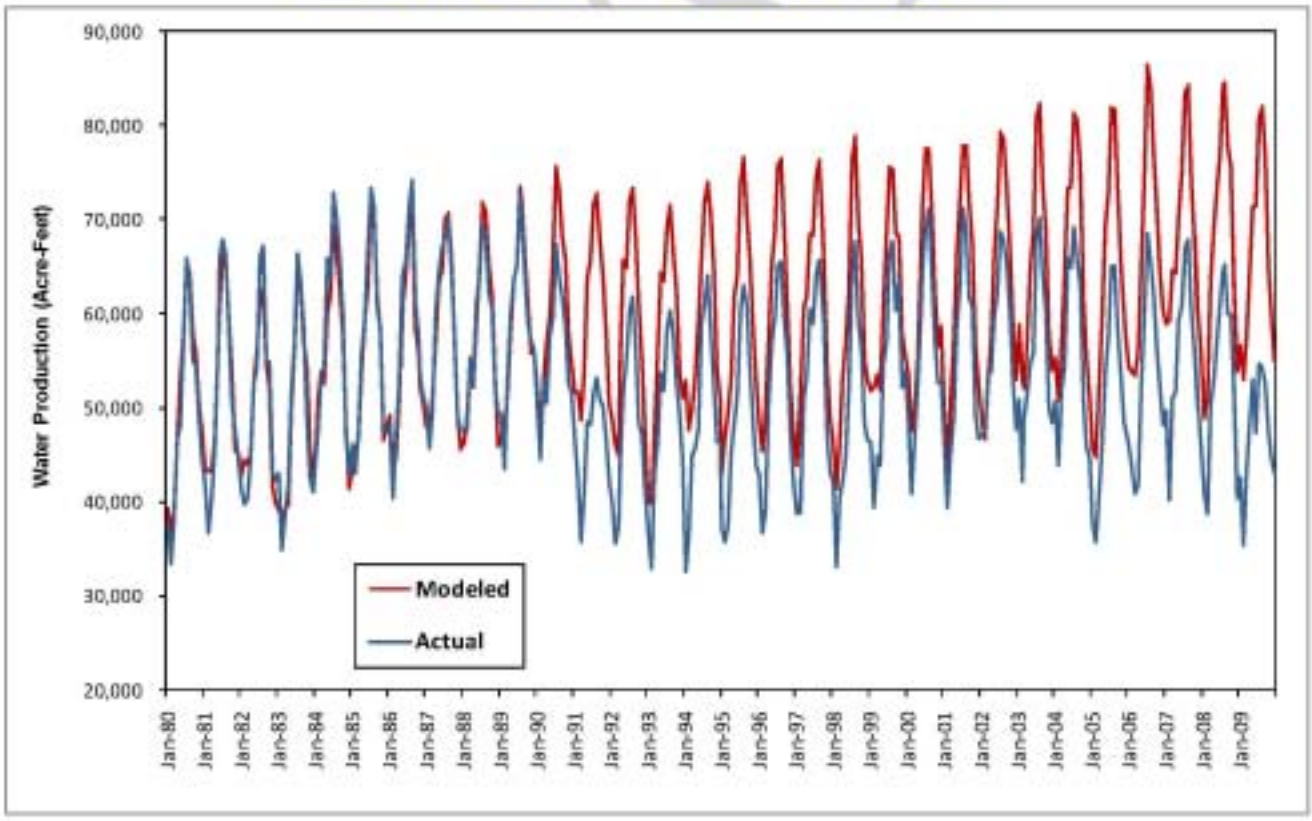


AR0070811

2.2 Quantification of Historical Water Conservation

LADWP has invested hundreds of millions of dollars in water conservation since 1990. These conservation investments include various active programs such as high efficiency toilet rebates, commercial/industrial water audits, education and public outreach and much more. During periods of water shortage, public education and outreach is especially important and has contributed to significant reductions in water use. In an effort to quantify its water conservation efforts, LADWP developed a statistical Conservation Model that correlates total monthly water use in the City with population, weather, the presence of mandatory water conservation, and economic recessions. The model can be used to predict what the water demand would be under actual weather conditions, population growth and economy; but without active or drought water conservation in place. This modeled water consumption without conservation is then compared to actual water consumption—with the difference being attributed to water conservation. In order to assess the model's accuracy, the model is used to "back cast" the period 1980 to 1990 when conservation was not implemented. In this case, the modeled water consumption should be very close to the actual water consumption. After 1990, it is expected that the modeled water consumption will be greater than actual water consumption as LADWP has implemented increasing levels of water conservation measures. Exhibit 2E presents modeled and actual monthly water consumption from 1980 to 2009. As seen, the Conservation Model is performing as expected. The modeled water consumption (red line) is nearly identical to the actual water consumption (blue line) up until 1990. After 1990, the modeled water consumption is greater than actual water consumption.

Exhibit 2E
Modeled vs. Actual Monthly Water Consumption for LADWP



AR0070812

Exhibit 2F summarizes the annual estimated water conservation using the Conservation Model. During periods of water shortage, even when mandatory water conservation is not in place, there is more conservation occurring due to extensive public education and outreach. Water conservation in 2009 represents the highest levels of conservation so far, which reflects a combination of active conservation programs, heightened public education and outreach, and mandatory conservation measures.

2.3 Water Demand Forecast

Demand Forecast Methodology

LADWP has developed a water demand forecast for each of its major categories of demand. This allows the City to better understand trends in water use and target conservation programs. The methodology used for the demand forecast is called a modified unit use approach. The following steps are used in this approach:

AR0070813

Step 1: Estimate baseline per unit water use – take each billed category of water demand (e.g., single-family, industrial, etc.) for a base (or starting) period and divide by associated demographic driver (e.g., number of single-family homes or number of industrial employees). This yields for instance, a baseline of 359 gallons used each day in a single-family residence.

Step 2: Modify the estimated baseline per unit water use to account for future changes in the following socioeconomic variables: price of water, personal income, family size, economy, drought conservation effect, and passive water conservation (which accounts for efficiencies in water use from state and local plumbing codes and ordinances).

Step 3: Multiply modified per unit water use for each category in Step 2 by the associated projected demographic drivers (see Exhibit 2G) in order to obtain projected water demands by billed category that does not include active water conservation (which is defined as conservation that LADWP incentives through rebates and programs).

Exhibit 2G
Projected Demographic Drivers
(Based on MWD allocated 2008 SCAG forecast data with corrected service area boundary, 5-17-2010)

Fiscal Year Ending	Single-Family (# Homes)	Multi-Family (# Homes)	Commercial/ Government (# Employees)	Industrial (# Employees)	Landscaping (# of MF Homes)	NRW* (%)
2010	627,395	764,402	1,674,032	163,382	764,402	6.9%
2015	646,067	804,013	1,724,106	157,652	804,013	6.9%
2020	665,261	846,257	1,754,998	155,012	846,257	6.9%
2025	678,956	880,580	1,790,798	152,426	880,580	6.9%
2030	691,703	914,125	1,828,765	150,009	914,125	6.9%
2035	701,101	942,846	1,865,156	147,508	942,846	6.9%

* Calculated from difference between historical production and billing data

Step 4: Estimate non-revenue water (the difference between total water consumption and billed water use) by applying a non-revenue water use factor, and add non-revenue water to the billed category water demands in Step 3 in order to get a forecast of total water consumption without active water conservation.

Step 5: Subtract future projections of active water conservation from the total water consumption in Step 4 in order to determine the water demand forecast that is fully inclusive of both passive and active water conservation.

Applying the Methodology

In Step 1 of this method, historical water demands for single-family, multifamily, commercial/government, and industrial were averaged from 2005 to 2008 to determine the baseline. This period was used because on average, it represented normal weather conditions, and it was before mandatory water use restrictions that occurred in 2009 and 2010. For each of these categories, the water demand was divided by a demographic driver that could be projected into the future. The result of this calculation is a water demand expressed as a unit use water rate. Exhibit 2H presents this unit use calculation for the baseline.

AR0070814

Exhibit 2H
Baseline Unit Use Water Rates (2005-2008)

Demand Category	Average Water Demand (AFY)	Average Demographic Driver *	Average Unit Use Rate (gallons/day/driver)
Single-Family	244,407	607,301 (homes)	359
Multifamily	184,428	734,461 (homes)	224
Commercial/Gov	153,199	1,631,896 (employees)	84
Industrial	23,613	160,328 (employees)	132

* Source: California Department of Finance and Employment Development Department

Step 2 in the methodology involves modifying these baseline unit use rates to account for changes in the following socioeconomic variables: price of water, personal income, family size, economy, drought conservation effect and passive water conservation. MWD has developed an econometric water demand model as part of its 2010 Integrated Water Resources Plan that is able to account for the impact that personal income, family size and price of water have on water demands. For each of these factors, a statistical coefficient or elasticity was estimated from MWD's Econometric Water Demand. The elasticity is generally interpreted as a percent change in water use resulting from a percent change in the socioeconomic variable. For example, a price elasticity of -0.131 would imply that a 10 percent increase in the real price of water would result in a 1.24 percent decrease in water demand (e.g. $1.24\% = 1-(1+10\%)^{-0.131}$). The following elasticities used in MWD's econometric water demand model were also used for LADWP's water demand forecast:

	Price of Water	Income	Family Size
Single-Family	-0.131	+0.270	+0.550
Multifamily	-0.109	+0.310	+0.450
Commercial/Government	-0.107		
Industrial	-0.107		

Source: MWD 2010 Integrated Water Resources Plan Update Appendix A.1 Demand Forecast

The price elasticities reflect a reduction of approximately 1/3 from those tabulated in MWD's 2010 IRP. However, MWD's 2010 IRP Appendix A.1 states that consumers respond to price increase by installing water-conserving fixtures and appliances. As more water efficient fixtures are installed, the impact of changing water-using behavior through rates is reduced. This is known as "demand hardening". Reducing the price elasticity is to avoid double-counting conservation savings and to account for demand hardening.

Exhibit 2I presents the modified per unit water use over time that incorporates future real increases in the price of water, personal income, and projected changes in family size. Also incorporated are the residual drought conservation effect from the significant public education and mandatory water restrictions that occurred during the drought period of 2009 through 2010, and the effect of passive conservation due to mandated efficiencies from plumbing codes and ordinances.

Water Demand Forecast Results

Steps 3, 4, and 5 involve applying the modified per unit water use factors shown in Exhibit 2J to the projected demographics for LADWP (see Chapter 1), then adding non-revenue water, and subtracting projected active water conservation (that is summarized in Chapter 3). The result of these steps is the water demand forecast for each of the major categories of demand.

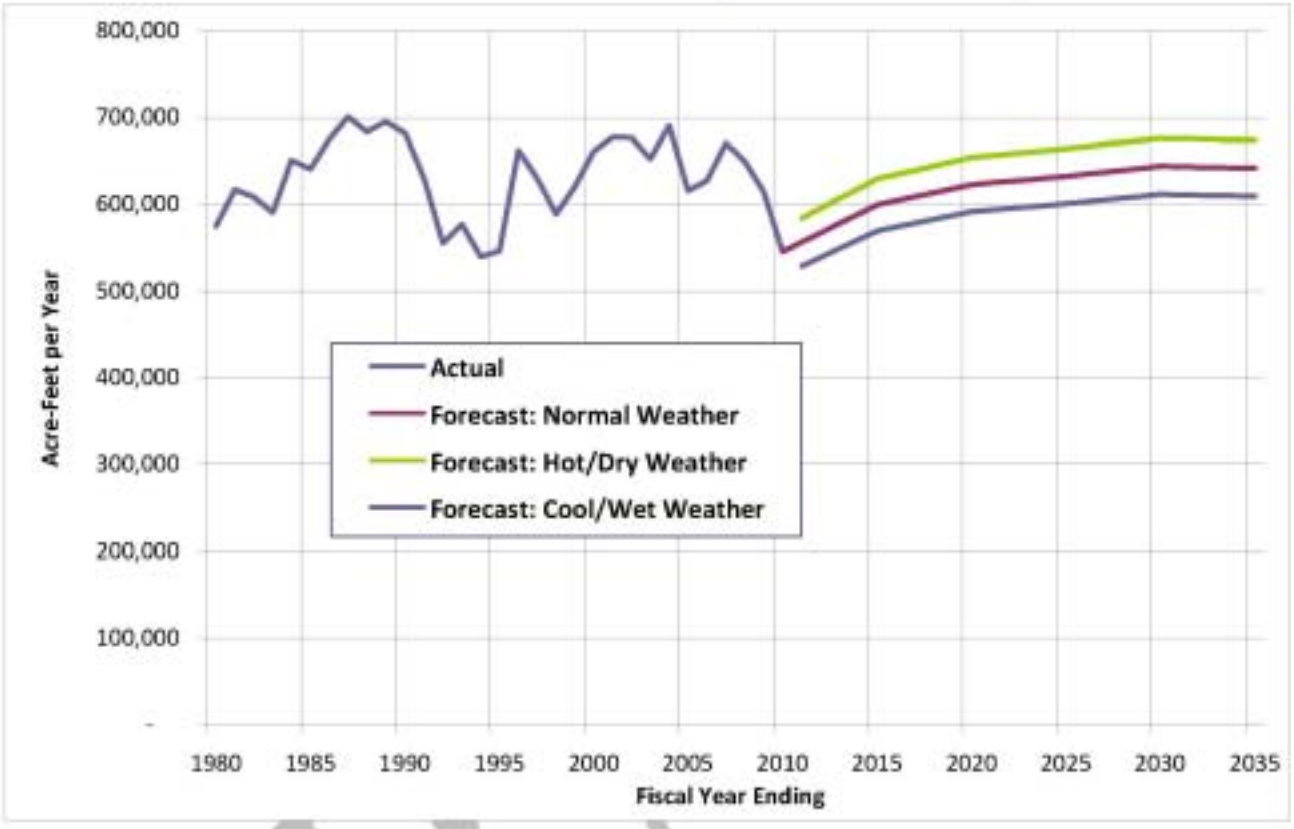
Water Demand Forecast with Average Weather Variability

Using the weather coefficients from the statistical water conservation model (see Exhibit 2E), annual weather adjustment factors can be derived to determine the range in forecasted water demands due to historical weather variability. This is accomplished by projecting water demands assuming long-term normal weather, and then comparing this normal-weather demand to actual demands. After adjusting for economy and drought conditions, projected water demands can vary by approximately ± 5 percent in any given year due to average historical weather variability. Meaning that water demands under cool/wet weather conditions could be as much as 5 percent lower than normal demands on average; while water demands under hot/dry weather conditions can be as much as 5 percent higher than normal demands on average. Exhibit 2K presents LADWP's historical and forecasted total water demands with both passive and active conservation, under the full range of historical weather variability.

AR0070817

Exhibit 2K
Water Demand Forecast with Average Weather Variability



Low-Income Water Demand Projections

The requirements for the 2010 UWMP call for projections of water demands for low-income customers. For rate relief purposes, LADWP maintains records of low-income water customers. For the fiscal year 2009 - 2010, approximately 6.6 percent of the total number of single-family homes in the City was classified as low-income. On average, these customers used about 20 percent less water per household than overall single-family customers. To forecast low-income single-family water demand, the 6.6 percent ratio of low-income to total single-family homes was applied to the total projection of single-family homes for a projection of low-income single-family homes. The system wide per unit water use for single-family homes was reduced by 20 percent and multiplied by the projection of low-income single-family homes.

Because the water services of LADWP's multifamily residential customers are mostly not individually metered—meaning a multifamily water account can represent 2 or even 100 homes—a different approach was used. LADWP's power system does individually meter multifamily homes and also classifies homes as low-income for rate relief purposes. Therefore, the ratio of current low-income to total multifamily homes in the City was applied to the total projection of multifamily homes in order to get a projection of low-income multifamily homes. For the fiscal year 2009 – 2010, approximately 16.3 percent of the total number of multifamily homes in the City was classified as low-income. Assuming that low-income multifamily homes also use 20 percent less water than overall multifamily homes, an adjusted per unit water use for multifamily homes was multiplied by the projection of low-income multifamily homes. Exhibit 2L presents the water demand forecast for low-income residential water customers.

AR0070819

DRAFT Chapter Three
Water Conservation

3.0 Overview

Multiple factors are increasingly restricting LADWP's traditional water supply sources. The City of Los Angeles has long recognized water conservation as one of multiple methodologies to reduce demands and improve overall water supply reliability. In May of 2008, LADWP's Water Supply Action Plan (Plan), "Securing L.A.'s Water Supply", was released in response to factors impacting LADWP's major water supply sources beginning in 2007. This plan calls for reducing potable water demands by an additional 50,000 AFY by 2030 through conservation, with multiple conservation strategies to increase the sustainability of LADWP's water supply.

Los Angeles has historically taken a leadership role in managing its demand for water. Los Angeles consistently ranks among the lowest in per person water consumption when compared to California's largest cities. This significant accomplishment has resulted from the City's sustained implementation of effective water conservation programs since the 1980s.

One of LADWP's most effective conservation tools is its customers. During past droughts and water shortages, residents and businesses have aggressively implemented conservation to achieve demand reductions. During FY 09/10, water use was below 1979 water use levels thanks to extraordinary conservation efforts by LADWP customers. Specifically, water use in FY 09/10 was almost 20% lower than water use in FY 06/07 with single-family residential water use 25% lower, multi-family water use 11% lower, commercial water use 16% lower, industrial water use 15% lower, and governmental water use 33% lower.

LADWP has continually invested in water conservation programs and measures targeting cost-effective reductions in water use. Looking forward, LADWP plans to continue to make investments in conservation programs and expand its focus on landscape water use efficiency and conservation opportunities in the commercial/industrial/institutional (CII) customer sectors. LADWP's conservation planning process includes working with other City departments to ensure that mutual needs are addressed and goals are achieved (e.g., landscape water use efficiency and dry weather runoff reduction).

The civic culture of water conservation in Los Angeles began with the installation of water meters on all services in the early 1900's. At that time, this foundational conservation measure resulted in a 30 percent reduction in water use. Throughout the recurrence of periodic water shortages, LADWP customers have demonstrated the necessary concern and responsiveness. When faced with significant supply shortages, City residents have responded with unprecedented reductions in their water use. Los Angeles was one of the cities in southern California to invoke mandatory water rationing during the 1976 through 1977 drought. While severe, the two-year drought resulted in only a temporary reduction in water use, as a subsequent series of wet years erased memories of the water shortage experienced during the brief drought period. However, it was the drought that followed the 1978 through 1986 wet cycle that would prove to be the turning point in Los Angeles' water use awareness.

The drought of 1987-1992 left a permanent imprint on Los Angeles water customers. In response to this drought, LADWP expanded a voluntary water conservation program in 1990. Prompted by an extensive public awareness program and education campaign, LADWP customers responded not only with water saving practices but also by installing conservation measures in their homes and businesses. Devices such as low-flow showerheads and ultra-low-flush (ULF) toilets replaced existing non-water saving devices. These hardware changes, coupled with more responsible use habits, have significantly reduced the amount of imported water that the City would have to otherwise buy as the City's population and commerce has

AR0070820

continued to grow. In response to the current water shortage conditions the City has reinitiated its extensive public awareness campaigns in addition to campaigns launched by MWD to encourage water saving practices and installation of conservation devices in homes and businesses.

With the recent water supply shortage and reduced deliveries of imported water from MWD, residential customers have repeated conservation levels exceeding 20 percent in the period between 2007 and 2010 as a result of mandatory conservation. During the current water supply shortage, the City has updated its Emergency Water Conservation Plan Ordinance with enforceable water waste provisions and implemented mandatory outdoor watering restrictions. In addition, the City has implemented water shortage year rates reducing Tier 1 water allotments for customers by 15%. Since July 2007, 63 billion gallons of water were saved through conservation. As a direct result of conservation, imported water purchases from MWD are 23% below baseline allocations for fiscal year 2009/2010. In response to recently enacted State laws, LADWP has developed new water conservation goals which aim to reach approximately 64,000 AFY in hardware conservation savings by 2035.

Conservation has had a tremendous impact on Los Angeles' water use patterns and has become a permanent element of LADWP's water management philosophy. Water usage in the City in 2010 was less than it was in 1979 despite an increase in population of over 1,000,000 people (see Exhibit 3A). Exhibit 3B shows historical conservation savings from fiscal year 1990/1991 through 2009/2010 based on installation of distributed conservation devices and rebates/incentives claimed as well as conservation achieved through customers' behavior and lifestyle changes to use water more responsibly. Cumulative yearly savings for the period total 223,593 AFY.

2002/2003	2,507	79,321	10,405	89,726
2003/2004	3,047	82,368	14,999	97,366
2004/2005	3,124	85,492	48,932	134,423
2005/2006	3,030	88,522	63,664	152,186
2006/2007	2,197	90,719	77,982	168,701
2007/2008	782	91,501	65,587	157,088
2008/2009	3,127	94,628	106,307	200,935
2009/2010	4,269	98,897	124,696	223,593

1. Negative non-hardware savings are due to overestimation in hardware savings due to years with extreme wet weather conditions.

Conservation benefits the City by improving water supply reliability and reducing embedded energy use for water treatment and pumping. Conserving customers see a tangible benefit as well through monetary savings on their water bill. Another ancillary benefit of conserving water is that the need for costly sewer facility expansions is deferred by reducing wastewater discharge into the sewer collection and treatment systems, thus increasing the lifespan of current sewer infrastructure. Water conservation also has the added benefits of reducing greenhouse gas emissions and energy use associated with delivering water supplies to and within the LADWP service area. In the end, the primary beneficiaries of conservation are the water customers and the environment from where the sources of supply originates. Furthermore, increased conservation will result in decreased dry weather runoff which will decrease the amount of pollutants flowing into the rivers and oceans.

Los Angeles has been implementing permanent conservation since the 1980's. In 1988, the City adopted a plumbing retrofit ordinance to mandate the installation of conservation devices in all properties and to require water-efficient landscaping in new construction. The ordinance was amended in 1998, requiring the installation of ULF toilets and water saving showerheads in single-family and multi-family residences prior to resale. A new ordinance adopted in 2009, the Water Efficiency Requirements ordinance, establishes water efficiency requirements for new developments and renovations of existing buildings by requiring

AR0070822

installation of high efficiency plumbing fixtures in all residential and commercial buildings. LADWP's past water conservation programs have assisted customers affected by the ordinances by offering free ULF toilets and showerheads, free installation of ULF toilets, showerheads and faucet aerators, as well as rebates for ULF toilets purchased and installed. Current water conservation programs co-sponsored by MWD through the SoCal Water$mart Program for residential customers and the Save Water Save a Buck Program for CII customers continue to assist customers in complying with ordinances and reducing overall water demands.

3.1 Water Conservation Goals

Water conservation reduces demand that typically rises over time with growth in population and commerce. By mitigating those increases in demand, water supply reliability is improved while costs are reduced. In the early 1990s, City residents responded with conservation levels exceeding 20 percent due to increasingly drier conditions and mandatory conservation. As normal water supply conditions returned and with continuation of LADWP's conservation program, conservation levels stabilized at approximately 15 percent. With the recent drought and reduced deliveries of imported water from MWD, residential customers have repeated conservation levels exceeding 20 percent in the period between 2007 and 2010 as a result of mandatory conservation. Since July 2007, 63 billion gallons of water were saved through conservation. As a direct result of conservation, imported water purchases from MWD are 23% below baseline allocations for fiscal year 2009/2010. In response to the goals provided in the Plan and recently enacted State laws, LADWP has developed water conservation goals.

3.1.1 Water Supply Action Plan Conservation Goal

To continue increased conservation levels once mandatory outdoor watering restrictions are lifted, LADWP has set a water conservation goal in the Water Supply Action Plan of reducing potable water demands by an additional 50,000 AFY by 2030. This conservation level will further lessen the City's reliance on imported water while providing a drought-proof resource that is not subject to weather conditions. This aggressive approach includes multiple strategies: investments in state-of-the-art technology; a combination of rebates and incentives promoting installation of weather-based irrigation controllers (WBICs), efficient clothes washers and urinals; expansion and enforcement of prohibited water use; reductions in outdoor water use; extending education and outreach efforts; and encouraging regional conservation.

LADWP's commitment to conservation is a proven multi-faceted approach that includes tiered water pricing, education and awareness, financial incentives for the installation of a variety of conservation measures, free water saving showerheads, Technical Assistance Program (TAP) incentives for business and industry, and large landscape irrigation efficiency programs. Conservation is a key component of LADWP's water resource planning efforts and will continue to be implemented over the long term.

3.1.2 Water Conservation Act of 2009

The Water Conservation Act of 2009, Senate Billx7-7, requires water agencies to reduce per capita water use by 20% by 2020 (20x2020). This includes increasing recycled water use to offset potable water use. Water suppliers are required to set a water use target for 2020 and an interim target for 2015 using one of four methods. The 2020 urban water use target may be updated in a supplier's 2015 UWMP. Failure to meet adopted targets will result in the ineligibility of a water supplier to receive water grants or loans administered by the State unless one of two exceptions is met. Exception one states a water supplier may be eligible if they have submitted a schedule, financing plan, and budget to DWR for approval to achieve the per capita water use reductions. Exception two states a water supplier may be eligible if an entire water service area qualifies as a disadvantaged community.

DRAFT

AR0070823

Four methodologies are stipulated for calculating the water use target. Three of the methods are listed in Water Code § 10608.20(a)(1). The fourth method was developed by DWR. The four methodologies are:

- Method 1 - Eighty percent of the water supplier's baseline per capita water use
- Method 2 – Per capita daily water use estimated using the sum of performance standards applied to indoor residential use; landscape area water use, and commercial, industrial, and institutional uses
- Method 3 – Ninety-five percent of the applicable state hydrologic region target as stated in the state's *draft 20x2020 Water Conservation Plan.*
- Method 4 – Description to be added at end of 2010 once developed by DWR

In 2015, urban retail water suppliers will be required to report interim compliance followed by actual compliance in 2020. Interim compliance is halfway between the baseline water use and 2020 target. Baseline, target, and compliance-year water use estimates are required to be reported in gallons per capita per day (gpcd).

For consistent application of the Act, DWR produced *Methodologies for Calculating Baseline and Compliance Urban Water Per Capita Use* in October 2010. Following requirements provided in the document, LADWP has calculated baseline per capita water use, an urban use target for 2020, and an interim water use target for 2015. Reporting compliance daily per capita water use is not required until the 2015 UWMP cycle as it compares the interim target to actual water use in 2015. Exhibit 3C presents results of the calculations. Calculations and technical bases for the calculations are presented in Appendix X.

Baseline per capita water use is 154 gpcd using a ten-year average ending between December 31, 2004 and December 31, 2009 and 146 gpcd using a five-year average ending between December 31, 2007 and December 31, 2009.

LADWP has adopted Method 3 to set its 2015 interim and 2020 water use targets. Method 3 requires setting the 2020 water use target to 95% of the applicable State hydrologic region target as provided in the *State's Draft 20x2020 Water Conservation Plan.* LADWP is within State hydrologic region 4, the South Coast region. LADWP was required to further adjust the calculated 2020 target to achieve a minimum reduction in water use. The gpcd at 95% of the hydrologic region was 142 gpcd and using 95% of the five-year average base daily per capita water use was equal to 138 gpcd. Therefore, LADWP was required to set the 2020 target at the smaller of the two resultant values. LADWP's interim 2015 target is 146 gpcd and the 2020 target is 138 gpcd.

DRAFT

AR0070824

Exhibit 3C
20x2020 Base and Target Data

20x2020 Required Data	Gallons Per Capita Per Day (GPCD)
Base Per Capita Daily Water Use	
10-Year Average[1]	154
5-Year Average[2]	146
2020 Target Using Method 3[3]	
95% of Hydrologic Region Target (149 gpcd)	142
95% OF Base Daily Capita Water Use 5-Year Average (146 gpcd)	138
Actual 2020 Target	**138**
2015 Interim Target	146

1. Ten-year average based on calendar year ending between 12/31/04 and 12/31/10.

2. Five-year average based on calendar year ending between 12/31/07 and 12/31/10.

3. Methodology requires smaller of two results to be actual water use target to satisfy minimum water use target.

3.2 Existing Programs, Practices, and Technology to Achieve Water Conservation

LADWP has developed aggressive water conservation programs to address recently enacted State laws and to meet its goal of achieving an additional 50,000 AFY conservation by 2030. LADWP uses multiple programs, practices, and technologies in conjunction with enactment of ordinances to achieve its current water conservation levels throughout its service area and customer classes.

3.2.1 State Laws and City Ordinances

State Laws

In addition to the Water Conservation Act of 2009 multiple legislative bills have been enacted in the past few years requiring water agencies to enact measures to increase water conservation, establishing new plumbing standards, and linking grants and loans to implementation of best management practices (BMPs).

The Water Conservation in Landscaping Act of 2006, Assembly Bill 1881, reduces outdoor water waste through improvements in irrigation efficiency and selection of plants requiring less water. The Act required an update to the existing Model Water Efficient Landscape Ordinance and adoption by location agencies or an equivalent ordinance no later than January 1, 2010. If any agency failed to adopt the ordinance or its equivalent then the ordinance was automatically adopted by statute. The ordinance requires development of water budgets for landscaping, reduces erosion and irrigation related runoff, utilization of recycled water if available, irrigation audits, requirements for landscape and irrigation design, and scheduling of irrigation based on localized climate for new construction and redevelopment projects.

In 2009, Assembly Bill 1465, Urban Water Management Planning, was approved to include language in the UWMP Act that deem water suppliers that are members of the California Urban Water Conservation Council (CUWCC) and comply with the "Memorandum of Understanding Regarding Urban Water Conservation in California," dated December 10, 2008, as it may be

AR0070825

amended, to be in compliance with the requirement to describe the supplier's water demand management measures in its urban water management plan. A more detailed discussion of the CUWCC and BMP compliance is provided in Section 3.2.3.

Assembly Bill 1420 links state funding for water management by urban water suppliers to implementation of water conservation measures. Urban water suppliers are required to be in compliance with the CUWCC MOU to be eligible for water management grants or loans. Senate Bill X7-7 further clarifies the grant funding conditions required by AB 1420 are repealed on July 1, 2016 and replaced with eligibility determined by compliance with 20x2020 targets.

In the recent years there has been a lot of regulations approved increasing the water use efficiency requirements of plumbing devices, specifically, Assembly Bill 715 (2007), Senate Bill 407 (2009), and the CALGreen Building Standards. AB 716 requires that all toilet and urinal fixtures sold through retail or installed in existing and new residential and commercial building meet the high efficiency standards by January 1, 2014. SB 407 does not address the sale of plumbing fixtures but adds a requirement that beginning in January 1, 2017 all residential and commercial property sales must disclose all non-efficient plumbing fixtures. CALGreen has an effective date of January 1, 2011 and requires use of water efficient plumbing fixtures for all new construction and renovations of residential and commercial properties.

City Ordinances

Los Angeles has utilized ordinances as a tool to reduce water waste since 1988, beginning with the adoption of its first version of a plumbing retrofit ordinance. The ordinance mandated installation of conservation devices in all existing residential and commercial properties and installation of water-efficient landscaping in all new construction. Toilets were required to use less than 3.5 gallons per flush (gpf), urinals less than 1.5 gpf, and showerheads less than 2.5 gallons per minute (gpm). Customers with three acres or more of turf were required to reduce water consumption by 10 percent from 1986 levels or face a 100 percent surcharge on their water bills.

In 1998 the ordinance was amended, requiring the installation of ULF toilets and water saving showerheads in single-family and multi-family residences prior to the close of escrow. This progressive requirement is implemented with the help of local real estate professionals. LADWP has explored the expansion of the City's Retrofit on Resale Ordinance to include nonresidential properties

Los Angeles further increased its water efficiency mandates in 2009 with adoption of the Water Efficiency Requirements ordinance. This ordinance establishes water efficiency requirements for new developments and renovations of existing buildings by requiring installation of high efficiency plumbing fixtures in all residential and commercial buildings. Exhibit 3D summarizes the minimum requirements for new construction and replacement of fixtures in existing buildings.

DRAFT

AR0070826

Exhibit 3D
Water Efficiency Requirements Ordinance Summary

Device	Requirement
High Efficiency Toilets	1.28 gallons per flush
Urinals	0.125 gallons per flush
Faucets	
Indoor Faucets (Maximum)	2.2 gallons per minute
Private Lavatory Faucets	1.5 gallons per minute
Public Use Lavatory Faucets[1]	0.5 gallons per minute
Showerheads	2 gallons per minute
Dishwashers	
Commercial Dishwashers	varies by type between 0.62 and 1.16 maximum gallons per rack
Domestic Dishwashers	5.8 gallons per cycle
Cooling Towers	5.5 cycles of concentration
Single-Pass Cooling Systems	Prohibited[2]

1. Metering faucets shall not deliver more than 0.25 gallons per cycle.

2. Single pass cooling systems are prohibited unless installed for health and safety purposes that cannot otherwise safely operate.

In an effort to lead by example, LADWP has been retrofitting all its facilities with high efficiency plumbing fixtures since before the effective dates of the ordinance. As of early June 2010, LADWP is 57 percent complete in upgrading its 600 buildings to high efficiency faucets, toilets, urinals, showers, flexible hose connectors, angle valves, as well as correcting leaks and removing existing water damage.

In May 1996, the City's Landscape Ordinance (No. 170,978) became effective with an overarching goal to improve the efficient use of outdoor water. This ordinance was recently amended in 2009 to comply with the previously discussed Water Conservation in Landscaping Act of 2006 and the Model Water Efficient Landscape Ordinance.

LADWP first adopted an Emergency Water Conservation Plan ordinance in the early 1990's in response to drought conditions. Subsequently in the current water shortage LADWP has adopted two amendments expanding prohibited uses, increasing penalties for violating the ordinance, and modifying water conservation requirements. Five phases of water conservation are incorporated into the plan with prohibitions and water conservation measures steadily increasing by phase. Regardless of water supply availability, at a minimum Phase I conservation requirements are in effect unless a more stringent phase is in effect. In response to the ongoing drought conditions, LADWP implemented Phase III restrictions on June 1, 2009, allowing outdoor irrigation only two days per week. Upon the recent ordinance amendment, Phase II implementation began on August 25, 2010 which allows outdoor watering three days per week. Exhibit 3E summarizes the five phases as defined in the latest amendment approved in August 2010.

AR0070827

Exhibit 3E
Emergency Water Conservation Plan Ordinance Restrictions by Phase

Phase	Restrictions
I	No use of a water hose to wash paved surfaces
	No use of water to clean, fill, or maintain levels in decorative fountains, ponds, lakes or similar structures used for aesthetic purposes unless a recirculating system is used
	No drinking water shall be served unless expressly requested in restaurants, hotels, cafes, cafeterias, or other public places where food is sold, served, or offered for sale
	No leaks from any pipes or fixtures on a customer's premises; failure or refusal to fix leak in a timely manner shall subject the customer penalties for a prohibited use of water
	No washing vehicles with a hose if the hose does not have a self-closing water shut-off device attached or the hose is allowed to run continuously while washing a vehicle
	No irrigation during rain
	No irrigation between 9am and 4pm, except for public and private golf courses and professional sports fields to maintain play areas and event schedules. System testing and repair is allowed if signage is displayed.
	All irrigation of landscape with potable water using spray head and bubblers shall be limited to no more than ten minutes per water day per station. All irrigation of landscape with potable water using standard rotors and multi-stream rotary heads shall be limited to no more than 15 minutes per cycle and up to 2 cycles per water day per station. Exempt from these restrictions are irrigation systems using very low-flow drip-type irrigation when no emitter produces more than 4 gallons of water per hour and micro-sprinklers using less than 14 gallons per hour. This restriction does not apply to Schedule F water customers or water service that has been granted the General Provision M rate adjustment under the City's Water Rate Ordinance, subject to the customer having complied with best management practices for irrigation approved by LADWP.
	No watering or irrigation of any lawn, landscape, or other vegetated area shall occur in a manner that causes or allows excess or continuous water flow or runoff onto an adjoining sidewalk, driveway, street, gutter, or ditch
	No installation of single-pass cooling systems shall be permitted in buildings requesting new water service.
	No installation of non-recirculating systems shall be permitted in new conveyor car wash and new commercial laundry systems.
	Operators of hotels and motels shall provide guests with the option of choosing not to have towels and linens laundered daily.
	No large landscape areas shall have irrigation systems without rain sensors that shut off the irrigation systems.
II	All prohibited uses in Phase 1 shall apply, except as provided.
	No landscape irrigation shall be permitted on any day other than Monday, Wednesday, or Friday for odd-numbered street address and Tuesday, Thursday, or Sunday for even-numbered street addresses. If a street address ends in 1/2 or any fraction it shall conform to the permitted uses for the last whole number in the address. For non-conserving nozzles (spray head sprinklers and bubblers) watering times shall be limited to no more than 8 minutes per watering day per station for a total of 24 minutes per week. For conserving nozzles (standard rotors and multi-stream rotary heads watering times shall be limited to no more than 15 minutes per cycle and up to two cycles per watering day per station for a total of 90 minutes per week.
	Irrigation of sports fields may deviate from non-watering days to maintain play areas and accommodate event schedules with written notice from LADWP. However, a customer must reduce overall monthly water use by LADWP's Board of Water and Power Commissioners adopted degree of shortage plus an additional 5% from the customer baseline water usage within 30 days.

DRAFT

	If written notice is received from LADWP, large landscape areas may deviate from the non-watering days if the following requirements are met: 1) approved weather-based irrigation controllers registered with LADWP 2) Must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus and additional 5% from the customer baseline within 30 days 3) Must use recycled water if available
	These restrictions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase II, except between the hours of 9am and 4pm.
III	All prohibited uses in Phases I and II shall apply, except as provided.
	No landscape irrigation shall be permitted on any day other than Monday for odd-numbered street address and Tuesday for even-numbered street addresses. If a street address ends in 1/2 or any fraction it shall conform to the permitted use for the last whole number in the address.
	No washing of vehicles allowed except at commercial car washes.
	No filling of residential swimming pools and spas with potable water.
	Irrigation of sports fields may deviate from non-watering days and be granted one additional watering days for a total of two watering days with written notice from LADWP. However, a customer reduce overall monthly water use by LADWP's Board of Water and Power Commissioners adopted degree of shortage plus an additional 10% from the customer baseline water usage within 30 days.
	If written notice is received from LADWP, large landscape areas may deviate from the non-watering days and be granted one extra day of watering for a total of 2 watering days if the following requirements are met: 1) approved weather-based irrigation controllers registered with LADWP 2) Must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus and additional 10% from the customer baseline within 30 days 3) Must use recycled water if available
	These restrictions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase III, except between the hours of 9am and 4pm.
IV	All prohibited uses in Phases I, II, and III shall apply, except as provided.
	No landscape irrigation is allowed.
V	All prohibited uses in Phases I, II, III, and IV shall apply, except as provided.
	The LADWP Board of Water and Power Commissioners is authorized to implement additional water prohibitions based on the water supply situation.

Specific procedures for determining the initiation of a phase and termination of a phase are provided in the Emergency Water Conservation Plan Ordinance. Phases are initiated through recommendations provided by LADWP to the Mayor and City Council (Council).

3.2.2 Conservation Pricing

In 1993, Los Angeles restructured its water rates to provide customers with a clear financial signal to use water more efficiently. It was the first time in LADWP's history that an ascending tiered rate structure was used. This conservation-based rate structure remains in use and applies a lower first tier rate for water used within a specified allotment, and a higher second tier rate for every billing unit (748 gallons) that exceeds the first tier allotment. A unique feature of the rate structure is that the first tier allotment considers factors that influence individual residential customer's water use patterns (i.e. lot size, climate zone, and family size).

The goals of LADWP's two-tiered water rate structure are to:

- Use price as a signal to encourage the efficient use of water

AR0070829

- Provide basic water needs at an affordable price
- Provide equity among customers
- Use price to stabilize water use during a shortage
- Generate adequate revenue for maintaining and upgrading the water system

In a period where increasing demands and reductions in water supply are becoming more commonplace, a rate structure that provides appropriate signals to encourage efficient water use has become a necessity for many areas, including Los Angeles.

The substantial investments required for water quality improvements, security, and supply development have significantly raised the cost of delivering water. As rates increase, water agencies have noticed a change in use patterns. Because there is a known correlation between price and use, agencies use rates to encourage conservation activities and to postpone the need to construct new facilities or purchase even larger quantities of imported water.

LADWP's tiered rate structure, first implemented in 1993 with assistance from a broad-based group of stakeholders, applies a lower tier block rate for responsible water use within a specified amount of water, and a much higher rate for every billing unit above this block. The higher block rate reflects the "marginal cost," or the projected cost for additional water that would be required to meet these needs.

To further emphasize the conservation message, water charges are based solely on water used. This eliminates the inclusion of fixed charges. There are automatic adjustments triggered when a water shortage exists. In June 2009 shortage year rates went into effect reducing first tier allotments for all customers by 15%. These adjustments are based on the actual water use patterns that occurred during the 1991 period of mandatory water rationing. The purpose of these adjustments is to use price to encourage additional conservation and to provide LADWP with the revenue necessary to operate the system efficiently during a shortage.

3.2.3 CUWCC Best Management Practices

The CUWCC is the voice of urban water conservation in California, and LADWP has been active in the CUWCC since its inception in 1991. Instrumental in the development of the MOU, LADWP was also one of the original signatories. The MOU identifies BMPs as proven conservation measures as determined by the CUWCC. The most recent amendment to the MOU was adopted on June 9, 2010 updating compliance alternatives with the adopted BMPs. A water agency can now comply with the MOU through one of three methodologies: BMP compliance, accomplishing water conservation through a set of measures equal or greater than the water savings provided by the BMPs (Flex Track Menu), or accomplishing water conservation goals as measured in gpcd. All Group One (water suppliers) signatories to the MOU are committed to implement the BMPs.

Over the last 19 years, LADWP has played a significant role in the governance and policy making at the CUWCC, holding a seat on the Board of Directors, Strategic Planning Committee, By-Laws Committee, Research and Evaluation Committee, CII Committee, co-chair of the Membership Committee, and chair of the Group 1 Representation Selection Committee. LADWP also has been actively involved in all of the revisions that the MOU has undergone to date.

AR0070830

One of the obligations as a signatory to the MOU is to submit a Best Management Practices Retail Water Agency Report to the CUWCC. Previously submitted annually, this report is now submitted biennially and details progress in implementing the foundational and programmatic BMPs as currently specified in the MOU. LADWP actively implements the BMPs and the CUWCC BMP reports are available for review through the internet by accessing CUWCC's website at www.cuwcc.org.

In the early 1990s, the State Water Resources Control Board identified urban water conservation as a major means for resolving problems in the Bay-Delta. Large water agencies, including LADWP, actively participated in work groups to develop conservation strategies. The result of this effort is in the aforementioned MOU.

The MOU commits signatory water suppliers to develop comprehensive conservation programs using sound economic criteria and to consider water conservation on an equal footing with other water management options. The MOU established the CUWCC to monitor implementation of the BMPs and to maintain the list of BMPs.

A BMP is defined as:

(a) An established and generally accepted practice among water suppliers resulting in more efficient use or conservation of water.

(b) A practice for which sufficient data are available from existing water conservation projects to indicate that significant conservation or conservation-related benefits can be achieved; that the practice is technically and economically reasonable and not environmentally or socially unacceptable; and that the practice is not otherwise unreasonable for most water suppliers to carry out.

LADWP implements all of the BMP requirements in the MOU except for wholesale agency assistance programs, which applies only to wholesale water agencies. Foundational BMPs are considered as essential BMPs for any water utility and are ongoing practices not subject to time limitations. Programmatic BMPs are minimal activities required to be completed by each utility within the timeframe of the implementation schedules provide in the MOU. A listing of the BMPs is shown in Exhibit 3F.

DRAFT

AR0070831

Exhibit 3F
CUWCC BMPs and Implementation Status

Category	Sub-category	Practices	Status
		Foundational	
Utility Operations	Operations Practices	Maintain the position of a trained conservation coordinator	Implemented
		Prevent water waste – enact, enforce or support legislation, regulations, and ordinances	Implemented
		Wholesale agency assistance programs	Not applicable
	Water Loss Control	Conduct Standard Water Audit and Water Balance	Implemented
		Measure performance using AWWA software	Implemented
		Locate and Repair all leaks and breaks	Implemented
	Metering with Commodity Rates	100% of existing unmetered accounts to be metered and billed by volume of use	Implemented
	Conservation Pricing	Maintain a water conserving retail rate structure	Implemented
Education	Public Information Programs	Maintain active public information program to promote and educate customers about water conservation	Implemented
	School Education Programs	Maintain active program to educate students about water conservation and efficient water use	Implemented
		Programmatic	
Residential		Residential Assistance – provide leak detection assistance	Implemented
		Landscape Water Surveys for single family residential accounts	Implemented
		High efficiency clothes washer incentive program	Implemented
		WaterSense Specification (WSS) for toilets	Implemented
Commercial/ Industrial/ Institutional (CII)		Implement unique conservation programs to meet annual water savings goals for CII customers	Implemented
Landscape		Implement Large Landscape custom programs	Implemented
		Offer technical assistance and surveys upon request	Implemented
		Implement and maintain incentive program(s) for irrigation equipment retrofits	Implemented

3.2.3 LADWP Conservation Programs

LADWP develops cost effective programs to achieve multiple goals of cost-effective demand reduction, customer service, environmental responsibility, and compliance with CUWCC BMPs. Conservation potential is considered in determining program approach and duration. Some types of conservation programs result in savings that are more easily measured than others. LADWP's programs include traditional demand-side management measures, as well as infrastructure improvement programs that contribute to water waste reductions. Demand-side management programs, like the rebate programs for water-saving toilets and high-efficiency washing machines, produce results that are measurable. Public information, education, and other general conservation awareness programs are intended to alter customers' behavioral patterns on water use and thus, are more difficult to quantify. It is such behavioral change in water use, however, that the City can point to as the primary reason for significant reduction in water consumption during drought periods. Combined with LADWP's conservation pricing

AR0070832

structure discussed in Section 3.2.2, these programs increase system reliability and efficiency and will provide a secondary benefit of reducing runoff.

Specific conservation programs (past and present) associated with these categories are broken down in Exhibit 3G, and are fully discussed below. Appendix XX contains the latest biennial reports provided to the CUWCC.

Exhibit 3G
Current and Past Conservation Programs

CUWCC Category	Conservation Measures	pre 1985	Year in Service

Awareness/Support Measures

Awareness/support measures can be active or passive. Active components include full metering of water use, assessment of volumetric sewer charges, and a conservation rate structure. Passive components typically include providing educational materials for schools, community and customer presentations, maintaining a conservation hotline, and a wide range of information distributed through customer bills, advertising in public venues, LADWP's website, and direct mail. Passive awareness/support measures provide the foundation for the conservation movement to build upon by raising water use awareness, water conservation program visibility, and encouraging community involvement.

In 2008, LADWP entered into an MOU with the Los Angeles Unified School District to further improve our water conservation outreach program. In fiscal year 2009/2010 LADWP budgeted approximately $500,000 in funding for educational programs within area schools. Programs included:

AR0070834

- Los Angeles Times in Education – provided newspapers to 50,000 students in grades 4-12 and lesson packages for teachers on supply sources and conservation
- "Thirsty City" Live Performances – Play presented to more than 4,300 students introducing students to water supply sources, water supply challenges, and conservation
- Renewable Energy and Conservation Curriculum – 660 teachers were trained in an extensive model conservation program reaching approximately 50,000 6th grade students
- Renewable Energy and Conservation Center – Funding was provided for a science teacher position to set up and establish a Renewable Energy and Conservation Center with students to be bused to center for hands-on lessons focusing on conservation and renewable energy
- Outdoor Education Multi-Day Environmental Experiences – Approximately 700 students in 20 classes in grades 4-12 attended two or three days of outdoor education experiences focusing on environmental measures, including lessons on energy and water
- Eastern Sierra Institute – Training of 25 teachers over three days about the environment and geology of the Eastern Sierra
- Teacher Fellowships – Ten math and science teachers from middle and high schools served in fellowships at LADWP for six weeks during the fall and summer of 2008 working in multiple offices with the intent of developing classroom lessons based on the experiences.
- Infrastructure Academy – 40 students from the Infrastructure Academy completed water conservation audits at 120 schools, including fixture counts, analysis of toilet makes and models, and analysis of irrigation controllers and field conditions

Included within the short-term strategies of the City of Los Angeles' Water Supply Action Plan is a strategy to increase water conservation in the City through an aggressive $2.3 million conservation education campaign. LADWP Public Affairs Office implemented a media campaign that included radio, TV, and newspaper advertisements, billboards, outreach to Neighborhood Councils; and marketing of City rebates for water-efficiency.

Another aspect of awareness/support is that of advocacy. LADWP has been instrumental in the development of more stringent standards for toilets (e.g. Supplementary Purchase Specification for ULF toilets) that are in use within the City as well as by other water agencies in California and other areas. LADWP also assisted in the adoption of higher residential clothes washer efficiency standards by the California Energy Commission. Recognizing the importance of this activity, LADWP actively participates in advocating local and statewide conservation research and planning.

Residential Category

Multiple residential conservation programs were first developed and launched by LADWP during the drought of 1987 through 1992. In 1990, the ULF Toilet Rebate Program was initiated, followed two years later by the ULF Toilet Distribution Program. In 2003, a well-received free installation service component was added to the ULF Toilet Distribution Program that included

AR0070835

free water-saving showerheads, faucet aerators and replacement toilet flapper valves. Today distribution of free faucet aerators and showerheads continues for all single-family, multi-family, and commercial customers.

In 2008 MWD initiated the region-wide SoCal Water$mart Program for residential water conservation replacing previous LADWP rebate programs and rebate programs offered by individual water service providers throughout the MWD service area. This program sponsored by MWD sets uniform rebate requirements across the MWD service area and provides a clearinghouse for processing rebates for all MWD member agency customers. Local agencies have the option of supplementing baseline rebate amounts to their customers through the program. LADWP has increased baseline rebates for several of the qualifying products. Eligible customers include residential customers residing in single-family and multi-family homes, even if multi-family residents do not receive a water bill.

Although the SoCal Water$mart Program has discontinued rebates for high efficiency toilets (HET), LADWP continues to provide local funding for rebates for its customers of $100 per HET which has proven to be highly successful with over 1900 units installed in fiscal year 09/10 which equates to over 80 AFY savings.

Prior to the SoCal Water$mart Program, LADWP was assisted by community-based organizations (CBOs) to reach the milestone of more than 1.27 million toilets installed through December 31, 2006. CBOs were integral to LADWP's success, reaching into the communities they serve to convey the conservation message and directly undertake conservation activities. Benefits of this approach accrued to community participants through reduced water bills, to the CBOs through employment opportunities and revenues earned, and to the City through significant water savings achieved. Prior to its discontinuation, the program was funded at more than $7 million annually. The toilets replaced through the program continue to produce estimated water savings of more than 20,600 AFY today.

LADWP initiated a High Efficiency Washer Rebate Program in 1998 promoting the purchase and installation of high efficiency washing machines saving both water and energy. As of January 2009, rebates have been paid for more than 66,100 machines purchased and installed throughout the City. The program's minimum efficiency requirements for rebate eligibility were increased in January 1, 2004, resulting in the promotion of higher efficiency models. Initial co-funding of the program was provided by the City's Department of Public Works Bureau of Sanitation, and by the Southern California Gas Company.

In February of 2009 the High Efficiency Washer Rebate Program transferred from LADWP to the SoCal Water$mart Program with co-funding provided by MWD. Since the inception of the SoCal Water$mart Program and through June 2010, over 11,800 rebates for washing machines were issued to LADWP customers with a total annual savings of 368 AFY. Generally rebates are $300 per washing machine with a water factor (a measure of efficiency) of 4.0 or less. As of April 22, 2010 an additional $100 rebate was available for a limited time through the California Cash for Appliances program for a total rebate of $400 per washing machine.

A sprinklerhead rotating nozzle retrofit rebate of $8 per nozzle is available through the SoCal Water$mart Program for a minimum of 25 nozzles. Replacing standard sprinkler heads with rotating nozzles can use up to 20% less water. Rotating nozzles are able to distribute water in a water-efficient manner more uniformly across a landscape than standard sprinklers. Spray from rotating nozzles is less likely to result in misting conditions, misdirection from winds, and reduces runoff onto pervious surfaces thus reducing dry-weather runoff. Between March 2009 and June 2010 2,878 rotating nozzle rebates were issued to LADWP customers saving approximately 12.7 AFY.

AR0070836

Rebates for installation of weather-based irrigation controllers are also available through the SoCal Water $mart Program. Rebates amounts are $200 per controller for landscape areas of less than one acre and $25 per station for landscape areas greater than one acre. Weather-based irrigation controllers provide customized irrigation schedules based on local site conditions and in response to weather changes. These smart controllers receive weather updates to automatically adjust the schedule and amount of water applied. Between March 2009 and June 2010 81 LADWP customers received rebates for installation of the controllers saving approximately 6.2 AFY.

Initially a synthetic turf rebate program was offered through the SoCal Water$mart Program, but has been discontinued as of June 1, 2010. The program provided rebates of $1.00 per square foot. Approximately 316,547 square feet of synthetic turf was installed by LADWP customers between February 2009 and June 2010 saving approximately 44.3 AFY.

LADWP through the SoCal Water$mart program is offering turf removal rebates of $1 per square foot up to $2,000 per residence. Not all MWD member agencies are participating in the turf removal program and participating agencies have additional requirements beyond MWD's requirements. Areas targeted for turf removal must currently be turf irrigated with potable water for a minimum of one year. All replacement materials must be permeable and either hand watered or irrigated with drip irrigation. A minimum of 250 square feet must be converted to be eligible for a rebate. No invasive plants are permitted and all exposed soil must be covered with mulch. Synthetic turf is an acceptable replacement if it is not used in right of ways or parkways. Applicants are required to maintain the converted area for ten years. The program commenced in December 2009, and as of fiscal year 09/10, over 280,000 square feet of turf area has been converted saving over 39 AFY. In conjunction with the turf removal program, LADWP is conducting a drip system pilot program and is offering free residential drip starter kits.

Water-saving showerheads and faucet aerators remain available to LADWP customers, free of charge, upon request. Approximately 12,124 showerheads and 14,792 faucet aerators were distributed between July 2007 and June 2010 saving approximately 241 AFY. During past droughts, more than 1.5 million water conservation retrofit kits were distributed throughout Los Angeles; the kits included one-gallon toilet displacement bags, low-flow showerheads, and toilet leak detection tablets.

As part of past programs promoting residential water conservation measures, students conducted home water surveys through a resource efficiency education program implemented by LADWP in Los Angeles area high schools. Additionally, local community based organizations visited many Los Angeles residences throughout the year, assessing water conservation opportunities in the home and installing applicable measures to immediately capture water savings.

Another element of LADWP's past efforts was a toilet flapper valve replacement pilot program. Although long-term water savings from ULF toilets are predicated on timely replacement of leaking toilet flapper valves with appropriate replacement units, findings from the pilot program indicate a small incidence of leaking flapper valves in toilets rebated or distributed by LADWP. However, toilet leak testing and flapper valve replacement was added to the past ULF Toilet Distribution Program's installation service component for toilets not replaced through the program.

Commercial/Industrial/Institutional Category

This category represents some of the largest volume water users in LADWP's customer base, and represents a great deal of conservation potential. LADWP, in partnership with MWD, developed and has implemented a commercial rebate program, Save Water Save a Buck Program, designed specifically for customers in the CII sector and multi-family residences with five

AR0070837

or more units represented by a homeowners association. In the CII sector, the program provides rebates for water saving plumbing fixtures, food service equipment, and landscaping equipment. Within the multi-family sector the program provides rebates for high efficiency washers, high efficiency toilets, and landscape equipment. In addition, packaged water use efficiency solutions are being developed for specific business sectors. Efforts are also underway to better promote the financial incentives available that make water conservation retrofits more cost effective for business and industry. LADWP takes full advantage of regional programs offered through MWD for the CII sector and for many product rebates, provides supplemental funding to boost the base rebate provided by MWD.

The Save Water Save a Buck Program was launched in 2001 to provide menu-based rebates for water conserving measures applicable to many types of CII facilities. Categories of products eligible for rebates, rebate amounts, number of rebates for the LADWP service area, and estimated savings are provided in Exhibit 3H for the period July 2007 through June 2010. During the period, an estimated annual savings of 6,585 AFY, inclusive of LADWP inhouse programs and the Technical Assistance Program (TAP). The program design provides for ease of participation and has been well-received by LADWP customers. The program has been so successful that the SoCal Water$mart Program for residential customers was modeled after it.

AR0070838

Exhibit 3H
CII Conservation Programs and Savings July 2007 through June 2010

Device Type	Rebate Amount Retrofit	Devices Installed	Estimated Annual Savings (AFY)
Save Water Save a Buck Program			
Current Programs			
High Efficiency Toilets (1.28 gpf or less)	$150 each ($50 new construction)	58,432	2,408.6
Zero and Ultra Low Water Urinals	$500 each ($250 new construction)	6,063	630.9
Cooling Tower pH Conductivity Controller	$3000 each	41	79.7
Cooling Tower Conductivity Controller	$625 each	57	36.7
Air Cooled Ice Machine	$300 each	0	0.0
Connectionless Food Steamer	$600 compartment	23	5.8
Dry Vacuum Pump (maximum 2.0 horsepower)	$125 per 0.5 horsepower	8	0.7
Water Broom	$150 each	73	11.2
Weather Based Irrigation Controller	$50 per station	391	127.1
Central Computer Irrigation Controller	$50 per station	0	0.0
Rotating Nozzles for Pop-up Spray Heads (25 minimum)	$8 each	22,534	99.1
High Efficiency Spray Nozzles for Large Rotary Sprinklers	$13 per head	8,558	308.1
Past Programs			
High Efficiency Coin Clothes Washer	-	1,738	186.8
Pre-Rinse Sprayhead	-	5	0.8
Steam Sterilizer Retrofit	-	6	7.8
X-Ray Processor Recirculation System	-	1	3.2
Synthetic Turf (square feet)[1]	-	15,177	2.1
Subtotal Save a Buck Program	-		**3,908.7**
LADWP Inhouse Programs			
Commercial Showerheads	-	5,180	85.3
Commercial Faucet Aerators	-	20,844	96.5
Water Brooms	-	262	40.2
CII Landscape Program Turf Removal[2]	-	1,251,043	95.6
Technical Assistance Program[3]	-	-	2358.4
Subtotal LADPW Inhouse	-		**2676.0**
Total CII	-		**6584.8**

1. Synthetic Turf rebates as of June 1, 2010 are available through LADWPs Technical Assistance Program.

2. Rebate amount varies and is determined during pre-approval process.

3. Rebates for Technical Assistance Program are $1.75 per 1,000 gallons saved over a two year period with a cap not to exceed the actual cost of the project. Devices installed vary per project.

DRAFT

AR0070839

LADWP created the Technical Assistance Program (TAP) in 1992 to provide custom-type incentives for retrofitting water-intensive equipment. Different from the Save Water Save a Buck Program, the TAP encourages site-specific projects and TAP incentives are based on a given project's water savings. Financial incentives up to $250,000 are available for products demonstrating water savings. Incentives are calculated at the rate of $1.75 per 1,000 gallons saved over a two-year period with a cap not to exceed the actual cost of the installed product. Projects must save a minimum of 150,000 gallons over a two-year period and operate for a minimum of five years. Eligible customers are CII or multi-family residential customers. Past TAP projects include cooling tower controller upgrades and x-ray processor recirculation systems. The estimated unit cost for TAP overall is about $228 per acre-foot saved with an annual savings of 2,358.4 AFY based on projects installed between July 2007 and programs until June 2010.

Similar to the residential turf removal program, LADWP has a turf removal program for commercial properties. This program started in September 2009 and the rebate is $1.00 per square foot of turf with the total project rebate amount as defined in the pre-approval letter provided by LADWP. Areas targeted for conversion must have live healthy turf irrigated with potable water (recycled water is ineligible) via automatic sprinkler valves when a project approval letter is provided by LADWP. Converted areas must contain enough plants to create at least 30% landscape coverage at maturity. Converted areas may not contain turf or synthetic turf (synthetic turf rebates are available through the TAP). All replacement materials must be permeable and plants must be drought tolerant or California native plants. A minimum of 250 square feet must be converted to be eligible for a rebate. No invasive plants are permitted and all exposed soil must be covered with three inches of mulch. If an irrigation system is used it must be a low flow drip or bubbler system. Applicants are required to maintain the converted area for 15 years.

Water-saving showerheads and faucet aerators are available to LADWP commercial customers, free of charge, upon request. Bathroom faucet aerators are provided in 1.5, 1.0, or 0.5 gallons per minute (gpm), kitchen faucet aerators are provided in 1.5 gpm, and showerheads are provided in 2.0 gpm. Approximately 5,180 showerheads and 20,844 faucet aerators were distributed between July 2007 and June 2010 saving approximately 181.8 AFY combined. LADWP additionally offers an inhouse water broom program in addition to the rebates offered through the Save Water Save a Buck Program.

Landscape Category

Recognizing that a substantial amount of water is used outdoors for irrigation, LADWP continues to invest in landscape irrigation efficiency programs and projects. In addition to the previously discussed landscape ordinances (Section 3.21.), LADWP has sponsored free training courses specifically targeting the City's large turf customers to help these customers comply with the landscape ordinance. To further assist this group, LADWP developed a guidebook, "Improving Irrigation Performance" to demonstrate ways for enhancing existing irrigation systems.

LADWP has also sponsored conservation and garden expos to highlight various aspects of efficient outdoor water use and planting practices, and emphasizing native, drought-tolerant plants. Funding was provided for three demonstration gardens to showcase the use of drought-tolerant plants and flowers, including the landmark Lummis Home in Highland Park. Lawn watering guides were mailed to all single-family and duplex residences. Planting guides for native and drought-tolerant plants are also available upon request. Additionally, to demonstrate the beauty and appeal of a water-conserving landscape, LADWP's John Ferraro Building facility (below) has a drought-tolerant garden that is open to visitors year-round.

AR0070840

In addition to the Residential and Commercial Landscape Incentive Programs for turf removal, other types of landscape irrigation improvement projects are also funded through the TAP, with incentives calculated on the basis of a project's water savings. LADWP staff includes certified landscape auditors, and large landscape audits are available upon request.

LADWP is also investigating new programs using data obtained through pilot program efforts. A pilot program was conducted to determine the effectiveness of weather based irrigation controllers in large landscape applications. On the basis of the pilot program results showing water savings, financial incentives are available to LADWP customers for the purchase and installation of weather based irrigation controllers through the SoCal Water$mart and Save Water Save a Buck Programs. Additional efforts are being undertaken to make available a landscape irrigation education program for homeowner associations and other large landscape customers. This program would focus on common green areas in multi-unit complexes to improve irrigation efficiency, including irrigation system maintenance and repair, and plant selection.

LADWP has been implementing an internal program to retrofit outdoor landscaping at department-owned facilities to California-friendly and native plantings with efficient irrigation systems. Additionally, a joint effort between the Department of Recreation and Parks and LADWP is targeting public parks through the City Park Irrigation Efficiency Program. City parks with inefficient irrigation systems, leaks, and runoff problems are identified and upgraded with water efficient distribution systems and sprinkler heads, installation of smart irrigation controllers, and planting of California-friendly landscaping. Since the program began in 2007, seven parks have been completed and 4 new weather stations have been installed. An additional benefit of this program is the educational, trade training, and employment opportunity given to the youth of Los Angeles.

There is also potential for the use of non-potable water for irrigation, which can help extend the utility of the City's traditional water supplies. Through increased stormwater capture, groundwater recharge with captured storm and irrigation runoff, and recycled water, imported surface water and local groundwater used for landscape irrigation can be conserved. The potential to use such non-potable water supplies is further discussed in the Recycled Water and Watershed Management chapters (Chapters 4 and 7 respectively).

New Low Impact Development (LID) projects implemented within the City and innovative work by non-profit organizations demonstrate pioneering ways to conserve water for landscapes. As discussed in Chapter 7, LADWP's Watershed Management Group is proactively developing programs in conjunction with other departments to highlight water conservation through LID and implementing stormwater Best Management Practices (BMPs). A local non-profit, TreePeople, has partnered with various City departments, including LADWP on a number of stormwater capture projects.

For over a decade, TreePeople has demonstrated that rainwater is a viable local water resource. The Open Charter Elementary School Stormwater Project is one of several sustainable stormwater management systems that TreePeople installed in Los Angeles. Other examples include: the Center for Community Forestry which harvests rainwater from its entire hardscape into a 216,000 gallon underground cistern for landscape irrigation use; a retrofitted single family residential home in South Los Angeles that captures a 100 year storm event on site; a 7,600 square foot subsurface stormwater infiltration gallery on the Broadous Elementary School campus in Pacoima. Most recently, TreePeople partnered with the Los Angeles and San Gabriel Rivers Watershed Council, LADWP, and other state and federal agencies to retrofit an entire residential block on Elmer Avenue in Sun Valley. This project now intercepts stormwater from 40 acres upstream and infiltrates it back to the aquifer while also demonstrating effective distributed stormwater BMPs on residential homes.

AR0070841

In partnership with the Los Angeles County Department of Public Works, TreePeople was instrumental in developing the Sun Valley Watershed Management Plan: an alternative stormwater management plan that prioritizes green infrastructure and multi-benefit stormwater capture projects instead of stormdrains. Many projects have been completed, and more are scheduled for construction. These activities create the foundation that will lead to further landscape water conservation and stormwater capture to enhance the City's limited water supplies.

DRAFT

AR0070842

CASE STUDY:
Los Angeles River Revitalization and the North Atwater Park Project

Background

The Los Angeles (LA) River flows 51 miles through some of the most diverse communities in Southern California—its first 32 miles are within the City of LA. The River has a year-round low flow due to contributions from upstream wastewater treatment plants, urban runoff, groundwater inflow, and natural springs, but can become a torrent of racing flows during the rainy season. The River is almost entirely concrete-lined except for a few reaches. Although the design of the River has served its flood control purpose, the River holds far greater potential to serve as a focal point for environmental restoration, economic growth, community revitalization, and recreation.

Realizing that the River should stand as a symbol of pride for the City of LA and its residents and that it should be a landmark for the public to enjoy and admire, the LA City Council established the Ad Hoc Committee on the River in 2002 and adopted the LA River Revitalization Master Plan (LARRMP) in 2007 (www.lariver.org). Led by the City's Bureau of Engineering and funded by the LA Department of Water and Power, the LARRMP was created through a collaboration of elected officials, city departments and agencies, residents, multi-disciplinary experts, and a wide variety of private and non-profit environmental and recreational groups as the 25-to-50 year blueprint for transforming the City of LA's stretch of the River into an extensive network of parks, walkways, bike paths, and diverse land uses that will ensure the growth and sustainability of healthy communities.

Key Features

In October 2010, the City celebrated the groundbreaking of the North Atwater Park Expansion and Creek Restoration project as the first project to emerge from the LARRMP, which is expected to be open to the public by December 2011. The project was undertaken in connection with the settlement of two Clean Water Act enforcement action, Santa Monica Baykeeper v. City of Los Angeles and United States, and State of California ex. Rel. California Regional Water Quality Control Board, Los Angeles Region v. City of Los Angeles and also funded in part by Proposition 50 through the California Resources Agency to improve River Parkways and the Integrated Resources Water Management. The project will use both structural and natural solutions to restore a degraded creek that is a tributary of the River while also expanding River-adjacent parkland with multiple recreational, wildlife habitat, and water quality benefits. The project will add nearly 3 acres to an existing 5-acre City park, connecting it to the River, where visitors will enjoy watching a wide variety of bird species that presently live in that soft-bottomed stretch of the River, framed by stunning views of Griffith Park in the distance. Some of the project's highlights include:

Outdoor Classroom

The project will encourage young children to explore nature via an educational gathering space near the LA River. This "outdoor classroom" will feature a nature-based art area for independent and guided activities—designed particularly for local students to learn about nature, native plants, and the opportunities and challenges associated with revitalizing the LA River.

Native Demonstration Garden

The park's central focus will be a demonstration garden, which will contain a variety of native plants that are used throughout the park, with interpretive displays to educate visitors about the plant species' characteristics, care, and relationship to water conservation. The park will only include native plants because they are considered "drought-tolerant" given their abilities to thrive in Southern California's climate, requiring much less water than other plants. The park's landscape design aims to set an example in the use of such plants, but also to educate the public on the merits of embracing native vegetation as an important component of solving the region's water crisis.

Creek Restoration

North Atwater Creek currently conveys polluted runoff to the River from an upstream stormdrain system that receives flow from a 40-acre urban area. The Creek will be restored and landscaped with native plants to prevent erosion and to naturally filter stormwater before it is discharged to the River, featuring a 1000-foot-long meandering streambed sustained by intermittent street runoff flows. Water quality improvements will include installation of a device at the entrance of the creek to intercept and capture trash and bacteria and special treatment of flows from adjacent equestrian facilities.

AR0070843

Accommodating Visitors

While the park's landscape design capitalizes on the opportunity to educate visitors about the many connections between urban life, nature, and water, its structural features do also. For example, the parking lot will be transformed by installing a gravel bioswale along the borders and replacing existing parking spaces with permeable surfaces. These changes will not only address surface water contamination, but also allow stormwater to infiltrate so that it will assist with groundwater augmentation.

Summary

The North Atwater Park project will utilize innovative Low Impact Development (LID) and Best Management Practice (BMP) technologies to simultaneously achieve a variety of benefits, including responsible water conservation, improved water quality, expanded wildlife habitat connectivity, co-located multi-generational recreation, and public education.

The park's goals recognize that, while it is important to transform the existing park into a beautiful, scenic landmark and natural resource, it is equally important to educate the public about the huge potential such achievements have in encouraging wiser water use practices. Fundamentally, the park is about water—respecting LA's water supply and celebrating the River—by simultaneously improving the survivability of our wildlife and human habitat. North Atwater Park is an example of what can happen when public agencies and residents tackle complicated problems with creative planning and successful collaboration.

"The LA River cause is reaching more and more people every day. We are incredibly encouraged by the USEPA's July 2010 decision regarding the River's federal protection status and particularly because of the context in which it was announced—President Obama's America's Great Outdoors initiative is exactly the kind of support we need now and the visit of so many distinguished Administration officials to the River reinforces the belief that the River is important to millions of people here and across the country."

Carol Armstrong, Ph.D., Environmental Supervisor, Project Manager, LA River Project Office

"The City's commitment to LA River revitalization has only gained in momentum over the years and we have now reached an important crossroads for answering the big questions—such as how to capture and reuse storm flows, how to expand our recycled water uses, how to ensure we have enough water to maintain critical wildlife habitat, and how much flood capacity can we add? The River is central to each and every one of the answers."

Larry Hsu, P.E., Senior Civil Engineer, Project Manager, LA River Project Office

AR0070844

System Maintenance Category

Maintaining system infrastructure reduces water waste and allows for greater water accountability. Infrastructure maintenance is a high priority for LADWP. On-going programs such as pipeline replacement, pipeline corrosion control, and meter replacement preserve the operational integrity of City water facilities, and aims to reduce unaccounted water losses.

In recent years, the LADWP has ramped up its pipeline replacement program from 70,000 LF annually to 130,000 LF annually. LADWP has also made significant progress in replacing and/or retrofitting water meters through its meter replacement program that started in 1988. As a result of extended flow or usage, the moving parts in a water meter can wear down and begin to under-register the actual water consumption. The meter replacement program has been valuable in ensuring the accuracy of the approximately 700,000 meters within the City. Recently, all of the large-sized meters (3-in and larger) in the system were replaced as part of a Large Meter Replacement Program, and the LADWP is also replacing 35,000 small meters annually.

3.3 Future Programs, Practices, and Technology to Achieve Water Conservation

LADWP, on its own, and in cooperation with other agencies continues to investigate future programs, practices, and technology to improve water conservation.

3.3.1 Graywater

As defined by State regulations, graywater is untreated household wastewater which has not come into contact with toilet waste or unhealthy bodily wastes. It includes water sources from bathtubs, showers, bathroom wash basins, and water from clothes washing machines and laundry tubs. It specifically excludes water from kitchen sinks and dishwashers. Graywater is a drought-proof source of supply for subsurface landscape irrigation. Graywater regulations do not allow for its application using spray irrigation. Graywater is also not allowed to pond or runoff, discharge to or reach a storm drain system or surface water body, and is not permitted for irrigation of root crops or edible food crops that are directly in contact with the surrounding soil.

The Graywater Systems for Single Family Residences Act of 1992 legally incorporated the use of graywater as part of the California Plumbing Code. In September 1994, the City approved an ordinance that permitted the installation of graywater systems in residential homes. However, installing graywater systems under the Act was costly in terms of both installation and maintenance. To address the current water shortage and reduce water demands, emergency graywater regulations added Chapter 16A (Part I) "Nonpotable Water Reuse Systems" to the 2007 California Plumbing Code. These regulations were approved by California Building Standards Commission in 2009 and became effective on August 4, 2009. Further revisions were made to the regulations and the regulations became permanent on January 12, 2010 with an effective date of January 20, 2010. These new code changes allow the use of certain types of untreated graywater systems as long as specific health requirements are met as defined by the authority having jurisdiction. The ordinance can be acquired from the City of Los Angeles Department of Building and Safety (LADBS) website at the following link.

http://ladbs.org/LADBSWeb/LADBS_Forms/InformationBulletins/IB-P-PC2008-012Graywater.pdf

Graywater systems in residential buildings are regulated by LADBS. LADBS requires a plumbing permit prior to construction, reconstruction, installation, relocation, or alteration of any graywater systems, treated or untreated. As of fiscal year 2009-10,

DRAFT

LADWP does not offer any rebates or incentives for graywater systems, but continues to assess the potential for this water conservation technology.

Untreated Graywater Systems

Untreated graywater systems are systems where graywater is collected from non-toilet and non-kitchen sources and is utilized without treatment, for uses such as landscape irrigation. According to a 1999 study prepared by the Soap and Detergent Association, the average untreated graywater system in the US uses 6.3 gallons per day. In a 2010 White Paper prepared by Bahman Sheikh, for the WateReuse Association, Water Environment Federation, and American Water Works Association the potential for graywater generation in 2030, adjusted for conservation devices, is estimated at approximately 75.5 gallons per household per day. Potentially 50 percent of indoor potable water use could be re-used as graywater. Multiple manufacturers have developed untreated graywater systems and many households have installed such systems. However, these systems are not typically monitored, thus health and safety risks associated with the products have not been determined.

Under the recently approved revisions to the graywater system regulation, LADBS does not require a permit for untreated graywater systems supplied by only a clothes washer in a one or two-family dwelling as long as the system does not require modification of existing plumbing. Multiple requirements must be met for a system to be exempt from a permit including, but not limited to:

- Discharge shall be released not less than two inches below the surface of rock, mulch, or soil;
- Designs shall incorporate a means to allow the user to divert flow to the disposal area or the building sewer;
- Design of the system shall not allow contact with humans or pets;
- Water from diapers or other similarly soiled or infectious garments shall be diverted to the building sewer;
- Hazardous chemicals from washing activities, such as soiled rags, shall be diverted to the building sewer;
- An operation and maintenance manual shall be provided and remain with the building.

DRAFT

AR0070846

CASE STUDY:
Single-Family Home Graywater System

As a community environmental leader, Janie Thompson is taking extraordinary steps in efficient use of water and conservation. With the help of her husband, her household has become an excellent example of a rainwater capture residence, catching rain in 18 separate rain barrels with 60 gallons each. To save even more water, the couple is installing an impressive graywater network, distributing water to the furthest extent of their large 14,850 square foot property.

"In June 2009, when the Mayor announced the ordinance limiting watering to two days per week, we freaked out, and originally thought most of our landscaping would die. With all of our conservation, rainwater capture, and use of graywater, our usage has dropped from 117 hcf to around 54 hcf per month in the summer months. We couldn't be happier. It just goes to show you how much most people in the City over water." – Janie Thompson

Their existing graywater system currently uses the drainage pump from the clothes washer to pump water slightly up grade to tree and flower areas of the backyard. Upon exiting the washer, a 3-way valve reserves the option to divert washer effluent to the sewer system. The graywater piping travels beneath their raised foundation home, into the subsoil, and onto the areas it serves. Once construction is complete, all piping (left) will be buried with existing soil or mulch.

When the stream is pumped to the highest point of the yard, it is sent to numerous subsoil infiltration chambers, through a distribution system of 1" HDPE (High-density polyethylene) pipe. The infiltration chambers are made from 1 gallon paint buckets turned upside down with holes cut in the bottoms (below). The chambers allow for unobstructed exit flow and appropriate soil surface area for infiltration. In addition, they provide a significant volume for water storage during the surge of a pumped load of laundry. Plant roots are attracted toward these water outlets, essentially feeding on nutrients and organics in the graywater. The tops of the chambers are cutout for frequent access, and covered with mulch or stepping stone. The pipe exits can be checked as necessary to ensure free flow.

The next steps in the construction are connection of the bathtub and bathroom sinks. Effluent from these water sources will enter a surge tank and float switch assembly. A graywater dedicated pump will then automatically push water to existing and newly installed infiltration chambers throughout the yard.

AR0070847

Graywater used from these indoor sources will provide two main benefits. It will displace water used for irrigation and prevent additional water from entering the sewer. This decreases the load on the City sewer system lowering the overall cost of treatment for the Bureau of Sanitation.

The water savings are approximated in the following table. Please note that the clothes washer is a high efficiency front loading model. Showers are estimated at 10 minutes long with a head using 2.5 gallons per min.

Yearly Water Savings				
Washer	14 gal/use	10 uses/wk	140 gal/wk	7,280 gal/yr
Bathtub	40 gal/person/day	3 people	840 gal/wk	43,680 gal/yr
Bath Sink	2 gal/person/day	3 people	42 gal/wk	2,184 gal/yr
			Total	53,144 gal/yr

AR0070848

Treated Graywater Systems

Treated graywater systems treat water collected from non-kitchen and non-toilet sources for nonpotable reuse indoors and outdoors. Treated graywater systems for indoor use of graywater are not currently permitted by LADBS as there are no water quality standards nor mean to certify onsite treatment systems. Testing agencies are working to address safety concerns while manufacturers are working to improve the technology gap in the systems. Both manufacturers and testing agencies are working together to address gaps in standards to allow the future use of treated graywater for outdoor surface irrigation and for indoor uses in toilets and urinals.

The National Center for Disease Control and Prevention in conjunction with North Carolina State University is developing a program to examine the public health values and impacts associated with decentralized water reuse at eight project sites across the country. Under this program wastewater from homes would be treated to Title 22 standards as required by local health regulators. One of the proposed sites is located in Los Angeles County.

On the international level, treated graywater systems are used in both Europe and Australia. However, treated graywater systems in the United States are not common. A lack of accepted standards for graywater systems imposes a financial risk to companies manufacturing graywater systems. The International Association of Plumbing and Mechanical Officials (IAMPO) and NSF International are the two testing agencies working to develop standards for uniform treated graywater systems applicability in the US. LADWP is closely following the development of the NSF Standard 350 and IAPMO standards to ensure that once a set of standards have been approved by model codes and adopted by the Building Standards Commission, the citizens of Los Angeles can safely install treated graywater systems to maximize water reuse without any health and safety risks.

3.3.2 Demand Hardening

Although LADWP regularly assesses new water conservation opportunities, conservation programs may, at some point in time, diminish a customer's ability to further conserve water, in particular during short-term water supply shortages caused by droughts or other emergencies. This phenomenon is known as "demand hardening." The California Urban Water Agencies defines demand hardening as, "the diminished ability or willingness of a customer to reduce demand during a supply shortage as the result of having implemented long-term conservation measures." Long term conservation measures can include hardware conservation measures, such as the installation of high efficiency toilets and behavioral conservation, such as watering during specified periods of the day.

Demand hardening occurs when options available for reducing water use are limited as the customer base is saturated with hardware conversions causing efficient water usage patterns to prevail. During "dry" years, utility customers who have actively participated in water conservation programs can be disproportionately impacted by water reductions as there is a limited ability for further conservation. The impact of demand hardening would be most prevalent during water supply shortages where customers have already been implementing long-term water conservation measures. Proponents of demand hardening believe that implementation and saturation of new hardware-based conservation devices would generally not occur rapidly enough during a water supply shortage, such as a drought, to reduce short-term water use.

However, it can be argued that hardware-based conservation devices will continue to be developed, piloted and implemented, such as the previously discussed weather based irrigation controllers, thus improving the ability to further conserve in the future. During droughts, consumers will respond to the call for more conservation by behaviorally adjusting their water use

AR0070849

through methods such as not leaving water running and taking shorter showers. Additionally, full saturation of current conservation devices has not occurred. For these reasons, others believe demand hardening is irrelevant and there is a continued need for aggressive conservation programs.

Full implementation of current conservation measures, including reducing leaks, has the potential to reduce per capita water demands even further. Past water conservation efforts have reduced water use within LADWP's service area even though the population has continued to expand as illustrated in Exhibit 3A. It is expected that future water conservation efforts will continue this trend as increased saturation of water saving hardware devices occurs and new hardware devices are developed.

Though not easily quantifiable, saturation of current water saving hardware devices and installation of future water saving hardware devices combined with potential demand hardening have the ability to impact demand forecasts. As a worst case scenario, demand hardening and its effects are considered in LADWP's water demand forecasts to ensure that the appropriate supply of water is planned for. However, LADWP will continue to maintain its aggressive water conservation program discussed within this section. In the future, LADWP's water demand forecasts will continue to be examined and adjusted accordingly to compensate for additional implementation of long-term water conservation measures as saturation increases and new technology results in new hardware devices.

3.3.3 Projected Water Conservation Savings

To assist in planning future water demands, meeting the Water Supply Action Plan goal, and complying with 20x2020 requirements, LADWP has taken numerous steps to project future water conservation savings by major customer classification for indoor and outdoor use.

Indoor and outdoor active conservation through 2035 has been estimated by major billing sectors as provided in Exhibit 3I. Values presented are cumulative year to year. The bulk of conservation is expected to occur in the indoor portion of the commercial/government sector followed by the industrial sector. Past conservation programs have heavily focused on residential conservation reflecting the smaller residential conservation projections. Residential conservation initially provided the greatest volume saved for the cost. Water use in the CII sector is varied and relatively more expensive to achieve than in the residential sector.

Exhibit 3I
Active Conservation Projections by Sector

Sector	Acre-feet per Fiscal Year				
	2014/2015	2019/2020	2024/2025	2029/2030	2034/2035
Single-Family Residential	3,416	5,882	8,349	10,815	12,249
Multi-Family Residential	871	1,504	2,137	2,770	3,150
Commercial/Government	7,969	16,000	24,030	32,061	39,629
Industrial	1,924	3,847	5,824	7,774	9,339
Total Active Conservation Projections	14,180	27,260	40,340	53,420	64,368

AR0070850

To determine potential conservation savings for indoor water use in the CII sector, LADWP conducted a high-level study to first estimate CII water use for each subsector (e.g. hospitals, refineries, schools, business parks, restaurants, etc.) and indoor end-use (e.g., toilets, showers, kitchen, laundry, food processing, cooling/heating, etc.), and second determine the potential for indoor water savings for each subsector and end-use. This study involved a sample of water use for approximately 150 of LADWP's largest CII customers to estimate total sector water use, along with employment data from Dunn & Bradstreet. Additional data sources listed below were used to determine indoor end-use estimates for each subsector, as well as the potential for water savings. :

- *BMP 9: A Handbook for Implementing Commercial Industrial & Institutional Conservation Programs.* (2001). California Urban Water Conservation Council.
- *Commercial and Institutional End Uses of Water.* (2000). American Water Works Association Research Foundation.
- *Waste Not, Want Not: The Potential for Urban Water Conservation in California.* (2003). Pacific Institute.
- *Water Efficiency in the Commercial and Institutional Sector: Considerations for a WaterSense Program.* (2009). U.S. Environmental Protection Agency.
- *Watersmart Guidebook---A Water-Use Efficiency Plan-Review Guide for New Businesses.* (2008). East Bay Municipal Utility District.
- *Santa Clara Valley Water District Commercial Institutional Industrial Water Use & Conservation Baseline Study.* (2008). CDM.
- *Water and Energy Efficiency Program for Commercial, Industrial, and Institutional Customer Classes in Southern California.* (2009). U.S. Bureau of Reclamation.
- *Water Use Efficiency Comprehensive Evaluation.* (2006). CALFED Bay-Delta Program.

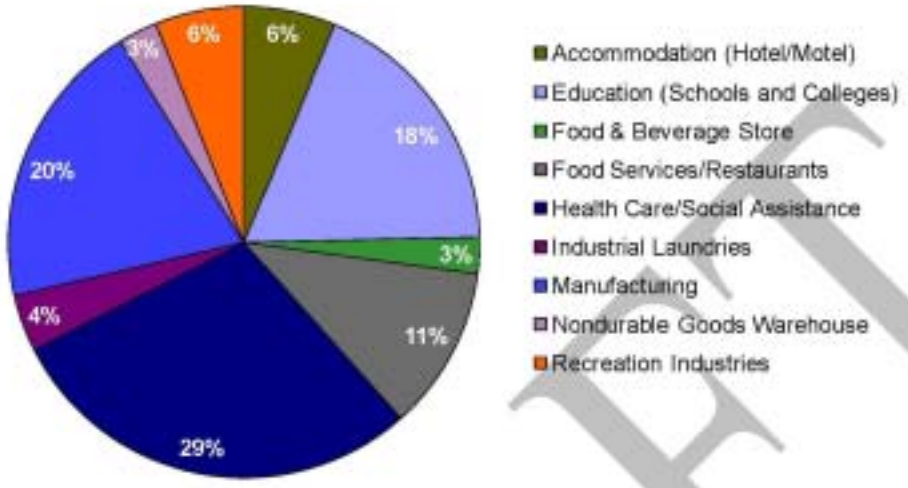
The study concluded that by targeting just the top 100 or so largest CII users, approximately 4,600 AFY of water could be saved (representing about 3 percent of total CII water use). The study also found that the subsectors that use the most water in the city are: health care (18%), education (14%), food services/drinking places (9%), accommodation (5%), fabricated metal product manufacturing (5%), textile mills (5%), amusement (4%), and food manufacturing (4%). The study also concluded that the potential for indoor water conservation was approximately 23,000 AFY or 15 percent of total CII water use. Exhibit 3J presents the breakdown of this potential indoor water conservation for subsectors and end-uses.

DRAFT

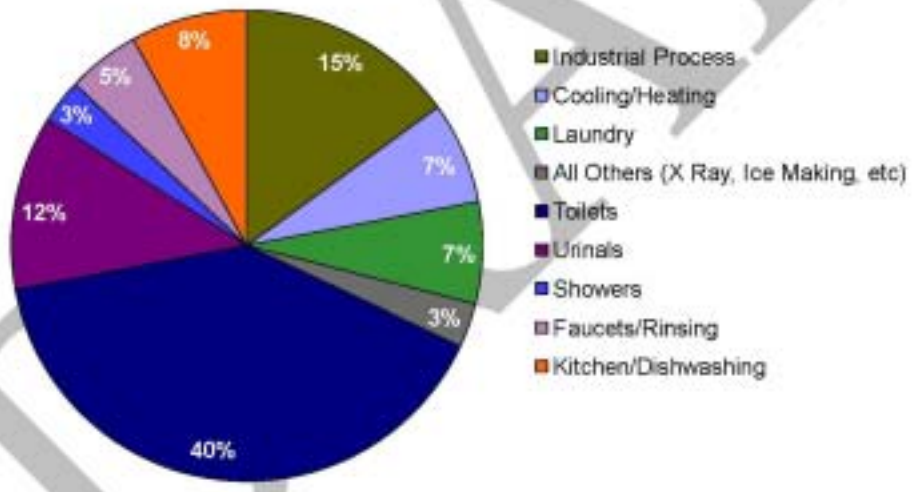
AR0070851

Exhibit 3J
Breakdown of Estimated CII Indoor Water Conservation Potential of 23,000 AF

Percent Water Saved per Subsector



Percent Water Saved per End-Use



Outdoor water use as a percentage of water use was approximated using three methodologies to determine the potential for outdoor water conservation savings. The methodologies and percent outdoor water use determined for each methodology are:

- Minimum-Maximum Methodology (outdoor water use is approximately 39.98%) – based on the premise that during wet months outdoor water use is minimal and during dry months outdoor water use is at its peak

DRAFT

- Wastewater Treatment Plant Influent Methodology (outdoor water use is approximately 38.32%) – based on determining the average monthly influent flows to the City's four wastewater treatment plants during the dry-weather months of June through September and adjusting for contract agency flows and dry-weather stormwater diversions

- Infrared Analysis Methodology (outdoor water use is 39.67%) – based on an infrared analysis of the City to determine tree canopy and landscape coverages for use in estimating applicable water use requirements for greenscapes based on rainfall data, plant factors, evapotranspiration rates, and irrigation efficiencies

The resultant range between the low and high outdoor water use percentage is approximately 1.35%. This narrow range resulting from the three methodologies confirms the methodologies are fairly accurate.

Greenscape areas related to commercial and residential land uses are the most likely areas to be targeted for outdoor water conservation. Rehabilitation of these areas to meet or exceed the evapotranspiration adjustment factor (ETAF) of 0.7 as required in the Model Water Efficient Landscape Ordinance would result in significant savings ranging from 21,774 to 165,870 AFY. Currently, these savings are not represented in the projected active conservation in Exhibit 3I. Exhibit 3K illustrates the potential savings under three scenarios by customer sectors. Scenario 1 represents an improvement in average irrigation efficiencies and/or installation of less water intensive vegetation to achieve and ETAF of 0.7. Scenario 2 represents an improvement in average irrigation efficiencies and/or replacement of high water use vegetation with less water intensive vegetation in the moderate to low water use range to achieve an ETAF of 0.49. Scenario 3 represents an improvement in average irrigation system efficiency and replacement of all vegetation with very low water use vegetation almost entirely dependent upon effective precipitation to achieve an ETAF of 0.07. This would require incentive programs, such as cash for grass programs. Other large greenscape area, including parks, cemeteries and golf courses, were not considered in the analysis as they would more than likely be preserved as turf or tree canopy areas to retain quality of life benefits. These areas are likely to be targets for recycled water use.

Exhibit 3K
Potential Outdoor Water Use Savings by Sector

Customer Sector	Scenario 1	Scenario 2	Scenario3
	(AFY)		
Single-Family Residential	13,246	42,464	100,901
Multi-family	5,956	19,095	45,371
Commercial	2,573	8,247	19,597
Total	**21,774**	**69,806**	**165,870**

3.4 Cost & Funding

The average cost of conservation rebates, incentives, and hardware installation programs ranges from approximately $325/AF to $400/AF based on current LADWP conservation programs. More than $200 million has been invested in water conservation since 1991. Conservation is the cornerstone of LADWP's water demand management activities and ongoing investments will be made in viable programs, subject to funding availability and LADWP's ability to implement such programs. Outside sources of funding are sought to complement the City's resources. A stronger commitment is also being made to acquire outside grant funding for City conservation projects.

Currently, the funding sources for conservation are:

AR0070853

- ***Water Rates*** – Water conservation programs are primarily funded through water rates.

- ***MWD Conservation Credits Program*** - MWD offers both commercial and residential rebates to member agency customers that install specified conservation devices. The rebates equate to $195 per AF of water saved, or half the project cost. In addition, MWD reimburses the LADWP for pre-approved projects when completed. In 2009 MWD reimbursed the Department $139,000 for a water broom distribution program. LADWP also expects to be reimbursed in 2011 through the MWD Member Agency Administered funding program for $968,000. The monies are reimbursement for 22.2 acres of turf reduction projects through the Department's Commercial/Industrial Drought Resistant Landscape Incentive Program.

- ***Outside Agency Co-Funding*** - Other agencies realizing benefits from conservation programs are solicited for co-funding of program costs.

- ***Grant Funding*** - LADWP has successfully received grant funding from the State under Proposition 13. A grant for $615,000 supplemented the rebate funding available for commercial ULF toilets and high efficiency clothes washers. LADWP expects to receive a final payment totaling $128,299 for the Commercial High Efficiency Clothes Washer and Ultra Low Flow Toilet Consolidated Water Use Efficiency grant. LADWP has already received $164,691 in support of 1,498 commercial high efficiency washer rebates. LADWP was awarded three grants in 2005 under Proposition 50, which are summarized below:
  - The Cooling Tower Conductivity Controller Replacement Program: Grant to improve the water efficiency of 100 cooling towers in the city of Los Angeles. Total grant amount up to $350,000. Expect completion in 2012.
  - The Los Angeles City Park Irrigation Efficiency Program: Grant to improve the irrigation efficiency at 15 City of Los Angeles municipal parks by installing Weather Based Irrigation Controllers and by upgrading irrigation piping and rotors. Total grant amount up to $362,000. Expect completion in 2011.
  - The Large Landscape "Smart Irrigation" Program: Grant to replace existing manually-adjusted irrigation controllers with "smart irrigation" Weather Based Irrigation Controllers at 75 large landscape customer sites. Total grant amount $131,000. Expect completion in 2011.

DRAFT

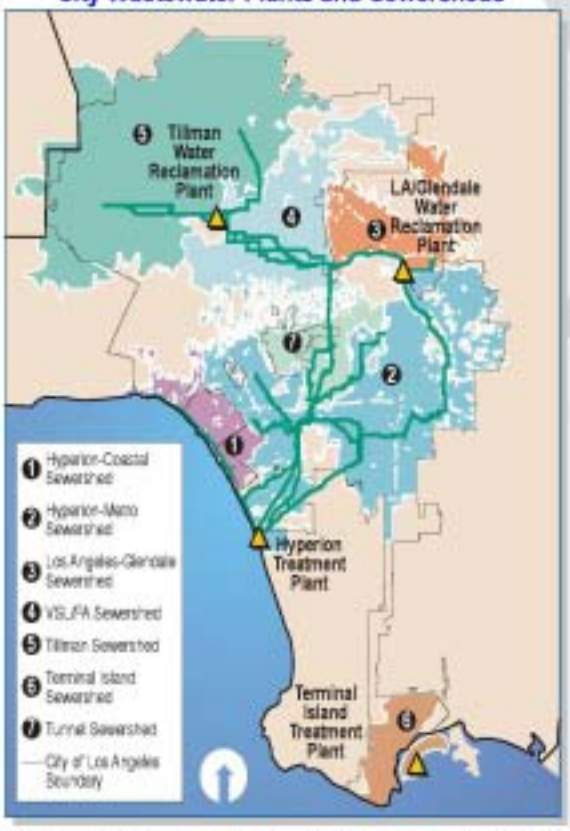
AR0070854

DRAFT Chapter Four
Recycled Water

LADWP is committed to significant expansion of recycled water in the City's water supply portfolio. Realizing multiple factors are decreasing the reliability of imported water supplies, LADWP released the City of Los Angeles Water Supply Action Plan (Plan), "Securing L.A.'s Water Supply" in May of 2008. The Plan established the goal of using 50,000 AFY of recycled water to offset demands on potable supplies. In order to meet this goal, LADWP, in conjunction with the Department of Public Works Bureau of Sanitation (BOS), are working together to develop a Recycled Water Master Plan (RWMP). Opportunities to expand the water recycling program are being studied through development of the RWMP. These include expanding the recycled water distribution system for Non-Potable Reuse (NPR) such as for irrigation and industrial use, along with replenishment of groundwater basins with highly purified recycled water. Beyond 50,000 AFY, LADWP expects to increase recycled water use by approximately 1,500 AFY annually, bringing the total to 59,000 AFY by 2035.

LADWP's water recycling program is dependent on the City's wastewater treatment infrastructure. Wastewater in the City of Los Angeles is collected and transported through some 6,500 miles of major interceptors and mainline sewers, more than 11,000 miles of house-sewer connections, 46 pumping plants, and four treatment plants. BOS is responsible for the planning and operation of the wastewater program. The City's wastewater system serves 515 square miles, of which 420 square miles are within the City. In addition to the City, service is provided to 29 non-City agencies through contract services. Exhibit 4A shows the City's four wastewater treatment plants and seven sewersheds that feed those plants.

Exhibit 4A
City Wastewater Plants and Sewersheds



A portion of the treated effluent from the wastewater plants is utilized by LADWP to meet recycled water demands.

As early as 1960, the City recognized the potential for water recycling and invested in infrastructure that processed water to tertiary quality, a high treatment standard for wastewater. This resulted in the building of tertiary wastewater treatment plants upstream instead of enlarging the two existing terminus treatment plants. These system enhancements brought about the City's expanded recycled water projects, which now supplement local and imported water supplies. The original policy allowing the use of recycled water was adopted by the State Legislature in 1969.

In 1979, LADWP began delivering recycled water to the Department of Recreation and Parks for irrigation of areas in Griffith Park. This service was later expanded to include Griffith Park's golf courses. In 1984, freeway landscaping adjacent to the park was also irrigated with recycled water. In addition, the Japanese Garden, Balboa Lake and Wildlife Lake in the Sepulveda Basin now utilize recycled water for environmentally beneficial reuse purposes. The Greenbelt Project, which carries recycled

AR0070856

water from the Los Angeles-Glendale Water Reclamation Plant to Forest Lawn Memorial Park, Mount Sinai Memorial Park, Lakeside Golf Club of Hollywood and Universal Studios, began operating in 1992, and represents LADWP's first attempt at water recycling. LADWP continues to successfully implement the use of recycled water for various purposes. In 2009 phase 1 of the Playa Vista development began receiving recycled water. Playa Vista is the first planned development in the City that uses recycled water for all landscape needs. Future recycled water projects will continue to build on the success of these prior projects so that recycled water becomes a more prominent component of the City's water supply portfolio.

The City's water recycling projects seek to displace the use of potable water with recycled water for non-potable uses where infrastructure is available. In compliance with Chapters 7.0 and 7.5 of the California Water Code, the quality of LADWP's Recycled water meets all of the following conditions:

- The source of recycled water is of adequate quality for those uses;
- The recycled water may be furnished for these uses at a reasonable cost to the user;
- The use of recycled water from the proposed source will not be detrimental to public health; and
- The use of recycled water will not adversely affect downstream water rights or degrade water quality.

In addition, the California Water Code requires public agencies, such as the LADWP, to serve recycled water for non-potable uses if suitable recycled water is available.

LADWP is expanding irrigation, industrial/commercial, and studying groundwater replenishment uses of recycled water. Demand for recycled water is driven by customer acceptance of recycled water as a viable alternative to traditional potable supplies. Outreach efforts designed to educate the public on the viability of recycled water and its potential uses are an essential part of the process as the City's recycled water program expands.

4.1 Regulatory Requirements

Recycled water use is governed by regulations at the State and local levels. These regulations are based on multiple factors including the type of use and water quality. LADWP currently uses recycled water for non-potable reuse and is pursuing in-direct potable reuse through groundwater replenishment (GWR) using advanced treated recycled water. Requirements for these two categories of recycled water use are different. This section provides a summary of the complex recycled water regulations, a more in-depth description of these regulations will be included as part of the RWMP.

4.1.1 Non-Potable Reuse Regulations

Non-potable water reuse (NPR) regulations in the City of Los Angeles are governed by the California Department of Public Health (CDPH), State Water Resources Control Board (SWRCB), Los Angeles Regional Water Quality Control Board (LARWQCB) and the Los Angeles County Department of Public Health (LACDPH).

California Department of Public Health

Criteria and guidelines for the production and use of recycled water were established by the CDPH in the California Code of Regulations, Title 22, Division 4, and Chapter 3 (Title 22). Title 22, also known as Water Recycling Criteria, establishes required wastewater treatment levels and recycled water quality levels dependent upon the end use of the recycled water. Title 22 additionally establishes recycled water reliability criteria to protect public health.

AR0070857

Title 22 specifies recycled water use restrictions based on the potential degree of public exposure to the water and the distance of drinking water wells and edible crops from the area of intended use. Recycled water use applicability also depends on the different levels of treatment. A higher quality water will have a wider variety of applicable uses than a lower quality water. At a minimum, secondary treatment of wastewater is required for recycled water use. In the City of LA, however, all recycled water used is treated, at a minimum, to tertiary levels with additional disinfection. Wastewater treatment levels are discussed in detail in subsection 4.2 of this chapter. Title 22 allows for other treatment methods, subject to CDPH approval. The reliability of the treatment process and the quality of the product water must meet the Title 22 requirements specified for each allowable treatment level. Exhibit 4B provides a summary of the currently approved recycled water uses.

Exhibit 4B
Allowable Title 22 Recycled Water Uses

Irrigation Uses
Food crops where recycled water contacts the edible portion of the crop, including all root crops
Parks and playgrounds
School yards
Residential landscaping
Unrestricted access golf courses
Any other irrigation uses not prohibited by other provisions of the California Code of Regulations
Food crops, surface irrigated, above ground edible portion, and not contacted by recycled water
Cemeteries
Freeway landscaping
Restricted access golf course
Ornamental nursery stock and sod farms with unrestricted public access
Pasture for milk animals for human consumption
Non edible vegetation with access control to prevent use as park, playground or school yard
Orchards with no contact between edible portion and recycled water
Vineyards with no contact between edible portion and recycled water
Non food bearing trees, including Christmas trees not irrigated less than 14 days before harvest
Fodder and fiber crops and pasture for animals not producing milk for human consumption
Seed crops not eaten by humans
Food crops undergoing commercial pathogen destroying processing before consumption by humans
Supply for impoundment
Non restricted recreational impoundments, with supplemental monitoring for pathogenic organisms
Restricted recreational impoundments and publicly accessible fish hatcheries
Supply for Impoundment Uses
Non restricted recreational impoundments, with supplemental monitoring for pathogenic organisms
Restricted recreational impoundments and publicly accessible fish hatcheries
Landscape impoundments without decorative fountains
Supply for cooling or air conditioning
Industrial or commercial cooling or air conditioning involving cooling tower, evaporative condenser, or spraying that creates a mist
Industrial or commercial cooling or air conditioning not involving cooling tower, evaporative

AR0070858

condenser, or spraying that creates a mist
Other Uses
Dual plumbing systems (flushing toilets and urinals)
Priming drain traps
Industrial process water that may contact workers
Structural fire fighting
Decorative fountains
Commercial laundries
Consolidation of backfill material around potable water pipelines
Artificial snow making for commercial outdoor uses
Commercial car washes, not heating the water, excluding the general public from washing process
Industrial process water that will not come into contact with workers
Industrial boiler feed
Nonstructural fire fighting
Backfill consolidation around non potable piping
Soil compaction
Mixing concrete
Dust control on road and streets
Cleaning roads, sidewalks and outdoor work areas
Flushing sanitary sewer
Groundwater recharge

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Non-Potable Reuse Regulatory and Policy Assessment TM, September 8, 2009

Areas where recycled water is used occurs within defined boundaries. Title 22 stipulates use area requirements to protect public health. Use area regulations include requirements addressing recycled water application methods and runoff near domestic water supply wells, drinking fountains, and residential areas. Other requirements include posting signs notifying the public where recycled water is being used, utilization of quick couplers instead of hose bibs, and the prohibition against connecting recycled water systems with potable water systems. Dual plumbed recycled water systems in buildings are also addressed; these systems must meet additional reporting and testing requirements.

To protect public health, Title 22 requires reliability mechanisms. During the design phase, a Title 22 Engineering Report is required to be submitted to CDPH and the local Regional Water Quality Control Board (RWQCB) for approval. Contents of the report include a description of the system and an explanation regarding how the system will comply with Title 22 requirements. Redundancy in treatment units or other means to treat, store, or dispose of recycled water are required in case the treatment unit is not operating within specified parameters. Alarms for operators are required to indicate treatment plant process failures or power failures. In case of power failures, either back-up power, automatically activated short-term or long-term recycled water storage, or a means of disposal is required. Furthermore, system performance must be monitored by water quality sampling and analyses.

As mentioned previously, cross-connections between the potable and recycled water systems are not permitted. The California Code of Regulations, Title 17, Division 1, Chapter 5, Group 4 prevents cross-connections between potable water supply systems and recycled water supply systems. Title 17 specifies that water suppliers must implement cross-connection control programs and backflow prevention systems.

AR0070859

In addition to Title 22 and Title 17 requirements, CDPH has additional regulations and guidance established in the following documents:

- Guidelines for the Preparation of an Engineering Report for the Production, Distribution, and Use of Recycled Water (2001)
- Treatment Technology Report for Recycled Water (2007)
- Guidance Memo No. 2003-02: Guidance for the Separation of Water Mains and Non-Potable Pipelines (2003)

State Water Resources Control Board and Los Angeles Regional Water Quality Control Board

In May 2009, the SWRCB adopted "Recycled Water Policy" developing uniform standards across all Regional Water Quality Control Boards for interpreting the "Anti-Degradation Policy". When planning and implementing recycled water projects the following must be taken into consideration:

- Mandate for recycled water use – encourages recycled water use and establishes targets to increase use
- Salt/nutrient management plans – requires submittal of salt/nutrient management plans by 2014
- Landscape irrigation projects' control of incidental runoff and streamlined permitting – addresses controlling incidental runoff and streamlining permit processes for recycled water use in landscape areas
- Groundwater recharge – establishes requirements for groundwater recharge projects
- Anti-degradation – establishes that salt and nutrient management plans can address groundwater quality impacts
- Chemicals of emerging concern – establishes a blue-ribbon advisory panel to develop a report on chemicals of emerging concern and update the report every five years.

Water Recycling Requirements (WRR) for each of the City's applicable wastewater treatment plants engaged in water recycling are issued by the LARWQCB. These requirements specify end-users of recycled water and enforce treatment and use area requirements.

In July 2009, the SWRCB adopted a general landscape irrigation permit, "General Waste Discharge Requirements for Landscape Irrigation Uses of Municipal Recycled Water" (General Permit). The General Permit streamlines the regulatory approval for landscape irrigation using recycled water. Agencies with existing WRRs, such as the City, are not required to apply for the General Landscape Irrigation Permit.

Earlier in April 2009, the LARWQCB adopted a general region-wide permit, "General Waste Discharge and Water Recycling Requirements for Non-Irrigation Uses over the Groundwater Basins Underlying the Coastal Watersheds of Los Angeles and Ventura Counties" for non-irrigation uses of recycled water. Similar to the General Permit, this permit streamlines the permitting process and specifies the application process for qualifying projects.

AR0070860

Los Angeles County Department of Public Health

Title 22 and Title 17 water use regulations are enforced by the LACDPH, Environmental Health Division. LACDPH has published "A Guide to Safe Recycled Water Use, Pipeline Construction and Installation" requiring compliance with Title 22, CDPH, and LARWQCB requirements. After CDPH has approved the plans and specifications and the City has an agreement to serve the customer, LACDPH reviews and approves all plans and specifications prior to construction. After construction LACDPH inspects the systems and conducts cross-connection, pressure, and back-flow prevention device tests. Recycled water use must occur in compliance with the Los Angeles County Recycled Water Advisory Committee's "Recycled Water Urban Irrigation User's Manual". Each site must also have a site supervisor responsible for recycled water use.

City of Los Angeles

Recycled water responsibilities of the City of Los Angeles include complying with all LARWQCB permits for the wastewater treatment plants and production of recycled water, approving recycled water use sites, conducting post-construction inspections, and periodically inspecting use areas and site supervisor records.

LADWP customers are permitted to use recycled water when service is available and per LADWP Ordinance No. 170435 (subsequently amended by Ordinance No. 178902 in 2008). Users are responsible for operations and maintenance of their recycled water systems up to the connection point with LADWP. Users are required to use recycled water in accordance with Titles 22 and 17 and the "Recycled Water Urban Irrigation User's Manual". If a customer is violating these requirements, LADWP may stop providing recycled water to the customer.

4.1.2 Groundwater Replenishment Regulatory Requirements

The regulations governing recharge of groundwater or groundwater replenishment (GWR) with recycled water are established by the CDPH and LARWQCB. Additional approval is required by the SWRCB and California Department of Fish and Game (DFG) if flows will be diverted from surface waters, such as in Los Angeles where recycled water is currently discharged by two treatment plants into the Los Angeles River. The City's GWR project as described in section 4.4.3 will be subject to these regulations.

For groundwater replenishment, LADWP will implement advanced treatment that includes reverse osmosis, microfiltration, and advanced oxidation. This level of treatment will address water quality concerns for the health of the basin along with emerging contaminants of concern.

California Department of Public Health

Regulatory oversight of groundwater recharge projects is provided by the CDPH. CDPH regulates groundwater recharge projects under Title 22 requiring the CDPH to make recommendations on a case by case basis after a public hearing. Requirements for recharge are not provided in Title 22. Draft Groundwater Recharge Reuse Criteria, released in August 2008, are used by the CDPH to evaluate projects for approval or denial. The draft regulations are designed to protect public health through the establishment of stringent requirements by:

- Requiring recycled water to meet maximum contaminant levels (MCLs) established for drinking water;
- Establishing the volume of recycled water used based on Total Organic Carbon (TOC), dilution, and treatment levels;
- Requiring retention of groundwater for six months before reaching a well used for drinking water with validation by a tracer study;

AR0070861

- Monitoring on a quarterly basis for specified pollutants and chemicals and yearly monitoring of constituents indicating the presence of wastewater in produced recycled water and in downgradient monitoring wells;
- Implementing a source control program; and
- Establishing additional requirements for projects with recycled water contributions greater than 50%, including a review by an Independent Advisory Panel.

Similar to non-potable reuse, project proponents must submit a Title 22 Engineering Report to the CDPH and LARWQCB for review. After completion of the report, the CDPH holds a public hearing followed by issuance of Findings of Fact and Conditions for submission to the LARWQCB.

Los Angeles Regional Water Quality Control Board

Prior to the issuance of a permit, the LARWQCB reviews CDPH's Findings of Fact and Conditions and considers provisions in the adopted Los Angeles Basin Plan (Basin Plan) for the LARWQCB region, applicable State policies (including the SWRCB Recycled Water Policy), and applicable federal regulations if recycled water is discharged to water of the US. The Basin Plan establishes water quality objectives for surface water and groundwater to protect beneficial uses. The LARWQCB then holds a public hearing to consider the permit. Ultimately, if approved, the LARWQCB issues permits in the form of water reclamation requirements and waste discharge requirements.

4.2 Wastewater Treatment Plants

There are four wastewater treatment plants owned and operated by the BOS. City wastewater treatment consists of a series of processes that, at a minimum, remove solids to a level sufficient to meet regulatory water quality standards. During the preliminary, primary, secondary, and tertiary treatment processes, progressively finer solid particles are removed. Preliminary treatment removes grit and large size particles through grit removal basins and screening. Primary treatment relies on sedimentation to remove smaller solids. With most of the grit, large sized particles, and solids already removed, secondary treatment converts organic matter into harmless by-products and removes more solids through biological treatment and further sedimentation. At the end of secondary treatment, most solids will have been removed from the water. Tertiary treatment follows secondary treatment to eliminate the remaining impurities through filtration and chemical disinfection. At this stage, sodium hypochlorite (the chemical contained in household bleach) provides disinfection. All recycled water used within the City is given, at a minimum, tertiary treatment and disinfection. In the Harbor, recycled water is also given advanced treatment with microfiltration/reverse osmosis (MF/RO). MF/RO is a two-stage process using high-pressure membrane filters to remove microscopic impurities from the source water. Exhibit 4C summarizes the treatment levels, capacity, and average flows at the four plants.

AR0070862

Exhibit 4C
Wastewater Treatment Plants Summary

WastewaterTreatment Plants	Treatment Level	Capacity (mgd)	Average Flows (mgd)[1]
Donald C. Tillman Water Reclamation Plant	Tertiary to Title 22 standards with Nitrification/Denitrification	80	53
Los Angeles - Glendale Water Reclamation Plant	Tertiary to Title 22 standards with Nitrification/Denitrification	20	17
Terminal Island Water Reclamation Plant	Tertiary; Advanced treatment (MF/RO) of 5 mgd	30	15
Hyperion Treatment Plant	Full secondary[2]	450	320

1. Average dry weather flows 2008, except for DCT January 2005 through December 2008.

2. 31 mgd of full secondary treated water delivered to West Basin Water Reclamation Plant operated by West Basin Municipal Water District. Water treated to Title 22 standards for recycled water use.

Sources: City of Los Angeles Recycled Water Master Plan Technical Memorandum, DCT Data Summary, January 29, 2010

City of Los Angeles Recycled Water Master Plan Technical Memorandum, Wastewater Treatment, November 2, 2009

4.2.1 Donald C. Tillman Water Reclamation Plant

In service since 1985, the Donald C. Tillman Water Reclamation Plant (DCT) has an average dry-weather flow capacity of 80 million gallons per day (mgd) and currently treats about 53 mgd. During wet weather, treatment capacity is limited to 40 mgd to prevent downstream infiltration surcharges on the sewer system while utilizing the remaining capacity for limited wet weather storage. Currently, the Bureau of Engineering (BOE) is designing wet-weather storage basins to allow year around operation at 80 mgd. The current level of treatment is Title 22 (tertiary) with nitrogen removal (nitrification/denitrification (NdN). Currently, this plant is providing recycled water to the Japanese Garden, Wildlife Lake, Lake Balboa, treatment plant reuse, irrigation, and industrial uses. Irrigation uses in the adjacent areas include golf courses, parks, and a sports complex. Industrial uses include the Valley Generating Station. The remaining tertiary-treated water is discharged into the Los Angeles River. The city intends on implementing a groundwater replenishment project supplied with tertiary treated Title 22 recycled water from DCT that is purified through advanced treatment to recharge the San Fernando Groundwater Basin. The project will initially recharge 15,000 AFY with the eventual goal of achieving 30,000 AFY.

4.2.2 Los Angeles-Glendale Water Reclamation Plant

The Los Angeles-Glendale Water Reclamation Plant (LAG) is a joint project of the City of Los Angeles and City of Glendale. LAG began treating wastewater in 1976. Originally the plant was designed without considering nutrient removal. Its average dry-weather flow design capacity is 20 mgd and it currently treats about 17.7 mgd. Each city is entitled to 50 percent of the plant's capacity. The City of Pasadena purchased rights to 60 percent of Glendale's capacity but has not yet exercised these rights. The current level of treatment is Title 22 (tertiary) with nitrogen removal (NdN). Recycled water from the LAG provides landscape irrigation to Griffith Park and the Los Angeles Greenbelt Project, including Forest Lawn Memorial Park, Mount Sinai Memorial Park, Universal Studios, and the Lakeside Golf Course. The City of Glendale retains the right to half of the recycled water produced at the plant and serves a number of customers in their service area. As with the DCT, the remaining tertiary-treated water from LAG is discharged into the Los Angeles River.

AR0070863

4.2.3 Terminal Island Water Reclamation Plant

Originally built in 1935, the Terminal Island Water Reclamation Plant (TIWRP) has been providing secondary treatment since the 1970s. Tertiary treatment systems were added in 1996. The current average dry-weather flow capacity is 30 mgd with average flows of about 15 mgd. Recent completion of the Advanced Wastewater Treatment Facility added MF/RO treatment to a portion of the wastewater effluent producing approximately 3.0 mgd of recycled water. Recycled water is supplied to the Dominguez Gap Seawater Intrusion Barrier to reduce seawater intrusion into drinking water aquifers and to LADWP's Harbor Generating Station for landscape irrigation. Effluent in excess of the MF/RO component is discharged to the Los Angeles Harbor. Future recycled water use is expected to increase to more fully supply the Dominguez Gap Seawater Intrusion Barrier along with other potential customers in the Harbor Area.

4.2.4 Hyperion Treatment Plant

Operating since 1894, the Hyperion Treatment Plant (HTP) is the oldest and largest of the City's wastewater treatment plants. Its $1.2 billion construction upgrade, completed in 1999, allows for full secondary treatment. The current average dry-weather flow capacity of HTP is 450 mgd during dry weather, with an average wastewater flow of 342 mgd. A majority of the treated water is discharged through a 5-mile outfall into the Santa Monica Bay, and the rest, approximately 31 mgd, is delivered to the West Basin Water Reclamation Plant to meet recycled demands in the West Basin Municipal Water District (WBMWD) service area and parts of the City of Los Angeles. As of 2008, approximately 37,000 AFY of water from HTP Plant is sold to West Basin for additional treatment. A portion of this water is sold back to LADWP for the Westside Water Recycling Project, and the rest is then used to meet recycled water demands in West Basin's service area. Users of the Westside Water Recycling Project include Loyola Marymount University and Playa Vista.

4.2.5 Projected Wastewater Volume

Average dry-weather wastewater influent projections for the City's wastewater treatment plants are expected to increase by approximately 20 percent over the next 25 years. Projections include 29 agencies outside of the City with contracts for wastewater treatment. Wastewater effluent that is not recycled is discharged to either the Los Angeles River to the Pacific Ocean or outfalls leading directly to the Pacific Ocean. Wastewater treatment projections for average dry-weather flows to 2035 and disposal methods are provided in Exhibit 4D.

Exhibit 4D
Wastewater Treatment Plant Average Dry-Weather Flows, Reuse and Dischargel Method

Wastewater Treatment Plants	Reuse and Discharge Method	Average Dry-Weather Flow Projections (AFY)					
		2010	2015	2020	2025	2030	2035
Donald C. Tillman Water Reclamation Plant	Recycling and Pacific Ocean via Los Angeles River	82,779	84,347	85,915	87,483	90,283	93,084
Los Angeles - Glendale Water Reclamation Plant	Recycling and Ocean via Los Angeles River	23,299	25,427	27,331	29,460	31,588	33,716
Terminal Island Water Reclamation Plant	Recycling and Outfall to Ocean	18,258	18,594	18,818	19,154	19,715	20,163
Hyperion Treatment Plant	Conveyance to WBMWD for Recycling and Ocean outfall	333,690	339,739	345,788	362,814	366,063	400,899

AR0070864

4.3 Existing Recycled Water Deliveries

The City has several recycled water projects currently providing recycled water for landscape irrigation, industrial, and commercial uses spread throughout four service areas:

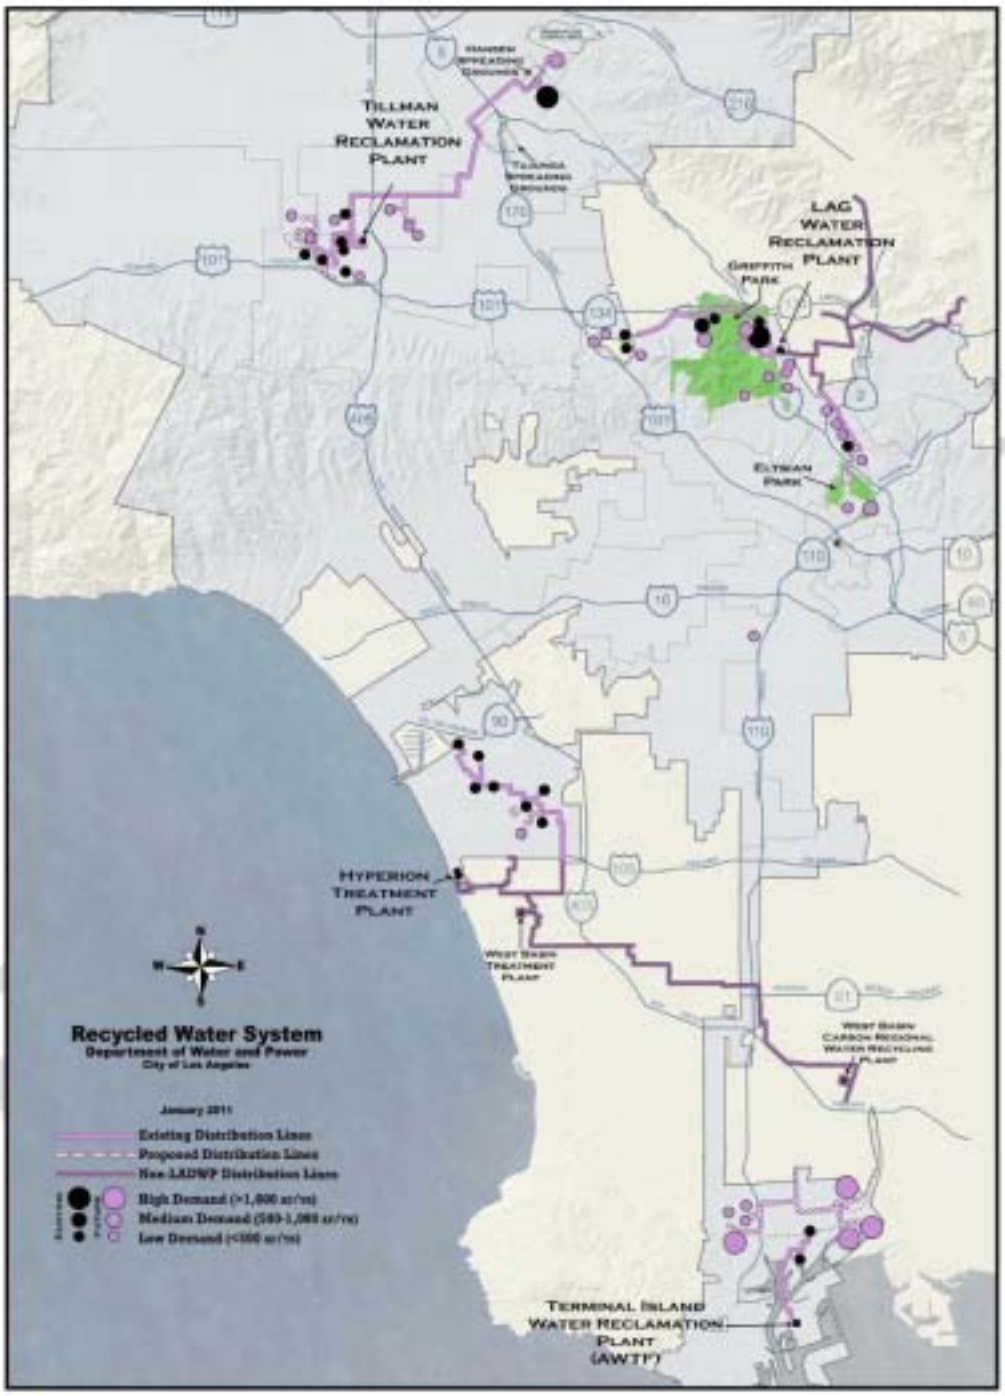
- Harbor – located in the southern portion of the City and currently served from the water reclamation plant at the TIWRP
- Central City (Metro) – located in the central/eastern portion of the City and is served by LAG
- San Fernando Valley – located in the northern portion of the City and is served by DCT
- Westside – location in the central/western portion of the City and is served by HTP through the WBMWD West Basin Water Reclamation Plant

Locations of the service areas are depicted in Exhibit 4E. Recycled water service areas coincide with potable water service areas. Recycled water deliveries for 2009 were 35,939 AFY, inclusive of municipal and industrial, environmental, and in-plant reuse. Estimated annual demands for online projects were 38,614 AFY.

DRAFT

AR0070865

Exhibit 4E
Recycled Water System



4.3.1 Harbor Area

Recycled water in the Los Angeles Harbor area is currently produced at the Advanced Water Treatment Plant (AWTP) located at the TIWRP. The AWTP was online in 2002 with first deliveries to customers commencing in 2006. This project was

AR0070866

developed jointly by LADWP, BOS, and BOE. Operations and maintenance is provided by BOS with funding from LADWP. Recycled water, treated using microfiltration and reverse osmosis, is currently used for landscape irrigation and groundwater injection with current demands of approximately 3,050 AFY. Treatment capacity of the AWTP is approximately 5,600 AFY. Excess recycled water is discharged into the Los Angeles Harbor. Exhibit 4F summarizes typical annual demands in the Harbor area. Currently two customers are served; LADWP's Harbor Generating Station and the Water Replenishment District (WRD).

Exhibit 4F
Harbor Recycling

Program	Existing Annual Demand (AFY)
Irrigation	
Harbor Generating Station	50
Subtotal Irrigation	50
Groundwater Barrier	
Dominguez Gap Barrier (Water Replenishment District)	3,000
Subtotal Groundwater Barrier	3,000
Total Harbor Water Recycling Project	**3,050**

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Tier 1 Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Harbor Generating Station

The Harbor Generating Station's demands that could potentially be met with recycled water are approximately 50 AFY including industrial cooling and landscape irrigation. Initially, recycled water was intended for use in the station's cooling tower and boiler make-up feed system components, however, recycled water is not used for these purposes currently as a result of concerns about potential incompatibility between recycled water and these systems. Connections have been installed for recycled water use in these systems and future use will be further investigated as part of the Recycled Water Master Plan.

Water Replenishment District

The WRD's recycled water demands are approximately 3,000 AFY for groundwater injection in the Dominguez Gap Seawater Intrusion Barrier. A blend of 50 percent recycled water and 50 percent imported water is injected into the barrier. The Dominguez Gap Barrier protects the West Coast Groundwater Basin from seawater intrusion.

LADWP is currently expanding recycled water infrastructure in the Harbor area that will increase recycled water usage at least 9,300 AFY by 2014/2015.

4.3.2 Metro Area

The Metro Recycled Water System has supplied the Metro Service Area with recycled water produced at LAG to irrigation customers since 1979. LAG provides recycled water treated to a tertiary level meeting Title 22 standards with Nitrogen removal to customers in the eastern San Fernando Valley. As previously stated, recycled water produced at LAG is equally split between the cities of Los Angeles and Glendale. Current recycled water demands for the Metro Service Area are 1,933

AR0070867

AFY. Unused recycled water is discharged to the Los Angeles River. Exhibit 4G summarizes current demands for Metro Recycled Water System. Currently 11 customers are served by the Metro Recycled Water System.

Exhibit 4G

Griffith Park Project

Started in 1979, the Griffith Park project was the City's first recycled water project. Recycled water is used to irrigate two golf courses, parkland, The Los Angeles Zoo Parking Lot, and a seven-mile stretch along the Golden State Freeway (Interstate 5) adjoining the park. Current demands in the Griffith Park Project's service area are 1,120 AFY.

Greenbelt Project

Dedicated in 1992, the Los Angeles Greenbelt Project was the City's first commercial recycling project. Recycled water is used for landscape irrigation at Forest Lawn Memorial Park-Hollywood Hills, Mount Sinai Memorial Park, Lakeside Golf Course and Universal Studios. Current demands in the Greenbelt Project's service area are 720 AFY.

Taylor Yard Project

Rio de LA State Park was connected as the first Taylor Yard project in July 2009. Recycled water is used for landscape irrigation on the park. Current demands in the Taylor Yard Project's service area are 93 AFY.

4.3.3 San Fernando Valley Area

The Valley Recycled Water System receives water from DCT to satisfy irrigation, environmental, and industrial demands. Recycled water is treated to a tertiary level meeting Title 22 standards with Nitrogen removal. Water for in-plant uses at DCT and for environmental uses is dechlorinated. Current estimated recycled water demands for the San Fernando Valley Area are 33,594 AFY. Recycled water produced in excess of demand is discharged to the Los Angeles River providing added environmental benefits. Exhibit 4H summarizes current demands for the Valley Recycled Water System. The East Valley trunkline, a 54 inch diameter pipeline, was previously constructed as the initial backbone of the Valley Recycled Water System's distribution system to deliver water throughout the San Fernando Valley for irrigation, commercial, and industrial use. Eleven customers are currently served by the Valley Recycled Water System, excluding DCT reuse and environmental use.

2. Does not include environmental benefits provided to Los Angeles River.

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Tier 1 Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Sepulveda Basin Project

LADWP began serving recycled water to portions of the Sepulveda Basin area in 2007. The latest project was added in 2010. Current recycled water customers in the Sepulveda Basin recreation area include Woodley Golf Course, Balboa Golf Course, Encino Golf Course, Anthony C. Beilenson Park, Van Nuys Golf Course and the Balboa Sports Complex. Current demands in the recreation area are 1,570 AFY.

Van Nuys Area Project

The Van Nuys Area project currently provides recycled water for irrigation purposes to St. Elisabeth's Church, the First Foursquare Church of Van Nuys, Van Nuys High School, and LADWP's Power Distribution Station 81. Current Van Nuys Area Project demands are 14 AFY.

Hansen Area Project

The Hansen Area project currently provides recycled water for industrial purposes to the Valley Generating Station. Recycled water service began in 2008 and demands are approximately 2,100 AFY. Recycled water is used in a cooling tower for one of the generation units at the power generating facility.

AR0070869

Donald C. Tillman Water Reclamation Plant Reuse

Recycled water is used at DCT for in-plant purposes. Demands vary from year to year based on needs. Between 2006 and 2008 2,920 AFY were used on average.

Environmental Use

Recycled water from DCT has provided environmental benefits since 1984 commencing with deliveries to the Japanese Garden followed by Balboa Lake in 1990 and Wildlife Lake in 1991. Approximate demands are 26,990 AFY. Overflows from these facilities are discharged to the Los Angeles River providing additional environmental benefits in conjunction with unused recycled water discharges to the river.

Japanese Garden

The 6.5 acre Japanese Garden is located at the Sepulveda Dam Recreation Area. The Garden receives more than 10,000 visitors per year. DCT provides about 4,590 AFY of recycled water for the lake and landscaping at the Japanese Garden.

Wildlife Lake

Located in the Sepulveda Basin, the Wildlife Lake uses about 7,700 AFY of recycled water from DCT for wildlife habitat management.

Lake Balboa

Lake Balboa is the centerpiece of the Sepulveda Dam Recreation Area and is a popular recreational facility located in Anthony C. Beilenson Park. About 14,700 AF per year of recycled water is provided for this lake from DCT.

4.3.4 Westside Area

Recycled water supplied to the Westside Recycled Water System is provided by WBMWD via the Edward C. Little Water Recycling Plant (WBWRP), located in the City of El Segundo, for irrigation and commercial (toilet flushing) demands. The WBWRP further treats secondary-treated effluent received from HTP to a tertiary level meeting Title 22 standards. Under an agreement between WBMWD and the City, WBMWD purchases secondary-treated effluent from HTP and LADWP has a right to purchase up to 25,000 AFY of recycled water following tertiary treatment at the WBWRP. Approximately 37,300 AFY of secondary-treated effluent was purchased from HTP in 2008 and LADWP purchased 380 AF of recycled water to serve the Westside of Los Angeles. The WBWRP can treat up to 40 mgd. Recycled water not purchased by LADWP is sold to users within WBMWD's service area.

Deliveries of recycled water from the Westside Recycled Water System first began in 1996. To increase the use of recycled water on the Westside, LADWP has constructed more than five miles of distribution trunk lines to serve the Westchester, Los Angeles International Airport, and Playa Vista development areas. Current estimated recycled water demands for the Westside Area are 676 AFY as shown in Exhibit 4I. Currently 106 customers are served by the system.

AR0070870

Playa Vista, Phase 1

Playa Vista is the first planned development in the City to use recycled water for irrigation of all of its landscaping including residential outdoor use. This project began receiving recycled water in 2009 as part of Phase 1. Phase 2 is considered as a "Near-Term" project (or "Tier 1" use), which are projects to be implemented by the year 2015. Outdoor recycled water is required under the development's mitigation requirements established during the environmental review process. Recycled water is additionally used for toilet flushing in commercial buildings. Annual demands are approximately 200 AFY for Phase 1.

Los Angeles International Airport

Los Angeles International Airport began using recycled water in 1996 for landscape irrigation purposes along its boundaries. Current demands for the airport are 158 AFY.

Westchester Golf Course

Westchester Golf Course began using recycled water in 2009 for irrigation. Current demands for the airport are 62 AFY.

Loyola Marymount University

Loyola Marymount University has been connected to the Westside system since 1996. Recycled water is used to irrigate a portion of the campus landscaping area. Average annual demands are approximately 65 AFY. In 2006, Loyola Marymount

AR0070871

University installed an on-site disinfection system using hydrogen peroxide to address odor problems related to stagnant water in an oversized pipeline servicing the university.

Westchester Park and Carl Nelsen Youth Park

Westchester and Carl Nelsen Youth Parks both use recycled water for irrigation purposes. Both parks were connected to the system in 1996. Westchester Park demands are approximately 43 AFY and Carl Nelsen Youth Park demands are 16 AFY.

Scattergood Generating Station

Scattergood Generating Station operated by LADWP and located in El Segundo receives recycled water to meet irrigation demands. Average annual demand is approximately 31 AFY. The pipeline servicing the facility is oversized to potentially provide cooling water in the future.

Street Medians and The Parking Spot

Street medians on Manchester Avenue and The Parking Spot were connected to the recycled water system in 2008 and 2003, respectively. Recycled water is served to both facilities to meet irrigation demands. The Parking Spot is a commercially operated parking facility near Los Angeles International Airport. Demands for The Parking Spot are approximately 1 AFY and demands for the street medians are approximately 5 AFY.

Hyperion Treatment Plant

HTP uses recycled water for both landscaping and toilet flushing within the administration building. HTP was connected to the system in 1996. About 65 AFY of recycled water are provided to HTP per year. HTP also provides additional treatment for recycled water use onsite similar to Loyola Marymount University to address odor problems associated with stagnant water in an oversized supply pipe. The pipeline to HTP was oversized to accommodate expanded deliveries to the Scattergood Generating Station in the future. HTP uses filters and disinfection to treat the water prior to its use onsite.

4.3.5 Comparison of 2010 Projections Versus Actual Use

LADWP has made substantial progress in increasing recycled water use in the interim period between completion of the 2005 and 2010 UWMPs. Municipal and industrial recycled water use between 2005 and 2010 increased from 4,870 AFY to 10,651 AFY. The 2005 UWMP projected municipal and industrial recycled water use in 2010 would be approximately 19,870 AFY, however actual use was lower than estimated as shown in Exhibit 4J. Environmental water use of recycled water fluctuates slightly year to year based on lake levels, but is typically 26,990 AFY. For 2010 actual use was 25,129 AFY, or approximately 7 percent less than estimated. Overall total recycled water use in 2010 was approximately 23 percent less than projected.

AR0070872

Exhibit 4J
2005 UWMP Recycled Water Projections for 2010 versus Actual Use

Program	2005 Projection for 2010 (AFY)	09/10 Actual Use (AFY)
Municipal & Industrial Purposes[1]	19,870	6,864
Environmental Use[2]	26,990	25,008
Total	**46,860**	**31,872**

1. These recycled water supplies offset the demand for imported water within LADWP's service area and include DCT reuse of 2,920 AFY, but do not include deliveries to WBMWD of 34,000 AFY. DCT reuse was not included in 2005 UWMP projections for 2010.

2. Water is ultimately discharged into the Los Angeles River, providing additional environmental benefit. 2005 UWMP projections for 2010 is based on average demands.
Sources: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Tier 1 Recycled Water Systems TM, December 14, 2009; 2005 Urban Water Management Plan for the Los Angeles Department of Water Power, and LADWP Water Recycling Staff

Although LADWP did not meet the 2010 recycled water projection, significant progress has been made including the completion of multiple projects since 2005 as described in Section 4.3.1 through 4.3.4. Additional projects that are proposed for construction in the near future are described in Section 4.4, Recycled Water Master Planning Documents. Additionally, LADWP in conjunction with the BOS is currently developing the City's Recycled Water Master Plan (RWMP) to guide future optimization of this supply source with the goal of increasing municipal and industrial use of recycled water to 50,000 AFY, inclusive of indirect potable reuse.

4.4 Recycled Water Master Planning Documents

LADWP in partnership with BOS is developing the RWMP Documents to replace 50,000 AFY of potable water supplies with recycled water by 2029 and to plan for long-term recycled water use. As previously discussed, the City of Los Angeles' Water Supply Plan, "Securing LA's Water Supply", the City has established a goal of 50,000 AFY with recycled water to reduce the need for potable water and diversify LADWP's available water supply options. Exhibit 4K summarizes LADWP's timeline to achieve the goal of recycling 50,000 AFY by fiscal year (FY) 2029. This goal can be achieved sooner if additional funds are made available such as state and federal grants. The RWMP efforts were initiated in 2009 and are forecast for completion by the middle of 2011. To meet near-term challenges and plan for long-term recycled water the following major tasks were outlined for inclusion in the RWMP Documents:

- Groundwater Replenishment Report;
- Non-Potable Reuse Report;
- Groundwater Replenishment Treatment Pilot Study;
- Max Reuse Concept Report;
- Satellite Feasibility Concept Report;
- Existing System Reliability Concept Report; and

AR0070873

Within these tasks the RWMP Documents will determine where the existing recycled water system (purple-pipe network) should be expanded to satisfy needs of new customers. A cost benefit analysis will be conducted to identify potential customers considering location and projected use. A review of the wastewater treatment plants will be performed to determine which plants can supply the recycled water and the treatment technologies required. The RWMP Documents will also review available options for maximizing reuse through a combination of alternatives including expansion of non-potable uses, groundwater replenishment with advanced treated recycled water, and/or injection of recycled water as a seawater intrusion barrier. A set of alternatives will then be developed and analyzed for both the near-term and long-term goals. Alternatives will be evaluated as part of an integrated analysis.

The RWMP Documents will include Near-Term recycled water projects (projects to be implemented through 2015 to achieve 20,000 AFY of recycled water use), expansion of the non-potable distribution system beyond 20,000 AFY, and groundwater replenishment with advanced treated recycled water options. When combined with existing reuse, these options are expected to result in 50,000 AFY of reuse by FY 2029, exclusive of environmental reuse, DCT in plant reuse, and sales to WBMWD. Exhibit 4K provides a timeline for projects featured in the RWMP Documents.

Exhibit 4K
Recycled Water Master Planning Documents Implementation Timeline

Timeline	Reuse Volume[1] (AFY)	Description
Existing as of Fiscal Year 2009/2010	6,700	Existing demands already being served
Recycled Water Use by 2015	20,000	Near-Term projects already identified for implementation by 2015
Groundwater Recharge by 2021	15,000	New groundwater replenishment opportunities as identified as part of the Groundwater Master Plan task
Non-Potable Reuse Recycled Water by 2029	Up to 15,000	New projects identified between 2015 and FY 2029 to serve existing potable customers as part of the non-potable reuse master plan

1. Volume to offset municipal and industrial potable water demands. Does not include environmental use, DCT plant reuse, and sales to WBMWD.

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Tier 1 Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Recycled water projections in five year increments beginning in 2015 through 2035 are presented in Exhibit 4L. Total recycled water production is estimated to increase by 42,000 AFY over the projection period or 84 percent. Environmental reuse and seawater intrusion barrier water are expected to remain constant at 26,990 AFY and 3,000 AFY, respectively. Municipal and industrial use, inclusive of DCT reuse, is expected to increase by 27,000 AFY or approximately 136 percent. Indirect potable reuse (groundwater recharge) with advanced treated recycled water is forecast to provide 15,000 AFY of groundwater recharge beginning in 2021. Recycled water use up to 2025 is inclusive of the near-term options under development in the RWMP. Projections for 2030 and 2035 assume that long-term options being developed as part of the RWMP will increase recycled water use by approximately 1,500 AFY annually beyond FY 2029. Once the alternatives for the RWMP are finalized, the allocation of recycled water use by the municipal, industrial, and groundwater recharge categories may change to achieve the RWMP's recycled water goal of 50,000 AFY.

AR0070874

Exhibit 4L
Recycled Water Use Projections

Category	Projected Use (AFY)[1]				
	2015	2020	2025	2030	2035
Municipal and Industrial	20,000	20,400	27,000	29,000	29,000
Indirect Potable Reuse (Groundwater Recharge)	0	0	15,000	22,500	30,000
Subtotal[2]	**20,000**	**20,400**	**42,000**	**51,500**	**59,000**
Environmental[3]	26,990	26,990	26,990	26,990	26,990
Seawater Intrusion Barrier (Dominguez Gap Barrier)	3,000	3,000	3,000	3,000	3,000
Total	**49,990**	**50,390**	**71,990**	**81,490**	**88,990**

1. Projected use by category is subject to change per completion of Recycled Water Master Plan, but overall total will not change. Does not include deliveries of 34,000 AFY of secondary treated water to WBMWD for further treatment to recycled water standards.

2. To offset potable use and included in supply reliability tables in Chapter 11.

3. Environmental use includes Wildlife Lake, Balboa Lake, and the Japanese Gardens. Additional environmental benefits associated with recycled water discharges to the Los Angeles River are not included.

Estimates of projected use and implementation timelines in the tables above as well as the annual demands and service dates for individual customers in the following sections may be affected by varying usage patterns of potential customers, timelines to reach agreements, as well as potential financial constraints and changing regulatory requirements.

4.4.1 Near-Term Projects through 2015

"Near-Term" projects are classified in the RWMP Documents as projects that will result in recycled water service between July 1, 2009 and 2015 to achieve 20,000 AFY of recycled water use to displace potable water. All Near-Term projects are either in the planning, design, or construction stage. Near-Term target customers have already been identified as potential recycled water users with a total demand of 15,021 AFY. Implementation of Near-Term projects will result in the connection of approximately 40 additional recycled water customers adding to the existing 130 customers. Full implementation of Near-Term projects with existing projects will result in annual recycled water demand of 20,000 AFY, exclusive of both environmental use and DCT in-plant use (26,990 and 2,920 AFY, respectively). Near-Term reuse is the largest in the commercial/industrial sector followed by the irrigation sector.

Harbor Area

Two projects are planned to meet Near-Term demands in the Harbor area, the Harbor Refineries Water Recycling Project (HRWRP) and the Port of LA Harry Bridges Development, for an estimated total demand of 9,461 AFY. Uses include industrial, irrigation, and toilet flushing in commercial facilities. Most of the recycled water, approximately 9,520 AFY, will be used for industrial purposes, including cooling towers and boiler make-up water at oil refineries. Exhibit 4M summarizes Near-Term demands for the Harbor area.

AR0070875

Exhibit 4M
Harbor Area Near-Term Estimated Demands

Type	Estimated Annual Demand (AFY)	Estimated Service Date
Harbor Irrigation	300	2014
Port of LA Irrigation/Commercial/Industrial	220	2015
Harbor Commercial/Industrial	9,000	2014-2015
Total Harbor Area Near-Term Demands	**9,520**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Meeting demands in the Harbor Area will require construction of additional infrastructure. Approximately 12 miles of 8 to 30-inch diameter pipeline and a 1 million gallon storage tank are proposed. All infrastructure to serve the Port of LA Harry Bridges Development will be constructed by the Los Angeles Harbor Department.

Through an agreement with WBMWD, LADWP intends on acquiring nitrified Title 22 water from the WBMWD Juanita Millender-McDonald Water Treatment Plant (JMMWTP) to supply recycled water to these customers.

Metro Area

Nine water recycling projects and connection of three miscellaneous customers are planned in the Metro Area with annual demands of approximately 1,813 AFY. Almost all recycled water customers propose to use recycled water for irrigation. Commercial uses of recycled water include street sweeping, vehicle washing, train washing, and laundry. LAG will continue to meet all recycled water demands in the Metro area. Exhibit 4N summarizes Near-Term demands for the Metro area.

Exhibit 4N
Metro Area Near-Term Estimated Demands

Type	Estimated Annual Demand (AFY)	Estimated Service Date
Irrigation	1,713	2010-2015
Commercial/Industrial	100	2011-2013
Total Metro Area Near-Term Demands	**1,813**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Multiple facilities are required in the Metro area to meet near-term demands. Approximately five pump stations ranging in size from 600 to 1,800 gallons per minute are planned for construction. Three water tanks with a combined capacity 4.75 million gallons, including the conversion of an abandoned potable water tank in Griffith Park into non-potable water storage tank, are necessary to meet demands. Pipeline construction will consist of 10 additional miles of pipeline ranging from 8 to 30-inch diameters, including conversion of an existing 16-inch pipeline to a 30-inch pipeline beneath Forest Lawn Road.

AR0070876

Valley Area

In the Valley area DCT will provide the potential Near-Term annual demands approximating 769 AFY. Almost all Near-Term use, except for 75 AFY, will be for irrigation purposes. These users are all located within close proximity to the existing recycled water system. Exhibit 4O summarizes the potential Near-Term demands for the Valley area.

Exhibit 4O
Valley Area Near-Term Estimated Demands

Type	Estimated Annual Demand (AFY)	Estimated Service Date
Irrigation	769	2010-2013
Commercial/Industrial	75	2010-2013
Total Metro Area Near-Term Demands	**844**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling staff

Only minor facilities will be required to connect near-term users to the existing system. Over 2 miles of pipeline ranging from 16 to 20-inch in diameter are proposed. Additionally, 1 storage tank between 1 to 1.5 million gallons and a pump station of an undetermined volume will be required to meet demands.

Westside Area

LADWP will continue to acquire recycled water from WBMWD to serve Near-Term demands of approximately 350 AFY in the Westside area. Near-Term demands include increasing use at Playa Vista and LAX and adding five new customers. Approximately two-thirds of the water will be for irrigation purposes and one-third for commercial/industrial uses in cooling towers located at LAX. Exhibit 4P summarizes Near-Term demands for the Westside Area.

Exhibit 4P
Westside Area Near-Term Estimated Demands

Project	Estimated Annual Demand (AFY)	Estimated Service Date
Irrigation		
Playa Vista Phase 2	100	2015
Westchester High School	10	2012
Subtotal Irrigation	100	
Commercial/Industrial		
LAX Cooling Towers	240	2015
Subtotal Commercial/Industrial	240	
Total Metro Area Near-Term Demands	**350**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

AR0070877

Serving Near-Term demands will require limited expansion of the existing recycled water system in the area as additional users will connect to the existing system. Connection of the cooling towers at LAX will require construction of an additional 0.7 miles of 12-inch diameter pipeline.

4.4.2 Non-Potable Reuse (NPR) Projects to be completed between 2015 - 2029

NPR projects to be completed between 2015 – 2029 are being identified through the development of the RWMP. These projects will make up the balance of recycled water demand up to 15,650 AFY to achieve the overall city goal of 50,000 AFY of recycled water displacing potable water uses.

As presented in Exhibit 4Q, the project options will have a total demand of approximately 23,100 AFY, inclusive of demands greater than 5 AFY, which is larger than the goal of up to 15,650 AFY and larger than the initial targeted customer demand of 14,390 AFY. Ultimately, an implementation plan will be developed for the recommended project options with a goal of beginning operations for all projects included in the implementation plan by FY 2029.

Exhibit 4Q
Project Option Demands by Service Area

Service Area	Total Demand[1] (AFY)
Harbor	3,300
Metro	6,100
Valley	10,100
Westside	3,600
Total	**23,100**

1. Includes customers with non-potable demand estimates greater than 5 AFY.

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Tier 2 Non-Potable Reuse Project Options, February 26, 2010

Project Selection

An initial step for evaluating these projects involves identification of potential potable customers that can utilize recycled water. These customers need to have sufficient demand and a viable use for recycled water. A preliminary list of potential of customers and associated demands was completed, identifying targeted customer demands of 14,390 AFY. Irrigation-only demands were focused on first as it is generally easier to convert irrigation-only customers to recycled water use than commercial or industrial users. As described below, during development of the project options potential additional recycled water customers were identified based on their non-potable water demands and distance from recycled water sources.

Next, recycled water project options were developed to meet the goal of maximizing recycled water use, while promoting cost efficiency as well as implement ability and adaptability. Two primary steps were utilized to develop recycled water project options:

- Identification of project segments to serve each customer with non-potable demands in excess of 50 AFY
- Identification of project options combining project segments that are linked and have similar unit costs

AR0070878

The first step in the development of project options was to define general project areas based on customers with non-potable demands in excess of 50 AFY. In the project areas, transmission pipeline alignments (backbone alignments) and laterals were defined to connect customers with demands greater than 50 AFY to existing recycled water infrastructure. Alignments were then redefined to connect demand clusters of less than 50 AFY, but large enough for consideration as a large demand. Finally, distribution pipeline (laterals) alignments were determined to connect customers with demands less than 50 AFY to backbone alignments.

Initial projects options and unit costs are being identified in the current phase of the RWMP. Refinement of these options will occur prior to development of the integrated alternatives for near-term recycled water use. Options for non-potable reuse transmission (purple) pipelines are considered in conjunction with options developed for groundwater replenishment (see section 4.4.3), maximizing reuse, and satellite plants to develop integrated alternatives. Additional information on recycled water unit cost is presented in section 4.4.5 – RWMP Cost and Funding.

Recycled Water Supply Sources

Recycled water availability varies by service area. Additional supplies may be required to meet longer term demands between 2015 – 2029 that may require a combination of expanding existing facilities, service connections to neighboring agencies outside the City, new facilities, and satellite treatment facilities. Satellite treatment facilities are being investigated in the Metro, Valley, and Westside service areas. The RWMP is investigating options to ensure adequate supplies are available for each service area. As part of the RWMP, LADWP met with neighboring agencies in 2009 to explore potential opportunities for regional development of recycled water reuse facilities. These agencies are listed in Exhibit 4T, in section 4.4.6, Stakeholder Process and Agency Coordination.

4.4.3 Groundwater Replenishment

As part of the RWMP, LADWP is pursuing a Groundwater Replenishment Project (GWR), also known as indirect potable reuse, using highly purified advanced treated recycled water from DCT for spreading in existing spreading basins in the San Fernando Valley area. A minimum goal of 15,000 AFY by 2021 has been set for recharging the San Fernando Basin, a major potable water supply for LADWP. The city anticipates having the ability to eventually deliver greater amounts of up to 30,000 AFY to the GWR. The RWMP includes a groundwater recharge plan providing a capital improvement program and outlines regulatory approval steps required to complete the "Phase 1". Additionally, the RWMP outlines various operational and infrastructure improvements required to meet the goal. When complete the RWMP will contain a recommended GWR alternative. Regulatory requirements for groundwater recharge are discussed in sub-section 4.1.2, Groundwater Recharge Regulatory Requirements.

Currently, LADWP uses multiple spreading grounds located in the eastern portion of the San Fernando Basin to recharge the underlying San Fernando Basin with stormwater and imported water. A detailed discussion of the San Fernando Basin and existing recharge operations is provided in Chapter 6, Local Groundwater. This project would recharge a minimum of 15,000 AFY of advanced treated water in the existing Hansen Spreading Grounds and possibly Pacoima Spreading Basins by allowing the water to percolate into the aquifer. It is expected that native stormwater recharge would continue to occur at the spreading grounds in conjunction with the project.

Infrastructure improvements are required to implement the groundwater replenishment program including an advanced water treatment facility and pipelines to convey the product water to the spreading basins.

AR0070879

An advanced water treatment facility is necessary to further treat tertiary effluent from DCT to produce highly purified recycled water for recharge. Goals for the advanced water treatment plant include as described in the RWMP are:

- Minimum capacity of 15,000 AFY; with the potential to expand to 30,000 AFY
- Initially in service by 2021;
- Utilization of proven technologies that have demonstrated effective removal of regulated chemicals, constituents of emerging concern, and microorganisms; additional removal of constituents of wastewater origin of interest to CDPH, including pharmaceuticals, personal care products, and endocrine disrupting compounds; and
- Product water shall comply with requirements from the CDPH, RWQCB, and SWRCB and be suitable for indirect potable reuse.

To develop and implement the project within the short-time frame, the advanced wastewater treatment plant will be based on the recently permitted Orange County Water District Groundwater Replenishment System Project. This system provides product water for indirect potable reuse by recharging a groundwater basin used for potable water and preventing seawater intrusion. Proposed technologies include microfiltration or ultrafiltration, reverse osmosis, advanced oxidation using ultraviolet light with hydrogen peroxide, and post-treatment for product water stabilization.

As a by-product of advanced water treatment brine is created. Multiple brine disposal alternatives are presented in the RWMP and a final alternative will be selected upon completion of the plan.

Pipelines to convey water to the Hansen spreading grounds are already in place and were constructed as a part of the previous recycled water initiatives for the East Valley Water Recycling Project. However, if the Tujunga spreading basin will also receive water for spreading then additional pipeline infrastructure will be required.

LADWP is working closely with BOS and regulatory agencies to expedite completion of the project by 2021. Current ongoing tasks include completion of the RWMP, public outreach, pilot testing of processes, and formation of an independent advisory panel. Environmental documentation is expected to be initiated in 2011 and completed in 2013.

Independent Advisory Panel

GWR projects typically have the involvement of an independent third party with scientific and technical expertise to provide expert peer review of key aspects of the project, which can ensure the technical viability of the GWR and facilitate the regulatory process. To accomplish this, LADWP awarded a contract with National Water Research Institute (NWRI) to form an Independent Advisory Panel (IAP) to provide expert peer review of the technical, scientific, regulatory, and policy aspects of the proposed groundwater replenishment project, pilot project testing, and other potential groundwater replenishment projects to maximize reuse as part of the LADWP Recycled Master Planning Documents. The IAP process will provide a consistent, thorough, and transparent review of any proposed GWR projects and pilot testing during their critical formation phase, as well as during the long- term implementation phase.

NWRI has vast experience in the organization and administration of the IAP processes for other agencies such as the Orange County Water District Groundwater Replenishment System Project. NWRI will assist the IAP process by assembling the IAP

AR0070880

members, developing a detailed scope and approach for the IAP's review, coordinating and facilitating meetings, and preparing IAP reports.

Some of the immediate activities that have been identified for the IAP to address during the initial participation include, but are not limited to review of the following:

- General approach for Recycled Water Master Planning
- Hydrogeology (in-basin groundwater blending)
- Treatment (barriers to replace the fifty-percent blend criteria)
- Reliability features of the Advanced Water Treatment Facility
- Source Control Evaluation for groundwater replenishment
- Draft Engineering Report for groundwater replenishment
- Response to technical concerns raised by regulators and the public

The "Independent Advisory Panel for the City of Los Angeles Groundwater Replenishment Project" consists of 13 members with scientific and/or professional expertise in issues related to the implementation of groundwater replenishment projects. Members with different areas of expertise are based on the requirements of the California Department of Public Health Draft Groundwater Recharge Reuse Regulations dated August 2008, as well as the composition of panels used by the Orange County District and the City of San Diego for the implementation of similar groundwater replenishment projects.

NWRI convened the Independent Advisory Panel for the first time in October 2010 to receive introductory information about the recycled water program and groundwater replenishment project. The Panel is expected to be involved throughout the planning, permitting, design, environmental documentation, and implementation of the groundwater replenishment project.

4.4.4 Efforts Beyond 50,000 AFY

As part of the RWMP, LADWP is developing long-term alternatives to maximize recycled water use beyond 50,000 AFY. After 2029 and through 2035 LADWP expects to increase recycled water use by approximately 1,500 AFY anually. To maximize recycled water use LADWP is investigating the following options in its RWMP:

- Recycled water satellite treatment facilities;
- Expansion of recycled water systems;
- Increasing treatment levels at HTP to tertiary and advanced treatment;;
- Reviewing opportunities for partnerships with agencies within the City and outside the City
- Treatment plant upgrades at DCT and LAG; and
- Methods to increase reliability of the system.

AR0070881

Additionally, the RWMP will identify how the city can maximize recycled water usage unto the future beyond the 50,000 AFY goal. The long-term recycled water alternatives analysis as part of the RWMP has not been completed. However, LADWP forecasts that in 2035 municipal and industrial recycled water demands along with groundwater replenishment will be approximately 59,000 AFY. In addition to this, 26,990 AFY will also be used for environmental beneficial reuse.

4.4.5 RWMP Cost and Funding

The capital cost of expanding the recycled water system to achieve the initial goal of 50,000 AFY to displace the need of potable water was initially estimated to cost approximately $1 billion. Exhibit 4R summarizes the initial estimated capital costs for the RWMP. However, these estimates are being refined as part of the RWMP that are expected to be updated by early 2011.

Exhibit 4R
RWMP Estimated Capital Costs

Phase	Capital Cost[1] ($ million 2008)
Near-Term projects through 2015	$ 265
Long-Term projects through 2029	$ 435
Groundwater Recharge Project	$ 300
Total RWMP Capital Cost	**$ 1,000**

1. Capital costs will be updated and refined as part of the RWMP.

Unit Cost

Non-Potable Reuse (NPR) and Groundwater Replenishment (GWR) projects are diverse, and result in a wide range of costs to implement and sustain. NPR projects present numerous challenges including distance from treatment plant and the associated transmission pipeline construction costs. This factor is weighed against customer size as well as the adaptability to a particular commercial site or process. For GWR projects, nearby spreading grounds must be acquired, along with the construction of a conveyance pipeline. Initial findings of the RWMP have determined the approximate range of unit cost for recycling to be from $600 - $1,500 / AF. This approximation includes capital, operation and maintenance costs.

Funding

Capital costs for RWMP projects will be covered by the sources identified below, as well as other sources as they become available.

- Water Rates – LADWP water rates are the primary funding source for the recycled water program.
- Federal Funding – LADWP will pursue federal funding as it becomes available. In the past LADWP has received funding for recycled water projects from the Federal Water Project Authorization and Adjustment Act of 1992, Public Law 102-575 (HR429), and the United States Bureau of Reclamation Title XVI Program.
- State Funding – LADWP will pursue state funding as it becomes available, through the SWRCB and DWR for recycled water projects. Propositions 13 and 50 had funds specifically marked for recycled water projects. Funding is available through Proposition 84, Integrated Regional Water Management, for implementation projects, including recycled water projects. Low-interest loans are available through the SWRCB for eligible projects.

AR0070882

- MWD Local Resources Program Incentive – The Local Resources Program provides funding for water recycling and groundwater recovery projects that prevent a new demand on MWD or displace an existing demand on MWD. Financial incentives up to $250 per acre-foot are available dependent upon MWD water rates and projects costs. Funding is not received until production occurs and terminates upon the expiration of the funding agreement for the project.

4.4.6 Stakeholder Process and Agency Coordination

Stakeholder outreach and coordination with agencies plays a key role in LADWP's recycled water program and the RWMP.

Stakeholder Process

To encourage input as recycled water strategies are developed over the next few years in conjunction with the RWMP, LADWP has initiated an extensive stakeholder process. LADWP has developed two formats for participation of stakeholders, a more intensive Recycled Water Advisory Group (RWAG) and a less intensive Recycled Water Forum.

Over 200 stakeholders were invited to participate in the RWAG representing broad interests across the City, including community groups, environmental groups, neighborhood councils, homeowners' associations, and others. Approximately 60 stakeholders are participating in the process. The RWAG first met in 2009 and will continue to have approximately 5 workshops per year over the next 3 to 4 years. Through the RWAG, stakeholders are provided the opportunity to represent their respective organizations and share input with LADWP and BOS and convey they knowledge gained to their organizations. Two main roles of the RWAG are:

1) Allow stakeholders to provide input on recycled water options from technical, environmental, financial, and social viewpoints

2) Consider key project issues and discuss implementation challenges and acceptability.

Less intensive stakeholder participation opportunities are available through the Recycled Water Forums. The Recycled Water Forums will provide stakeholders the opportunity to hear briefings on recycled water efforts through several weekend or evening meeting throughout the year held within local communities. Stakeholders will have the opportunity ask questions and provide comments and suggestions.

Agency Coordination

To maximize recycled water use and move forward with RWMP efforts, LADWP closely coordinated with agencies at the local and state levels. Coordination is necessary to ensure adequate funding, identification of end-users, adequate availability of supplies, permitting and regulatory approvals, and regional cooperation. If federal funding opportunities become available, LADWP will also coordinate with the applicable federal agencies. Exhibit 4S provides a summary list of agencies LADWP is currently coordinating with to maximize recycled water use. LADWP also coordinates recycled water end use with potential customers by assisting with facility retrofits, providing financial incentives, and public education.

AR0070883

Las Virgenes Municipal Water District[1]	Los Angeles Regional Water Quality Control Board
State Water Resources Control Board	Los Angeles County Department of Public Health
City of Los Angeles Department of Public Works, Bureau of Sanitation, Watershed Protection Division	City of Los Angeles Department of Public Works, Bureau of Sanitation
California Department of Public Health	

1. Met with agencies individually to discuss potential regional recycled water use.

4.4.7 Recycled Water Quality

All recycled water provided by LADWP meets at minimum Title 22 standards. Title 22, Chapter 4, of the California Code of Regulations establishes water quality standards and treatment reliability criteria for water recycling to ensure public safety as discussed in Section 4.1. Title 22 standards are achieved with tertiary treatment and disinfection.

Advanced wastewater treatment is currently provided at the TIWRP by the AWTP. Advanced treatment, which includes microfiltration and reverse osmosis, removes many of the impurities remaining after tertiary treatment and disinfection. Water treated with advanced treatment techniques has the potential to be used for seawater barriers and groundwater recharge. As part of the RWMP, advanced treatment is proposed for DCT to provide indirect potable reuse through groundwater recharge. Exhibit 4C, located in Section 4.2, summarizes the level of treatment provided by each of the City's wastewater treatment plants.

DRAFT

AR0070884

Chapter Five
Los Angeles Aqueduct System

5.0 Overview

Water has been an integral part of the City's history. The City's population and economy was initially supported through a combination of local surface flows primarily from the Los Angeles River, and groundwater pumping primarily from the San Fernando Basin. When it became apparent that much of the local groundwater supply and local surface flows were fully utilized, the citizens of Los Angeles under the leadership of William Mulholland, then Chief Engineer of the Los Angeles Water Bureau, approved by a 10 to 1 margin a $23 million bond measure to construct the First Los Angeles Aqueduct in 1913. This investment was equal to 12 percent of the entire City's assessed valuation at that time. Then in 1940, an additional $40 million was spent to extend the first aqueduct 40 miles north from the Owens River to streams that were tributaries to Mono Lake, see Exhibit 5A.

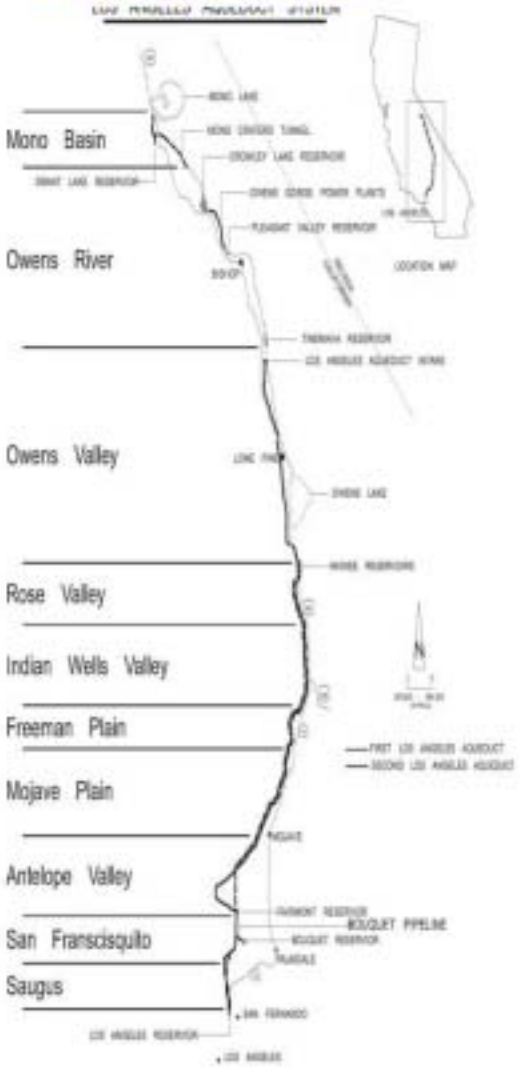
Finally, to meet the additional water needs of its population, the City decided to construct the second barrel of the Los Angeles Aqueduct in 1963, later to become known as the Second Los Angeles Aqueduct. Construction of the Second Los Angeles Aqueduct was completed in 1970. The second aqueduct increased the City's capacity to deliver water from the Mono Basin and the Owens Valley to Los Angeles from 485 cubic feet per second (cfs) to 775 cfs.

The value of the City's historical investment in the Los Angeles Aqueduct System is substantial. For nearly a century, the City has benefited from the delivery of high-quality, cost-effective water supplies from the eastern Sierra Nevada.

Over time, environmental considerations have required that the City reallocate approximately one-half of the Los Angeles Aqueduct (LAA) water supply to environmental enhancement projects. As a result, the City has used approximately 205,800 AF of water supplies for environmental enhancement in the Owens Valley and Mono Basin regions in 2010, which is in addition to the almost 107,300 acre-ft per year (AFY) supplied for agricultural, stockwater, and Native American Reservations. Limiting water deliveries to the City from the LAA has directly led to increased dependence on imported water supply from the Metropolitan Water District of Southern California (MWD). LADWP purchase of supplemental water from MWD in 2008-09 is at an all time high.

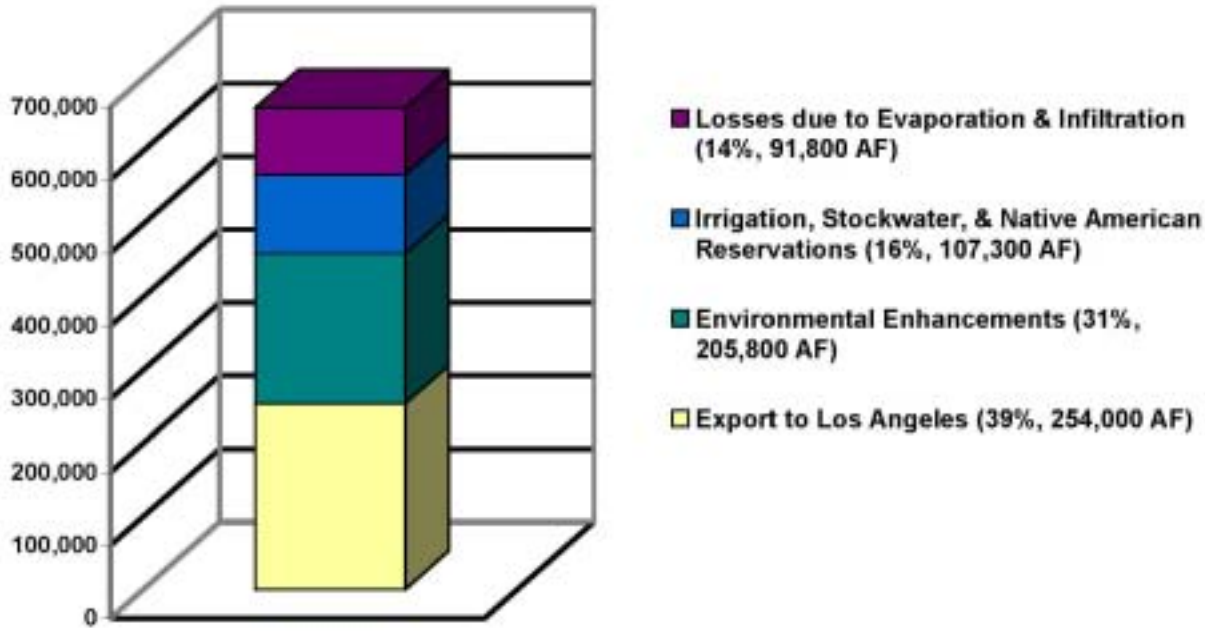
As indicated in Exhibit 5B, LAA deliveries comprise 39 percent of the total runoff in the Eastern Sierra in an average year. The vast majority of water collected in the Eastern Sierra stays in the Mono Basin, Owens River, and Owens Valley for ecosystem and other uses.

Exhibit 5A
Los Angeles Aqueduct System



AR0070886

Exhibit 5B
Mono Basin and Owens Valley Water Use Allocations



5.1 Historical Deliveries

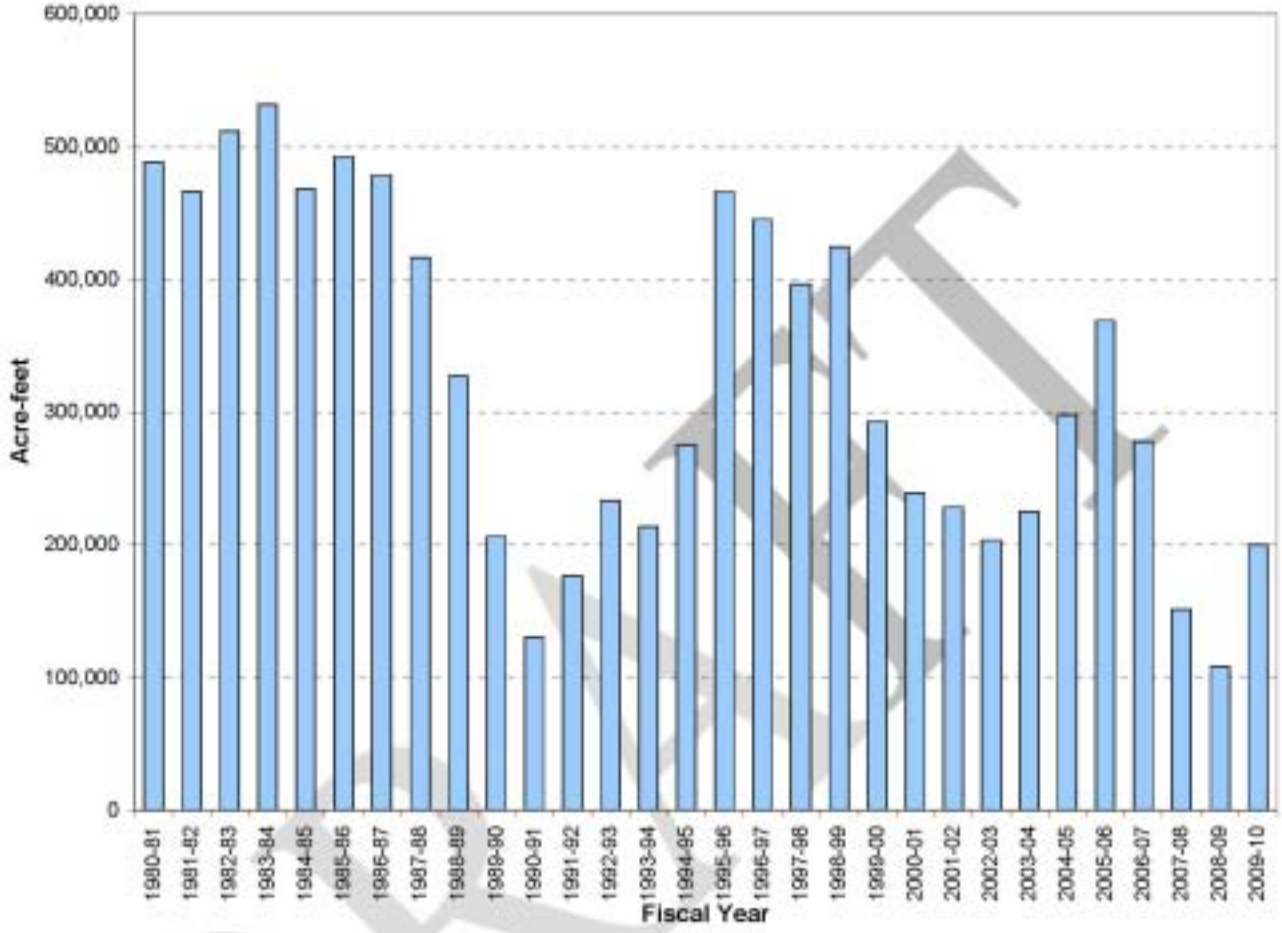
Annual LAA deliveries are dependent on snowfall in the eastern Sierra Nevada. Years with abundant snowpack result in larger quantities of water deliveries from the LAA, and typically lower supplemental water purchases from MWD. Unfortunately, a given year's snowpack cannot be predicted with certainty, and thus, deliveries from the LAA system are subject to significant hydrologic variability.

The impact to LAA water supplies due to varying hydrology in the Mono Basin and Owens Valley is amplified by the requirements to release water for environmental restoration efforts in the eastern Sierra Nevada. Since 1989, when City water exports were significantly reduced to restore the Mono Basin's ecosystem, LAA deliveries from the Mono Basin and Owens Valley have ranged from 108,503 AF in 2008-09 to 466,584 AF in 1995-96. Average LAA deliveries since 1989-90 have been approximately 264,799 AF, about 42 percent of the City's total water needs.

The cyclical nature of hydrology is exhibited best by Los Angeles Aqueduct (LAA) deliveries over the last ten years. This general period was characterized by a series of wet years, followed by a series of dry years. From 2000-01 through 2009-10, LAA deliveries supplied an average of 36 percent of the City's water needs. The reliability impact of hydrologic cycles on LAA supplies is evident through historical deliveries. A broader look at how deliveries from the LAA have fluctuated from year to year is shown in Exhibit 5C.

AR0070887

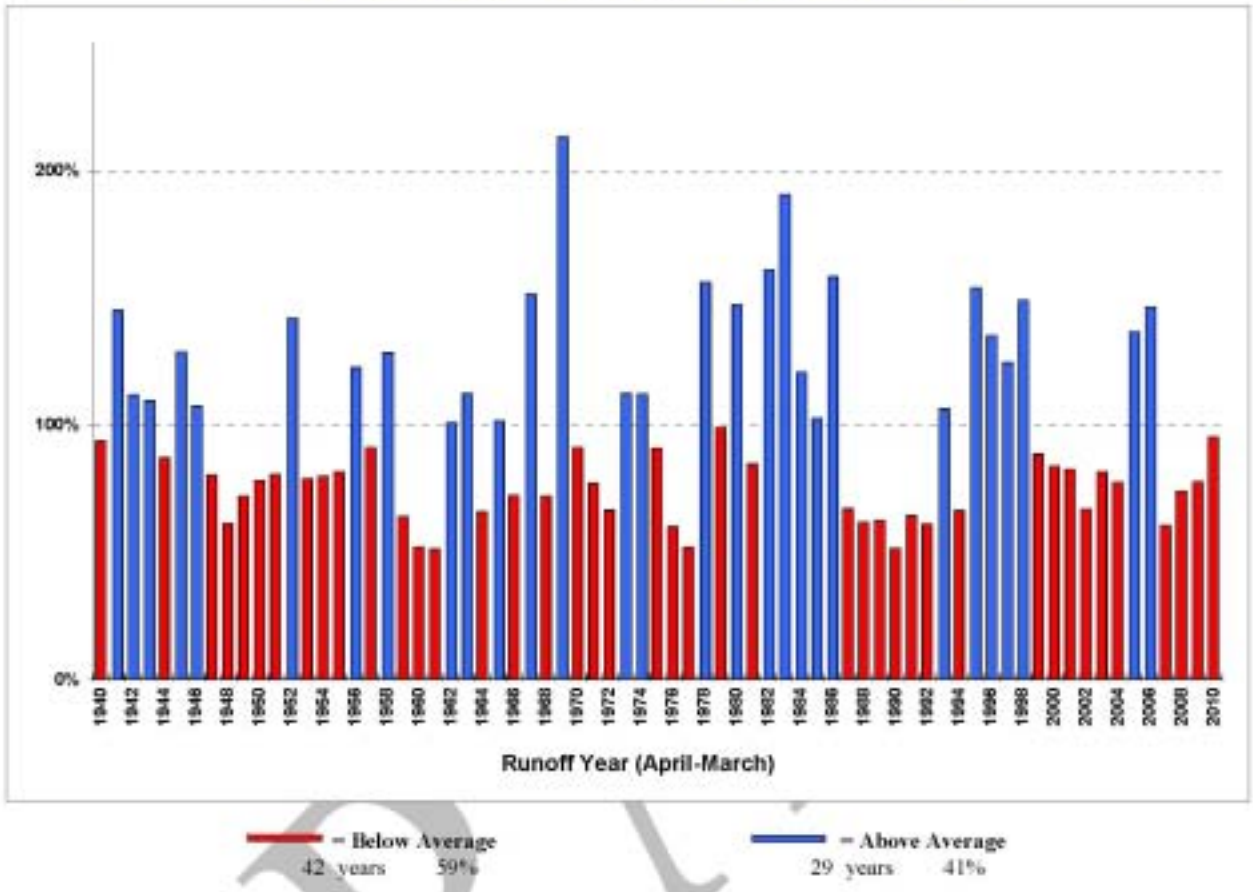
Exhibit 5C
Historical Los Angeles Aqueduct Deliveries



A long term perspective of the general cycle of wet and dry years for the Owens Valley is evident in Exhibit 5D, particularly since the late 1960s. As illustrated, reliance solely on one water supply source is not practical. Therefore, the City relies on the LAA in combination with the Colorado River Aqueduct and the State Water Project as the City's primary imported water sources. These imported sources combined with local groundwater, recycled water, and conservation make up the City's total water supply portfolio. This portfolio of water resources is fundamental to LADWP's ability to deliver a reliable water supply to meet the needs of over 4 million residents of Los Angeles.

AR0070888

Exhibit 5D
Eastern Sierra Nevada Runoff Owens Valley – Percent of Normal



5.2 Mono Basin and Owens Valley Supplies

Surface runoff from snowmelt in the eastern Sierra Nevada Mountains is the primary source of supply for the LAA. The LAA extends approximately 340 miles from the Mono Basin to Los Angeles. Water is conveyed the entire distance by gravity alone. LADWP regulates system output through storage control at seven reservoirs, beginning with Grant Lake Reservoir to the north and ending with Bouquet Reservoir to the south. The total combined reservoir storage capacity of the system is 300,560 AF. Hydroelectric power is also generated from 12 power plants along the LAA. Combined maximum capability of the power generation facilities is 205 mega-watts. Water-gathering activities for the LAA have a junior priority to meeting the Owens Valley and Mono Basin water obligations for environmental, domestic, agricultural, and recreational water needs.

The LAA is fed by runoff from the eastern slope of the Sierra Nevada. Runoff from the eastern slope reaches its maximum in the late spring and summer, after most of the year's precipitation has already occurred. The snowpack in the eastern Sierra Nevada provides natural storage for the LAA system. This snowpack storage is necessary in light of the minimal primarily regulatory storage capacity along the LAA system.

AR0070889

Water Rights

The City's export of water from the eastern Sierra Nevada is based on 166 Pre-1914 and 16 Post-1914 water right diversion licenses on various streams in the Mono Basin and Owens Valley. The majority of the City's water rights were filed prior to 1914 with the Counties of Mono and Inyo Recorder's Office. All Post-1914 licenses were granted by the State Water Resources Control Board. The most significant basis for export of surface water from the Eastern Sierra Nevada is an appropriation claim in 1905 to divert up to 50,000 miner's inches (1,250 cubic feet per second) from the Owens River at a location approximately 15 miles north of the town of Independence into the LAA for transport to Los Angeles. The City has since filed Supplemental Statements of Water Diversion and Use forms with the State Water Resources Control Board (SWRCB) for all LADWP diversions and licenses.

The City's water right licenses in the Mono Basin were amended by the SWRCB in 1994 through the Mono Lake Basin Water Right Decision 1631. Currently, water export from the Mono Basin is limited to 16,000 AF per year based on a court order to raise the target elevation of Mono Lake and restore four streams that flow to Mono Lake.

The primary groundwater right through which Los Angeles has developed groundwater resources in the Owens Valley is based on ownership of a majority of the land (approximately 314,000 acres) and associated water rights in the Owens Valley. Management of the groundwater supply in the Owens Valley is according to a 1991 agreement between Inyo County and LADWP. The goal of this agreement is to avoid defined decreases and changes in vegetation, and to cause no significant effect on the environment which cannot be acceptably mitigated, while providing a reliable supply of water for export to Los Angeles and for use in Inyo County.

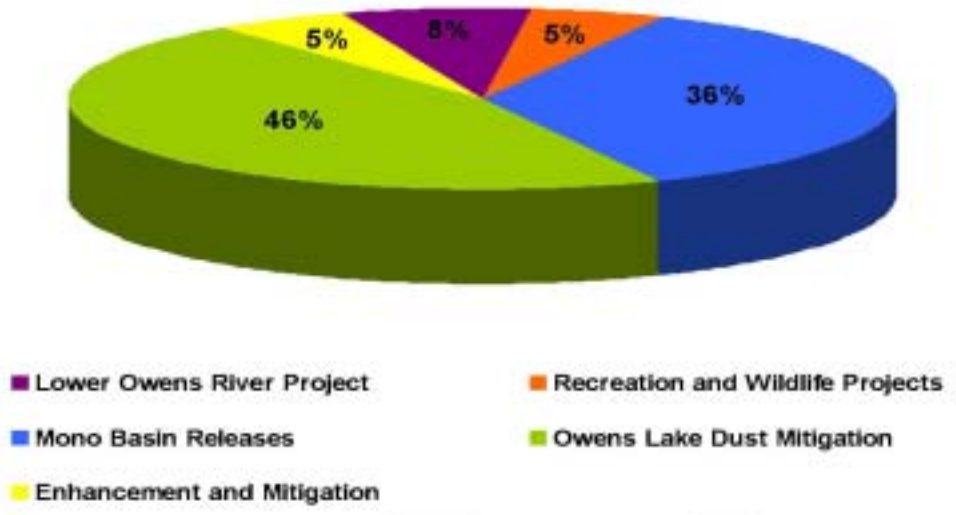
5.3 Environmental Issues and Mitigation

Over time an increasingly larger portion of the LAA water supply has been reallocated to the environment. As a result, the City's current supply for environmental enhancement in the Owens Valley and Mono Basin is approximately 205,800 AF per year. To accommodate LAA delivery reductions due to these environmental enhancements, LADWP has funded conservation and water recycling programs to improve water use efficiency within the City. Exhibit 5E illustrates the breakdown of LAA water supply commitments by category for Environmental Enhancement and Mitigation Projects have been implemented as part of the City's commitment to meet the environmental water needs of the Owens Valley. Among these environmental projects, LADWP is diverting 10,700 AF of water from the LAA for Owens Valley Enhancement and Mitigation Projects, 10,400 AF for Recreation and Wildlife Projects, and 15,700 AF for the Lower Owens River Project. These annual environmental project diversions are in addition to water that provides environmental benefits in the Mono Basin and Owens Lake.

DRAFT

AR0070890

Exhibit 5E
Mono Basin and Owens River Environmental Enhancement Commitments



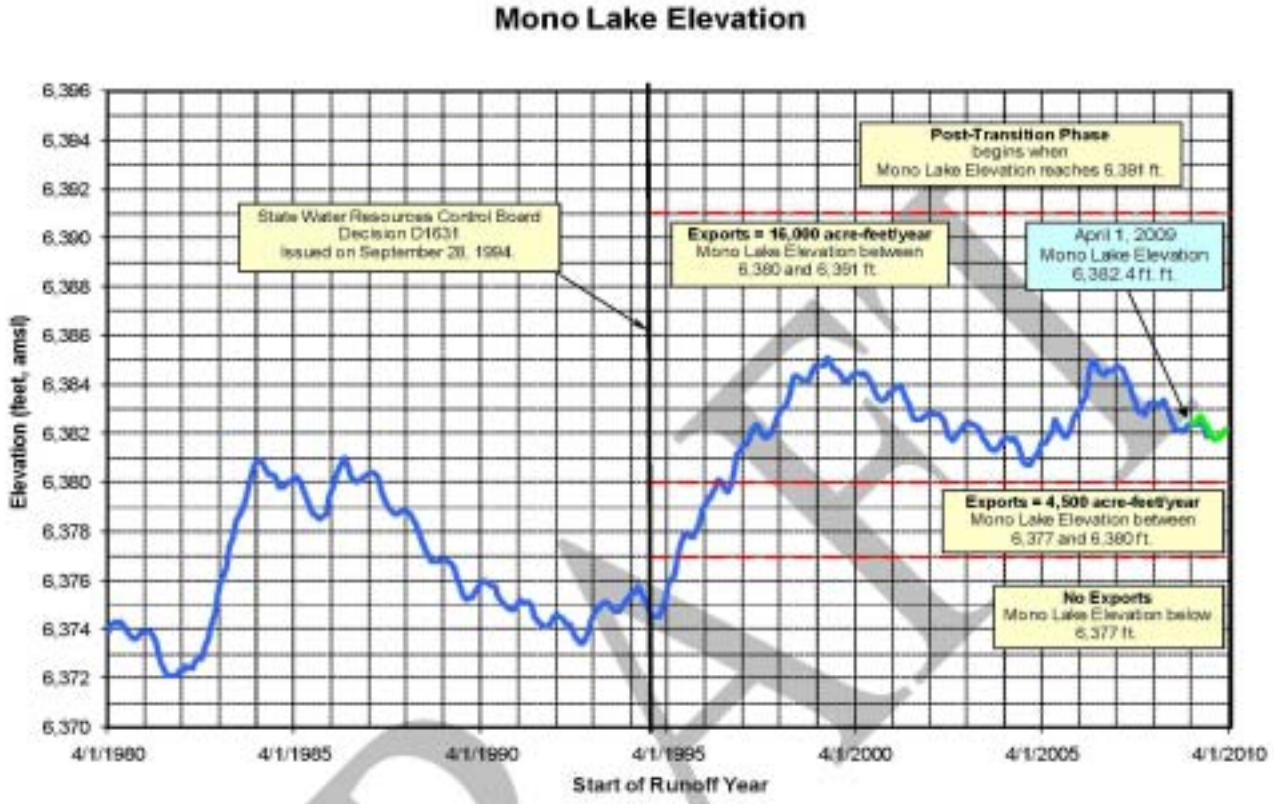
Environmental Enhancement Commitments	AFY
Lower Owens River Project	15,700
Recreation and Wildlife Projects	10,400
Mono Basin Releases	74,000
Owens Lake Dust Mitigation	95,000
Enhancement and Mitigation	10,700
Total	205,800

Mono Basin

Currently, Mono Basin exports will remain at no more than 16,000 AF per year until Mono Lake reaches its target elevation of 6,391 feet above mean sea level. Exhibit 5F provides the maximum export levels from the Mono Basin under specified conditions as defined in the State Water Resources Control Board Decision D1631 that was issued on September 28, 1994. Since the long-term average of Mono Basin exports before 1994 was approximately 90,000 AFY, the net reduction in water exports in the Mono Basin is estimated at 74,000 AFY of water mainly from Grant Lake Reservoir, Lee Vining Creek, Walker Creek, Parker Creek, and Rush Creek. As of January 2010, Mono Lake is at elevation 6,381 feet. Extensive restoration and monitoring programs in the Mono Basin have improved the streams, riparian, fishery, and waterfowl habitats. With reduced diversions from the basin, Mono Lake's elevation has risen, but has also been fluctuating due to lack of runoff as illustrated during the period of 2000 to 2005 on Exhibit 5F.

AR0070891

Exhibit 5F
Historical Mono Lake Elevations



To effectively maintain continuous base and peak water flows to the ecosystem restoration area of Lower Rush Creek in the Mono Basin, LADWP completed construction of the Mono Gate One diversion facility upgrade in November 2009. Exhibit 5G summarizes the base and peak flow requirements for Lower Rush Creek. Base and peak flow requirements vary in relation to seven hydrologic conditions ranging from dry to extreme wet as identified by forecasted runoff for Mono Basin. Mono Gate One was originally constructed to release excess water from the aqueduct system during high flows by diverting water into Lower Rush Creek with a system of diversion boards. However, it had no monitoring or flow control capabilities and was not designed for precise flow metering or full-time diversion. Construction completed in the fall of 2009, the new Mono Gate has enabled LADWP to greatly improve measuring and flow capabilities, satisfying one of the operational requirements of the SWRCB.

AR0070892

Exhibit 5G
Lower Rush Creek Base and Peak Flow Requirements

Hydrologic Condition	Base Flow (cfs)							Peak Flows (cfs)
	Apr	May - Jul	Aug - Sep	Apr - Sep	Oct- Mar	May - Aug	Sep - Mar	
Dry (runoff ≤ 83,665 AF)	N/A	N/A	N/A	31	36	N/A	N/A	None
Dry-Normal I (runoff 83,665 - 91,590 AF)	N/A	N/A	N/A	47	44	N/A	N/A	200 for 7 days
Dry-Normal II (runoff 91,590 - 100,750 AF)	N/A	N/A	N/A	47	44	N/A	N/A	250 for 5 days
Normal (runoff 100,750 - 130,670 AF)	N/A	N/A	N/A	47	44	N/A	N/A	380 for 5 days follows 300 for 7 days
Wet-Normal (130,750 - 166,700 AF)	N/A	N/A	N/A	47	44	N/A	N/A	400 for 5 days followed by 350 for 10 days
Wet (166,700 - 195,400 AF)	N/A	N/A	N/A	68	52	N/A	N/A	450 for 5 days followed by 400 for 10 days

Source: Mono Basin Operations, Guidelines A-G

Lower Owens River Project

Beginning December 2006, the Lower Owens River Project, depicted in Exhibit 5H, releases water from the LAA to create a warm water fishery along a 62-mile section of the Owens River. Water is released near the LAA intake facility and a pump back station is located downstream to return flows to the LAA or to Owens Dry Lake for dust control measures. In accordance with the Memorandum of Understanding between LADWP and Inyo County and the approved Environmental Impact Report, annual monitoring reports are to be prepared to measure project success. The first Lower Owens River Project Annual Monitoring Report was prepared in 2008.

The MOU prescribes requirements for project flows. Both base flows and seasonal habitat peak flows are required by the project. A flow schedule is provided in Exhibit 5I. Seasonal habitat peak flows vary between 40 cfs (zero additional flows beyond the base flow requirements) to 200 cfs. For below average runoff years, seasonal habitat flows may be incrementally lowered from the average runoff year requirements of 200 cfs to 40 cfs (base flow) in proportion to the forecasted runoff flows in the watershed. Base flows are constant at 40 cfs regardless of forecasted runoff flows. It is estimated that the long-term use and transit losses from the project will be approximately 15,700 AFY.

DRAFT

AR0070893

Exhibit 5H
Lower Owens River Project Area

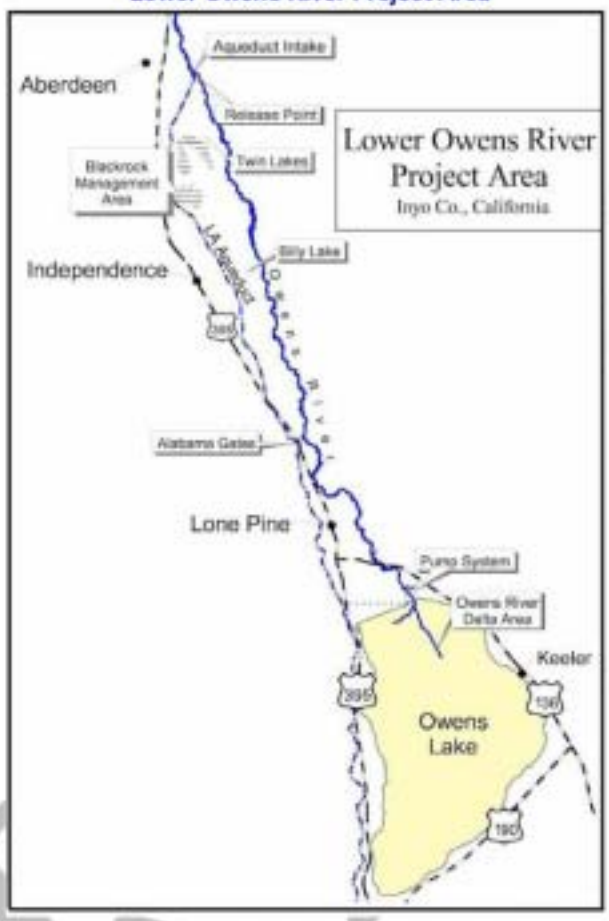

Exhibit 5I
Lower Owens River Base and Peak Seasonal Habitat Flow Requirements

Hydrologic Condition Forecasted[1] (Percent of Average Runoff)	Base Flow (cfs)	Peak Seasonal Habitat Flow (cfs)
50 percent or less	40	Base flow only
70 percent	40	100
100 percent or greater	40	200

1. Runoff forecast determined by LADWP's Runoff Forecast Model for Owens River Basin based on April 1st snow survey.

2. Peak season habitat flows are proportionately ramped up from 40 cfs to 200 cfs based on the percent of average runoff forecasted greater than 50 percent and less than 100 percent.

AR0070894

5.4 Owens Lake Dust Mitigation

Historically, the Owens River was the main source of water for Owens Lake. Diversion of water from the river, first by farmers in the Owens Valley and then by the City, resulted in the lake being reduced to a small brine pool. The exposed lakebed became a major source of windblown dust resulting in the United States Environmental Protection Agency (EPA) classifying the southern Owens Valley as a serious non-attainment area for particulates (dust) also known as PM_{10} emissions in 1991.

As a result of PM_{10} emissions exceeding regulations, the EPA required California to prepare a State Implementation Plan (SIP) to bring the region into compliance with Federal air quality standards by 2006. In July 1998, LADWP entered into a Memorandum of Agreement with the EPA that: 1) delineated the dust producing areas on the lakebed that needed to be controlled; 2) specified what measures must be used to control the dust; and 3) outlined a timetable for implementation of the control measures. The Memorandum of Agreement was incorporated into a formal air quality control SIP by the Great Basin Unified Air Pollution Control District (District). The plan was approved by the EPA in October 1999.

LADWP's water use for Owens Lake Dust Mitigation has been gradually increased over the years. Exhibit 5J summarizes yearly water use for the Owens Lake Dust Control Project. The 2005 UWMP estimated that up 55,000 AFY of water would be all that was required for the Project. Currently, up to 95,000 AF per year of water is expected to be diverted from the Aqueduct for dust mitigation at the Owens Lake.

Exhibit 5J
Yearly Water Use on Owens Lake (Fiscal Year)

Fiscal Year	Total AF
2002/2003	23,937
2003/2004	31,362
2004/2005	29,494
2005/2006	29,413
2006/2007	54,849
2007/2008	67,262
2008/2009	59,187
2009/2010	75,428
2010/2011	95,000

* Fiscal year 2010/2011 is projected

Since 2001, LADWP has diverted water from the LAA for the Owens Lake Dust Control Project. A combination of shallow flooding, managed vegetation, and a small amount of gravel are used at various lakebed locations as Best Available Control Measures (BACM) for dust control mitigation on almost 40 square miles. Exhibit 5K provides a description of the best accepted control methods. LADWP has completed 9.2 square miles of shallow flooding, 0.5 square miles of modified shallow flooding, and 0.4 square miles of sand fence as part of the Phase 7 project in accordance with the 2008 SIP. However, LADWP had proposed 3.1 square miles of a new waterless dust control measure called Moat and Row which was disallowed by the California State Lands Commission in April 2010. LADWP is working with the District to develop an alternative solution for the areas originally proposed for Moat and Row. LADWP has been ordered to complete an additional 2 square miles of dust control known as the Phase 8 project. LADWP is seeking a lease from the California State Lands Commission to construct Gravel BACM for Phase 8 as it does not require water for operation.

AR0070895

Exhibit 5K
Dust Control Mitigation Measures

Dust Control Measures		Description
Shallow Flooding	Sheet Flooding	Releases water from arrays of low-flow water outlets spaced at intervals of between 60 and 100 feet along pipelines laid along lake bed contours. Pipelines are spaced between 500 and 800 feet apart. This arrayed configuration of water delivery creates large, very shallow sheets of braided water channels. Water depths in sheet flooded areas are typically at most a few inches deep. The lower edge of sheet flooded areas has containment berms to capture and pond excess flows. The water slowly flows across the typically very flat lake bed surfaces downhill to tail-water ponds where pumps recirculate the water back to the outlets. To maximize project water use efficiency, flows to sheet flow areas are regulated at the outlets so that only sufficient water is released to keep the soil wet. Any water that does reach the lower end of the control area is collected and recirculated back through the water delivery system.
	Shallow Flooding (Pond Flooding)	Water containment berms that allow ponds to be formed that submerge the emissive lake bed areas. These ponds are up to four feet deep. The containment berms are typically rock-faced to protect them from delivery to the pond area until the pond reaches a size and depth sufficient to submerge the required amount of emissive water. Water delivery then ceases until evaporation reduces the pond size to a set minimum.
Managed Vegetation		Control measure consists of creating a farm-like environment from barren playa. The saline soil must first be reclaimed with the application of relatively fresh water and then planted with salt-tolerant plants that are native to the Owens Lake basin. Thereafter, soil fertility and moisture inputs must be managed to encourage rapid plant development and maintenance. Existing Managed Vegetation areas are irrigated with buried drip irrigation tubing and a complex network of buried drains to capture excess water for reuse on the Managed Vegetation area or in Shallow Flooding areas. Managed Vegetation is sustainable at Owens Lake only if salt from the naturally occurring shallow groundwater is prevented from rising back into the rooting zone.
Gravel Blanket		A four-inch layer of coarse gravel laid on the surface of the Owens Lake playa will prevent emissions by preventing the formation of efflorescent evaporate salt crusts, because the large pore spaces between the gravel particles disrupt the capillary movement of saline water to the surface where it can evaporate and deposit salts. The gravel also creates a surface that has a high threshold wind velocity so that direct movement of the large gravel particles is prevented and the finer particles of the underlying lake bed soils are protected. Gravel Blankets are effective on essentially any type of soil surface.

As part of an Interim Management Plan, LADWP and Inyo County have agreed to conduct a joint study to explore the feasibility of extracting and utilizing groundwater beneath Owens Lake to supplement the water supply necessary for dust mitigation activities. This feasibility study is scheduled for completion by November 2011. If groundwater pumping is considered feasible and acceptable, LADWP will first need to obtain required approval from Great Basin Unified Air Pollution Control District, California State Lands Commission, California Department of Fish and Game, and Inyo County.

AR0070896

5.5 Water Quality

As land owners of much of the Mono Basin and Owens River watersheds, LADWP has placed strict limits on the extent of development impacting the City-owned watersheds. Snowmelt from the eastern Sierra Nevada contains low total organic carbon (TOC), bromide concentrations, and other constituents that can form disinfectant byproducts during the water treatment process. LADWP conducts routine monitoring of all of its water supplies for over 170 constituents and contaminants. Ninety-eight of the constituents and contaminants have enforceable standards.

The LAA supply is the main source of arsenic in LADWP's water supply. Arsenic is collected as the Owens River makes its way down through volcanic formations in the vicinity of Hot Creek in Long Valley. Geothermal springs in these areas have arsenic concentrations of around 200 parts per billion (ppb). Concentrations are dramatically reduced as water in the area mixes with snow melt and other pristine water sources. Historic untreated LAA water arsenic concentrations have ranged from 10 to 74 ppb. During the latest 3-year routine compliance monitoring cycle from 2007 to 2009, the highest arsenic concentration after treatment was 8.1 ppb, while the average arsenic concentration within LADWP's water distribution system was 3.3 ppb, well below the current Federal and State drinking water standard of 50 ppb. In light of potential, more stringent arsenic regulations, LADWP is taking a proactive approach in addressing this issue by investing enhanced coagulation treatment.

LADWP completed an evaluation and preliminary design report for enhanced coagulation at the Los Angeles Aqueduct Filtration Plant in December 2006 as a means of addressing future water quality regulations faced by LADWP, including arsenic. An enhanced coagulation facility using the process as outlined in the report is planned as part of the treatment process at the Los Angeles Aqueduct Filtration Plant by 2021.

To comply with the Stage 2 Disinfectants and Disinfection Byproducts Rule, another water quality improvement effort being implemented is the conversion from chlorine to chloramine residual disinfectant. This transition, which is expected to be completed by April 2014, will allow LADWP to maintain the same high level of disinfection in its water supply while freeing itself from other potential disinfection issues associated with the use of chlorine. The use of chloramines will provide additional operational flexibility by allowing the blending of purchased MWD water (which is chloraminated) into the LADWP distribution system without the problems associated with creating a chlorine/chloramines interface when blending the two supplies.

5.6 Projected Deliveries

Near-term water deliveries are forecasted for the LAA using two models, the Runoff Forecast Model and the Los Angeles Aqueduct Simulation Model (LAASM). These two models used jointly and accurately predict the amount of water available from this the LAA.

The Runoff Forecast Model is used to predict total Owens Valley and Mono Basin stream runoff. The model's estimating equations were developed using historic rainfall and snowfall, as well as streamflow data of each year. Model input consists of 6 months of antecedent rainfall and streamflow data, as well as the final snowpack levels on April 1st. The model's output is the forecasted runoff for the Owens Valley and Mono Basin during the twelve month period following April 1st, assuming that median rainfall occurs during those twelve months.

Runoff flows from the Owens Valley to the City of Los Angeles are modeled by the LAASM. LAASM uses the output of the Forecast Model as input, along with estimates of various uses within the Owens Valley. LAASM uses historically derived

AR0070897

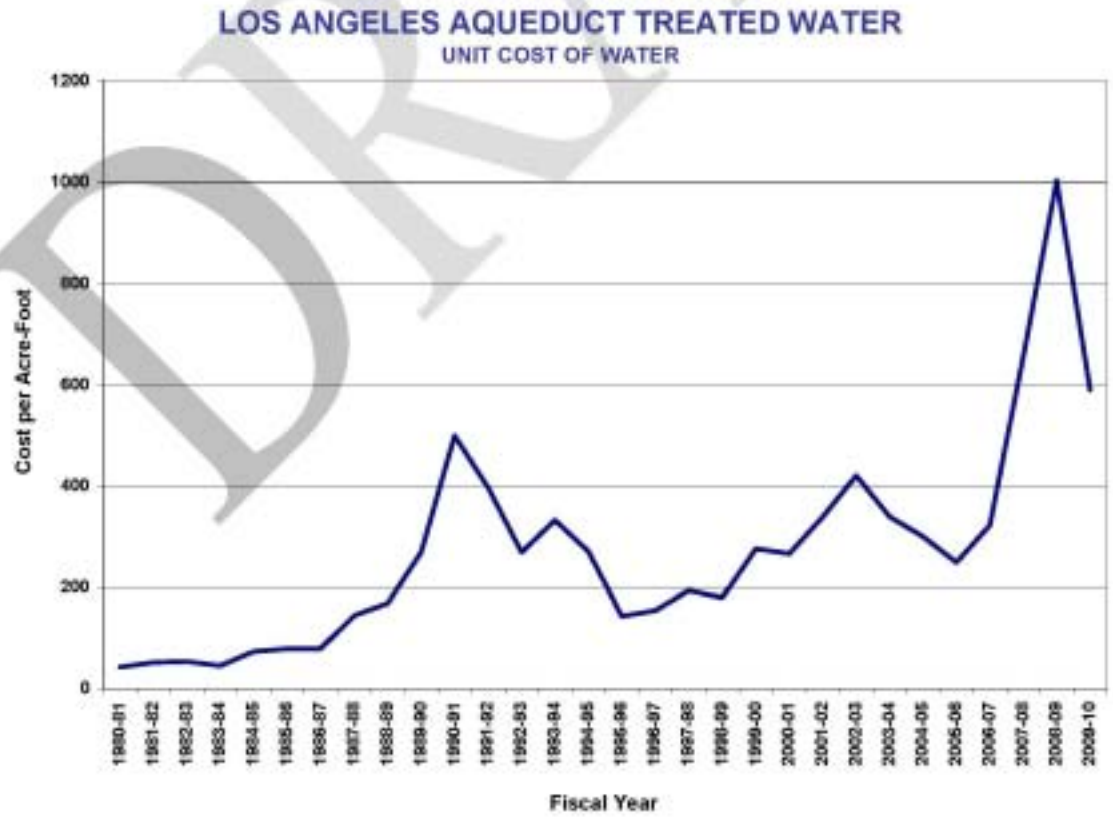
estimating equations to forecast various losses, including evaporation and infiltration, as well as other inflows such as unmetered springs. The final output from LAASM is the volume of LAA water projected to be delivered to the City of Los Angeles.

Taking the foreseeable factors discussed earlier in this chapter into consideration, the average annual long-term LAA delivery over the next 25 years is expected to be approximately 254,000 AFY and gradually decline to 244,000 AFY due to climate change impact. Deliveries for a series of dry years, using 1988/89 through 1992/93 hydrology, are expected to range from approximately 48,520 AFY to 105,770 AFY. A single dry year minimum of 48,520 AFY is expected with a repeat of the 1990/91 hydrology. Detailed LAA projected deliveries by year are provided in Chapter 11, Water Service Reliability Assessment.

5.7 LAA Delivery Cost

The costs associated with LAA water supply are primarily operation and maintenance costs. Therefore, the unit cost of exporting water from LAA to the City varies mainly with the quantity of water delivered and is highly dependent on hydrological conditions. During dry years, the amount of water delivered to the City decreases, which results in an increase to the unit cost. Over the years, eastern Sierra Nevada environmental enhancement projects also contributed to the overall LAA delivery cost, with increasing expenditures when the Owens Lake Dust Mitigation and Lower Owens River Project were initiated. Exhibit 5L summarizes the historical unit cost of treated water from LAA. The peaks occurred when LAA deliveries significantly decreased during fiscal years 1990-91, 2002-03, and 2008-09 with the LAA deliveries of 130,300 AF at $499/AF; 203,400 AF at $419/AF; and 108,500 AF at $1,003/AF respectively.

Exhibit 5L
Historical Cost of LAA Treated Water



AR0070898

Exhibit 5M shows the unit cost of LAA treated water from 2005/06 to 2009/10. The 5-year average was $563/AF. The sharp increase in 2008/09 was due to LAA delivery being the lowest on records.

Exhibit 5M
Annual Unit Cost

Fiscal Year	2005-06	2006-07	2007-08	2008-09	2009-10
Unit Cost	$248	$321	$654	$1,003	$589

DRAFT

AR0070899

DRAFT Chapter Six
Local Groundwater

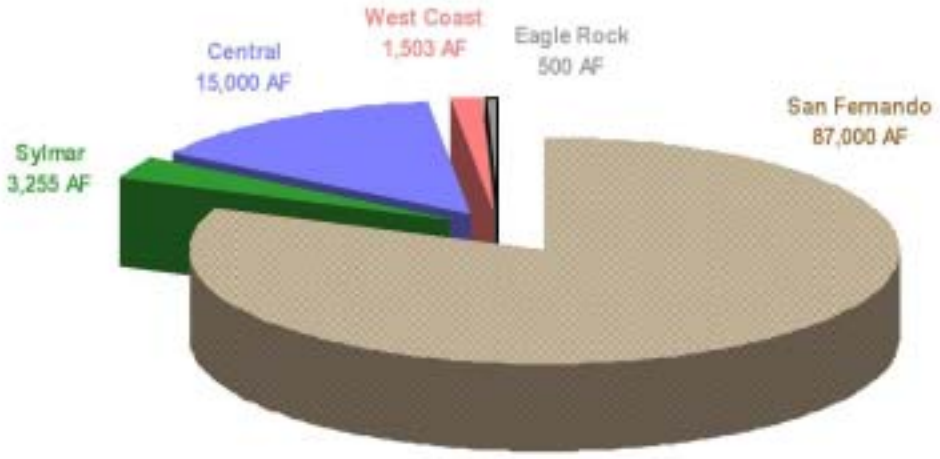
6.0 Overview

A key resource that the City has relied upon as the major component of its local supply portfolio is local groundwater. Over the last ten years local groundwater has provided approximately 12 percent of the total water supply for Los Angeles, and historically has provided nearly 30 percent of the City's total supply during droughts when imported supplies become unreliable. In recent years, contamination issues have impacted LADWP's ability to fully utilize its local groundwater entitlements. Additionally, reduction of natural infiltration due to expanding urban hardscape and channelization of stormwater runoff has resulted in declining groundwater elevations. In response to contamination issues and declining groundwater levels, LADWP is working clean-up of the San Fernando Groundwater Basin, and is making investments to recharge local groundwater basins through stormwater recharge projects, while at the same time replacing or rehabilitating old or deteriorating facilities.

6.1 Groundwater Rights

The City owns water rights in the San Fernando, Sylmar, Eagle Rock, Central, and West Coast Basins. Combined, these water rights total approximately 107,408 AFY. Water rights in the Upper Los Angeles River Area (ULARA), which comprises of the San Fernando, Sylmar, and Eagle Rock basins, total approximately 90,905 AFY which translates into approximately 87,000 AFY in the San Fernando Basin (SFB), 500 AFY in the Eagle Rock Basin, and 3,405 AFY in the Sylmar Basin. Water rights in the Central and West Coast Basin are 15,000 AFY and 1,503 AFY, respectively. However, LADWP does not exercise its pumping rights in Eagle Rock Basin and West Coast Basin at this time. Exhibit 6A summarizes the City's annual local groundwater entitlements by basin. Superior Court Judgments for the San Fernando, Sylmar, Eagle Rock, Central, and West Coast groundwater basins are attached in Appendices X, X, and X, respectively.

Exhibit 6A
Annual Local Groundwater Entitlement



Total: 107,258 AF per year

AR0070900

The ULARA Groundwater Basin Adjudication

The City's entitlements in the San Fernando, Sylmar, and Eagle Rock Basins were established in a Judgment by the Superior Court of the State of California for the County of Los Angeles in Case No. 650079, *The City of Los Angeles, Plaintiff, vs. Cities of San Fernando, et. al., Defendants*, dated January 26, 1979 (San Fernando Judgment) and the 1984 Sylmar Basin Stipulation (1984 Stipulation). Appendix X contains the Judgment and 1984 Stipulation. The Judgment was based on maintaining a safe yield operation for the basin, whereby groundwater extractions over the long-term will be maintained in a manner that does not create an overdraft condition in the basin. The City has no entitlement in the Verdugo Basin but may have the right to recapture a portion of its import return waters upon application to the Watermaster and issuance of an order after a hearing by the Court. The Judgment and 1984 Stipulation limit groundwater extraction from all four groundwater basins and establish a court-appointed Watermaster and an Administrative Committee made up of a representative from each of the five water supply agencies overlying the ULARA Basins. The five public agencies are the City of Los Angeles, the City of Glendale, the City of San Fernando, the City of Burbank, and the Crescenta Valley County Water District.

The Watermaster assists the Court in administering and enforcing the provisions of the 1979 Judgment and 1984 Stipulation. Among other duties, the Watermaster monitors groundwater levels, recharge operations, recycled water use, extractions, water imports and exports, and reports all significant water-related events in the Basin to the Court and to the parties to the Judgments. The activities of the Watermaster are key components for the effective management of the groundwater resources in the ULARA Basins. Key tasks of the Watermaster for the SFB include:

- Monitoring of radiological and synthetic organic compounds (SOCs) every three years;
- To continue to work with key regulators, such as the Los Angeles Regional Water Quality Control Board (LARWQCB), California Department of Public Health (CDPH), California Department of Toxic Substance Control (CDTSC), and the United States Environmental Protection Agency (USEPA), to expedite clean-up of groundwater at or near known contamination sites
- To continue to support the ongoing activities of the City of Los Angeles and others to recharge the groundwater basin at existing spreading basins on the east side of the San Fernando Valley;
- To help determine the technical feasibility of using advanced treated recycled water to recharge the groundwater basin;
- To continue to work with the Los Angeles Department of Public Works, Bureau of Sanitation, Watershed Protection Division, to enhance groundwater recharge of local basins via the Standard Urban Stormwater Mitigation Plans (SUSMP) procedures for stormwater infiltration at new development and redevelopment project sites; and
- To work with local purveyors in an effort to increase the quantity and quality of the groundwater database for the entire ULARA basin.

Historical Groundwater Production

On average over the past five years, about 83 percent (58,575 AFY) of the City's local groundwater supply was extracted from ULARA groundwater basins, while the Central Basin provided 17 percent (12,512 AFY). Exhibit 6B summarizes the City's local groundwater production by basin over the last five years.

DRAFT

Exhibit 6B
Local Groundwater Basin Supply
Fiscal Year (July through June in AF)

Groundwater Basin	2005-2006	2006-2007	2007-2008	2008-2009	2009-2010	Average	Percentage
San Fernando	35,486	75,640	57,060	49,106	62,218	55,902	79%
Sylmar	1,844	3,901	4,046	576	2,998	2,673	4%
Central	13,290	13,358	12,207	11,937	11,766	12,512	17%
Total	50,620	92,899	73,313	61,619	76,982	71,087	100%

Historically, LADWP operates groundwater production by utilizing conjunctive use of surface water and groundwater to optimize the supply and demand balance. Through conjunctive use, the timing of groundwater extractions can be used to meet varying demands. Furthermore, in the past, LADWP prevented against groundwater overdraft during multiple dry years through strategic pumping. When successive dry years occur, LADWP pumped at greater than average rates for the first few years of the drought, and then pumped at lower rates in subsequent years.

However, since 2007, groundwater contamination issues in the SFB have greatly limited LADWP's ability to pump its full groundwater entitlement. As a result, LADWP has been pumping the maximum amount capable that is not impacted by contamination sources, and therefore, has not been able to utilize its conjunctive use strategies for its groundwater operation. When the clean-up of the SFB is complete, LADWP will be able to return to these strategies to ensure reliability and protect from groundwater overdraft.

6.1 San Fernando Basin

The primary source of local groundwater for the City is the SFB providing over 79 percent of the City's groundwater supply ranging from 35,486 AF to 75,640 AF during the period Fiscal Year 2005-2006 to Fiscal Year 2009-2010. The SFB is the largest of the four ULARA basins. It consists of 112,000 acres and comprises 91.2 percent of the total valley in ULARA. It is bounded on the east by the Verdugo Mountains; on the north by the Little Tujunga Syncline and the San Gabriel and Santa Susana Mountains; on west by the Simi Hills; and on the south by the Santa Monica Mountains. A map of the basin is shown in Exhibit 6C. (ULARA Watermaster Service Report, Water Year 2008-2009)

LADWP has ten major wellfields within the SFB containing 115 wells: the Crystal Springs, Headworks, Tujunga, Rinaldi-Toluca, North Hollywood, Erwin, Verdugo, Whitnall, Pollock, and North Hollywood Operable Unit Wellfields. Of the ten major wellfields, LADWP is currently not pumping at Headworks. These wells were generally installed over a period spanning from 1924 to 1991, with the most recent installations being the Rinaldi-Toluca Wellfield in 1988 and the Tujunga Wellfield in 1991. Collectively these ten wellfields have the ability to pump and serve approximately 547 cubic feet per second (cfs) of water, of which the recent Rinaldi-Toluca and Tujunga wells comprise about 38 percent or 210 cfs.

Groundwater Rights

In accordance with the 1979 San Fernando Judgment, the City has the right to all native water within the SFB, based on its Pueblo Rights, and the right to imported water that is delivered and returned to the SFB by the City. With the native safe yield being fixed at 43,660 AFY and the return of imported water averaging approximately 43,000 AFY, the combined total equates to an average SFB entitlement for the City of approximately 87,000 AFY. The return of imported water right for LADWP is based on 20.8 percent of all water delivered within the San Fernando Basin including recycled water. The Judgment provides for storage of water within the basin when the amount pumped is less than the annual entitlement, and a portion of these stored water credits can be pumped in future years to supplement the City's water supply. The direct

DRAFT

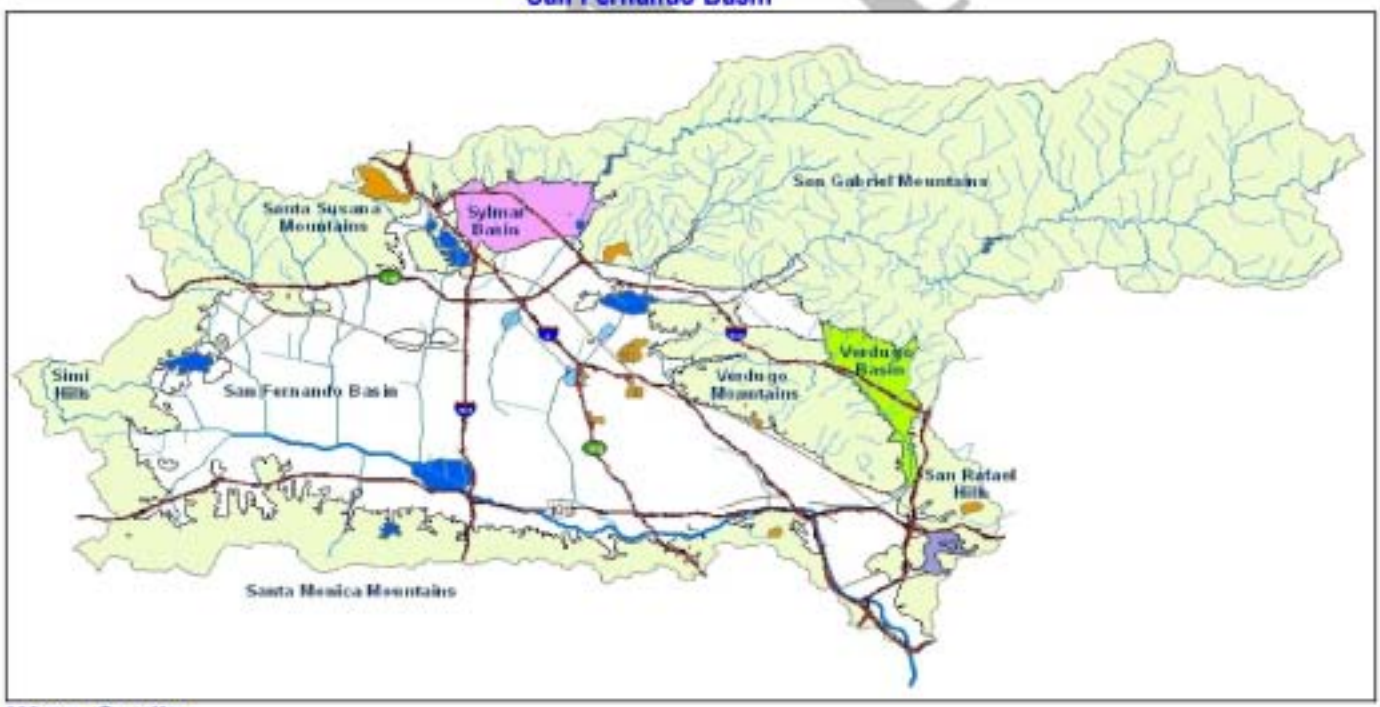
AR0070902

spreading of both imported or recycled water receives 100 percent stored water credit. Increased groundwater pumping due to stormwater capture activities will require an amendment to the Judgment to increase LADWP's groundwater pumping rights based on a demonstrated increase in groundwater levels.

In September 2007, the Cities of Los Angeles, Glendale and Burbank entered into a ten-year Interim Agreement for the Preservation of the San Fernando Basin Water Supply (Interim Agreement). The Interim Agreement is intended to address the overall long-term decrease in stored groundwater within the basin. The Interim Agreement restricts withdrawal of stored water credits and incorporates basin losses into groundwater basin accounting.

Under the Interim Agreement, stored water credits will be reduced for each party by 1 percent annually to account for outflow from the basin. Additionally as described in the Interim Agreement, a proportion of stored water credits available for use during a water year will be calculated for each year, and proportion not available for use during a given year will be reserved for later use. As of October 1, 2009, the City had a stored water credit of nearly 406,313 AF in the SFB, however LADWP's Available Credit or maximum allowable withdrawal of stored water credits for the year beginning October 1 was 108,574 AF. LADWP's Reserve Credits total was 321,316 AF. Reserve Credits (stored water credits minus available stored water credits) will not be available until groundwater levels in the basin recover to a level that will allow for their safe withdrawal. Total Reserve Credits held by all parties in the basin were 376,433 AF as of October 1, 2009.

Exhibit 6C
San Fernando Basin



Water Quality

During well testing in the SFB, trace levels of the contaminants trichloroethylene (TCE), perchloroethylene (PCE), and other volatile organic compounds (VOCs) were detected in the past. The presence of these contaminants is due to improper chemical disposal practices historically conducted by numerous companies in the San Fernando Valley utilizing such materials. Additionally, in the 1990s, detectable amounts of hexavalent chromium and perchlorate were found in various

AR0070903

wells within the SFB. Since the 1990s, SFB wells have also shown a trend of increasing nitrate levels. The source of nitrates is the result of decades of agricultural activity in the San Fernando Valley.

While LADWP is permitted to withdraw its allotted entitlement of 87,000 AFY from the SFB including a portion of its additional stored water, 2007 was the first year LADWP was unable to pump its allotted entitlement due to contamination impacts. LADWP has 115 wells in the SFB of which 54 wells have been inactivated due to contamination. These inactive wells represent a lost pumping capacity of approximately 221 cfs or 40 percent of LADWP's pumping capacity. Of the remaining 61 active wells, with a combined pumping capacity of approximately 326 cfs, 44 have recorded concentrations for various contaminants above the Maximum Contaminant Level (MCL). Most notable among these contaminants of concern are the VOCs (especially TCE, PCE, and carbon tetrachloride), nitrates, and perchlorate. The remaining 17 wells have recorded marginal levels of contamination, mostly due to VOCs. Hexavalent chromium threatens to be a significant future risk to LADWP's wells. Lastly, LADWP's two largest wellfields, Tujunga and Rinaldi-Toluca, which were the most recently-installed wells in an area believed to be outside the known contamination areas, are being significantly impacted by unknown contamination sources.

LADWP has developed programs to accelerate clean-up of the San Fernando Basin which includes a comprehensive Groundwater System Improvement Study, installing monitoring wells, interim wellhead treatment, and working with regulatory agencies and government officials to hold individuals responsible for the contamination responsible to help clean-up efforts.

Agency Cooperation of SFB Remediation

LADWP actively coordinates with the California Department of Public Health (CDPH), Los Angeles Regional Water Quality Control Board (LARWQCB), California Department of Toxic Substance Control (CDTSC), and the United States Environmental Protection Agency (USEPA) to pursue protective and remedial measures for the SFB. The CDPH, LARWQCB, and CDTSC are the three regulatory agencies with enforcement responsibilities within the SFB. The LARRWQCB and the CDTSC issue enforcement directives for pollutant sites and guide the development of cleanup workplans and the cleanup of polluted groundwater sites. The CDPH oversees the quality of potable water from groundwater sources.

In 1987, LADWP entered into a Cooperative Agreement with the USEPA to conduct the "Remedial Investigation of Groundwater Contamination in the San Fernando Valley." Under this agreement, LADWP has received more than $23 million in Federal grants from the USEPA's Superfund Program to carry out: (1) construction, operation, and maintenance of the North Hollywood Operable Unit, which consists of a groundwater treatment facility and a system of eight production wells (construction completed in 1989); and (2) completion of the Remedial Investigation (RI) to characterize the SFB and the nature and extent of its groundwater contamination. The RI included: (a) the installation in 1992 of 88 shallow and clustered monitoring wells that were developed to monitor contamination plumes of TCE, PCE, and nitrates in the SFB; (b) the development of a groundwater flow model (Flow Model) and the preparation of the RI report that was completed for the USEPA in 1992; and (c) on-going monitoring for TCE, PCE, nitrates, and emerging contaminants.

The Flow Model is a three-dimensional computer simulated model of the SFB based on the MODFLOW model program code that was developed by the United States Geological Survey. It consists of four layers that represent the various depth zones of the SFB. Geologic and hydrogeologic data for the basin, which was generated through field investigation, was analyzed to develop the physical site characterization of the basin for the MODFLOW Flow Model. The Flow Model produced simulated groundwater levels, gradients, and their fluctuations as a function of time. Based on field monitoring and

DRAFT

AR0070904

Flow Model simulations, groundwater production strategies are reviewed and adjusted monthly to balance the City's water supply need with SFB management.

San Fernando Basin Contamination Clean-Up Programs

In coordination with other agencies, LADWP has completed or is planning various projects to maintain its rights to use the SFB as a reliable local water supply for the City. The following are some of LADWP's completed, current, and planned projects for the SFB. Recharge projects are discussed separately in Chapter 7, Watershed Management.

Groundwater System Improvement Study

LADWP is working on a 6-year, $19.0-million Groundwater System Improvement Study (GSIS) in the SFB that will provide vital information to assist in developing both short- and long-term projects to maximize the use of the SFB. The $11.5-million GSIS professional service contract was awarded to Brown and Caldwell in February 2009.

The GSIS will aim to cover the following main objectives:

- Provide an independent study to identify, characterize, and evaluate emerging water quality constituents for the San Fernando Basin.
- Provide an independent expert evaluation of LADWP's existing groundwater facilities and its current operational strategies to address current issues on water quality regulations and groundwater treatments. Provide expert advice on the need of refurbishing existing groundwater wells.
- Research and evaluate the need for the installation of new monitoring wells in the SFB to characterize the basin for the constituents of concern.
- Develop a research monitoring program to characterize the nature and extent of the various constituents of concern that may pose a risk to LADWP maximizing the utility of the SFB.
- Provide independent expert recommendations on economically feasible short and long-term capital improvement projects to address all regulatory agency requirements.

Through the GSIS, the LADWP has begun developing a conceptual layout for Groundwater Treatment Facilities in the SFB that will include treatment facilities in the vicinity of LADWP's North Hollywood, Rinaldi-Toluca, and Tujunga Well Fields. It is anticipated that construction of the Groundwater Treatment Facilities could begin as early as July 2015. Construction of the Groundwater Treatment Facilities will greatly reduce LADWP's reliance on costly and scarce imported water supplies and will compliment LADWP's strategies for securing the City of Los Angeles' future water supply through sustainable means. The Groundwater Treatment Facilities will also enable LADWP to benefit from its activities to enhance local supplies through groundwater recharge and stormwater projects. An integral part of LADWP's Groundwater Treatment Facilities will be to work closely with the USEPA and the Cities of Burbank and Glendale to ensure that the facilities operations do not adversely affect the on-going cleanup activities being conducted by the aforementioned agencies. Towards this end, LADWP plans to enter into a Groundwater Management Plan with the USEPA.

As of November 2010, the work progress has included a technical review of USEPA's Focused Feasibility Study for the North Hollywood Operable Unit, preparation of conceptual layouts and renderings for the proposed Groundwater Treatment Facilities in the vicinity of the North Hollywood, Rinaldi-Toluca and Tujunga Well Fields, providing assistance in the planning

DRAFT

AR0070905

aspects for the installation of approximately 40 new monitoring wells in the San Fernando Basin, and providing an independent study to identify, characterize and evaluate emerging water constituents.

Tujunga Wellfield Joint Project. LADWP and MWD have developed a joint project utilizing simple liquid-phase granular activated carbon (GAC) to recover the use of two of the City's contaminated groundwater production wells in the Tujunga Wellfield. The total estimated cost of this project was approximately $7.0 million and was completed in November 2009. LADWP received the permit from the Department of Public Health in May 2010 and started to discharge into the distribution system on May 18, 2010.

Tujunga Wellfield Contamination. The Initial Discovery of the source of contamination at the Tujunga Wellfield by the USEPA and CDTSC is ongoing. Phase I is completed and has not conclusively identified the source of the contamination. The next phase will involve drilling 4-7 deep monitoring wells immediately up gradient of the wellfield to determine the direction of the contamination plumes. The well drilling is expected to be completed late 2011. LADWP is intending to construct up to 22 additional monitoring wells near other wellfields south of the Tujunga Wellfield. Water quality data from the new monitoring wells will assist with further characterizing the groundwater contamination in the SFB. Drilling of these additional wells is expected to begin in Fall 2011 and continue until Winter 2012.

North Hollywood Operable Unit. In 1989, the North Hollywood Operable Unit (NHOU) was placed into service with a capacity of 2,000 gallons per minute (GPM), or 3,230 AF per year. This facility has one aeration tower with vapor-phase granular activated carbon (GAC) air emissions control system. This technology uses air to remove the VOCs from the groundwater and uses the vapor-phase GAC to remove the VOCs from the air stream before it exits into the atmosphere. The fifteen year consent decree expired on December 31, 2004, however, the VOC plume has not been completely remediated. In Water Year 2008-2009, 1,038 AF of VOC contaminated groundwater was treated.

The USEPA is expected to start construction of the NHOU Second Remedy possibly as soon as 2014 to improve containment of contamination from two sites, the Honeywell and Lockheed sites. The primary plume contains high concentrations of VOCs, chromium, and other contaminants of concern. The USEPA issued the Record of Decision (ROD) in December of 2009. The first technical meeting with the potentially responsible party was held in July 2010. A consent decree is expected in early 2011. The ROD recommends more than doubling the capacity plus adding liquid phase GAC (a secondary treatment), construction of 37 monitoring wells, three new extraction wells, deepen existing abandoned well #1, rehabilitation of existing wells, and treatment of chromium and 1-4 Dioxane. As of 2010, Honeywell is continuing its removal of chromium plume at the source of contamination.

Chromium Treatment Research. A cost-effective treatment technology to remove low levels of hexavalent chromium from water does not exist for large scale applications. In 2001, LADWP, along with the Cities of Burbank, Glendale, and San Fernando, and the National Water Research Institute, entered into a research partnership with the American Water Works Association Research Foundation to identify and bench-test new technologies that can remove hexavalent chromium to extremely low levels. This research is being conducted in anticipation of a new standard for hexavalent chromium.

Pollock Wells Treatment Plant. In 1999, the Pollock Wells Treatment Plant was constructed and placed in service. This project was funded by LADWP, and it includes a groundwater treatment facility with four liquid-phase GAC units. Over 3,000 gallons per minute (4,840 AF per year) of groundwater is treated by direct adsorption with GAC to remove VOCs before delivery to customers.

AR0070906

Remedial Investigation. In 1992, the Remedial Investigation to characterize the nature and extent of groundwater contamination in the SFB was completed for the USEPA. The Remedial Investigation activity included the construction of 88 shallow and clustered monitoring wells, which were developed to monitor contamination plumes of TCE, PCE, and nitrates in the SFB. These monitoring wells are also being used to monitor for emerging chemicals. Updated information and reports can be found on USEPA Region 9 Superfund web page.

Biological Treatment Pilot Test . LADWP will be studying the effectiveness of biological treatment on removal of VOCs contaminants from the Tujunga Wellfield groundwater. Biological treatment is a proven technology for removal of perchlorate and nitrate contaminants from groundwater which are also present in the Tujunga Wellfield groundwater. If biological treatment can also effectively remove VOCs from the groundwater, LADWP can significantly reduce the capital as well as future operations and maintenance costs associated with cleanup and removal of contaminants from the Tujunga Wellfield groundwater.

Pilot Test of Advance and Emerging Groundwater Treatment Technologies. LADWP is investigating the utilization of other advance and/or emerging groundwater treatment technologies for removal of VOCs and perchlorate for possible pilot study(ies) at the Rinaldi-Toluca Wellfield within the next few years.

6.2 Sylmar and Eagle Rock Basins

The Sylmar Basin has provided slightly over 4 percent of the City's local groundwater ranging from 576 AF to 4,046 AF from Fiscal Year 2005-2006 through Fiscal Year 2009-2010. The Sylmar Basin, in the northern part of ULARA, consists of 5,600 acres and comprises 4.6 percent of the valley in ULARA. It is bounded on the north and east by the San Gabriel Mountains; on the west by a topographic divide in the valley fill between the Mission Hills and the San Gabriel Mountains; and on the south by the Little Tujunga syncline, which separates it from the SFB. (ULARA Watermaster Service Report, Water Year 2008-2009) LADWP originally had a total of 3 production wells installed in the Sylmar Basin between 1961-1977. One of these wells was removed from service and is no longer utilized. The remaining wells have the capacity to pump 5 cfs.

The Eagle Rock Basin is the smallest of the four basins. It is located in the extreme southeast corner of ULARA. It consists of 800 acres and comprises 0.6 percent of the total valley. LADWP is not pumping in the Eagle Rock Basin currently. The safe yield of Eagle Rock Basin is derived from imported water delivered by LADWP. There is no measurable native safe yield. LADWP has the right to extract the entire safe yield of the basin. Currently, the groundwater is being pumped by a private party and LADWP is reimbursed for such pumping in accordance with the San Fernando Basin Judgment.

Groundwater Rights

In 1996 upon the recommendation of the Watermaster, the ULARA Administrative Committee approved a temporary safe yield increase for the Sylmar Basin thus temporarily increasing LADWP's rights from 3,105 AFY to 3,255 AFY for a ten-year period. Per the 1984 Stipulation, the safe yield minus private party overlying rights are to be equally split between LADWP and the City of San Fernando. In 2006, a subsequent evaluation of the safe yield was conducted and completed in accordance with Section 8.2.10 of the 1984 Stipulation. Upon recommendation of the parties, the Court approved a new stipulation further increasing the temporary safe yield of the basin and resulting in a temporary increase in LADWP's rights to 3,405 AFY subject to multiple conditions. Conditions imposed on LADWP and the City of San Fernando include installing groundwater monitoring wells to assist in determining basin outflows. This new stipulation became effective on October 1, 2006 and is set to expire on October 1, 2016. As required by the 2006 Stipulation, the safe yield will be re-evaluated by October 1, 2011 and may result in a recommendation for additional changes to the safe yield of the Sylmar Basin.

AR0070907

Stored water credits accumulated in the basin are determined by adding the previous years stored water credit and the extraction right for the previous year together and then subtracting the actual extractions for the previous year. As of October 1, 2009, LADWP has accrued 9,423 AF of stored water credits in the Sylmar Basin. In 2006, the Watermaster recommended LADWP begin pumping these rights due to the large amount of stored water credits. LADWP has proposed the Mission Wells Improvement Project to initiate pumping the credits and to replace the existing wells that have significantly deteriorated. As proposed, the project consists of constructing a water tank, three wells, and other operational facilities at the Mission Wellfield. Phase 1 was completed in February 2009 and involved replacement of the water tank that was beyond its useful life. Phase 2 is in the planning stages and consists of three new wells with operational facilities and is forecast for completion in August 2014. These new facilities will allow LADWP to pump its current entitlement of 3,405 AFY on an annual basis and draw from its existing stored water credits.

Water Quality

Groundwater quality issues have occurred in the Sylmar Basin related to TCE contamination at one of the two production wells. The effluent from the wellfield is managed in such a way that the groundwater quality meets or surpasses water quality standards. Primary limitations on pumping are related to the deterioration of pumping facilities and not contamination. However, the Mission Wells Improvement Project as previously discussed, will replace the deteriorated wells and increase production capacity to allow LADWP to pump its annual water rights.

6.3 Central Basin

From Fiscal Year 2005-2006 through Fiscal Year 2009-2010 the Central Basin has provided on average approximately 17 percent of LADWP's local groundwater supply ranging from 11,766 AF to 13,358 AF through wells in two major production fields. The Central Basin Watermaster Service area overlies about 227 square miles of the Central Basin in the southeastern part of the Los Angeles Coastal Plain in Los Angeles County. The Watermaster Service Area is bounded by the Newport-Inglewood Uplift on the southwest, the Los Angeles-Orange County line on the southeast, and an irregular line that approximately follows Stocker Street, Martin Luther King Boulevard, Alameda Street, Olympic Boulevard, the boundary between the City of Los Angeles and unincorporated East Los Angeles, and the foot of the Merced and Puente Hills on the north. Twenty-three incorporated cities and several unincorporated areas are within the Central Basin Watermaster Service Area. Groundwater within the basin provides a large portion of the water supply needed by overlying residents and industries. In Fiscal Year 2008-2009 there were 140 parties with rights to water within the Central Basin (Central Basin Watermaster Service Report, Fiscal Year 2009-2010).

Two LADWP facilities provide groundwater supplies in the Central Basin, the Manhattan Wells and the 99th Street Wells. The active Manhattan Wells were installed between 1928-1974 and have a production capacity of 16.9 cfs. Wells at the 99 th Street location were installed between 1974-2002 and have a production capacity of 7.4 cfs. While the 99th Street Wells are newer and have relatively little mechanical or other problems, the Manhattan Wells are much older and have experienced maintenance problems and are approaching the end of their useful life. To restore the City's pumping capacity, LADWP is working on plans to install two new production wells, replace two deteriorated wells, and improve other related facilities at the Manhattan site.

Groundwater Rights

More than 50 years ago, groundwater overdraft and declining water levels in the Central Basin threatened the area's groundwater supply and caused seawater intrusion in the southern part of the Basin. However, timely legal action and adjudication of the water rights halted the overdraft and prevented further damage to the Basin. Today, groundwater use in the Basin is restricted to the allowed pumping allocations by a 1966 Superior Court Judgment and is monitored by a court-

DRAFT

AR0070908

appointed Watermaster, the Department of Water Resources (DWR). Annually, the Watermaster prepares a Watermaster Service Report indicating groundwater extractions, replenishment operations, imported water use, recycled water use, finances of Watermaster services, administration of the water exchange pool, and significant water-related events in the Basin.

The City's entitlement in the Central Basin of 15,000 AFY was established in a judgment by the Superior Court of the State of California for the County of Los Angeles through the Central Basin Judgment (Case No. 786,656 –second amended judgment). In addition to its annual entitlement, the Central Basin Judgment allows for carryover of unused water rights up to a maximum total cumulative amount of 20 percent of the purveyor's pumping allocation and also allows for over extraction of an additional 20 percent under emergency situations that would be debited against the purveyor's following year entitlement. The City uses its carryover storage right for operational flexibility and conjunctive use. LADWP has allowable carryover storage of 3,000 AF into Fiscal Year 2010-2011.

The Central Basin Judgment does not permit storing water in the basin for later extraction. Through the assistance of a facilitator, multiple parties with groundwater rights within the Central Basin have developed draft framework to allow conjunctive use groundwater storage in the basin and have filed to request amendment of the Judgment to allow groundwater storage.

Water Quality

Although the Manhattan and 99th Street Well fields in the Central Basin are located only approximately 4 miles apart, there is a large difference in water quality between the facilities. One of the Manhattan Wells currently exceeds the MCL of 5 ppb for TCE. The effluent from the wellfield is managed in such a way that the groundwater quality meets or surpasses water quality standards.

Water from 99th Street Wellfield complies with the National Primary Drinking Water Regulations, but requires treatment to comply with the National Secondary Drinking Water Regulations for manganese and iron. These contaminants are not considered to present a risk to human health, but at existing concentrations the contaminants may present taste, color, and odor problems. Corrosion control treatment using zinc orthophosphate as a sequestering agent and sodium hypochlorite to oxidize manganese has been in place at the wellfield for twenty years. Hydrogen sulfide is also present but not an imminent threat to the reliability of this well supply when chlorinated. In 2002, two new wells were drilled and placed into operation. During the first several months of operation of the new wells, numerous color complaints were received from customers. Adjustments in the treatment process were made which improved water quality.

6.4 West Coast Basin

LADWP has not been able to pump its water entitlement from the West Coast Basin since 1980 due to localized groundwater contamination issues and deterioration of the wells at the Lomita Wellfield. The West Coast Basin underlies 160 square miles in the southwestern part of the Los Angeles Coastal Plain in Los Angeles County. The Basin is bounded on the west by Santa Monica Bay, on the north by Ballona Escarpment, on the east by the Newport-Inglewood Uplift, and on the south by San Pedro Bay and the Palos Verdes Hills. Twenty incorporated cities and several unincorporated areas overlie the Basin (West Coast Basin Watermaster Service Report, Fiscal Year 2009-2010).

Groundwater Rights

In 1945, when intrusion of sea water caused by declining water levels threatened the quality of the groundwater supply, legal action was taken to halt the overdraft and prevent further damage to the West Coast Basin. In 1955, the Superior Court of

AR0070909

Los Angeles County appointed the DWR as the Watermaster to administer an Interim Agreement, and in 1961, the Court retained the DWR as the Watermaster of the Final West Coast Basin Judgment (Case No. 506,806 –amended judgment). Similar to the Central Coast Basin, an annual Watermaster Service Report is prepared. The West Coast Basin Judgment provided the City with a right to 1,503 AFY of groundwater.

Water Quality

Groundwater quality problems in the West Coast Basin were previously related to high levels of total dissolved solids and chlorides. LADWP abandoned operations in the basin in September of 1980 with closure of the Lomita Well Field, and intends to study the feasibility and cost of restoring groundwater pumping.

6.5 Water Quality Goals and Management

The groundwater management efforts that LADWP has undertaken have resulted in all groundwater delivered to customers meeting or exceeding all water quality regulations. As part of its regulatory compliance efforts, LADWP works with the California Department of Public Health (CDPH) to perform water quality testing on production and monitoring wells.

Groundwater Monitoring

LADWP conducts nearly 250,000 field and laboratory tests on more than 25,000 samples collected throughout the year for hundreds of different chemicals such as arsenic, chromium, lead, and disinfection by-products to ensure that they are will within the safe levels before we serve the water to our customers

Every well that is pumped to supply water to the City is actively monitored by LADWP as required by CDPH. LADWP's groundwater monitoring program is comprised of several distinct components, including monitoring of metals, coliform bacteria, inorganics, volatile organic compounds (VOCs) and unregulated compounds such as vanadium, boron, and perchlorate. The frequency and level of monitoring (i.e., annually, quarterly, or monthly), depending on the level of contamination found in each well.

Monitoring for all contaminants is performed at entry points into the distribution system in close proximity to where the water is being pumped from the wells. If water quality problems are detected, the well source is immediately isolated and retested.

Operating Goals

LADWP has established operating goals for TCE, PCE, nitrates, perchlorate, and total chromium that are more stringent than the maximum contaminant levels (MCLs) permitted by Federal or State regulations. These stricter operational goals provide an additional safety margin from these contaminants for City customers. Exhibit 6D summarizes these water quality goals and compares them with the State-regulated requirements, which are generally more stringent than Federal requirements.

DRAFT

AR0070910

Exhibit 6D
Operating Limits of Regulated Compounds

Compound	State of California Limit	LADWP Operational Goals	LADWP Added Safety Margin
Trichloroethylene (TCE)	5 ppb	3 ppb	40%
Perchloroethylene (PCE)	5 ppb	3 ppb	40%
Nitrate (N03)	45 ppm	30 ppm	33%
Perchlorate (ClO4)	6 ppb	4 ppb	33%
Total Chromium	50 ppb	30 ppb	40%

TCE and PCE compounds are commonly used in industries requiring metal degreasing. PCE is also used in dry cleaning and automotive repair industries.

Nitrate is a concern because of its acute effect of impeding the uptake of oxygen to the blood. Infants (who are in the earliest stages of development) are most sensitive to the effects of nitrates. The current standard for nitrate is 45 parts per million (ppm). A single exceedence of the nitrate standard is classified as an acute violation requiring immediate public notification. Treatment for nitrates may eventually become necessary for affected City groundwater supplies.

In October 2007, a MCL was adopted for perchlorate of 6 ppb. Perchlorate is an inorganic compound that is most commonly used in the manufacture of rocket fuels, munitions, and fireworks. In addition to its detection in groundwater, the compound has also been detected in Colorado River Aqueduct water.

Managing Emerging Contaminants of Concern

LADWP addresses emerging contaminants on many levels: 1) by encouraging the development of standardized testing to enable early detection, and supporting the regulatory framework by providing early occurrence data, 2) by advocating good science and a balanced approach to risk assessment, 3) by seeking to gain a risk perspective with other existing contaminants to manage the emerging contaminants in the absence of regulations, 4) by supporting early interpretation of emerging contaminants in collaboration with research and regulatory agencies, and 5) by supporting the research to develop cost-effective treatment for the removal and management of these emerging contaminants.

An example of how LADWP addresses an emerging contaminant is chromium VI (otherwise known as hexavalent chromium). Hexavalent chromium does not have an enforceable drinking water standard at this time. However, hexavalent chromium is included in the State total chromium standard of 50 ppb. CDPH is expected to establish drinking water standards for the compound in the near future. Chromium is a heavy metal that has been used in industry for various purposes including electroplating, leather tanning, and textile manufacturing, as well as controlling biofilm formation in cooling towers. LADWP began low level monitoring of hexavalent chromium long before monitoring was required by regulators. LADWP supported new health-effects research needed to support risk assessment, and advocated a balanced approach to risk management. LADWP funded research to develop new treatment technologies to reduce hexavalent chromium detection levels.

Most recent among emerging contaminants are pharmaceutically active compounds and personal care products that are finding their way into rivers, lakes, and waterways from urbanized areas. There are concerns about the occurrence and effects of endocrine disrupters, hormone-shifting compounds, and pharmaceuticals. Technology now allows the detection of compounds down to the parts per trillion levels, thus some of these compounds are now being detected. The risk

DRAFT

assessment field is finding it difficult to keep pace with advances in analytical technology. The question of these contaminants posing a health risk at low levels needs more investigation. LADWP will continue to proactively address emerging contaminants through early monitoring and utilization of a balanced approach to risk management.

LADWP will be incorporating appropriate treatment processes into future groundwater treatment facilities. LADWP has and will continue to solicit input from stakeholders to properly plan and develop processes for removal and treatment of emerging contaminants. LADWP's Recycled Water Advisory Group (RWAG) is an example of ongoing efforts to solicit input.

6.6 Groundwater Pumping Cost

The costs associated with groundwater pumping are primarily operation and maintenance costs. Therefore, the unit cost of groundwater pumping varies mainly with the quantity of water delivered. Exhibit 6F summarizes the historical unit cost of groundwater pumping.

Exhibit 6F
Historical Cost of Groundwater Pumping

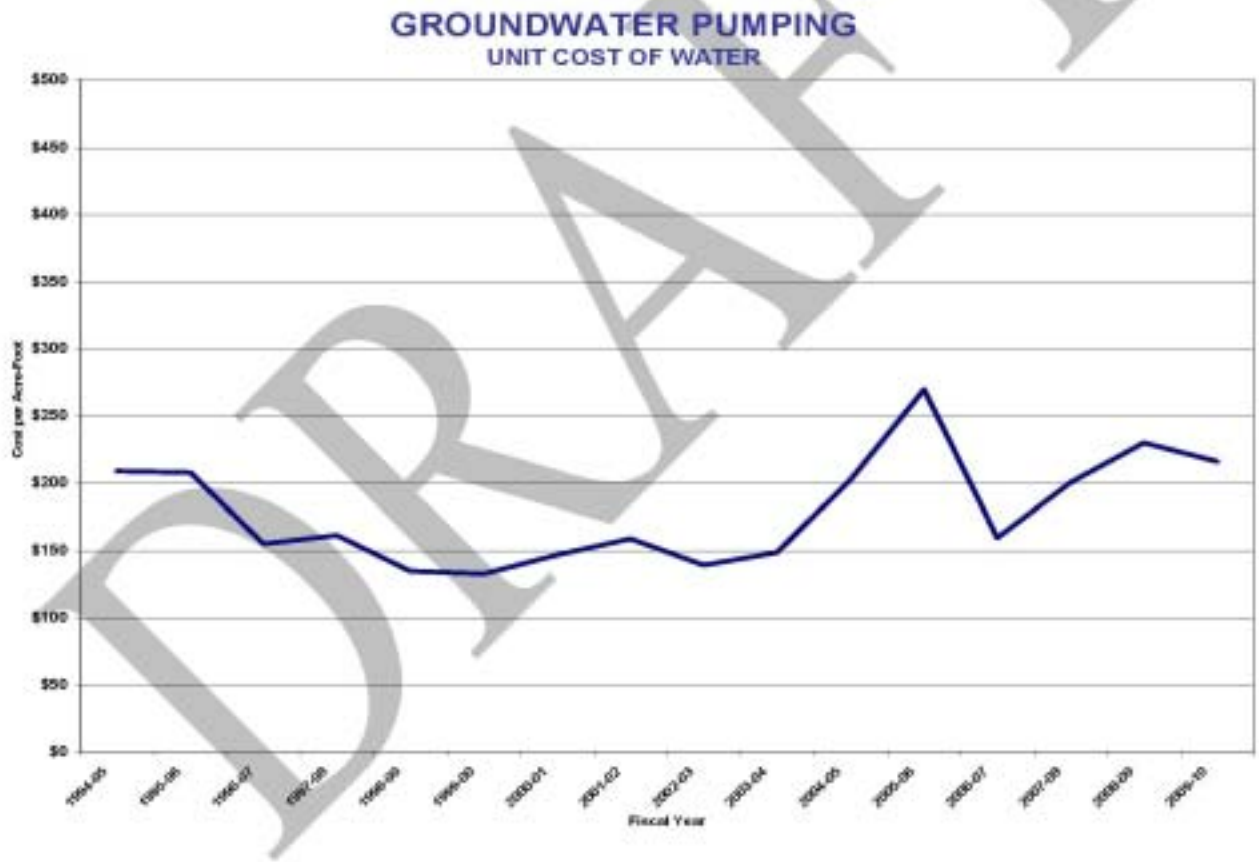


Exhibit 6G shows the unit cost of groundwater pumping from fiscal year 2005/06 to 2009/10. The 5-year average was $215/AF.

DRAFT

AR0070912

Exhibit 6G
Annual Unit Cost

Fiscal Year	2005-06	2006-07	2007-08	2008-09	2009-10
Unit Cost	$270	$160	$200	$230	$216

6.7 Groundwater Production Projections

Historically, with conjunctive use management of groundwater, storing imported water in the groundwater basins during wet and normal years, groundwater production can actually be increased during dry years. LADWP operated its groundwater resources in this manner. On average, LADWP pumped its adjudicated right of approximately 107,000 AFY, but in dry years LADWP could pump larger quantities of groundwater. For the purposes of an average, single-dry, and multi-dry year drought analysis, after the implementation of the purification complex for SFB and completing the construction of new wells in Sylmar and Central Basins, 110,405 AFY is assumed to be the City's local groundwater production in 2035. After completion of the purification complex for the SFB, if successive dry years occur, LADWP would likely pump at greater-than-average levels for the first few dry years, then start pumping at lower levels in order to prevent groundwater overdraft. LADWP would then replenish the groundwater in wet or normal years following the successive dry period. Exhibit 6E provides groundwater pumping projections by basin between 2010 and 2035 for average, single-dry, and multi-year dry weather conditions in five-year increments.

Exhibit 6E
Groundwater Production 2010 to 2035 for Average, Single-Dry, and Multi-Year Dry Weather Conditions
By Fiscal Year

Basin	FY 2009-10	FY 2014-15	FY 2019-20	FY 2024-25	FY 2029-30	FY 2034-35
	AFY					
San Fernando	62,218	21,000	76,800	92,000	92,000	92,000
Sylmar	2,998	4,500	4,500	4,500	4,500	3,405
Central	11,766	15,000	15,000	15,000	15,000	15,000
Total	76,982	40,500	96,300	111,500	111,500	110,405

- 2015 San Fernando pumping levels are decreased due to anticipated well contamination from plume migration.
- Assumes existing annual rights to 87,000 AFY in SFB will remain unchanged. The Purification Complex is expected to be in operation in 2018-19. Storage credit of 5,000 afy will be used to maximize the pumping thereafter.
- Sylmar Basin production temporarily increases to 4,500 AFY to avoid the expiration of stored water credits then return back to the entitlement of 3,405 AFY in 2030-31.

Not included in the figures above is increased groundwater pumping due to groundwater replenishment of advanced treated wastewater, as well as enhanced stormwater recharge. This Urban Water Management Plan projects increased groundwater pumping through groundwater replenishment of advanced treated wastewater of 15,000 AFY, and increased groundwater pumping through enhanced storm water recharge of and additional 15,000 AFY, both by 2035.

AR0070913

DRAFT Chapter Seven
Watershed Management

7.0 Overview

This Urban Water Management Plan projects stormwater capture providing increased groundwater pumping rights in the San Fernando Basin of 15,000 AFY, and 10,000 AFY of additional water conservation from capture and reuse solutions such as rain barrels and cisterns, for a total of 25,000 AFY by fiscal year ending 2035. The Stormwater Capture Master Plan (refer to Section 7.3 below) will comprehensively evaluate stormwater capture potential within the City.

Stormwater runoff from urban areas is an underutilized resource. Within the City of Los Angeles, the majority of stormwater runoff is directed to storm drains and ultimately channeled into the ocean. Unused stormwater reaching the ocean also carries with it many pollutants that are harmful to marine life. In addition, local groundwater aquifers that should be replenished by stormwater are receiving less recharge than in the past due to increased urbanization. Urbanization has increased the City's hardscape, which has resulted in less infiltration of stormwater and a decline in groundwater elevations.

In addition, development has encroached onto the floodplains requiring the channelization of large waterways that once recharged the groundwater aquifers with large volumes of stormwater runoff. When the floodplains were undergoing rapid development, LADWP and the Los Angeles County Flood Control District (LACFCD) reserved several parcels of land for use as spreading facilities, which are adjacent to some of the largest tributaries of the Los Angeles River, and the Pacoima and Tujunga Washes.

During average and below average years, these spreading facilities are very effective at capturing a large part of the stormwater flowing down the tributaries. However they are incapable of capturing a significant portion of the flows during wet and extremely wet years. Weather patterns in Los Angeles historically are highly varied between very wet years and very dry years. Some climate studies predict that these patterns may become more extreme.

Furthermore, a significant portion of the watershed is not located adjacent to large tributaries and therefore, cannot be served by existing spreading facilities. These areas are the urbanized low-lying flatlands that also produce stormwater, therefore a strategy to create and implement distributed stormwater infiltration solutions is needed. These distributed solutions include widespread, smaller projects at the neighborhood scale and landscape changes at the individual parcel scale.

With the increased attention being placed on stormwater capture, other challenging conditions beyond imperviousness and climate patterns have been identified. These include antiquated spreading facilities, landfills adjacent to spreading, floodplain encroachment, substructures, and other man-made conditions that limit the ability to capture stormwater for later use. Some conditions such as the antiquated delivery systems at the spreading facilities can easily be retrofitted with new gates and telemetry. Whereas other conditions such as the presence of large sanitary landfills adjacent to recharge facilities, are more difficult to rectify.

In January 2008, LADWP created the Watershed Management Group which is responsible for developing and managing the water system's involvement in emerging issues associated with local and regional stormwater capture. The Watershed Management Group coordinates activities with other agencies, departments, stakeholders and community groups for the purpose of planning and developing projects and initiatives to improve stormwater management within the City. The Group's primary goal is to increase stormwater capture by enhancing existing centralized stormwater capture facilities and promoting

AR0070914

distributed stormwater infiltration systems to achieve the City's long-term strategy of enhancing local stormwater capture. While working to increase stormwater capture for improving long-term groundwater reliability, other watershed benefits can be achieved including increased water conservation, improved water quality, open space enhancements, and flood control.

Additionally, the City is investigating recharge of the San Fernando Basin (SFB) with advanced treated recycled water. A more in-depth discussion of efforts to maximize groundwater recharge with advanced treated recycled water is provided in Chapter 4, Recycled Water.

7.1 Importance of Watershed Management to Groundwater Supplies

Managing native stormwater is a necessary step towards maintaining groundwater elevations in the underlying groundwater basin. Urbanization and its associated increase in impervious surfaces has altered the ability of groundwater basins to naturally replenish pumped groundwater. Stormwater systems in the City were designed primarily for flood control to convey stormwater runoff to the Pacific Ocean as quickly as possible, therefore minimizing the potential for flooding or damage to structures while maximizing land available for development. Within LADWP's service area, the SFB is the most amenable to regional stormwater capture and recharge through spreading basins because of its predominantly sandy soils. However, stormwater once percolated into the groundwater in the underlying SFB is being channeled across impervious surfaces then through concrete-lined canals or conduits to areas outside of the San Fernando Valley.

The essential task of watershed management is to retain as much stormwater runoff as possible for groundwater recharge. Groundwater recharge is the process of increasing an aquifer's water content through percolation of surface water. This occurs in the SFB primarily with captured stormwater, and imported water. Groundwater recharge is essential to maintain groundwater supplies, address the overall long-term decrease in stored groundwater within the SFB, and ensure the long-term water supply reliability of the basin. Furthermore, increasing groundwater recharge and improving the groundwater levels of the SFB could potentially lead to larger pumping rights for LADWP in the future.

During storm events, large portions of stormwater are captured with existing facilities for spreading purposes. LADWP coordinates these activities with the Los Angeles County Department of Public Works Flood Control District (LACFCD) to effectively recharge the SFB through the spreading of native stormwater. Flood control facilities are the primary means to divert native runoff into the spreading ground facilities listed and mapped on Exhibits 7A and 7B. LACFCD oversees operations at the Branford, Hansen, Lopez, and Pacoima Spreading Grounds. The Tujunga Spreading Grounds are operated by LACFCD in partnership with LADWP. LADWP has the ability to spread imported supplies at the Tujunga Spreading Grounds and the Pacoima Spreading Grounds for storage in the SFB, but LADWP has not utilized imported water for groundwater recharge since 1998.

7.2 Additional Benefits of Watershed Management

Watershed management provides additional important benefits to the City of Los Angeles, including surface water quality improvements, water conservation, open space enhancements, and flood control.

Water quality improvements are necessary because stormwater runoff is a conveyance mechanism that transports pollutants from the watershed into waterways and ultimately the Pacific Ocean. Pollutants include, but are not limited to, bacteria, oils, grease, trash, and heavy metals. The City must also comply with adopted Total Maximum Daily Loads (TMDLs) for pollutants. TMDLs set maximum limits for a specific pollutant that can be discharged to a water body without causing the water body to become impaired or limiting certain uses, such as water body contact during recreation. In 2008, the Los Angeles Board of Public Works adopted the Water Quality Compliance Master Plan for Urban Runoff (WQCMPUR). This 20-year plan provides a strategy for cleaning stormwater and runoff to protect the City's waterways and the Pacific Ocean. Capturing stormwater runoff for groundwater recharge removes a portion of the pollutant conveyance mechanism reducing downstream pollution thereby assisting the City with water quality compliance and improving the overall health of its waterways.

Water conservation is achieved by enhancing the capture and management of localized runoff for local uses. Centralized and distributed mechanisms that provide for water conservation include spreading grounds, rain barrels, and residential cisterns.

Open space enhancement is an added benefit of groundwater recharge projects, which typically provide additional open space areas that may include passive and/or active recreation, educational opportunities, and habitat restoration. Most projects involve increasing vegetation and recreational amenities to create opportunities for wildlife habitat and a recreational/educational resource for the local community. Additionally, open space enhancements assist the City in improving the overall quality of life for residents.

Flood control benefits are achieved when additional storage capacity is added to the storm drain system. Groundwater recharge projects reduce potential flooding by diverting a portion of storm flows into recharge areas, thereby increasing the overall capacity of the storm drain system.

7.3 Stormwater Capture Master Plan

The Stormwater Capture Master Plan (Master Plan) will investigate potential strategies for advancement of stormwater and watershed management in the City. The Master Plan will be used to guide decision makers in the City when making decisions affecting how the City will develop both centralized and distributed stormwater capture goals. The Master Plan will include evaluation of existing stormwater capture facilities and projects, quantify the maximum stormwater capture potential, develop feasible stormwater capture alternatives (i.e., projects, programs, potential policies, etc.), and provide potential strategies to increase stormwater capture. The Master Plan will also evaluate the multi-beneficial aspects of increasing stormwater capture, including potential open space alternatives, improved downstream water quality, and peak flow attenuation in downstream channels, creeks, and streams such as the Los Angeles River.

The Master Plan will recommend stormwater capture projects, programs, policies, and incentives for the City of Los Angeles.

Benefits of the Master Plan include:

AR0070918

- Investigate stormwater capture models such as the Groundwater Augmentation Model and the Watershed Management Modeling System to identify maximum potential groundwater recharge
- Increased water conservation
- Improved water quality
- Reduced peak flow in the Los Angeles River

Project partners and supporters include:

- City of Los Angeles Department of Water and Power
- City of Los Angeles Department of Public Works
- County of Los Angeles Department of Public Works
- TreePeople, Inc.

7.4 Tree People – Memorandum of Agreement

The Memorandum of Agreement (MOA) with TreePeople has been forged to facilitate a high-level of collaboration between LADWP and TreePeople with the aim of fostering a more sustainable Los Angeles. The partnership it outlines leverages TreePeople's experience in public education and agency integration to further the long-term sustainability objectives of LADWP. Specifically, LADWP and TreePeople are working together to research opportunities within LADWP's facilities and operations for widespread groundwater recharge. This research includes an educational component wherein LADWP and TreePeople learn about each other's initiatives and core business. Ultimately, this exchange of ideas will help the two partners develop concepts for projects that will increase stormwater capture for groundwater recharge.

LADWP was an early sponsor for the TreePeople Trans-agency Resources for Environmental and Economic Sustainability (T.R.E.E.S.) Project, during which time TreePeople developed best management practices for capturing, cleaning and using stormwater; published the handbook Second Nature; created a computerized cost-benefit model; and facilitated a number of design workshops for public agencies. TreePeople has also been integral to the construction and management of three demonstration sites -- a single-family home (Hall House) retrofitted to capture all the rainwater onsite, and two elementary schools (Broadous and Open Charter) that feature strategic landscaping and a cistern or underground infiltrators. LADWP has supported public tours and educational materials for Hall House, and is a key partner in the school projects which were partially funded through the Cool Schools and Sustainable Schools programs.

The overlap between the objectives of LADWP and those of TreePeople is notable in the Tujunga Wash and Sun Valley watersheds, where both have been especially active. Stakeholder processes where the two have worked successfully to further mutual goals including the City's Integrated Resources Plan, the Integrated Regional Water Management Plan, and objectives of the California Urban Water Conservation Council.

7.5 Centralized Stormwater Capture Projects

Existing stormwater capture facilities are inadequate for capturing runoff during very wet years. Weather patterns vary dramaticly in Los Angeles with very wet years and very dry years. Therefore, new projects are necessary to expand the

DRAFT

AR0070919

capability to capture a larger portion of stormwater flows during wet years. LADWP is working proactively in close partnership with LACFCD on multiple stormwater projects, as listed in Exhibit 7C. These projects will increase centralized stormwater recharge capacity by approximately 26,000 AFY in the SFB, raising groundwater levels and ensuring the future water supply reliability of the SFB. These projects are designed to maximize groundwater recharge into the basin by increasing the total average recharge to approximately 51,700 AFY.

Multiple opportunities exist to develop new recharge projects and improve existing recharge projects in the SFB. LADWP, in collaboration with LACFCD has supported and contributed resources toward the design, construction, and implementation of a variety of projects to increase groundwater recharge of the SFB. Additionally, multiple agreements between LADWP and LACFCD have been approved to facilitate preparing recharge studies, design work, and construction of projects in the SFB for groundwater recharge, flood protection, and other benefits.

Exhibit 7C
Planned LADWP Centralized Stormwater Capture Projects and Expected Annual Recharge

Project	Current Annual Recharge (AFY)	Increased Annual Capture/ Recharge (AFY)	Expected Annual Recharge (AFY)	Estimated Project Completion	Total Project Cost (millions)	LADWP Share (millions)
Sheldon-Arleta Gas Collection System	-	4,000 [1]	-	Complete Nov 2009	$8.2	$6.3
Big Tujunga Dam Rehabilitation [3]	-	4,500	-	Sep 2011	$105.7	$9.0
Hansen Spreading Grounds Upgrade	13,834	1,200	17,284 [2]	Dec 2011	$9.3	$4.8
Tujunga Spreading Grounds Upgrade	4,419	8,000	18,669 [4]	2015	$24.0	$24.0
Pacoima Spreading Grounds Upgrade	6,453	2,000	8,453	2015	$32.0	$16.0
Lopez Spreading Grounds Upgrade	527	750	1,277	2016	$8.0	$4.0
Strathern Wetlands Park	-	900	900 [5]	2016	$46.0	$4.0
Hansen Dam Water Conservation	-	3,400	3,400	2017	$5.0	$2.5
Valley Generating Station Stormwater Capture	-	700	700	2018	$9.7	$9.7
Branford Spreading Basin Upgrade	549	500	1,049	2018	$4.0	$2.0
Total Estimated Yield	**25,782**	**25,950**	**51,732**		**$251.9**	**$82.3**
Total Expenditure-to-date						$18.6
Total Expenditure Remaining						$63.7

1. This will allow increased collection of 4,000 AFY at Tujunga Spreading Grounds.
2. Includes 1/2 benefits from Big Tujunga Dam Rehabilitation Project.
3. No recharge occurs at the facility. All additional capture has been divided between Hansen & Tujunga Spreading Grounds.
4. Including benefits from Sheldon-Arleta Project and 1/2 benefits from Big Tujunga Dam Rehabilitation Project.
5. To be recharged at Sun Valley Park.

DRAFT

Sheldon-Arleta Methane Gas Collection Project. In 1998, a Task Force comprised of representatives from LADWP, other City Departments (Bureau of Sanitation (BOS), Bureau of Engineering, and Environmental Affairs) and the Upper Los Angeles River Area Watermaster was formed to review the issues surrounding the recharge of groundwater through spreading at the Tujunga Spreading Grounds. The objective of this Task Force was to maximize water spreading at the Tujunga Spreading Grounds without causing off-site landfill gas migration. An outcome of the Task Force was the Sheldon-Arleta Methane Gas Collection Project. The project is designed to restore the original Tujunga Spreading Grounds capacity of 250 cubic feet per second (cfs) with the potential for future enhancement by bringing the Tujunga Spreading Basins closest to the Sheldon-Arleta landfill back online. The Tujunga Spreading Grounds are located adjacent to the closed Sheldon-Arleta Landfill. During spreading operations, water displaces air from the ground potentially increasing migration of methane gas generated by the landfill. In the past, elevated levels of methane gas have been detected in the surrounding communities. Therefore, restrictions were enacted curtailing spreading operations to 20 percent of their original capacity. This project is a joint effort between LADWP and BOS to replace the methane gas collection system within the landfill and thereby contain methane gas onsite. The project is being implemented by LADWP through LABOS's Proposition "O" Clean Water Bond program. Proposition "O" funded approximately $3 million of the $9 million cost. Construction began in 2007 and was completed in November 2009.

Big Tujunga Dam – San Fernando Groundwater Enhancement Project. LADWP and LACFCD approved Cooperative Agreement No. 47717 on September 18, 2007 for the Big Tujunga Dam –San Fernando Groundwater Enhancement Project. This Project will increase stormwater capture and provide other benefits including improvements in flood prevention and environmental enhancement through seismically retrofitting the dam and spillway. Annual stormwater capture will increase by 4,500 AFY for a total capture amount of 6,000 AFY. The project is integrated with the following projects in this section: Hansen Spreading Grounds Enhancement Project, Tujunga Spreading Grounds Enhancement Project, and the Sheldon-Arleta Methane Gas Collection Project. Both the Integrated Regional Watershed Management Plan for the Upper Los Angeles River Watershed and the Tujunga/Pacoima Watershed Plan are being incorporated into the Project. LADWP is contributing $9 million of the $105 million project cost. Construction of the Project is in progress with an anticipated completion date by September 2011.

Hansen Spreading Grounds Enhancement Project. The Hansen Spreading Grounds is a 120 acre parcel located adjacent to the Tujunga Wash Channel downstream from the Hansen Dam. Under Cooperative Agreement No. 47739, the Los Angeles County Flood Control District (LACFCD) and LADWP propose to modernize the facility to increase intake and storage capacity thereby improving groundwater recharge, flood protection and water quality while providing recreational benefits and native habitat improvements. To accomplish the goals of the project, a phased approach is being proposed. Phase 1A will deepen and reconfigure the existing basins; Phase 1B will improve the intake capacity by replacing a radial gate with a new rubber dam and telemetry system; and Phase 2 will develop other compatible uses such as recreational trails and native habitat for the community. Estimated recharge is 17,284 AFY, and estimated cost of this project is $10 million of which LADWP will fund $5 million. The reconstruction of the spreading grounds was completed in December 2009 and the intake structure will be completed in December 2011.

Tujunga Spreading Grounds Enhancement Project. The Tujunga Spreading Grounds Enhancement Project is designed to increase average annual stormwater capture by 8,000 AFY through relocating and automating the current intake structure on the Tujunga Wash, installation of an automated intake structure on the Pacoima Wash, and reconfiguration of the Tujunga Spreading Basins. Other multiple benefits include habitat improvements, passive recreation, educational opportunities, flood protection, and water quality improvements. Owned by LADWP, the Tujunga Spreading Grounds are

DRAFT

AR0070921

operated by LACFCD in conjunction with other facilities along the Tujunga and Pacoima Wash Channels. Construction is expected to begin in 2012.

Valley Generating Station Stormwater Capture Project. LADWP is leading efforts to capture and infiltrate stormwater from the Valley Generating Station, from adjacent streets, and from the Tujunga Wash Channel. Phase 1 will capture and infiltrate all stormwater from the Valley Generating Station. Phase 2 will divert water from the Tujunga Wash Channel for infiltration at the abandoned gravel pit at the generating station. Total stormwater capture is estimated at 700 AFY. Project designs are expected to be completed at the end of 2011.

Pacoima Spreading Grounds Enhancement Project. LADWP in conjunction with LACFCD is proposing to upgrade the Pacoima Spreading Grounds by improving the intake and stormwater storage capacity. Annual average stormwater capture is expected to increase by approximately 2,000 AFY with completion of the project. Other project benefits include flood protection, water quality improvements, and passive recreation. The final concept report and design has an expected completion date by the end of 2012.

Lopez Spreading Grounds Enhancement Project. The Lopez Spreading Grounds Enhancement Project involves deepening the existing Lopez Spreading Grounds and improving the intake and delivery system. LACFCD is the lead agency for the project. Additional groundwater recharge to the SFB of approximately 750 AFY is expected from the project. Project designs are anticipated to begin in 2013.

Strathern Wetlands Park Project. The Strathern Wetlands Park Project involves the conversion of a 45-acre gravel pit into a multipurpose facility for flood protection, stormwater retention, treatment, groundwater recharge, habitat restoration, and recreation. Estimated stormwater capture is approximately 900 AFY. Proposition "O" funding of $17.8 million has been approved for acquisition of the site. LACFCD purchased the land and project planning is underway. Designs are expected in 2012, and construction is expected to occur in two phases from 2013 to 2016.

Hansen Dam Water Conservation Project. In 2000 the Army Corps of Engineers (ACOE) completed a feasibility study to examine operational changes and facility improvements at the Hansen Dam as part of a cost-shared study with LACFCD. Four scenarios are recommended with additional stormwater capture amounts of up to 3,400 AFY depending on the selected scenario. Designs for the project are anticipated in 2013.

Pacoima Dam Reservoir Sediment Removal Project. The Pacoima Dam Reservoir Sediment Removal Project involves removing sediment from behind Pacoima Dam to increase storage volume. The sediment build-up behind the Dam has decreased the capacity to about 3,300 acre-feet. In the fall of 2009 approximately 80 percent of the Pacoima Dam watershed was burned. This damage will likely increase sediment flow into the reservoir above the estimates provided based on 2005 topography. The Project will involve excavating 5 million cubic yards of sediment and increasing the storage volume by 3,000 acre-feet. Increased storage would decrease the number of reservoir spill events and increase the available recharge flow for the Pacoima and Lopez Spreading Grounds. The excavation will extend over 7,000 feet upstream of the existing dam. The project will produce an additional annual water recharge benefit of 670 AFY.

Branford Spreading Basin Upgrade. The Branford Spreading Basin Project will remove fine silts from the basin and install new pumps to drain the basin. These pumps could be used to drain the existing facility into the Tujunga Spreading Grounds. The expected additional recharge for this project is approximately 500 AFY.

DRAFT

AR0070922

7.6 Distributed Stormwater Capture

Throughout the City of Los Angeles there are opportunities to capture localized dry and wet weather runoff for local reuse. However, Los Angeles' storm drain systems have historically been designed to protect life and property from flood impacts by quickly redirecting rainfall and runoff from impervious surfaces into the City's storm drain system and ultimately the Pacific Ocean without regard to water quality impacts. The September 2, 2002 Municipal Stormwater National Pollutant Discharge Elimination System Permit (NPDES Permit No. CAS004001) for the Los Angeles region requires all new development or redevelopment projects to develop and comply with a Standard Urban Stormwater Mitigation Plan (SUSMP) to reduce runoff leaving the project site and to improve the project's water quality impacts.

Recently the City has taken initial steps towards promoting distributed capture and infiltration of runoff through development of a suite of distributed runoff demonstration projects. Distributed stormwater capture (also known as decentralized stormwater capture) is defined as any groundwater recharge system less then 500 af or any direct stormwater capture system capturing less then 10 af. In addition, the City is developing a Low Impact Development (LID) ordinance requiring retention of stormwater onsite for new and redevelopment projects which extends beyond SUSMP regulations. The Watershed Management Group is working with the Los Angeles and San Gabriel Rivers Watershed Council (LASGRWC), TreePeople, Los Angeles Department of Public Works Bureau of Sanitation (BOS), Department of Building and Safety (DBS), Los Angeles County Department of Public Works (LACDPW), The River Project and others to evaluate and study the impacts of localized stormwater capture and source control within the City.

LADWP is providing various resources for projects that would enhance the City's ability to capture additional dry and wet weather runoff for beneficial use. Both dry and wet weather runoff can be beneficially used. Dry weather runoff occurs in the absence of rainfall while wet weather runoff occurs as a direct result of rainfall. Dry weather runoff is typically related to inefficient irrigation systems, overwatering, and other wasteful outdoor water use practices. Wet weather runoff represents a significantly larger volume of water than dry weather runoff. Exhibit 7D summarizes the potential water yield and average unit cost of the different resources available to increase localized capture and infiltration of runoff.

7.6.1 Watershed Council – Water Augmentation Study

The Los Angeles Basin Water Augmentation Study (WAS) is a long-term research project, initiated in 2000, created to determine the benefits of implementing a broad-based approach to stormwater infiltration within the Los Angeles Region. The study was led by the Los Angeles & San Gabriel Rivers Watershed Council in partnership with local, state, and federal agencies and organizations, with major support from the federal Bureau of Reclamation. LADWP assisted in the funding and creation of the study report as part of the Technical Advisory Committee.

While centralized strategies such as spreading basins and dams are reliable and effective methods to capture stormwater, increased urbanization, high land costs, and scarcity of imported water for recharge signal the need to pursue additional stormwater capture methods. Furthermore, centralized stormwater infiltration is unable to capture the entire watershed which leaves a large quantity of additional stormwater to be tapped into. The WAS research has concluded that decentralized strategies (distributed stormwater capture such as rainbarrels & cisterns) would provide a local and reliable supply of water that would not negatively impact groundwater quality. Distributed stormwater capture and infiltration systems techniques provide a viable means of augmenting groundwater recharge and reducing the overall cost of treating urban runoff. Based on the findings of this study, the WAS partnership moved forward on a demonstration project in a 24-single family residential home neighborhood in northeast San Fernando Valley to validate study findings.

DRAFT

AR0070923

CASE STUDY:
Elmer Avenue Neighborhood Retrofit Project

The Background

Initiated in 2000, the Los Angeles Basin Water Augmentation Study (WAS) is a long-term research project led by the Los Angeles & San Gabriel Rivers Watershed Council in partnership with eight local, state, and federal agencies of which LADWP is an active partner. The study is evaluating the practical potential to improve surface water quality and increase local groundwater supplies through infiltration of urban stormwater runoff.

Based on positive findings of the study, the WAS partnership moved forward with a demonstration project to display an integrated and comprehensive approach to water management by retrofitting a neighborhood with strategies to address water conservation, pollution reduction and treatment, flooding, and habitat restoration. The Elmer Avenue Neighborhood Retrofit Project was chosen after an extensive selection process that evaluated neighborhoods based on more than 80 criteria.

The Project

The Elmer Avenue Neighborhood Retrofit Project commenced in July 2009 and was completed in June 2010 and cost approximately $2.5 million. Elmer Avenue receives stormwater runoff from approximately 40 acres of upstream residential area causing flooding in most storms. To address these 40 acres, the project encompasses improvements to both the public right-of-way as well as the private residences. As such, the project required active interaction and cooperation between the WAS partnership and the residents to work together and come up with a solution for the neighborhood.

Public Right-of-Way Improvements:

Infiltration Gallery-

A large infiltration gallery was installed underneath the street right-of-way which is estimated to infiltrate 16 acre-feet annually. The gallery is a sub-surface groundwater collection system, shallow in depth, constructed with perforated pipes where runoff water flows into and then is allowed to infiltrate into the ground to recharge the local groundwater basin.

Bioswale-

The newly installed sidewalks include bio-swales in the parkways to capture and treat stormwater runoff from the local sub-watershed mostly from residential landuse. The bioswales are open shallow channels with gently sloped sides and bottoms filled with vegetation and rip rap where stormwater runoff is collected. Bioswales help reduce the flow velocity and treat stormwater runoff through filtering by the vegetation in the channel, through the subsoil matrix, and/or into the underlying soils. In addition, bioswales trap particulate pollutants (suspended solids and trace metals), promote infiltration and serve as part of the whole stormwater drainage system installed for this project.

AR0070924

Private Residence Improvements:

Numerous improvements were offered to residents who chose to participate to help reduce runoff as well as exercise better outdoor water conservation such as porous pavers, rain gardens, rain barrels, and drought-tolerant and native landscaping.

The Benefits

The finished project incorporates a mixture of strategies to produce multiple levels of benefits (to the neighborhood but also to the local, regional, and national community whom can take this work as an encouraging model):

- Capture stormwater and dry-weather runoff to prevent flooding and decrease pollution of local rivers and oceans
- Reduce impermeable surfaces and increase groundwater recharge
- Improve neighborhood aesthetics through increased green space and public right-of-way improvements
- Increase community awareness of watershed issues
- Encourage community awareness to being more water and environmentally responsible.

As a result of the success and positive feedback from citizens for the Elmer Avenue Neighborhood Retrofit Project, a second phase is currently underway to Elmer Avenue to retrofit its alleyway. These small projects aim to spark large change by showing citizens and other communities that they too can make changes and improve their neighborhoods to be more water and environmentally friendly.

"By turning our yards into rain gardens and our streets into water recharge facilities, we can ensure clean water for the future. In contrast to a typical urban street, Elmer Avenue now reduces flooding and water pollution, improves water quality, replenishes groundwater supplies, and increases native habitat."

Nancy Steele, Executive Director
Los Angeles and San Gabriel Rivers Watershed Council

"This project is a prime example of how homeowners and the city can work together on a project that demonstrates smart watershed management through stormwater capture and water conservation measures that are beautiful and effective"

Edward Belden, Water Programs Manager
Los Angeles and San Gabriel Rivers Watershed Council

AR0070925

7.6.2 Integrated Water Resources Plan Analysis

As part of the City of Los Angeles Integrated Water Resources Plan (IRP), further described in Chapter 10, the City investigated the beneficial reuse of urban runoff for both dry and wet weather conditions.

7.6.2.1 Dry Weather Runoff Options

The beneficial use option for dry weather runoff consists of runoff capture, treatment, and reuse. For dry weather flow, most of the runoff could potentially be diverted directly for beneficial use, particularly during the summer months when demands for non-potable water are high (due to the higher irrigation demands in the summertime). The level of treatment of the runoff before being beneficially used would be determined by the ultimate use of the water.

A computer modeling analysis was performed during development of the IRP based on the recycled water demands in Los Angeles and the available dry weather runoff. Based on the data, the model determined which of the recycled water demands could be realistically met through treated runoff. The dry weather runoff available for reuse throughout the City is estimated at 97 mgd (approximately 26,000 million gallons per year). Exhibit 7E identifies the amount of this runoff that could, after treatment, be used to meet the recycled water demands.

Exhibit 7E

Potential Non-Potable Water Demands Met with Dry Weather Treated Runoff

Service Area	Total Demand Served	
	(AF per year)	(million gallon per year)
Aliso Wash	1,400	460
Canoga	3,250	1,050
Reseda	2,900	950
Tujunga / Burbank	9,050	2,950
LA River Reach 3	1,100	360
Dominguez Channel	8,500	2,770
Compton Creek	1,450	470
Ballona	10,850	3,530
Verdugo Wash	100	30
LA River/Arroyo	9,600	3,130
Total	48,200	15,700

Source: City of Los Angeles Integrated Resources Plan, Facilities Plan, Volume 3: Runoff Management

7.6.2.2 Wet Weather Runoff Options

Rain Barrels

Rain barrels are distributed stormwater capture devices used to store rainwater collected from roofs via roof rain gutter systems. Harvested water can be used for outdoor irrigation at a later time. Rain barrels vary in size with a typical rain barrel holding approximately 55 gallons that can be readily installed under any residential roof gutter downspout. Installation of rain barrels at residences throughout Los Angeles, assuming 400,000 residences, could potentially capture 6,400 AFY assuming an annual average rainfall of 17.8 inches, one 55-gallon rain barrel installed per residence, and an average roof area of 500

AR0070926

square feet. If overflow infiltration is provided, and/or greater roof area is utilized, annual rainfall volume captured can be significantly greater.

DRAFT

AR0070927

Case Study:
Ballona Creek Watershed Rainwater Harvesting Pilot Program

Funded by the Safe Neighborhood Parks, Clean Water, Clean air and Coastal Protection Bond Act of 2000 (Prop 12) through the Santa Monica Bay Restoration Commission and the California Coastal Conservancy, the City of Los Angeles, Department of Public Works, Bureau of Sanitation, Watershed Protection Division (Stormwater Program) began the City's first free Rainwater Harvesting pilot program in July 2009. The goal of this program is to engage as many property owners as possible, and limiting the installation to one downspout per property allows the City to reach the maximum number of residences.

Liz Herron, Land Use Chair of Mt. Washington Association, supports rainwater harvesting systems: "Rain barrel systems serve environmental purposes by allowing homeowners to collect the rainwater for personal irrigational purposes. It also reduces the amount of rainwater entering into the streets and ocean. These residential systems are successful programs that save water and prevent pollution."

Designed to conserve potable water and reduce the amount of polluted rainwater that runs untreated into the ocean, the $1-million pilot plan has enough funds to install 490 residential rain barrels, disconnect 100 barrels implemented with consultation on rain gardens, and provide one custom-made commercial planter box for each of ten businesses. It is estimated to save 584,100 gallons of water each year. The City estimates there are roughly 18 rain events in LA each year filling each barrel at least once each time.

In a typical year, about 9,600 gallons of water is generated on an average 1,000-square foot residential LA roof top. If each of the 400,000 residential parcels in LA were to install a single rain barrel, the City estimates that about 400 million gallons of water would be saved, which would reduce the demand for water. An evaluation of the program is scheduled for completion in Spring 2011.

The 55-gallon capacity rain barrel was chosen because the weight of 200 pounds is relatively manageable. The rain barrels are also made from food-grade plastic, repurposed from containers in case the harvested rainwater is used to grow food. They are equipped with mesh netting to keep out debris and mosquitoes and connected to the downspouts by a trained rain barrel installation specialist.

Planter boxes that businesses are eligible for will be custom-made to fit the layout and dimensions of the property. The City will be working with the business to make sure they are content with the presentation of the planter box.

The program addresses the City's broad problems of water scarcity and stormwater pollution. Currently outdoor water usage accounts for 1/3 of the average family's overall water consumption. The Rainwater Harvesting program helps to meet the City's water conservation goals by reducing the amount of potable water used for irrigation and other outdoor purposes.

AR0070928

Cisterns

Cisterns are larger than rain barrels and can range from 100 to 10,000 or more gallons. They store diverted runoff from roof areas and other impervious surfaces. This stored runoff can provide a source of untreated water for gardens and compost, free of most sediment and dissolved salts. Because residential irrigation can account for up to 40 percent of domestic water consumption, water conservation measures such as cisterns can be utilized to reduce demands, especially during hot summer months.

An analysis of the effect of installing cisterns in all single family and multi-family residences in the City was conducted as part of the IRP, which was based on projected household demands, irrigation needs, and historical rainfall data. The results showed that during a storm event of 0.45 inches, the result of installing 1,000-gallon cisterns at all single-family and multi-family residences in the City would be a maximum capture of approximately 440 million gallons. This provides a substantial amount of water conservation and reduction in potable water demands within the City.

The primary beneficial use of dry and wet weather runoff is to meet irrigation demands. These demands are typically non-existent during rain events and low throughout the rainy season. Therefore, the wet weather runoff would need to be stored until the demand exists. This can be done through a regional and/or a localized approach. A regional approach to seasonal storage could include the use of out-of-service reservoirs for seasonal storage. A localized approach would be to construct distributed underground storage facilities, located in open spaces, parks, schools, etc. throughout the City.

Exhibit 7F demonstrates a modular storage media that holds the runoff in a honeycomb-like box under the ground. The storage media has approximately 95 percent voids, so almost all of the storage volume would be filled with water. The maximum depth is 8 feet, which translates to approximately 2.44 million gallons per acre of water storage potential. The containers can also be constructed to be impermeable to prohibit infiltration.

Exhibit 7F
Construction of Underground Cistern for Stormwater Capture

(Photo courtesy of TreePeople)

DRAFT

AR0070929

According to studies conducted during the development of the IRP, the City currently has an estimated open space area of 6,000 acres, which includes parks, open space, and vacant lots. School sites are also a potential option for installing modular storage media under playgrounds and athletic fields. The total school area in the City is approximately 6,000 acres. Assuming that only 25 percent of this area has no buildings or other structures, this equals approximately 1,500 acres of potentially suitable land. Additionally, there are approximately 900 abandoned or no longer maintained alleys of various unknown dimensions that could potentially be converted to underground storage facilities. Exhibit 7G summarizes the approximate underground storage potential throughout the City.

Exhibit 7G

Underground Storage Potential throughout the City

Land Use	Acres (acres)	Potential Storage Volume[1] (million gallons)
Open space	6,000	15,000
Schools (assume only ~ 25 percent suitable land)	1,500	4,000
Alleys	900 count	Unknown
Total	7,500	19,000

Note: 1. Maximum storage potential shown assumes 4.22 million gallons of storage per acre of land. Actual usable volume may be less.
Source: City of Los Angeles Integrated Resources Plan, Facilities Plan, Volume 3: Runoff Management

The City has the potential to store a considerable volume of wet weather runoff in order to meet the potential future surface water quality regulations if the underground storage options were utilized. This stored water could then be drawn down and beneficially used during the dry weather months.

Rain Gardens

Rain Gardens are another simple form of relatively small scale rainwater harvesting. As gardens or depressions, usually constructed sub-grade, they act as small retention/percolations basins for rainwater collection. Not only do they provide for an attractive landscape, but they are effective in treating and infiltrating stormwater for local groundwater recharge.

While extremely functional, these are basically regular gardens and can be designed to fit well into the surrounding landscape. Many cities and states across the country have extensive rain garden programs, and years of research have gone into their design and performance. Acting as a bio-retention systems, rain gardens treat runoff naturally as it seeps underground. In the case of lowered percolation rates or in hillside developments, rain gardens are typically installed with impermeable liners and supplied with under drains.

Unit cost of rain gardens are similar to that of rain barrels, as the mechanism for collecting water is the same. Cost is dependent upon the form and extent of construction and on the type and quantity landscape used, as well as the associated maintenance. Installation of rain gardens at residences throughout Los Angeles, assuming 400,000 residences, could potentially capture 6,400 AFY assuming an annual average rainfall of 17.8 inches, and an average roof area of 500 square feet. Under these conditions, assuming a 10-15 year lifespan, the cost of rain gardens varies from $308-$5,000 / AF.

Neighborhood Recharge

Neighborhood recharge involves installing recharge facilities in portions of vacant urban lots, abandoned alleys, and City parklands, where the soil is highly permeable. This option involves installing underground storage (such as a honeycomb

AR0070930

shaped device shown in Exhibit 7F, but without the lining to allow infiltration). This would allow the runoff to be stored underground, while still maintaining a safe area above ground for human activity. The runoff would be pumped or would flow by gravity to the site where it would be collected temporarily until it is able to infiltrate.

The amount of runoff that could be managed by neighborhood recharge was determined as part of the IRP by assuming that only the east San Fernando Valley area has predominantly permeable soils appropriate for infiltration (though there may be other areas within the City that could be usable for recharge with smaller-scale projects). Based on an analysis of the City's Geographical Information System, the maximum total area available for neighborhood recharge facilities is approximately 831 acres, which includes vacant urban lots, abandoned alleys, and 25 percent of City parklands. Assuming an infiltration rate of 2 feet per day, the maximum runoff that could potentially be managed by recharge facilities would be 550 million gallons per day (mgd).

7.6.3 Distributed Stormwater Capture Projects

As an outgrowth of the IRP, neighborhood recharge concept efforts are moving from the conceptual stage visualized in the IRP to actual identified projects in the City which infiltrate wet weather runoff as close as possible to the point of origin. A few of the identified projects are highlighted here.

Whitnall Highway Power Line Easement Stormwater Capture Project. This project involves the capture, treatment, and infiltration of stormwater from streets in the eastern San Fernando Valley using LADWP's Whitnall Power Line Easement in the lower Sun Valley Watershed. Average annual recharge is estimated at 110 AFY. Additional uses of the project site may include open space and recreational enhancements. Designs are anticipated for completion by the end of 2011.

Elmer Avenue Neighborhood Retrofit Project. In December of 2008, the City of Los Angeles partnered with TreePeople and the LASGRWC to retrofit an existing neighborhood in the Sun Valley portion of Los Angeles that is prone to flooding during wet weather events. A combination of Best Management Practices (BMPs); including vegetated swales, infiltration trenches, rain gardens, rain barrels, native and drought tolerant landscaping, roof gutters, street tree plantings, and aligning driveways to drain to vegetated swales are incorporated into this project. This project was designed to capture and infiltrate the equivalent of a 2-year storm, increasing groundwater recharge. Project funding was provided by the US Bureau of Reclamation, DWR, LACDPW, MWD, Water Replenishment District of Southern California and LADWP. Construction was completed in June 2010.

Woodman Avenue Median Retrofit Demonstration Project. LADWP in partnership with the BOS Watershed Protection Division and The River Project, a non-profit organization, are developing the Woodman Avenue Median Retrofit Demonstration Project to capture, treat, and infiltrate stormwater runoff along a portion of Woodman Avenue. The Project will replace the existing median with pre-treatment devices, a vegetated swale, and an underground retention system. Project benefits include reductions in localized flooding, open space enhancements, groundwater recharge, and native habitat enhancement. The CalFed Watershed Program awarded the project a $1.6 million grant. Construction is expected to be completed by the end of 2012.

North Hollywood Alley Retrofit BMP Demonstration Project. The Project's goal is to demonstrate the ability to infiltrate stormwater near the point of origin while increasing groundwater recharge, reducing flooding, and improving water quality. Four segments of alleyways in the San Fernando Valley are proposed to be retrofitted with pervious surfaces and diversion of flows from intersecting streets into these alleyways. Construction is anticipated to begin in early 2011.

AR0070931

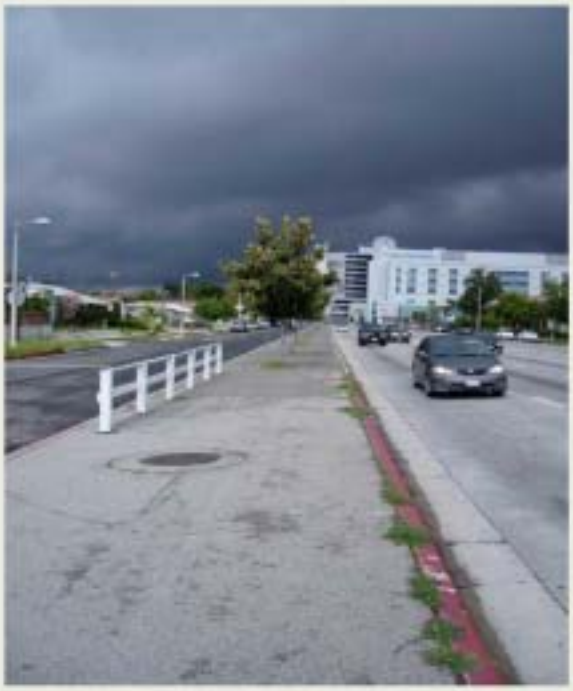
Laurel Canyon Parkway Infiltration Swale Project. Construction of the Laurel Canyon Parkway Infiltration Swale Project will involve construction of an infiltration trench and parkway swale between the street curb and sidewalk near LADWP's Tujunga Spreading Grounds in the San Fernando Valley. Stormwater will be collected and infiltrated into the groundwater from the local residential neighborhood. Construction of the project is anticipated to occur in late 2011.

DRAFT

AR0070932

CASE STUDY:
Woodman Avenue Multi-Beneficial Storm Water Capture Project

Originally proposed by the local Panorama City Neighborhood Council for the Tujunga-Pacoima Watershed Plan, the Woodman Avenue project represents an innovative example of stormwater capture, which includes extensive benefits for the environment, the City's groundwater basin, and the surrounding community. The Woodman Avenue median is located along the west side of Woodman Avenue from Lanark Street to Saticoy Street.



The Project's construction will be relatively simple but effective. The Project will capture surface runoff from approximately 130 acres that currently flows along street gutters to storm drains, through the Tujunga Wash and ultimately down the Los Angeles River and into the Pacific Ocean. Instead flows will now be directed through pre-treatment devices into a vegetated swale and an underground retention system for groundwater basin infiltration. The vegetated swale and underground retention/infiltration system will replace an existing 16-foot wide, 3,500-foot long concrete median. After construction of the project, participants will conduct active monitoring of water flows, water quality, and vegetation for approximately three years. This data should provide valuable information to facilitate the development of future projects, and optimize system processes.

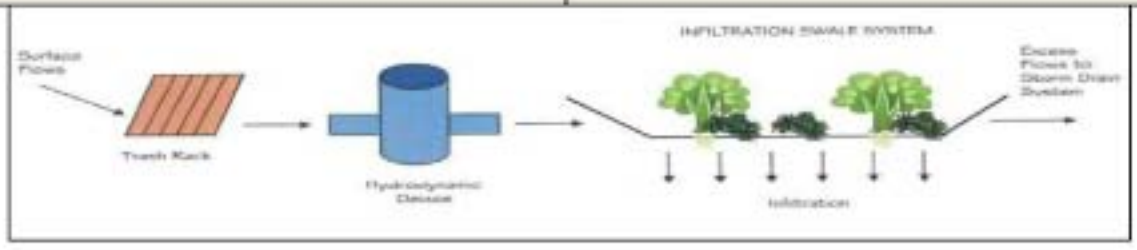
The direct water resource related benefits from this project are three fold. First, the additional water captured will recharge the San Fernando Groundwater Basin with approximately 80 AF per year. This replenishes the City's local groundwater supply, and helps protect pumping rights for City, which ultimately guarantees a more reliable water supply. Secondly, diverted flow alleviates local flooding, particularly during sizable rain events. Finally, the infiltration prevents contaminant carrying runoff and debris from entering local waterways and ultimately coastal areas.

Also recognized are the Community benefits associated with this project. These include creation of open space enhancements such as improved aesthetics and pedestrian access near schools, a walking path, benches, and native vegetation. The River Project will be running an active education program with the local community, including workshops with nearby business owners/residents and the introduction of a curriculum for students at the local elementary school. The organization's goal is to get the students involved in monitoring and maintenance of the project as part of their service learning requirements. Establishing knowledge of sustainable water supplies with the City's youth is an investment in constituent water use practices for generations to come.

Project participants include the Panorama City Neighborhood Council, Council District 6, the Los Angeles Bureau of Sanitation, the Los Angeles Bureau of Street Services, the State of California Water Resources Control Board (SCWRCB), The River Project, and LADWP. This cooperative partnership is anticipating the project's construction to be completion around the end of 2012.

State funding used for the project is provided through Proposition 50. SCWRCB has dedicated $1.6 million through the CALFED Watershed Grant Program, which covers roughly half of the overall project cost.

Melanie Winter from The River Project speaks positively of this stormwater capture project: "The community's involvement in the watershed planning process helped them identify a prime opportunity site that maximizes all the potential benefits. It helps reduce our dependence on imported supplies, addresses peak flows, improves water quality, and re-establishes habitat. It's gratifying to receive State funding to work in a well-rounded partnership to implement this integrated watershed project conceived at the grassroots level."



AR0070933

7.6.4 Low Impact Development and Best Management Practices

LADWP, in conjunction with other City Departments, is developing programs to highlight water conservation through Low Impact Development (LID) and installation of BMPs. Low Impact Development (LID) is a stormwater management strategy that has been adopted by many localities across the country for the past several years. It is a stormwater management approach that is designed to reduce runoff of water and pollutants from the site(s) at which they are generated.

The past few decades of stormwater management have resulted in the current convention of control-and-treatment strategies. They are largely engineered, end-of-pipe practices that have been focused on controlling peak flow rate and suspended solids concentrations. Conventional practices, however, fail to address the widespread and cumulative hydrologic modifications within the watershed that increase stormwater volumes and runoff rates and cause excessive erosion and stream channel degradation.

In general, implementing integrated LID practices into new development and retrofit of existing facilities can result in enhanced environmental performance while at the same time reducing development costs when compared to traditional stormwater management approaches.

According to the USEPA, infrastructure costs associated with LID practices as compared to traditional stormwater treatment practices result in significant cost savings ranging between 15 percent and 80 percent less than traditional practices. BMPs consist of practices designed to infiltrate runoff for groundwater recharge, reduce runoff volume, and capture rainwater for reuse. Programs under development include pilot projects, retrofitting of existing facilities, new development standards, and assistance in ordinance development.

Retrofit of LADWP Facilities to Meet LID Standards

LADWP is assessing its existing facilities for potential retrofits using LID BMPs. LID BMPs under consideration include pervious pavement, stormwater capture, curb cuts, bioretention cells, and amended soils. Expected benefits include:

- Increased groundwater recharge;
- Decreased outdoor water use;
- Increased compliance with stormwater regulations;
- Improved environmental conditions for employees and the public;
- Improved public image;
- Increased awareness of LID and provide examples for residents; and
- Compliance with Model Water Efficient Landscape Ordinance.

New LADWP Facility Development Using LID Standards

LADWP's Watershed Management Group is developing a framework for implementation of LIDs and BMPs during the new facility development process. Within the framework, LID and BMPs are taken into consideration during the planning, design, implementation, and maintenance processes associated with new LADWP facilities. Benefits include:

DRAFT

AR0070934

- Reductions in costs associated with stormwater infrastructure and landscape maintenance;
- Reduced costs for grading by using natural drainage;
- Reduced sidewalk costs by using narrower sidewalks;
- Increased groundwater recharge;
- Reduced runoff volume and pollutant loading;
- Reductions in long-term maintenance and operation costs by using drought tolerant landscaping;
- Reduction in life cycle costs of replacing or rehabilitating pipe and below ground infrastructure.

Assistance in Ordinance Development

LADWP is represented on the City of Los Angeles Landscape & Stream Protection Ordinances Joint Meeting Committee through the Watershed Management Group. Other committee members include the Department of Parks and Recreation, the Department of Public Works, the Department of Environmental Affairs, the Department of City Planning, and the Department of Building and Safety. The committee is tasked with developing ordinances for city-wide implementation that in combination reduce water use and improve groundwater recharge among other multiple benefits. Ordinances under review include the:

- Green Building Ordinance using the US Green Building Council's Leadership in Energy and Environmental Design (LEED) Green Building Rating System;
- LID Ordinance to incorporate improvements in stormwater management at the point of origin;
- Stream Protection Ordinance to incorporate methodologies for improving surface and groundwater quality;
- Hillside Ordinance revisions to include modifications in policies regarding front yards, side yards, height, fire protection, street access, lot coverage, off-street parking requirements, and exceptions in relation to the ordinances above.

7.6.5 Future Distributed Stormwater Programs

LADWP continues to investigate the potential for implementation of future distributed stormwater programs. Through its Watershed Management Group, LADWP will continue to develop partnerships and programs to improve utilization of stormwater runoff for outdoor water use and groundwater recharge. Potential programs that could be considered in the future include rain barrel/cistern rebates and retrofit incentives for installation of LID BMPs.

7.7 Integrated Regional Water Management Plan (IRWMP) Program

LADWP is a participating agency for the IRWMP which encompasses 92 cities in the Greater Los Angeles County Region. The IRWMP aims to address the water quality, resource, and supply issues of the region. A final plan was adopted on December 16, 2006.

Highlights of the plan that pertain to Watershed issues include:

DRAFT

AR0070935

- Short and long term objectives to comply with water quality regulations (including TMDLs) by improving the quality of urban runoff, stormwater, and wastewater
- Optimize local water resources to reduce the Region's reliance on imported water
- Long term priority to protect groundwater supplies through stormwater recharge
- Target goal to reduce and reuse 150,000 AFY (40%) of dry weather urban runoff and capture and treat an additional 170,000 AFY (50%) for a total target of 90%
- Target goal to reduce and reuse 220,000 AFY (40%) of stormwater runoff from developed areas and capture and treat an additional 270,000 AFY (50%) for a total of 90%

For more detailed information on the IRWMP, please refer to Chapter 10.

7.8 Cost Analysis

Exhibit 7H compares side by side the various watershed management opportunities LADWP is pursuing and/or investigating to add to its water portfolio.

Exhibit 7H

Water Source	Water Yield (AFY)	Average Unit Cost ($/AF)
Centralized Stormwater Capture[1]	25,950	$60 - $200
Distributed Stormwater Capture		
Urban Runoff Plants[2]	5,000	$4,044
Rain Barrels[3]	6,400	$701 - $1,875
Cisterns[4]	8,000	$2,426
Rain Gardens[5]	6,400	$308 - $5,000
Neighborhood Recharge[6]	12,000	$3,351

Notes:

1. Water Yield and cost is based on LADWP's current planned centralized stormwater capture projects. Additional centralized stormwater capture potential will be identified once the Stormwater Master Plan is complete. Cost assumes 50 year project life.

2. Source: City of Los Angeles Integrated Resources Plan (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSA.

3. Source: Tree People. Assumes 10 - 15 year life, 55 gallon barrels, 1 barrel per residence, 17.8 in annual rainfall, $200-$300 per barrel installed, average used roof area 500 square feet, and 400,000 residences for yield (AFY); 2010 dollars

4. Source: City of Los Angeles Integrated Resources Plan (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSA; capturing and reusing stormwater on-site for schools and government only.

5. Source: Tree People. Assumes 10 - 15 year life, 17.8 in annual rainfall, $3.30 - $25.66 / ft² for rain garden construction, average used roof area 500 square feet, and 400,000 residences for yield (AFY); 2010 dollars

6. Source: City of Los Angeles Integrated Resources Plan (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSMSA.

DRAFT

It is important to note that the centralized stormwater capture values are based on the planned projects listed in Section 7.5. LADWP is currently compiling a Stormwater Master Plan (see Section 7.3) which will investigate the maximum potential for stormwater capture within the City (for both centralized and distributed capture). Nevertheless, even with this fraction of the potential, it is clear that centralized stormwater capture is a very cost effective, plentiful water supply asset to be pursued. Recognizing its great potential, LADWP will proceed with its efforts on the centralized stormwater capture projects listed in Section 7.5, and closely monitor findings of the Stormwater Master Plan to determine future potential centralized stormwater capture projects.

Distributed stormwater capture values are based on the maximum potential achievable by the City. While the cost listed is high, distributed stormwater capture options are highly variable based on a variety of factors such as the magnitude of the overall program, project locations, etc. Furthermore, distributed stormwater capture projects yield additional benefits to the public outside of water supply generation such as community beautification, public right of way improvements, as well as private residence safety and aesthetic improvements. LADWP will continue to investigate these options to evaluate the best approach to establish a cost effective program that will help add to LADWP's water portfolio.

DRAFT

AR0070937

Chapter Eight
Metropolitan Water District Supplies

8.0 Overview

As a member agency, the City of Los Angeles purchases water from the Metropolitan Water District of Southern California (MWD) to supplement its supplies from local groundwater, LAA deliveries, and recycled water. LADWP has historically purchased MWD water to make up the deficit between demand and other City supplies. As a percentage of the City's total water supply, MWD water varies from 4 percent in 1983-84 to 71 percent in 2008-09 with the 5-year average of 52 percent between 2005-06 and 2009-10. Exhibit 1F in Chapter 1 illustrates the City's reliance on MWD water during dry years and increasingly in recent years when LAA supply is being cut back for environmental enhancement projects. Although the City plans to reduce its reliance on imported water including LAA and MWD supplies, it has made significant investments in MWD and will continue to rely on the wholesaler to meet its current and future supplemental water needs.

MWD is the largest water wholesaler for domestic and municipal uses in California providing nearly 19 million people with on average 1.7 billion gallons of water per day to a service area of approximately 5,200 square miles. MWD was formed by the MWD Act, and exist pursuant to this statute which was adopted by the California legislature in 1927. MWD's adopted purpose is to develop, store, and distribute water to southern California residents. Additionally, the MWD Act allows MWD to sell additional water when it is available for other beneficial uses. In 1928 MWD was incorporated as a public agency following a vote by residents in 13 cities in southern California. Operating solely as a wholesaler, MWD owns and operates the Colorado River Aqueduct (CRA), is a contractor for water from the California State Water Project (SWP), manages and owns in-basin surface storage facilities, stores groundwater within the basin via contracts, engages in groundwater storage outside the basin, and conducts water transfers to provide additional supplies for its member agencies. Today MWD has 26 member agencies consisting of 11 water districts, one county water authority, and 14 cities, including the City of Los Angeles.

This Urban Water Management Plan projects LADWP's reliance on MWD water supplies will be reduced by half; from the five-year average of 52 percent of total demand between 2005-06 and 2009-10, to 24 percent by 2034-35 under average weather conditions.

8.0.1 History

Initially formed to import water into the southern California region from, MWD's first project was to build the CRA to import water from the Colorado River. The City of Los Angeles originally provided the capital dollars to initiate and complete land surveys of all proposed alignments for the project. Construction was financed through $220 million in bond sales during the Great Depression. Ten years after initiating construction Colorado River water reached southern California in 1941. To meet further water demands in the southern California region, MWD contracted with the SWP in 1960 to deliver almost half of the SWP's water from the San Francisco Bay-Delta region via the California Aqueduct into southern California. After completion of the California Aqueduct, deliveries of SWP water were first received in 1972.

8.0.2 Governance

MWD is governed by a Board of Directors composed of 37 individuals with a minimum of one representative from each of MWD's 26 member agencies. The allocation of the directors and voting rights are determined by each agency's assessed valuation. The city of Los Angeles has four Directors on MWD's Board and controls 19.44 percent of the vote. MWD's Administrative Code defines various tasks which the Board has delegated to MWD staff. A General Manager oversees MWD

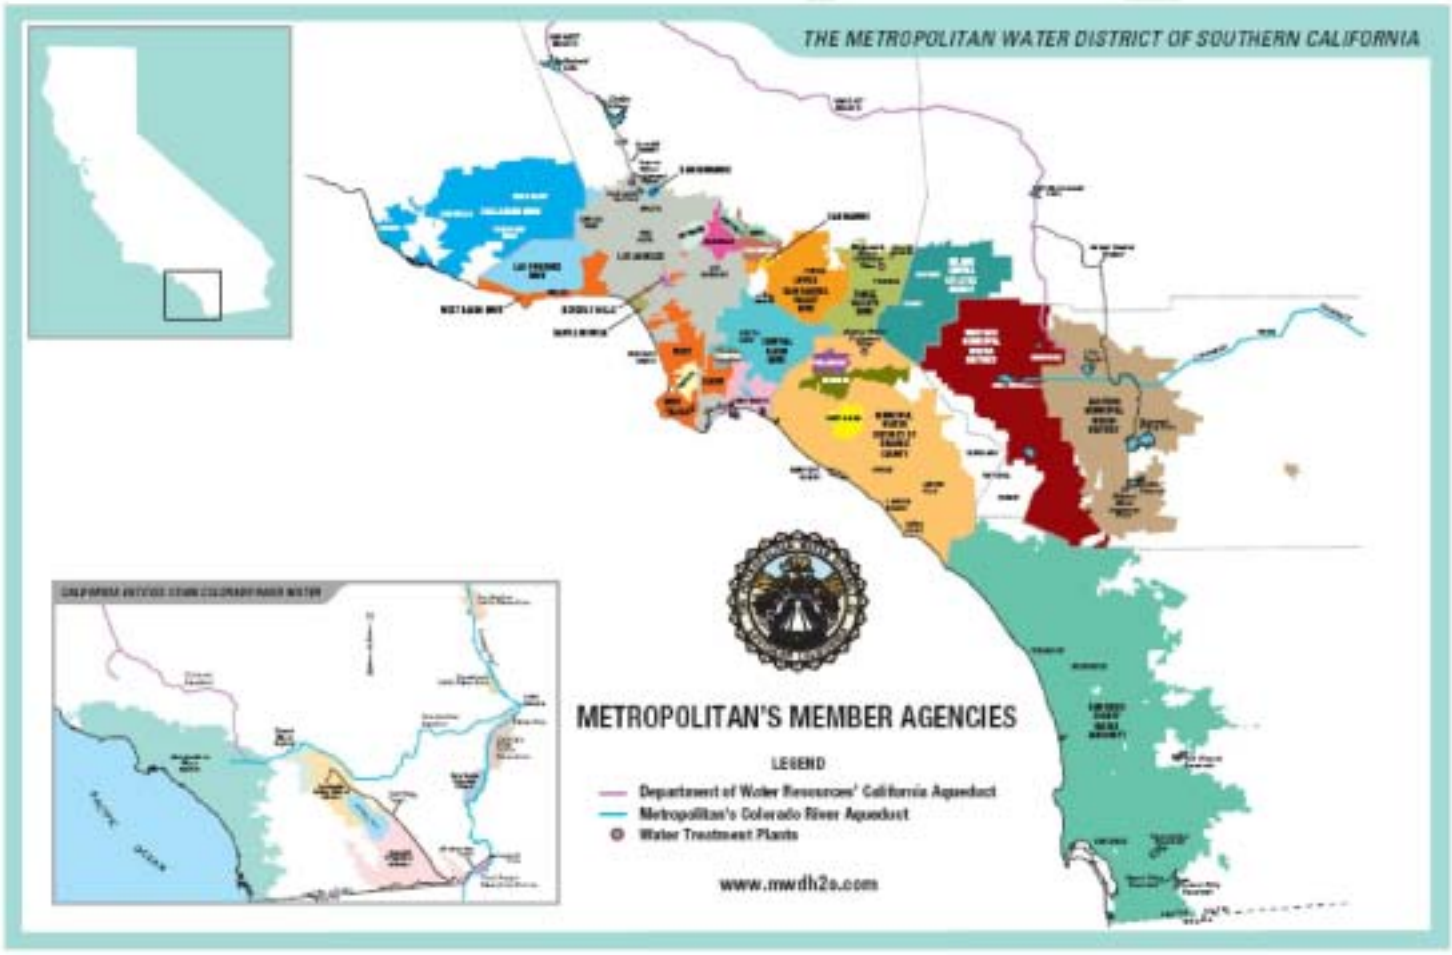
AR0070938

staff. The General Manager, General Auditor, General Counsel, and Ethics Officer serve under direction and authority given directly by the Board.

8.0.3 Service Area

Originally serving an area of 675 square miles in 1928, MWD's service area has grown to approximately 5,200 square miles serving 19 million people via its 26 member agencies. MWD's service area covers portions of Los Angeles, Ventura, Orange, Riverside, San Bernardino, and San Diego counties as depicted in Exhibit 8A. MWD member agencies serve 152 cities and 89 unincorporated areas. Member agencies provide wholesale, retail, or a combination of wholesale/retail water sales in their individual service territories.

Exhibit 8A
MWD Service Area



8.0.4 Major Infrastructure

MWD delivers approximately 6,000 AF per day of treated and untreated water to its member agencies through its vast infrastructure network. Major facilities include the CRA, pumping plants, pipelines, treatment plants, reservoirs, and

AR0070939

hydroelectric recovery power plants. A summary of the major facilities and capacities are provided in Exhibit 8B and Exhibit 8C illustrates the geographic locations of the facilities.

Exhibit 8B
Major MWD Facilities Summary

Facility	Units	Capacity
Colorado River Aqueduct		
Aqueduct	242 miles	1.3 million AFY
Pumping Plants	5 plants	1,617 feet of total lift
Pipelines	819 miles	
Water Treatment Plants		
Joseph Jensen		750 mgd
Robert A. Skinner		630 mgd
F.E. Weymouth		520 mgd
Robert B. Diemer		520 mgd
Henry J. Mills		220 mgd
Total Treatment Capacity		2,640 mgd
Reservoirs		
Diamond Valley Lake		810,000 AF
Lake Matthews		182,000 AF
Lake Skinner		44,000 AF
Copper Basin		24,200 AF
Gene Wash		6,300 AF
Live Oak		2,500 AF
Garvey		1,600 AF
Palos Verdes		1,100 AF
Orange County		212 AF
Total Reservoir Capacity		1,071,912 AF
Hydroelectric Recovery Plants	16 plants	122 megawatts

DRAFT

AR0070940

Exhibit 8C
Major MWD Facilities

8.1 Supply Sources

Colorado River supplies, State Water Project supplies, In-Basin Storage, Outside-Basin Storage, and Water Transfers together comprise MWD's total system water supply sources. These sources provide supplemental water to meet the demands in Venture, Los Angeles, Riverside, Orange, San Bernardino and San Diego Counties.

8.1.1 Colorado River

The Colorado River forms California's border with Arizona to the east. The drainage area in California that contributes water to the Colorado River is relatively small and has an arid climate. Accordingly, California has no major tributaries contributing water to the Colorado River.

AR0070941

The Colorado River Board of California (CRB) is the California state agency given authority to protect the interests and rights of the state and its citizens in matters pertaining to the Colorado River. The Board is comprised of 10 gubernatorial appointees representing the LADWP, MWD, San Diego County Water Authority, Palo Verde Irrigation District, Coachella Valley Water District, Imperial Irrigation District, Department of Water Resources, Department of Fish and Game, and two public members.

8.1.1.1 The Law of the River

The Secretary of the Interior (Secretary) is vested with the responsibility to manage the mainstream waters of the Colorado River pursuant to applicable federal law. This responsibility is carried out consistent with a body of documents referred to as the Law of the River. Water rights to Colorado River water are governed by a complex collection of federal laws, state laws, a treaty with Mexico, other agreements with Mexico, Supreme Court decrees, contracts with the Secretary, interstate compacts, state, and administrative actions at the federal and state levels. Collectively, these documents and associated interpretations are commonly referred to as the "Law of the River" and govern water rights and operations on the Colorado River.

Particularly notable among these documents are:

1) the Colorado River Compact of 1922, which apportioned beneficial consumptive use of water between the Colorado River Upper Basin and Lower Basin; and defined the term "States of the Lower Division" to mean the States of Arizona, California, and Nevada. Serving as the basis of the "Law of the River" the Compact apportioned water to each basin in anticipation of a dam on the Colorado River. The Upper Basin is the portion of the Basin upstream of Lee Ferry, Arizona, while the Lower Basin is downstream of this point. Each basin was apportioned 7.5 million MAF annually and the Lower Basin received the option to an additional 1 MAF annually based on excess flows. California is within the Lower Basin along with Arizona and Nevada;

2) the Boulder Canyon Project Act of 1928 was enacted by Congress to authorize construction of Hoover Dam and the All-American Canal, the Act required that water users in the Lower Basin have a contract with the Secretary, and established the responsibilities of the Secretary to direct, manage, and coordinate the operation of Colorado River dams and related works in the Lower Basin. The Act stipulated conditions, one of which required California to limit Colorado River water use to 4.4 MAF annually plus one-half of the excess water unapportioned by the Colorado River Compact. To satisfy the condition, the California Legislature enacted the Limitation Act in 1929 limiting its use of Colorado River water to the basic apportionment of 4.4 MAF;

3) the California Seven Party Agreement of 1931 was developed in response to the Limitation Act and through regulations adopted by the Secretary, established the relative priorities of rights among major users of Colorado River water in California. The Seven Party Agreement apportioned California's share of Colorado River water to California contractors. Within the agreement priorities were established for each of the four agencies holding contracts for Colorado River Water with the U.S. Bureau of Reclamation. These priorities are shown in Exhibit D. Seven priorities were established with the first four priorities satisfying California's allocation of 4.4 MAF annually and the fifth and sixth priorities relating to California's share of excess Colorado River flows. MWD holds the fourth and fifth priorities. The fourth priority allocates 550 thousand acre-feet (TAF) of California's apportionment to MWD and the fifth priority allocates 662 TAF of California's share of excess flows to MWD.

4) the 1944 Treaty (and subsequent minutes of the International Boundary and Water Commission) related to the quantity and quality of Colorado River water delivered to Mexico. The Treaty guaranteed an annual quantity of 1.5 MAF to be delivered in accordance with the provisions of the Treaty.

AR0070942

5) the 1963 United States Supreme Court Decision in *Arizona v. California* which confirmed the Lower Basin mainstream apportionments of:

2.8 million acre-feet per year (AFY) for use in Arizona,
4.4 million AFY for use in California, and
0.3 million AFY for use in Nevada;

provided water for Indian reservations and other federal reservations in Arizona, California, and Nevada; and confirmed the significant role of the Secretary in managing the mainstream Colorado River within the Lower Basin;

6) the 1964 United States Supreme Court Decree (Decree) in *Arizona v. California* which implemented the Supreme Court's 1963 decision; allocated 50 percent of the surplus water available for use in California; and allowed the Secretary to release water apportioned to but unused in one state for use in the other two states; the Decree was supplemented over time after its adoption and the Supreme Court entered a Consolidated Decree in 2006 which incorporates all applicable provisions of the earlier-issued Decrees; and

7) the Colorado River Basin Project Act of 1968, which authorized construction of a number of water development projects including the Central Arizona Project (CAP), provided existing California, Arizona, and Nevada water contractors a priority over the CAP and other users of the same character in Arizona and Nevada whenever less than 7.5 million afy is available, and required the Secretary to develop the Long Range Operating Criteria and issue an Annual Operating Plan for mainstream reservoirs.

Exhibit 8D

Listing of Priorities - Seven Party Agreement		
Priority Number	**Agency and Description of Service Area**	**Beneficial Consumptive Use (Acre-feet/year)**
1	Palo Verde Irrigation District - 104,500 acres	
2	Yuma Project, California Portion, not exceeding 25,000 acres	
3(a)	Imperial Irrigation District	
3(b)	Palo Verde Irrigation District - 16,000 acres	3,850,000
4	Metropolitan Water District, City of Los Angeles and/or others on the coastal plain	550,000
5	Metropolitan Water District, City of Los Angeles and/or others on the coastal plain	662,000
6(a)	Imperial Irrigation District	
6(b)	Palo Verde Irrigation District - 16,000 acres of adjoining mesa	300,000
	Total	**5,362,000**

8.1.1.2 Colorado Supply Reliability

Reliability of CRA water for MWD has decreased overtime as a consequence of multiple events. Historically California had used up to 5.4 million afy as Arizona and Nevada were not using their normal apportionments of Colorado River water and surplus water was made available by the Secretary. The 1964 Decree and the 2006 Consolidated Decree of the US Supreme

AR0070943

Court in *Arizona v. California* confirmed California's allocation was limited to 4.4 MAF annually. As a result MWD can now only rely on its fourth priority allocation of 550 TAF annually. Prior to this, MWD was able to satisfy its fifth priority allocation with Nevada and Arizona's unused water. However, in 1985 Arizona began increasing deliveries to its Central Arizona Project reducing the availability of unused apportionment to fill MWD's fifth priority.

Because of dry years on the Colorado River system and Arizona and Nevada using their full apportionment, the U.S. Secretary of Interior asserted that California must come up with a plan to live within its 4.4 MAF apportionment. Therefore, users from California have developed California's Colorado River Water Use Plan (California Plan). The users included: MWD, Palo Verde Irrigation District (PVID), Imperial Irrigation District (IID), and Coachella Valley Water District (CVWD). This plan identifies actions that California will take to operate within its 4.4 million acre-foot entitlement.

California currently consumes its normal apportionment of 4.4 million AFY, Exhibit 8E and Exhibit 8F illustrate the order of priority, is as follows:

1. PVID - gross area of 104,500 acres of land in the Palo Verde Valley.
2. Yuma Project-Reservation Division - not exceeding a gross area of 25,000 acres in California.

3(a). IID - lands in the Imperial Valley served by the All-American Canal. Export out of basin, primarily agricultural usage. Also, second 63,000 AF in priority 6(a) and balance of any remaining priority 6(a) and 7 water available.

3(b). CVWD - lands in the Coachella Valley served by the Coachella Branch of the All-American Canal. Export out of basin, agricultural usage. Also third 119,000 AF in priority 6(a) and balance of any remaining priority 6(a) and 7 water available.

3(c). PVID - 16,000 acres of land on the Lower Palo Verde Mesa, also priority 6(b).

4. MWD – 550,000 af, also 662,000 af in priority 5, and first 38,000 af in 6(a)

Exhibit 8E

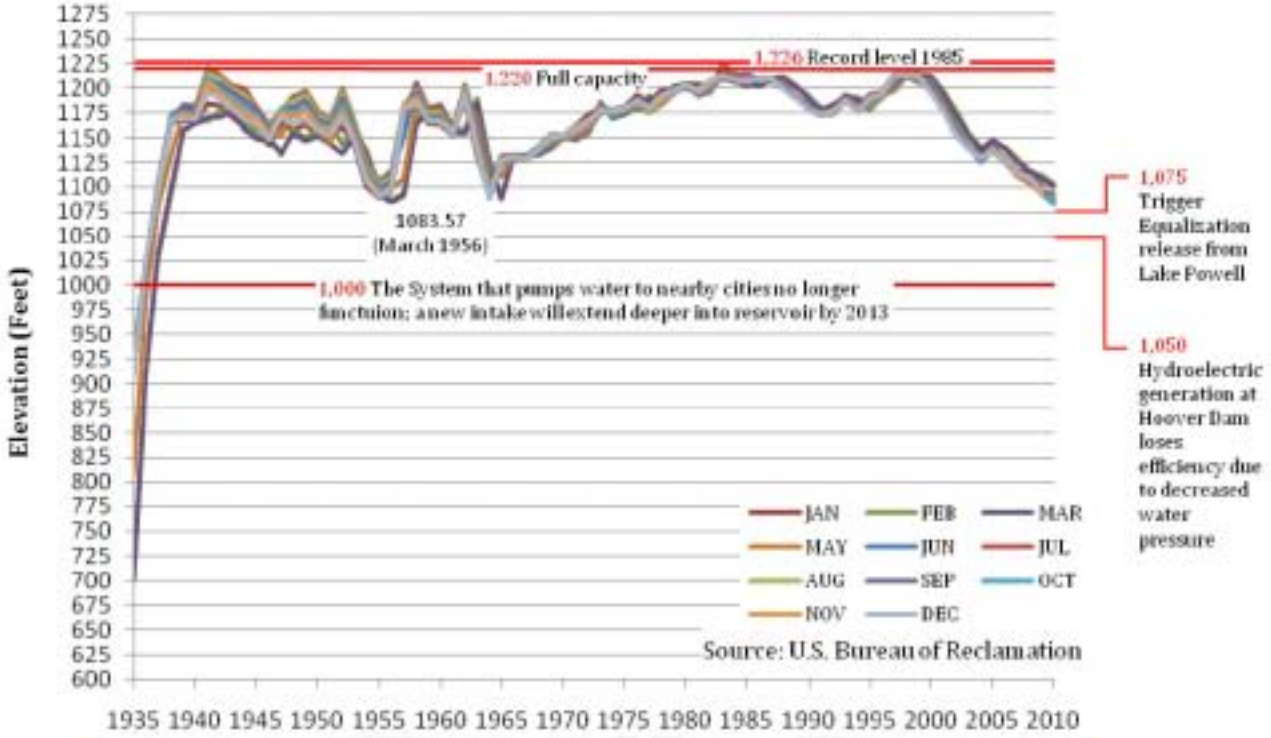
AR0070944

Exhibit 8F
Historical Lake Mead Elevation



The bathtub ring at Lake Mead, August 2010, lake elevation 1,087 feet.

AR0070945

A component of the California Plan was completion of the Quantification Settlement Agreement (QSA) in 2003, which established baseline water use for each California party with Colorado River water rights. Key to the agreement is the quantification of IID at 3.1 MAF, and CVWD at 330 TAF. Completion of the QSA facilitates the transfer of water from agricultural agencies to urban water suppliers by allowing water conserved on farm land to be made available for urban use. As a result of litigation, the QSA and eleven other agreements were ruled as invalid on February 11, 2010. MWD in conjunction with, CVWD and the SDCWA, have appealed the court's decision. Ultimately, the total impact of the court's decisions on MWD's Colorado River supplies cannot be determined at this time pending the outcome of the appeal. However, MWD's existing conservation, land fallowing, and transfer programs for Colorado River supplies are independent of the QSA and will not be impacted by the QSA lawsuit.

Along with MWD's apportionment, MWD has developed a number of water supply programs to improve reliability of Colorado River supplies, such as agricultural water transfers and storage programs, and has multiple programs under development as listed in Exhibit 8F. Developed programs in conjunction with MWD's apportionment will provide MWD with approximately 1.14 MAF in 2035 under an average year (1922 – 2004 hydrology). Proposed programs under development could add another 182 TAF per year. Non-MWD supplies conveyed through the CRA are forecast at 296 TAF for a total CRA supply capability of 1.61 MAF. However, the CRA has a supply capacity constraint of 1.25 MAF. After subtracting MWD's conveyance obligation of non-MWD supplies, MWD's supplies for 2035 under average year, single-dry year (1977 hydrology), and multi-dry year (1990 – 1992 hydrology) scenarios are all forecast at 954 TAF. Exhibit 8G summarizes the CRA supply forecast for 2035 under an average year.

Exhibit 8G
MWD's CRA Forecast Supplies in 2035, Average Year (1922 – 2004 Hydrology)

Program	Supply (Thousands of AF)/ Year
Current	
Basic Apportionment - Priority 4	550
Imperial Irrigation District/MWD Conservation Program	85
Priority 5 Apportionment (Surplus)	13
Palo Verde Irrigation District Land Management Crop Rotation and Water Supply Program	133
Lower Colorado Water Supply Project	5
Lake Mead Storage Program	400

Additional Non-MWD CRA Supplies	
San Diego County Water Authority/ Imperial Irrigation District Transfer	200
Coachella and All-American Canal Lining	
To San Diego County Water Authority	80
To San Luis Rey Settlement Parties[1]	16
Subtotal of Non-MWD CRA Supplies	**296**
Maximum CRA Supply Capability[2]	**1,614**
Minus Supply CRA Capacity Constraint of 1.25 MAF Annually	**-364**
Maximum Forecast CRA Deliveries	**1,250**
Minus Non-MWD Supplies[3]	**-296**
Maximum MWD Supply Capability[4]	**954**

1. Subject to satisfaction of conditions specified in agreement among MWD, the US, and the San Luis Rey Settlement Parties
2. Total amount of supplies available without taking into consideration of CRA capacity constraint of 1.25 MAF annually.
3. Exchange obligation for San Diego County Water Authority - Imperial Irrigation District transfer and the Coachella and All-American Canal Lining Projects
4. The amount of CRA water available to MWD after meeting exchange obligations.

Source: 2010 Regional Urban Water Management Plan, Metropolitan Water District of Southern California

8.1.1.3 Water Quality Issues

Water quality issues for Colorado River supplies encompass high salinity levels, perchlorate, nutrients, uranium, chromium VI, N-nitrosodimethlamine (NDMA), and pharmaceuticals and personal care products (PPCPs). High salinity levels present the most significant issue and the only foreseeable water quality constraint for the Colorado River supply. MWD expects its source control programs for the CRA to adequately address the other water quality issues. MWD has also bolstered its water security measures across all of its operations since 2001, including an increase in water quality tests. Details of MWD's water quality initiatives are available in MWD's 2010 Regional Urban Water Management Plan (RUWMP).

Salinity

Water obtained from the Colorado River has the highest salinity levels of all MWD supply sources averaging 630 mg/L since 1976. Salts are eroded from saline sediments deposited in prehistoric marine environments in the Basin, dissolved by precipitation, and conveyed into the Basin's water courses.

Salinity issues have been recognized in the Basin for over 30 years. The seven basin states formed the Colorado River Basin Salinity Control Forum (Forum) to mutually cooperate on salinity issues in the Basin. The Forum recommended the U.S. Environmental Protection Agency (USEPA) to act upon the Forum's proposal and in response the USEPA approved water quality standards and established numeric criteria for controlling salinity increases. Each Basin State adopted the water quality

AR0070947

standards, which are designed to limit the flow-weighted average annual salinity level to 1972 levels or below. An outgrowth of the Forum was the Colorado River Basin Control Program. At the core of the program is the reduction in salts entering the river system by intercepting and controlling non-point sources, wastewater, and saline hot springs. Salinity reduction projects have reduced salinity concentration of Colorado River water by over 100mg/L approximating $264 million per year, in 2005 dollars, in avoided damages.

MWD adopted a Salinity Management Policy in 1999 with the goal of achieving salinity concentrations of less than 500 mg/L at delivery. To reduce salinity levels, Colorado River supplies are blended with SWP water supplies to achieve the salinity target in seven out of ten years. In the other three years the target is not possible to achieve as a result of hydrologic conditions that increase salinity on the Colorado River and less SWP water is available for blending. Additionally, to maximize the use of recycled water in agriculture, MWD is trying to obtain lower salinity imported water during the spring/summer months to reduce salinity levels in recycled water.

Perchlorate

In 1997 perchlorate was first detected in the Colorado River attributed to an industrial site upstream of the Las Vegas Wash in Nevada, ultimately draining to the river. Subsequently, an additional groundwater plume was found to be migrating from an additional industrial site, but had not reached the Las Vegas Wash. Since the initial discovery of contamination, remediation efforts have significantly reduced perchlorate loading from the Las Vegas Wash. At Lake Havasu, downstream of the convergence of the Las Vegas Wash and Colorado River, perchlorate levels have decreased from 9 µg/L at their peak in 1998 to less than 6 µg/L in October 2002. Since June 2006 typical levels have been less than 2 µg/L.

Nutrients

Excessive nutrient levels in water can stimulate algal and aquatic weed growth leading to taste and odor concerns. Nutrients include both phosphorous and nitrogen compounds. Other impacts of algal and aquatic weed growth include reductions in operating efficiencies and potentially provide an additional food source for invasive aquatic species, such as quagga and zebra mussels.

Naturally, the Colorado River system has relatively low concentrations of phosphorous. Additional loading to the system as upstream urbanization increases has the ability to increase phosphorous concentrations and impact MWD's ability to blend low nutrient concentration CRA water with high nutrient concentration SWP water. MWD continues to work with agencies located along the lower Colorado River to improve their wastewater management to reduce phosphorous loading.

Uranium

Near Moab, Utah a 16-million ton pile of uranium tailings located approximately 750 feet from the Colorado River is a potential source of uranium loading to the river. In 1999, the US Department of Energy began remediating the site by removing tailings and treating contaminated groundwater. Complete removal of the pile is expected by 2025 or 2019 if additional funding is secured. MWD is tracking clean-up progress and continues to support rapid clean-up of the site.

To address recent uranium mining claims in the vicinity of the Colorado River and the Grand Canyon Area, MWD has sent letters to the Secretary of Interior to highlight MWD's concern of source water protection and recommended close federal oversight. In 1999, the Department of Interior placed a two-year hold on mining claims for 1 million acres adjacent to the Grand Canyon area to conduct additional analyses and H.R. 644, Grand Canyon Watersheds Protection Act, was introduced in 2009. H.R. 644, if approved, would prohibit new mining activities around the Grand Canyon area.

AR0070948

Chromium VI

Chromium VI has been detected in a groundwater aquifer in the vicinity of the Colorado River near Topock, Arizona. The source of the contamination is a natural gas compression site operated by Pacific Gas and Electric (PG&E) that previously used chromium VI in its operations. Currently, PG&E is engaged in interim clean-up operations to protect the Colorado River. A final treatment alternative is anticipated to be released in 2010. Monitoring upstream and downstream of the site range from non-detect (0.03 µg/L) to 0.06 µg/L which are considered within the background range for the river. MWD is actively involved in the corrective action process through its participation in stakeholder workgroups and partnerships with State and federal regulators, Indian tribes, and other stakeholders.

NDMA and Pharmaceuticals and Personal Care Products

N-nitrosodimenthylamine is a by-product formed by secondary disinfection of some natural waters with chloramines. MWD is involved with projects to understand the potential sources of NDMA precursors in its source watersheds and to develop treatment strategies to minimize NDMA formation at its water treatment facilities. In 2007, MWD initiated monitoring efforts to measure Pharmaceuticals and Personal Care Projects (PPCPs) in its source supplies. PPCPs have been detected at very low levels (low ng/L level; parts per trillion) consistent with monitoring results from other utilities. MWD is involved with programs to improve analytical testing methods, characterize PPCP in drinking water sources in California, and effects of PPCPs on groundwater recharge and recycled water use.

8.1.2 State Water Project

MWD began receiving water from the State Water Project (SWP) in 1972. MWD is the largest of 29 contractors for water from the SWP, holding a contract for 1.912 MAF per year, or 46 percent of the total contracted amount, of the 4.173 MAF ultimate delivery capacity of the project. Variable hydrology, environmental issues, and regulatory restrictions in the San Francisco Bay/Sacramento-San Joaquin River Delta (Bay-Delta) have historically reduced the quantity of water that the SWP delivers to MWD.

8.1.2.1 Major State Water Project Facilities

The SWP is owned by the State of California and operated by the Department of Water Resources (DWR) delivering water to two-thirds of the population of California and 750,000 acres of farmland. Major facilities in the SWP system consist of 701 miles of aqueduct, 34 storage facilities totaling 5.8 MAF of storage, five hydro-electric power plants, four pumping-generating plants, 17 pumping plants, and three pump stations. Exhibit 8H illustrates the location of major SWP facilities. SWP facilities originate in Northern California at Lake Oroville on the Feather River. Water released from Lake Oroville flows into the Feather River, goes downstream to its confluence with the Sacramento River, and then travels into the Bay-Delta. Water is pumped from the Bay-Delta region to contractors in areas north and south of the San Francisco Bay and south of the Bay-Delta. SWP deliveries consist solely of untreated water. In addition to delivering water to its contractors, the SWP is operated to improve water quality in the Delta region, control flood waters, and provide recreation, power generation, and environmental enhancement.

MWD receives SWP water at three locations, Castaic Lake in Los Angeles County, Devil Canyon Afterbay in San Bernardino County, and Box Spring Turnout at Lake Perris in Riverside County. In addition, MWD has flexible storage rights of 65 TAF at Lake Perris at the terminus of the East Branch of the SWP and 153.95 TAF at Castaic Lake at the terminus of the West Branch.

AR0070949

8.1.2.2 Contract Allocations

Contract allocations, also known as entitlements, for SWP contractors are provided by DWR in a table commonly referred to as Table A. Allocations are based on the original projected SWP maximum yield of 4.173 MAF. Table A is a tool used by DWR to allocate fixed and variable SWP costs and yearly water entitlements to the contractors. Table A contract amounts do not reflect actual deliveries a contractor should expect to receive. MWD has a Table A contract amount of 1.912 MAF. MWD's full Table A contract amount was made available to MWD for the first time in 2006.

Table A Maximum Annual SWP Amounts (acre-feet)

Contractor	Maximum SWP Table A
North Bay	
Napa County Flood Control and Water Conservation District	29,025
Solano County Water Agency	47,756

Butte County	27,500
Plumas County Flood Control and Water Conservation District	2,700
Yuba City	9,600
Subtotal	**39,800**
Total	**4,172,786**

DWR annually approves the amount of contract allocations SWP contractors will receive. The contract allocation amount received by contractors varies based on contractor demands and projected available water supplies. Variables impacting projected water supplies include snowpack in the Sierra Nevada, capacity available in reservoirs, operational constraints, and demands of other water users. Operational constraints include pumping restrictions related to fish species listed as either threatened or endangered under the federal or state Endangered Species Acts. Contractors' requests for portions of their entitlements cannot always be met. In some year there are shortages and in other years surpluses. In 2008 and 2009 SWP contractors received only 35 percent and 40 percent, respectively, of their SWP contract allocations. In 1991 and 1992 MWD received 391 TAF and 710 TAF, respectively, less than their requests.

DWR bi-annually prepares the State Water Project Delivery Reliability Report to provide contractors with current and projected water supply availability for SWP. The 2009 draft released in January 2010 indicates expected deliveries for multiple-dry year periods will vary from 32 to 38 percent of maximum Table A amounts and for multiple-year wet periods 72 to 94 percent of maximum Table A amounts. Overall the report shows increased reductions in water deliveries on average when compared to the previous 2007 report. Factors impacting deliveries include environmental constraints and hydrologic changes as a result of climate change.

AR0070951

Exhibit 8H
State Water Project Major Facilities

AR0070952

In addition to MWD's Table A amount, MWD has long term agreements in place to obtain additional SWP supplies through four other programs:

- Article 21
- Turnback Pool
- Yuba River Accord
- San Luis Carryover Storage
- Desert Water Agency and Coachella Valley Water District Table A Transfer.

Article 21 is in reference to a provision in the SWP contract with DWR that allows SWP contractors, such as MWD, to take additional water deliveries in addition to Table A amounts. Article 21 water is only available under certain conditions as outlined in Article 21. SWP Article 21 of the contracts permits delivery of water excess to delivery of SWP Table A and some other water types to those contractors requesting it. SWP Article 21 water is apportioned to those contractors requesting it in the same proportion as their SWP Table A.

Turnback Pool (Pool) water allows a contractor that has been allocated Table A annual entitlement that the contractor will not use to sell that water to other SWP Contractors through the Pool. If there are more request from contractors to purchase water from the Pool than the amount in the Pool, the water in the Pool is allocated among those contractors requesting water in proportion to their Table A entitlements. If requests to purchase water from the Pool total less than the amount of water in the Pool, the sale of water is allocated to the selling contractors in proportion to their respective amounts of water in the Pool.

In 2007, MWD and DWR signed an agreement allowing MWD to participate in the Yuba Dry Year Water Purchase Program. Under this program, transfers are available from the Yuba County Water Agency during dry years up to 2025. MWD completed purchases of 26.4 TAF and 42.9 TAF in 2008 and 2009, respectively.

As part of the Monterey Amendment, which modified the contractors' long term contracts with DWR, the use of carryover storage by contractors was permitted in the San Luis Reservoir for use during dry years. Carryover storage is curtailed if it impedes with the storage of SWP water for project needs.

MWD entered into a transfer agreement with the Desert Water Agency (DWA) and Coachella Valley Water District (CVWD) for their Table A contract amounts in exchange for an equal amount of water from the CRA. Both DWA and CVWD are SWP contractors, but have no physical connections to obtain SWP water. MWD is able to transfer CRA water to both agencies as a result of their locations adjacent to CRA facilities. DWA and CVWD have a combined Table A amount of 1.912 MAF per year. MWD additionally can provide DWA and CVWD with deliveries of MWD's other SWP water supplies and non-SWP supplies utilizing SWP facilities, thus allowing MWD additional flexibility in managing its water supply portfolio.

MWD also engages in short-term transfer agreements using SWP facilities to bolster supplies as opportunities become available as discussed in the Groundwater Storage and Transfers sub-section. Historically, MWD has obtained transfers through the Governor's Water Bank, Dry-Year Purchase Programs, and the State Water Contractors Water Transfer Program.

AR0070953

MWD expects to receive 2.046 MAF through its SWP supplies in 2035 under average conditions (1922 – 2004 hydrology). Exhibit 8I summarizes MWD's SWP supplies by program. Current programs are expected to result in 1.441 MAF and programs under development are expected to add an additional 605 TAF. Under multi-year dry conditions (1990 -1992 hydrology), MWD expects to receive only 956 TAF and 1,003 TAF under a single-dry year (1977 hydrology).

Exhibit 8I
MWD Forecast Supplies of SWP Water in 2035, Average Year (1922 – 2004 Hydrology)

Program	Supply (Thousands of AF)

8.1.2.3 Water Quality Issues

Water quality issues for SWP supplies include total organic carbon (TOC), bromide, arsenic, nutrients, NDMA, and pharmaceuticals and personal care products (PPCPs). TOC and bromide in SWP water present the greatest water quality issues and have restricted MWD's ability to use SWP water at various times as the contaminants form disinfection byproducts during water treatment processes. MWD has initiated a process to upgrade its treatment processes to ozone disinfection to reduce formation of disinfection byproducts and lift potential restrictions on SWP water usage. MWD requires low salinity levels of SWP water to meet blending requirements for CRA water, therefore any increase in salinity levels in SWP supplies is a concern to MWD.

MWD supported DWR in the establishment of a policy regarding water quality of non-SWP water transported through the SWP system and in the expansion of Municipal Water Quality Investigations Programs to include additional monitoring and advanced warnings to Contractors that may impact water treatment processes.

MWD is utilizing its water supply portfolio options to conduct water quality exchanges to reduce total organic compounds and bromide MWD has stored SWP water during periods of high water quality in groundwater storage basins for later use when

AR0070954

SWP is at a lower water quality. These storage programs were initially designed to provide water during dry SWP conditions, but a few of these programs are now operated for dual-purposes.

TOC and bromide in high concentrations lead to the formation of disinfection byproducts when source water is treated with disinfectants, such as chlorine. Agricultural drainage to the Delta and seawater comingling with Delta supplies increases these contaminants. The Bay Delta Conservation Plan (BDCP) has outlined multiple options to improve the water supply reliability and habitat protection, which is being prepared through a collaboration of state, federal, and local water agencies, state and federal fish agencies, environmental organizations, and other interested parties. The overall goal of BDCP is identifying water flow and habitat restoration actions to both improve water supply reliability and recover endangered and sensitive species and their habitats in California's Sacramento-San Joaquin River Delta. MWD is in the process of computing upgrades to its water treatment plants to use ozone as the primary disinfectant. Ozone disinfection is very effective treatment for control of bromate formation and will allow MWD to treat higher quantities of SWP supplies without blending those supplies with CRA water.

Arsenic

SWP supplies not banked in MWD's SWP groundwater storage programs naturally contain low levels of arsenic ranging from non-detect to 4.0 µg/L and do not require additional treatment for arsenic removal. SWP supplies banked in at least one of these groundwater storage programs contain arsenic levels close to or at the regulatory threshold of 10 µg/L requiring additional treatment for arsenic removal. Historically, MWD has at times restricted flows from one groundwater storage program as a result of arsenic levels. One groundwater storage partner has initiated a pilot arsenic removal program, albeit raising the cost of the groundwater storage program. Arsenic can also be removed at water treatment plants by increasing coagulant doses. To handle arsenic removed during water treatment processes, MWD has had to invest in solids handling facilities.

Nutrients

Nutrient levels in SWP water are significantly higher than in Colorado River water. Both phosphorous and nitrogen compounds are a concern in SWP water, but similar to CRA supplies phosphorous is the limiting nutrient. Nutrient sources in SWP water include wastewater discharges, agricultural drainage, and sediments from nutrient rich soils in the Delta. MWD reservoirs have been temporarily by-passed at times as a result of taste and odor events related to nutrients leading to short-term supply impacts.

MWD is working with other water agencies also receiving SWP water from the Delta region to reduce the impact of nutrient loading from wastewater plants discharging to the Delta. To assist in managing its operations, MWD has implemented an algae monitoring and management program designed to provide warnings in advance of algae and taste and odor issues at its reservoirs allowing adjustments in other system operations.

NDMA and Pharmaceuticals and Personal Care Products

Similar to all of its water supply sources, NDMA and PPCPs are constituents of emerging concern. As described above for Colorado River supplies, MWD is involved with efforts to address both NDMA and PPCPs.

Salinity

Over the long term salinity concentrations in SWP water are significantly lower than in CRA water, but the timing of supply availability and TDS concentrations can vary in response to hydrologic conditions. Additionally, salinity concentrations vary in

AR0070955

the short term in response to seasonal and tidal flow patterns. MWD requires lower salinity SWP water to blend with CRA water to meet salinity requirements for its member agencies. MWD's blended salinity objective is 500 mg/L.

Environmental constraints also impact MWD's ability to meet its salinity objective. Since 2007 pumping operations in the Bay-Delta have been limited to prevent environmental harm (as discussed in the Delta Issues subsection below). MWD must rely on higher salinity CRA water resulting in an exceedance in MWD's salinity objective at times.

SWP salinity concentrations as specified in the SWP Water Service Contract have not been met. Article 19 of SWP Water Service Contract specifies ten-year average salinity concentrations of 220 mg/L and a monthly maximum of 440 mg/L. MWD is working with DWR and other agencies to reduce salinity in SWP Delta supplies through multiple programs. These programs include modifying agricultural drainages and completing basin plans on the San Joaquin River, modifying levees around flooded islands in the Delta, and installing gates to reduce transportation of salts from seawater.

8.1.2.4 Bay-Delta Issues

The San Francisco Bay-Delta is a major waterway at the confluence of the Sacramento and San Joaquin rivers serving multiple and at times conflicting purposes exacerbated during dry years when water to meet the needs of both people and the environment is in short supply. Approximately two-thirds of Californians receive at least a portion of their water from the Bay-Delta. Almost all water delivered via the SWP to southern California must pass through the Bay-Delta. Runoff from more than 40 percent of the State is also conveyed through the Bay-Delta forming the eastern edge of the San Francisco bay's estuary. A large portion of the Bay-Delta region lies below sea level and is protected by more than 1,100 miles of levees to prevent flooding. Deterioration of the Bay-Delta ecosystem coupled with infrastructure concerns, hydrologic variability, climate change, litigation, regulatory restrictions, and previously discussed water quality issues have resulted in supply reliability challenges for SWP contractors who depend upon the Bay-Delta for water supplies.

Environmental

As an estuarine environment, the Bay-Delta provides habitat for migratory and resident fish and birds, including those placed on the threatened or endangered species list under the federal or California Endangered Species Act (ESA). Five fish species residing in the Bay-Delta were listed as endangered under the ESA, and one additional species was listed as threatened in 2009 under the California ESA. As a result of a combination of lawsuits regarding the ESA listed species and biological opinions and incidental take permits (permits for inadvertently harming ESA listed species) from the U.S. Fish and Wildlife Service and National Marine Fisheries Service, SWP exports and pumping operations in the Bay-Delta have been significantly curtailed. However, DWR prepared a Water Allocation Analysis in 2010 indicating that MWD could receive 150 to 200 TAF less water than forecast for 2010 under average hydrologic conditions. Ongoing litigation, additional species listing, and regulations could further curtail pumping operations and have an additional adverse impact on MWD's supplies and reserves. MWD has filed a lawsuit in conjunction with other SWP contractors challenging one of the biological opinions. As discussed below under the Delta Plan, the Delta Vision process is designed to develop long term solutions to these issues.

Infrastructure

Bay-Delta channels are constrained by a levee system to protect below sea level islands in the Bay-Delta from flooding. Land in the Bay-Delta subsides mainly from ongoing oxidation of aerated peat soils. Some islands are presently twenty feet or more below sea level. Land subsidence is expected to continue increasing the risk of levee failure and island flooding. Many of the levees are old and do not meet modern engineering standards. A catastrophic earthquake could cause widespread levee failure shutting down SWP operations for an extended period of time. Following a levee failure he flow of water onto an island

AR0070956

can pull saline water fro the San Francisco Bay into the central Delta area and if coupled with pumping in the south Delta draw saline water into the south Delta area. Therefore, pumping in the south Delta may need to be stopped or slowed down for an extended period, and additional flows may need to be released from Lake Oroville to flush saline water out of the Delta. Any salinity introduced into Delta may also impact Delta water quality for an extended period of time.

Recognizing the need for protecting these vulnerable Delta levees, the Bay-Delta Levees Program was formed to coordinate improvements to and maintenance of the Delta levees. Over the next few years the DWR and other agencies will conduct a Comprehensive Program Evaluation. This Program will supplement existing risk studies, develop a strategic plan, recommend priorities, and provide estimates for the Bay-Delta Levees Program.

8.1.2.5 Delta Plan

Former California Governor Arnold Schwarzenegger established the Delta Vision Process in 2006 to address ongoing Bay-Delta conflicts through long-term solutions. The independent Blue Ribbon Task Force completed their vision for sustainable management of the Bay-Delta in 2008. After delivery of the Delta Vision recommendations and goals, the State Legislature initiated the process to conduct information hearings and draft legislation. Ultimately, the Governor called the Seventh Extraordinary Session to address the Delta and water issues in the State. Resulting legislation included the approval of SB 1 X7 addressing Delta policy reforms and governance of the Delta.

A key concept of SB 1 X7 is the formation of a Delta Stewardship Council (Council). The Council is an independent State agency tasked to equally further the goals of Delta restoration and water supply reliability. One of the Council's first major tasks is to develop, adopt, and begin implementation of a Delta Plan by January 1, 2012. Key requirements of the plan as summarized in the MWD RUWMP are:

- Further the coequal goals of ecosystem restoration and water supply reliability;
- Attempt to reduce risks to people, property, and State interests;
- Promote Statewide water conservation, water use efficiency, and sustainable use of water to achieve the coequal goals;
- Improvements to water conveyance/storage and operations of such facilities to achieve the coequal goals;
- Consider including the Bay Delta Conservation Plan (BDCP) into the Delta Plan and allow the BDCP to be eligible for State funding if specific conditions are met.

The BDCP is a joint effort of State and federal fish agencies; State, federal, and local water agencies; environmental organizations; and other parties with the goal of providing for both improvements in water reliability through securing long-term permits to operate the SWP and species/habitat protection in the Delta. MWD is a member of the Steering Committee. An outcome of the plan will be the identification of water flow and habitat restoration actions that assist in recovery of ESA listed and sensitive species and their associated habitats in the Bay-Delta. A range of options to accomplish the outcome will be carried forward to the environmental review phase.

AR0070957

8.1.3 In-Basin Storage

In basin-storage facilities play a key role in maintaining MWD's reliability during droughts or other imported water curtailments and emergency outages. In-basin storage facilities consist of surface reservoirs and contracted groundwater basin storage. Conjunctive use of surface reservoirs and groundwater basins was first initiated by MWD in the 1950's. Long term storage goals for in-basin storage facilities were established in MWD's Water Surplus and Drought Management Plan (WSDM). The WSDM plan allows storage for hydrology variances, water quality, and SWP and CRA issues.

MWD has established emergency in-basin storage requirements based on a major earthquake that could potentially cutoff all supplies for six months from the all aqueducts serving the region, the CRA, both SWP branches, and LADWP's LAA. Under this scenario, MWD would maintain deliveries by suspending interruptible deliveries, implementing mandatory water use reductions of 25 percent of normal-year demands, water would be made available from surface reservoir and groundwater supplies stored as part of MWD's interruptible supply program, and full local groundwater production would occur. MWD's emergency storage requirement is a function of projected demands and varies with time.

8.1.3.1 Surface Reservoirs

MWD owns and operates seven in-basin surface storage reservoirs. Four of the reservoirs, Live Oak, Garvey, Palos Verdes, and Orange County, are used for regulatory purposes and do not provide drought or emergency storage. Additionally, MWD owns and operates two reservoirs, Copper Basin and Gene Wash, along the CRA outside of the basin for system regulation purposes. Outside its basin, MWD has 1.45 MAF storage rights in Lake Mead on the Colorado River pursuant to its intentionally created surplus agreement with the U.S. Bureau of Reclamation. MWD also has storage rights in DWR's SWP terminal reservoirs, Lake Perris and Castaic Lake, as previously discussed. The total capacity of all in-basin surface reservoirs, inclusive of the rights in the terminal reservoirs, is 1.26 MAF, as listed in Exhibit 8J.

Exhibit 8J
Major MWD Facilities Summary

Reservoir	Capacity (AF)
Dry Year/Emergency/Seasonal Storage Purposes	
Diamond Valley Lake	810,000
Lake Matthews	182,000
Lake Skinner	44,000
Lake Perris (Storage Rights)[1]	65,000
Castaic Lake (Storage Rights)[1]	153,940
Subtotal	1,254,940
Regulatory Purposes	
Live Oak	2,500
Garvey	1,600
Palos Verdes	1,100
Orange County	212
Subtotal	5,412
Total Reservoir Capacity	**1,260,352**

1. MWD holds storage rights for flexible use in DWR terminal storage facilities, Lake Perris and Castaic Lake. In addition, MWD has emergency storage of 334 TAF in DWR's reservoirs.

AR0070958

MWD operates its three main storage reservoirs, Diamond Valley Lake, Lake Skinner and Lake Matthews, for dry-year, emergency, and seasonal storage. MWD has identified a dry-year storage capacity goal of 620 TAF by 2020. To date this goal has been met and will be sustained with storage at Diamond Valley Lake and the two terminal reservoirs. Under an average year scenario for 2035 (1922-1994 hydrology), 576 TAF per year of in-basin surface storage is projected to be available, exclusive of emergency supplies, as summarized in Exhibit 8K.

Exhibit 8K
MWD Forecast Supplies of In-Basin Surface Storage Supplies in 2035, Average Year (1922 – 2004 Hydrology)

Program	Supply (Thousands of AF)/Year
In-Basin Surface Storage (Diamond Valley Lake, Lake Skinner, Lake Matthews)	444
Lake Perris and Castaic Lake MWD Storage Rights	132
Maximum MWD Supply Capability	**576**

Source: 2010 Regional Urban Water Management Plan, Metropolitan Water District of Southern California

MWD reserves a portion of its in-basin surface reservoir storage capacity for emergencies. MWD's emergency surface reservoir storage portfolio is split between storage in its three main reservoirs and DWR reservoirs. MWD's emergency storage capacity, based on demands for 2030, is forecast to be approximately 610 TAF. Approximately 276 TAF is projected to be stored in MWD's facilities and the balance of 334 TAF in DWR's facilities. The balance of available storage capacity, 975 TAF, is for dry-year and seasonal storage.

Any additional reservoir capacity is used for seasonal storage and system operations. Seasonal storage is required to meet peak demands. MWD incorporates reserves of 5 percent into reservoir operations to account for imported water transmission infrastructure maintenance that would restrict or temporarily halt imported water flows.

8.1.3.2 Contracted Groundwater Basin Storage

To improve reliability MWD engages in contracted groundwater basin storage within the basin area. By 2020 MWD aims to develop an annual dry supply of 300 TAF. To meet this goal MWD has worked with local water agencies to increase groundwater storage. Groundwater storage occurs using the following methods:

- Direct delivery – Water is delivered directly by MWD to local groundwater storage facilities including through the use of injection wells and spreading basins.
- In-lieu delivery – Water is delivered directly to a member agency's distribution system and the member agency uses the delivered water and forgoes pumping allowing water to remain in storage.

MWD engages in three main types of contracted storage programs, replenishment, cyclical, and conjunctive use. These programs are designed to deliver water to agencies prior to the actual need for the demands allowing MWD to store supplies for use in dry years. Since 2007 MWD has used these programs to address SWP shortages. MWD provides financial incentives and funding to assist agencies to assist with developing contracted storage programs.

AR0070959

Replenishment programs provide water to agencies at a discounted cost and can be withdrawn by the recipient after one year. Cyclic storage contracts allow surplus imported water to be delivered for recharge in advance of the actual water purchase. The delivered water is in excess of an agency's planned and budgeted deliveries. The agency purchases the water at a later time when they have a need for groundwater replenishment deliveries.

Conjunctive use contracts allow MWD to request an agency to withdraw previously stored MWD water from storage during dry periods or emergencies. Agencies must pay MWD the current water rate when they are requested to withdraw water from storage. Water withdrawn from storage allows MWD to temporarily curtail delivers by an equal amount. MWD currently has ten conjunctive use programs with a combined storage capacity of 421.9 TAF and a dry-year yield of 117.3 TAF per year as summarized in Exhibit 8L.

Exhibit 8L
In-Basin Conjunctive Use Programs

Program	Storage Capacity (Thousands of AF)	Dry-Year Yield (Thousands of AF/Year)	Balance 12/31/09 (Thousands of AF)

MWD prepared a Groundwater Assessment Study in 2007 in conjunction with local agencies and groundwater basin managers. As indicated in the report there is substantial groundwater storage available in the basin, but there are multiple challenges that must be met to utilize the identified storage. Challenges include infrastructure limitations, contamination, legal issues, and funding.

To further increase the availability of in-basin groundwater storage, MWD has identified nine potential storage programs in the basin and an additional two programs are under development. The Raymond Basin Conjunctive Use Program and the LADWP Groundwater Recovery Project are expected to add an additional 34 TAF per year in 2035 under an average year (1922 – 2004 hydrology).

AR0070960

In 2009 a reconnaissance-level analysis was prepared for analyzing the potential for using recycled water as a supply source for a conjunctive use program. The study concluded up to 100 TAF of groundwater storage and production could be potentially developed in four major groundwater basins using Los Angeles County Department of Sanitation supplies. MWD initiated a formal study in 2010 to further study. This concept along with the potential to use City of Los Angeles recycled water supplies from the Hyperion Waste Water Treatment Plant as an additional source.

Exhibit 8M provides a summary of forecast groundwater storage supplies available in 2035 under an average year (1922 - 2004 hydrology). Approximately 289 TAF per year are forecast to be available.

8.1.4 Groundwater Storage and Water Transfers

MWD engages in groundwater storage outside of the basin and water transfers to increase the reliability of SWP dry-year supplies. Groundwater storage and water transfers were initiated by MWD in response to concerns that MWD's supply reliability objectives could not be met by the SWP. Groundwater storage and transfer programs were developed to allow MWD to reach its SWP reliability goal. All groundwater storage and water transfer programs designed to bolster SWP reliability are located within the vicinity of the SWP or Central Valley Project (CVP) facilities to facilitate the ultimate deliver of water to MWD. Groundwater storage programs involve agreements allowing MWD to store its SWP contract Table A water in excess of MWD demands and to purchase water for storage. MWD calls for delivery of the stored water during dry years. Transfers involve purchases by MWD from willing sellers during dry years when necessary.

Exhibit 8N summarizes MWD's out of basin groundwater storage and transfer programs supplies in 2035, under an average year (1922 – 2004 hydrology). Current programs are expected to deliver 293 TAF in 2035. Five programs under development are forecasted to deliver an additional 110 TAF for a total of 403 TAF in 2035.

8.1.4.1 Groundwater Storage

MWD has four Central Valley groundwater storage programs with a fifth program under development as described below.

The Semitropic Water Banking and Exchange Program is a partnership formed in 1994 between Semitropic Water Storage District (SWSD) MWD, and five other banking partners. The bank has a total storage capacity of 650 TAF, of which MWD has 350 TAF of storage volume. During years of excess SWP deliveries, beyond MWD's demands, a portion of MWD's SWP entitlement water is stored for withdrawal during dry years. Deliveries for storage are transferred via SWP facilities for direct use by agricultural users that in turn forgo pumping an equal volume of water. In dry years water is pumped from storage to SWP facilities for delivery to MWD or entitlements are exchanged. MWD's average annual supply capability for a dry year (1977 hydrology) is 125 TAF and for multiple dry years (1990 – 1992 hydrology) 107 TAF. By the end of 2009, MWD had 45 TAF in storage.

Since 1997 MWD has had an agreement with Arvin-Edison Water Storage District to use 350 TAF of storage in their groundwater basins. The agreement was amended in 2008 to include the South Canal Improvement project to deliver higher quality water to MWD. During wet years MWD delivers SWP water in excess of its demands for storage and receives return water in dry years in a similar manner as the Semitropic program, except a combination of SWP and CVP facilities are used to

AR0070962

transfer the water and water can be stored by a combination of direct spreading or in lieu use by agricultural users. MWD's average supply capability is 75 TAF for either a single dry year (1977 hydrology) or multiple dry years (1990 – 1992 hydrology). In 2009 MWF had 95 TAF in storage.

The San Bernardino Municipal Water District Program allows for the purchase and storage of SWP water on behalf of MWD. MWD has a minimum purchase agreement with San Bernardino Municipal Water District (SBMWD) of 20 TAF per year of SBMWD's SWP Table A amount. Additionally, MWD has the option to purchase SBMWD's additional SWP allocation when available and the first right-of-refusal to purchase additional SWP supplies available to SBMWD beyond the minimum and option agreements. If MWD does not require the minimum purchase amount for operations, MWD can store up to 50 AF for future use in dry years within SBMWD's groundwater basins. Water is delivered to MWD via SWP facilities and groundwater pumping conveyed through local connections to MWD's service area. MWD's average annual supply capability for a dry year (1977 hydrology) is 70 TAF and for multiple dry years (1990 – 1992 hydrology) 37 TAF. By the end of 2009, MWD had no water in storage and deliveries have been suspended upon a mutual agreement between MWD and SBMWD.

MWD entered into an agreement with the Kern Delta Water District (Kern-Delta) for the Kern-Delta Water Management Plan in 2001 to allow up to 250 TAF of groundwater storage. During wet years MWD delivers SWP water in excess of its demands for storage and receives return water in a similar manner as the Semitropic program, except the water can be stored by direct recharge or in lieu use by agricultural users. Per terms of the agreement MWD can potentially store beyond 250 TAF. In dry years water is pumped from storage to SWP facilities for delivery to MWD or entitlements are exchanged. When the project is completed 50 TAF per year of dry year supply can be withdrawn. At the close of 2009 MWD had 10 TAF in storage and expects to fully withdraw the amount in 2010.

The Mojave Groundwater Storage Program is currently a demonstration project between MWD and Mojave Water Agency. Similar to the other groundwater storage programs, MWD's excess SWP water will be stored during wet years for withdrawal during dry years. When fully operational, the program is expected to have a dry year yield of 35 TAF.

8.1.4.2 Transfers

MWD utilizes Central Valley water transfers to obtain additional supplies originally destined for agricultural users on an as needed basis. Past transfer agreements have used both spot markets and option contracts. Spot markets occur when there are willing sellers and buyers. Option contracts lock-in MWD's ability to have the option to purchase supplies if needed. Additionally, MWD has multiple long-term transfer programs under development. MWD's ability to conduct transfers and the amount of water to be transferred using SWP facilities are a function of hydrologic conditions, market conditions, and pumping restrictions in the Bay-Delta region. Transfers may require the use of the Bay-Delta for conveyance dependent upon the origin of the water. Historic transfers, as listed in Exhibit 8O, indicate MWD is capable of negotiating contracts with agricultural districts and the State's Drought Water Bank to obtain transfers. MWD also has demonstrated it can work with DWR and the U.S. Bureau of Reclamation (USBR). Cooperation of both agencies is required as transfers use a combination of DWR's SWP and USBR's CVP facilities. Transfers from north of the Delta result in the loss of 20 percent of the water during conveyance while transfers via the California Aqueduct to MWD's service area result in the loss of 3 percent water during conveyance. During dry years and when pumping capacity in the Bay-Delta is available, MWD expects to be able to transfer 125 TAF through SWP facilities.

AR0070963

Exhibit 8O
MWD Historic Central Valley Water Transfers

Program	Purchases by MWD[1] (AF/Year)
1991 Governor's Water Bank	215,000
1992 Governor's Water Bank	10,000
1994 Governor's Water Bank	100
2001 Dry Year Purchase Program	80,000
2003 MWD Transfer Program	126,230
2005 State Water Contractors Water Transfer Program[2]	0
2008 State Water Contractors Water Transfer Program	26,621
2009 Governor's Water Bank	36,900

1. Transfers requiring use of Bay-Delta result in a water loss of 20 percent. Transfers requiring the California Aqueduct for delivery to MWD's service area result in a 3 percent water loss.

2. 127,275 in options were secured, but not needed.

8.2 MWD Supply Reliability and Projected LADWP Purchases

MWD's 2010 Integrated Water Resources Plan (IRP) Update serves as the foundation for supply forecasts discussed in the RUMWP and continues to ensure system reliability for its member agencies. The 2010 IRP update concluded that the resource targets identified in previous updates, taking into consideration changed conditions identified since that time, will continue to provide for 100 percent reliability through 2030. MWD's subsequent evaluation to extend the resource targets by an additional five years through their 2010 draft RUWMP also concluded the same full reliability during average (1922 – 2004 hydrology), single dry (1977 hydrology), and multiple dry years (1990 - 1992 hydrology). For each of the scenarios there is a surplus in every forecast year. Exhibit 8P summarizes MWD's reliability in five year increments extending to 2035.

The City purchases MWD water to make up the deficit between demand and other City supplies. Whether LADWP can provide reliable water services to the residents of Los Angeles is highly dependent on MWD's assurance on supply reliability. However, the recent water supply shortage caused by dry weather and pumping restrictions in the Delta prompted the City to develop a more sustainable water supply portfolio with emphasis on local water supplies such as recycled water, groundwater cleanup, stormwater capture, and conservation. LADWP's reliance on MWD water supply is projected to be cut in half from the five-year average of 52 percent of the total demand between 2005-06 and 2009-10, to 24 percent by 2034-35 under average weather conditions.

The reliability of MWD's water supply is more fully discussed in Chapter 10, Integrated Resources Planning. The projected LADWP water purchase is further discussed in Chapter 11, Water Service Reliability Assessment under various weather scenarios.

AR0070965

8.3 MWD Rate Structure and LADWP's Purchased Water Costs

8.3.1 MWD Rate Structure

MWD's rates are structured on a tier–based system with two tiers and a surplus category. Nine major elements determine the actual price a member agency will pay for deliveries. All of the elements are volumetric based except for two fixed rates, the Readiness-to Serve Charge and the Capacity Charge.

Tier 1 rates are reflective of actual costs of existing supplies and are designed to recover most of the supply costs. Member agencies are allocated a specified volume of Tier 1 water that can be purchased within a given year. In 2011 LADWP's Tier 1 limit is 304,970 AF. Any purchases above this are charged at the Tier 2 rate. MWD has instituted a temporary Delta surcharge to recover costs associated with lower SWP deliveries related to pumping restrictions. The surcharge will remain in effect until SWP yields improve.

Tier 2 rates send a price signal associated with MWD's costs of developing additional long-term firm supply options. Member agencies with growing demands on MWD will have a higher proportion of deliveries within the Tier 2 range.

Surplus water is water in excess of consumptive municipal and industrial demands. Surplus water is available at two discounted levels dependent upon the end use. Replenishment Program water is discounted for replenishing local agency supplies. The program has been suspended as a result of dry conditions and uncertain future supplies. The Interim Agricultural Water Program (IAWP) provides discounted water for agricultural use. This program is being phased out and will terminate beginning in 2013.

Exhibit 8Q summarizes the rates and charges for member agencies effective on January 1 of 2010, 2011, and 2012.

8.3.2 LADWP's Purchased Water Costs

MWD's water rates vary from $484 per AF of tier 1 untreated water to $811 per AF of tier 2 treated water in 2010. The average unit cost of MWD water supply depends on the proportions of treated water and untreated water, tier 1 water and tier 2 water purchased in a given period. From 2003 to 2009, LADWP purchased 88 percent tier 1 water and 12 percent tier 2 water, and 70 percent untreated water and 30 percent treated water on average. The tier 2 water purchase varied from no purchase in 2005 and 2006 to 29 percent in 2007 and 2008. The treated water purchase varied from 20 percent in 2007 to 46 percent in 2005. Exhibit 8R illustrates the various combinations.

The Readiness-to-Serve Charge and Capacity Charge are predetermined fixed charges for each member agency and not affected by the quantity of MWD water purchased. However, they add on to the unit cost of the City's MWD water purchase. The City's current share of the Readiness-to-Serve Charge is 15.12 percent or $17.24 millions in 2010. The Capacity Charge is calculated based on the summer daily peak flow from the previous three years. LA's 2010 Capacity Charge is $5.9 millions based on the daily peak flow of 822 cfs in 2008 summer. Both charges added an additional $110 per AF to the unit cost of LADWP's MWD water purchase in 2010.

DRAFT

DRAFT Chapter Nine
Other Potential Water Supplies

9.0 Overview

LADWP continually investigates other potentially feasible water supplies to ensure the sustainability of water supply for the City of Los Angeles. In recent years, LADWP has actively pursued and investigated various supply options including water transfers and banking and seawater desalination. Evaluating the viability of these and other water resource options is a key element to ensuring the City's future water supply reliability. Such options, with proper planning, can contribute toward fulfilling future demand under various conditions. Future water resource challenges, which include increased demand that must be met without increasing imported supply, warrant thoughtful consideration of these and other potentially feasible water supply resources.

Following is a discussion of each of the potential supply options described above, highlighting LADWP's progress in developing each alternative source of water. Factors that affect feasibility and influence potential implementation are also discussed, as well as advances that facilitate development of the resource option.

9.1 Water Transfers and Banking

Water transfers involve the lease or sale of water or water rights between consenting parties. Water Code Section 470 (The Costa-Isenberg Water Transfer Act of 1986) states that voluntary water transfers between water users can result in a more efficient use of water, benefiting both the buyer and the seller. The State Legislature further declared that transfers of surplus water on an intermittent basis can help alleviate water shortages, save capital outlay development costs, and conserve water and energy. This section of the Water Code also obligates the California Department of Water Resources (DWR) to facilitate voluntary exchanges and transfers of water.

The DWR is required to establish an ongoing program to facilitate the voluntary exchange or transfer of water and implement the various State laws that pertain to water transfers. In response to this mandate, DWR established an internal office dedicated specifically to water transfers in June 2001 and has developed various definitions and policies for transfers. Of particular importance are the rules protecting existing water rights. Water rights cannot be lost when they are transferred to another user if the transferor has an underlying right to the transferred water. DWR also developed three fundamental rules specifically regarding water transfers:

- There can be no injury to any legal user of water;
- There can be no unreasonable effect to fish and wildlife; and
- There can be no unreasonable economic effects to the economy of the county of origin.

Water banking, a form of conjunctive use, is the storage of water in groundwater basins for future use. Typically, during wet periods water is stored or banked within groundwater basins for potential extraction during dry periods. Water banking sets up accounts to track the volumes of water recharged and extracted per terms of contract agreements between water agencies. Water banking may occur outside of a water agency's service area. If the water agency's own conveyance facilities are not directly adjacent to the water bank, stored water can be extracted and transferred through wheeling and exchange via other

AR0070970

conveyance and storage facilities. Such movements of water involve institutional transfer agreements among water users and agencies.

9.1.1 LADWP Opportunities

LADWP is considering opportunities to acquire water through transfers to replace a portion of LAA water used for environmental enhancements in the eastern Sierra Nevada. The City would purchase water when available and economically beneficial for storage or delivery to LADWP's transmission and distribution system. The City is seeking non-State Water Project water to replace the reallocation of LAA water supply for environmental enhancements. MWD holds an exclusive contractual right to deliver State Water Project entitlement water into its service territory, which includes the City of Los Angeles. Purchasing only non-State Water Project supplies will ensure the City's compliance with MWD's State Water Project contract.

To facilitate water transfers, LADWP is constructing an interconnection between the LAA and the State Water Project's California Aqueduct, located where the two aqueducts intersect in the Antelope Valley (Neenach, California). This interconnection, the Neenach Temporary Pumping Station (NTPS) will allow for water transfers from the East Branch of the State Water Project to the LAA System, as well as provide operational flexibility in the event of a disruption of flows along the LAA System. Construction of the NTPS required a four-way agreement between DWR, MWD, LADWP, and the Antelope Valley-East Kern Water Agency (AVEK). When completed, the NTPS facility will be owned by DWR but will be designated as an AVEK interconnection. The NTPS will be operated on behalf of the LADWP. MWD is involved in the agreement to provide consent for the transferred water to enter its service territory.

LADWP's current goal is to transfer up to 40,000 AF per year once the NTPS facilities are in place. This will provide LADWP with the ability to replace some Los Angeles Aqueduct supplies reallocated to environmental enhancement projects. This will also provide increased operational flexibility and the ability to yield cost savings.

A demonstration study will be performed during the NTPS's first two years of operations; this study will include an evaluation of the operational and water quality aspects of the NTPS.

Neenach Temporary Pumping Station, construction site, looking northerly, taken September 16, 2010, by Aqueduct Aerial Patrol.

AR0070971

To supplement water transfers, LADWP is also investigating the possibility of water banking. A request for proposal (RFP) was issued in 2008 and five proposals were received for evaluation to determine the most mutually beneficial agreement for a water banking program. However, LADWP has decided to not pursue full scale water banking projects at this time and has instead chosen to proceed with the Indian Wells Valley Water District's proposal to explore a potential water banking opportunity directly adjacent to the LAA.

The City supports Statewide water transfer legislation that will ensure the efficient use of the State's limited water resources and provide safeguards to the environment, public facilities, water conservation efforts and local economies. LADWP will continue to develop a responsible water transfer program that can assist in replacing City supplies that have been reallocated to the environment in the Eastern Sierra Nevada.

9.1.2 MWD Opportunities

Regionally, MWD has been active with water transfers and banking, seeking and implementing agreements and cooperative arrangement opportunities to supplement southern California's water supply. MWD's water transfer activities are classified as *spot transfers*, *option transfers*, *core transfers*, *storage transfers*, or *exchanges*. Each activity is described briefly below.

- *Spot transfers* make water available through a contract entered into the same year that the water is delivered.
- *Option transfers*, through multi-year or single-year contracts, allow MWD to obtain water on an "as-needed" basis.
- *Core transfers* make water available through multi-year contracts that convey specific water entitlement to MWD each year.
- *Storage transfers* allow MWD to store and later recover available water that can then be transported immediately to southern California.
- *Exchange agreements* involve the transfer to MWD of another agency's entitlements in exchange for water entitled to MWD from another source.

MWD is in the process of developing and implementing transfer/storage projects in the Central Valley, and off-stream banking and dry year supplies of Colorado River water. Water transfers, including the programs highlighted below, are an important element of California's plan to live within its 4.4 million acre-feet per year entitlement to Colorado River water. These programs have also helped MWD adjust to regulatory restrictions on State Water Project pumping from the San Francisco Bay-Delta. Current and potential MWD transfer, storage, and exchange agreements/activities include:

- Semitropic Water Storage Program
- Kern Delta Water District Water Management Program
- Arvin-Edison Water Transfer and Storage Program, Kern County
- San Bernardino Valley Transfer and Storage Program
- Desert Water Agency/Coachella Valley Water District Exchange Program

- Chuckwalla Groundwater Storage Program (under development)
- Coachella Valley Water District Agreement (under development)

MWD's water rate structure is designed to allow water transfers using MWD infrastructure by establishing a water wheeling rate, which is a combination of the System Access Rate, Water Stewardship Rate, System Power Rate, and Treatment Surcharge. The wheeling rate applies to all water conveyed through MWD's infrastructure, regardless of the agency using the

DRAFT

AR0070973

system. MWD's unbundled rate structure and its associated wheeling rate encourage development of water markets by providing for competition at the supply level; MWD's member agencies can purchase supplies from any source and pay MWD's wheeling rate to transmit the water. MWD's current water rate structure establishes charges for each component on a per acre foot basis for all water moving through MWD's system. As of January 1, 2010, current wheeling rate charges are:

- System Access Rate: $154/AF
- Water Stewardship Rate: $41/AF
- System Power Rate: $119/AF
- Treatment Surcharge: $217/AF

The System Access Rate recovers costs associated with conveyance and distribution capacity to meet average annual demands. The Water Stewardship Rate recovers the cost associated with providing financial incentives for investments in local water resources, such as water conservation and recycled water programs. The System Power Rate recovers the cost for power to move water through MWD's system. The treatment surcharge applies to all water that is treated at one of MWD's five treatment plants.

MWD's water rate structure also incorporates a tiered supply rate format. The first tier price applies to a fixed base quantity of water as defined by each MWD member agency's purchase order contract. The second tier price reflects the incremental cost for MWD to acquire additional supplies that are above the first tier contract base amount

9.2 Seawater Desalination

Seawater desalination, the process of removing salts and other impurities from seawater, has reached an all-time high in terms of worldwide production capacity. According to the International Desalination Association, between 2007 and 2009, worldwide seawater desalination capacity increased by approximately thirty percent to a total capacity of 9.5 bgd. This is partly driven by the fact that the cost to desalinate water has reached an all-time low due to technological and process advancements. Of the more than 14,000 seawater and groundwater desalination plants in operation worldwide, the majority are located in the Middle East, where energy costs are relatively low. The world's largest seawater desalination plant in Saudi Arabia produces 232 mgd of desalted water. In contrast, the largest facility in the US, located in Tampa Bay, FL, produces 25 mgd.

LADWP's current water resource strategy does not include seawater desalination as a water supply. There are concerns with cost and the environmental impacts associated with the implementation of desalination. LADWP is primarily focused on enhancing recycling and conservation. While someday desalination may be explored further, it currently remains as a supply alternative.

9.2.1 Desalination Technology

Technology to desalt seawater to produce potable water which meets or exceeds drinking water standards has been available for some time, but has not been widely implemented primarily due to its high cost. Although the cost to desalinate seawater is still more expensive than obtaining water from conventional sources, continued research and development, as well as large scale projects, are being implemented in the United States and other parts of the world to improve technology and further drive costs down. Additionally, increasing costs associated with new water supplies and existing supplies is reducing the cost

AR0070974

differential between desalinated water and other water sources improving the viability of desalinated water as a part of an overall water supply portfolio.

The two basic seawater desalination processes are: 1) use of the distillation process to evaporate water from salts; and 2) use of semi-permeable membranes to filter the water while straining out the salts. While distillation has been the dominant seawater desalination technology (primarily in the Middle East), current worldwide desalination development is rapidly migrating toward membrane technology. Facilities using distillation are still prevalent in the Middle East. However, new plant installations are increasingly taking advantage of technological advancements (higher yield and lower energy requirements) in membrane-based process technology. Today, membrane filtration accounts for over half of the world's desalting capacity.

9.2.2 DWR Desalination Efforts

Recognizing the potential of seawater as a water resource, the DWR through a legislative mandate, convened a California Water Desalination Task Force in 2002. The task force was responsible for making recommendations to the Legislature on potential opportunities, impediments, and the State's role in furthering desalination technology.

The task force was effective in providing a forum where stakeholders could convene and discuss critical issues related to desalination. Key seawater desalination issues that have been raised through the task force fall into six general categories: environmental, economic, permitting, engineering, planning, and coordination.

To assist in addressing these issues, the California Water Desalination Task Force has developed draft guidelines for developing environmentally and economically acceptable desalination projects. These include the following:

- Each project should be considered on its own merits;
- Sponsoring agencies should be determined early in the planning process;
- Public and permitting agencies should be engaged early in the planning process;
- Collaborative processes should be used to enhance support for project implementation;
- A feedback loop should be incorporated to allow for continuously revisiting and revising the project at each step of the planning process; and
- Key decision points (e.g., costs, environmental acceptability) should be identified to test the general feasibility of the project as early in the planning process as possible.

After establishment of the task force, desalination was added to the California State Water Plan as an alternative for consideration in regional water supplies. Furthermore, in 2008, DWR published the *California Desalination Planning Handbook*, building upon the Task Force efforts. The handbook provides guidance on determining appropriate conditions for desalination plants, addressing concerns, and building public trust.

Proposition 50, Chapter 6, has provided funding for desalination research, feasibility studies, pilot projects, and construction of new facilities. Over $45 million was distributed under this proposition in two rounds of funding for both seawater and groundwater desalination. Fund recipients included LADWP.

AR0070975

With increasing demand for water and limited new supply options, the future value of seawater desalination as a part of California's water supply portfolio has become apparent. Within southern California, a range of 270,000 AFY to 422,000 AFY of desalinated seawater could be potentially produced based on current efforts (see Exhibit 9A). While this production represents less than five percent of the region's total water supplies, it is nonetheless considered by water planners as an important part of the region's water supply portfolio.

9.2.3 MWD Desalination Efforts

MWD first incorporated desalinated seawater as a potential new water supply source in its 2003 Integrated Resources Plan Update. Subsequently in 2009, MWD's Board of Directors created a special committee on Desalination and Recycling to study MWD's role in regional efforts to develop desalination facilities.

In response to a proposal solicitation in 2001, MWD received proposals by five member agencies to provide up to 142,000 AFY of potable water. To provide an incentive for the development of desalinated seawater, MWD is offering subsidies of up to $250 for each acre-foot (326,000 gallons) of desalinated seawater produced. LADWP, Long Beach Water Department, West Basin Municipal Water District, Municipal Water District of Orange County, and San Diego County Water Authority submitted detailed proposals that qualified for the MWD's Seawater Desalination Program. Exhibit 9A summarizes the status of the desalination efforts in MWD's service area, including projects not in the Seawater Desalination Program. Each of these agencies serves coastal areas, and is looking to desalination as a means to further diversify their water supply sources.

Exhibit 9A
Desalination Efforts in MWD Service Area

Project Name	Member Agency	Capacity (AFY)	Status
MWD Seawater Desalination Program			
Long Beach Seawater Desalination	Long Beach	10,000	Pilot Study[1]
Los Angeles Seawater Desalination	LADWP	28,000	On-hold
South Coast Coastal Ocean Desalination	Municipal Water District of Orange County	16,000 - 28,000	Pilot Study
Carlsbad Seawater Desalination	San Diego County Water Authority	56,000	Permitting Complete
West Basin Seawater Desalination	West Basin Municipal Water District	20,000	Pilot Study[1]
Subtotal		130,000 - 142,000	
Other Potential Projects in MWD Service Area			
Huntington Beach Seawater Desalination	Municipal Water District of Orange County	56,000	Initiating Permitting
Camp Pendleton Seawater Desalination	San Diego County Water Authority	56,000 - 168,000	Planning
Rosarito Beach Seawater Desalination	San Diego County Water Authority	28,000 - 56,000	Feasibility Study
Subtotal		140,000 - 280,000	
Total		270,000 - 422,000

AR0070976

9.2.4 LADWP Seawater Desalination Efforts

Scattergood Generating Station Seawater Desalination Plant

LADWP initiated efforts in 2002 to evaluate seawater desalination as a potential water supply source with the goals of improving reliability and increasing diversity in its water supply portfolio. These efforts led to the selection of Scattergood Generating Station as a potential site for a seawater desalination plant. For the City, seawater desalination is a potential resource that could also offset supplies that had been committed from the LAA for environmental restoration in the eastern Sierra Nevada. LADWP has reallocated approximately fifty percent of its historical average LAA supplies to benefit the eastern Sierra Nevada environment. As an identified program in MWD's Seawater Desalination Program, the proposed full-scale project would have qualified for MWD's grant of $250 per acre-foot of water produced. However, in May 2008, LADWP decided to focus on water conservation and water recycling as the primary strategies in creating a sustainable water supply for the City.

While seawater desalination is not a potential water supply strategy at this time, studies performed to date have provided beneficial data that in the future can assist LADWP with any future evaluations of seawater desalination. Completed studies include the LADWP Proposed Seawater Desalination Plant Site Selection Fatal Flaw Analysis (2002), LADWP Seawater Desalination Facility Feasibility Study for the Scattergood Generating Station in Playa Del Rey (2004), Brine Dilution Study for the LADWP Desalination Project at Scattergood Generating Station (2005), and Scattergood Seawater Desalination Pilot Project Preliminary Evaluation Report (2008).

To determine the proper site location for a City desalination plant, LADWP conducted the LADWP Proposed Seawater Desalination Plant Site Selection Fatal Flaw Analysis evaluating three City-owned coastal power generating plants. Based on the findings from this analysis, LADWP initially decided to investigate development of a 12 to 25 mgd desalination facility at the Scattergood Generating Station.

Optimum capacity of a future desalting facility at the Scattergood Generating Station was evaluated in the LADWP Seawater Desalination Facility Feasibility Study. Results of the study indicated a 25 mgd facility would be the most economical. Estimated capital costs for a 25mgd facility were approximately $148.5 million in 2004 dollars with an annual operations and maintenance cost of $28.9 million (2004 dollars) resulting in a total water cost of approximately $1,257 per acre-foot. The study also identified the five-mile Hyperion Treatment Plant Outfall, which is adjacent to the Scattergood Generating Station, as the most environmentally advantageous method to dispose of the brine concentrate produced from the desalting process.

In an effort to develop an environmentally compatible project, LADWP evaluated the feasibility of discharging the desalted concentrate into Hyperion Wastewater Treatment Plant's 5-mile outfall. The Brine Dilution Study for the LADWP Desalination Project at Scattergood Generating Station performed by the Scripps Institute of Oceanography found that there are potential environmental benefits to the Santa Monica Bay's marine biology due to improved salt balance if the effluent discharged by the Hyperion Wastewater Treatment Plant were to include brine from a desalination facility.

In March 2008 the Preliminary Evaluation Report of the Scattergood Generation Station Seawater Desalination Pilot Project was completed. This was the first task of multiple tasks that was to ultimately result in the operation of a pilot plant. Co-funded by the US Bureau of Reclamation and DWR through Proposition 50 funding the overall goal was to further investigate the viability of seawater desalination for LADWP. Recommendations on site specific technologies and processes were provided for carry over to the pilot plant design stage. Items for further study included subsurface intake evaluation, cooling alternatives for warm water, second pass RO, post treatment stabilization, and finished water blending strategy.

AR0070977

After completion of the first task, the other tasks were not initiated reflecting the City's new primary strategies of conservation and recycled water to create a sustainable water supply for the City. Studies completed to date and LADWPs other seawater desalination efforts discussed below have provided important data that can assist LADWP to move forward with seawater desalination in the future, if conditions are amenable.

Other LADWP Seawater Desalination Efforts

LADWP historically engaged in multiple partnerships to advance seawater desalination in southern California. Seawater desalination is hindered by multiple challenges including, but not limited to, capital costs, operating costs, environmental considerations, water quality, and public acceptance. To overcome these challenges, LADWP has supported efforts to lower the capital and operating costs of producing desalinated ocean water. LADWP also participated with California stakeholders through multiple venues, such as the MWD and the California Water Desalination Task Force to develop desalination study projects within southern California.

LADWP, the Long Beach Water Department (LBWD), and the United States Bureau of Reclamation partnered in the construction of a 300,000 gpd prototype seawater desalination facility to complete testing of LBWD's proprietary two-stage nanofiltration process (using membranes that require lower operating pressures and thus, the potential for lower operating costs). LBWD successfully performed a 9,000-gpd bench-scale testing of this technology and began testing on a larger scale in October 2006 at LADWP's Haynes Generating Station in Long Beach. By March 2010, LBWD has completed its testing and is currently preparing the final report.

LADWP also partnered with the West Basin Municipal Water District and other agencies in the American Water Works Association Research Foundation Tailored Collaboration project, "Water Quality Implications for Large-Scale Applications of MF/RO Treatment for Seawater Desalination." A 30,000-gpd pilot facility operating off the coast of El Segundo, California, from 2002 to 2008, was tested for membrane performance, water quality, and operational cost.

In a joint study by LADWP, LBWD, and West Basin Municipal Water District, preliminary sampling of raw seawater quality was initiated at three potential seawater desalination sites - Scattergood Generating Station in Playa Del Rey, Haynes Generating Station in Long Beach, and El Segundo Power Generating Station. Water quality analysis on the seawater was performed at various times of the year to analyze seawater quality variations during storm events when city surface runoffs drain into the ocean. The next step would be to collaborate with the California Department of Health Services on developing guidelines to ensure that product water from future desalting facilities will meet all State and Federal water quality regulations.

9.3 Potential Water Supply Yield and Cost

The range of potential water supply, the unit cost, risks, and other benefits besides reductions in water demands for these potential water supplies are presented in Exhibit 9B.

LADWP recognizes the value of potential water supplies to offset unanticipated changes to supply or demand. Strategic water planning necessarily includes continuous monitoring of existing and future alternative water resources in preparation of these needs.

AR0070978

Exhibit 9B

Other Potential Water Supplies

Potential Water Supplies	Potential Water Yield (AFY)	Average Unit Cost ($/AF)	Implementation Risks	Additional Benefits
Seawater Desalination [1]	25,000	$1,500-$2,000	Environmental permitting may be difficult.	Replaces water committed to the environment. Hedges against climate change.
Water Transfer	40,000	$440-$540[2]	Wheeling and other institutional issues must be addressed.	Replaces water committed to the environment.

For Comparison Purposes:
Local Groundwater Pumping Unit Cost = $230/AF
MWD Treated Tier 2 Water Supply Unit Cost = $811/AF

Notes:

1. Source: LADWP Seawater Desalination Facility Feasibility Study for the Scattergood Generating Station in Playa Del Rey (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSA.While the ocean is a virtually unlimited supply, yield shown here is the maximum given available land, outfall capacity, and other constraints.
2. Cost includes cost of water and wheeling fees. Treatment costs not included.

DRAFT

AR0070979

Chapter Ten
Integrated Resources Planning

10.0 Overview

Integrated resources planning is a process used by many water and wastewater providers to meet their future needs in the most effective way possible, and with the greatest public support. The integrated planning process incorporates:

- public stakeholders in an open, participatory process;
- multiple objectives such as reliability, cost, water quality, environmental stewardship, and quality of life;
- risk and uncertainty; and
- partnerships with other agencies, institutions, and non-governmental organizations.

LADWP has been actively involved in integrated resources planning since 1993, when the Metropolitan Water District of Southern California (MWD) initiated the region's first Integrated Resources Plan (IRP). LADWP was an active member of the technical workgroup that oversaw the development of alternatives and recommendations from MWD's IRP. In 1999, the City of Los Angeles embarked on its first IRP for wastewater, stormwater and water supply. The LADWP was a partner in this effort, working with the City's Bureau of Sanitation (BOS). In 2006, the Greater Los Angeles County IRWMP was approved. LADWP is a member of the IRWMP Leadership Committee and serves as the chair of the of the Upper Los Angeles River Watersheds sub-region for the IRWMP region.

10.1 City of Los Angeles Integrated Water Resources Plan

Description and Purpose

The City's Water Integrated Resources Plan (IRP) is a unique approach of technical integration and community involvement to guide policy decisions and water resources facilities planning. As part of the IRP development, an Environmental Impact Report (EIR) was prepared identifying the recommended alternatives for implementing the City's wastewater, runoff, and recycled water programs for 2020. On November 14, 2006, the City Council unanimously adopted the IRP recommendations and implementation strategy and certified the final EIR. The IRP development was a seven year stakeholder-driven process that at the time was an innovative approach to guide the City's policy decisions and facilities planning. The IRP recognizes the interrelationship of water, wastewater, and runoff management in forming a future vision for the City's water resources activities and functions. In the past, the City traditionally utilized single-purpose planning efforts for each agency, such as one plan for wastewater and a separate plan for water supply. With the IRP, the City can meet its 2020 needs in a more cost-effective and sustainable way by addressing and integrating all its water resources. Additionally, the IRP was designed to meet multiple objectives, including evaluation of innovative supply opportunities that were once thought of as being too expensive. The City's LADWP and BOS are partners in this effort, joined by public stakeholders and other agencies.

The objectives for the IRP were developed by the City and public stakeholders, and represent the major reasons why the plan was developed. These objectives are:

- Protect Public Health and Safety
- Effectively Manage System Capacity

AR0070980

- Protect the Environment
- Enhance Cost Efficiency
- Protect Quality of Life
- Promote Education

The IRP was developed in three phases. The first phase set policy guidelines for managing the City's water resources for the next 20 years. The second phase had three main deliverables: (1) detailed facility plans for wastewater, stormwater, and recycled water; (2) comprehensive financial plans for wastewater and stormwater; and (3) a certified Environmental Impact Report (EIR). The third phase of the IRP, which is now underway, represents implementation of the facility plans and more detailed studies to support implementation.

Integrated Watershed Approach

By taking an integrated watershed approach, the IRP identified opportunities that would normally not have been identified if water, wastewater, and stormwater were planned separately. The IRP recognized that all of the City's water resources are linked from a technical, social, and institutional aspect.

The City's IRP has also assisted in identifying partnerships between City agencies for project implementation potentially leading to increases in outside funding from grants and low-interest loans.

An example is the potential three-way partnership between the City's Recreation and Parks Department, BOS, and LADWP. Land reclamation of blighted industrial and warehouse uses allows the City to create more parks and recreational areas while simultaneously allowing for underground storage of wet weather runoff for subsequent beneficial reuse. With this integrated approach, the City can potentially obtain more parkland, assist BOS in reducing wet weather runoff to improve water quality, and assist LADWP in increasing water supplies. The integrated approach also allows the City to better position itself for grants and loans that typically prioritize projects that demonstrate multiple benefits (e.g., water quality, water supply and recreation).

Stakeholder Involvement

A key element of the IRP was involvement of stakeholders at the beginning and throughout the entire IRP process. Stakeholders represent a wide range of the City's interests including, but not limited to, community, business, and environmental organizations. Stakeholders were instrumental in development of the guiding principles and identification of innovative water resource opportunities.

During Phase 2, stakeholders participated in a Steering Group. Steering Group members regularly attended scheduled workshops and provided on-going input on the technical, environmental, and financial development of the IRP. Members provided necessary feedback to keep the facilities planning efforts aligned with the decision-making process. The Steering Group also considered key project issues in regards to the development of alternatives, such as facilities siting, implementation risks, and acceptability of costs that will invariably arise during the project.

IRP Alternatives

The IRP evaluated a broad range of integrated alternatives. Each alternative represented different combinations of wastewater treatment options, wastewater collection system options, recycled water options, conservation options, and dry and wet weather urban runoff management options.

AR0070981

Twenty-one (21) preliminary alternatives were created with different focuses, allowing stakeholders and decision-makers to see trade-offs in key planning objectives. Based on the evaluation of the preliminary alternatives, nine (9) hybrid alternatives were created that incorporated the best elements from the preliminary alternatives in order to improve overall performance. City staff recommended the top-scoring four (4) hybrid alternatives to be carried through to the EIR process. Public stakeholders concurred with staff recommendations.

In November 2006, City Council approved the staff-recommended alternative, which consists of "Go-Projects" , "Go-If-Triggered Projects" and "Go-Policy Directions". "Go-Projects" are projects recommended for immediate implementation because the flow and regulatory triggers have already been met. "Go-If-Triggered Projects" will only be implemented if or when additional information or circumstances, such as regulatory requirements, population growth, or increases in sewage flow are reached.. "Go-Policy Directions" are specific directions to City staff on the next studies and evaluations necessary to progress on programmatic elements.

IRP Implementation Status

The City's Department of Public Works (DPW) in partnership with the Department of Water and Power (DWP) has been working collaboratively along with other City departments on coordinating and implementing the various IRP recommendations. As part of the IRP implementation phase, the City has worked on keeping IRP stakeholders engaged through annual stakeholder meetings. Through these meetings, the City has provided updates on the IRP implementation and has obtained valuable input from stakeholders on IRP related issues. In addition, the Board of Water and Power and the Board of Public Works have held three public joint meetings to review the IRP progress and provide directions on policy issues. Since the adoption of the IRP by Council in November 2006, a number of initiatives have been undertaken by the City which fulfill the IRP goals, including the Green Streets and Green Alleys Committee, the development of a Low Impact Development Ordinance, Conservation Initiatives (Chapter 3), the Recycled Water Master Plan (Chapter 4), and Watershed Management (Chapter 7). Projects and policies in the IRP implementation strategy are detailed below. Some projects are currently being implemented, while others continue to be monitored for triggers or policy direction:

Go Projects

- Construct wastewater storage facilities at Tillman
- Construct wastewater storage facilities at Los Angeles-Glendale Water Reclamation Plant (LAG)
- Construct recycled water storage facilities at LAG
- Construct solids handling and truck loading facility at Hyperion
- Construct two new sewer lines, Glendale Burbank Interceptor Sewer (GBIS) and Northeast Interceptor Sewer (NEIS) Phase II

Go-If-Triggered Projects

- Potential upgrades at Tillman to advanced treatment at current capacity (if triggered by regulations and/or decision to reuse Tillman effluent for groundwater replenishment)

AR0070982

- Potential expansion and upgrade of Tillman to 100 mgd (if triggered by an increase in population, regulations, and/or groundwater replenishment decision), In the unlikely event that the overall framework for recycled water changes to disallow its use, then Hyperion would be potentially expanded to 500 mgd instead.

- Potential upgrades at LAG to advanced treatment at current capacity (if triggered by regulations and/or availability of downstream sewer capacity)

- Design and construct additional secondary clarifiers at Hyperion to provide 450 mgd operational performance

- Design and construct up to 12 solids digesters at Hyperion (if triggered by increased biosolids production in the service area)

- Design/construction of Valley Spring Interceptor Sewer

Of the "Go-Policy Directions" which provide specific directions to City staff on the next studies and evaluations necessary to progress on programmatic elements., those applicable to or with the potential to impact LADWP operations include:

Recycled Water – Non-Potable Uses

- Direct LADWP and Public Works to work together to maximize use and identify recycled water for non-potable uses in the Terminal Island Treatment Plant service area, west side, and LAG service areas. LADWP is to conduct additional Tier 1 and 2 customer analyses to verify potential demands and feasibility. Develop a long-range marketing strategy for recycled water that includes a plan for recruiting and retaining new customers.

- Direct Building and Safety to evaluate and develop ordinances to require installation, where feasible, of dual plumbing for new multi-family, commercial and industrial development, schools, and government properties in the vicinity of existing or planned recycled water distribution systems in coordination with the LA River Revitalization Master Plan. Proximity and demand will be considered when determining feasibility. The dual plumbing will consist of separate plumbing and piping systems, one for potable water and the second for recycled water for non-potable uses, such as irrigation and industrial use

- Direct Public Works and LADWP to continue to coordinate, where feasible, the design/construction of recycled water distribution piping (purple pipe) with other major public works projects, including street widening, and LA River Revitalization Master Plan project areas. Also coordinate with other agencies, including the Metropolitan Transit Authority and Caltrans, on major transportation projects.

Recycled Water –Indirect Potable Uses (Groundwater Replenishment)

- Direct LADWP to develop a public outreach program to explore the feasibility of implementing groundwater replenishment with advanced treated recycled water.

Recycled Water – Environmental Uses

- Direct LADWP and Public Works to continue to provide water from Tillman to Lake Balboa, Wildlife Lake, and the Japanese Garden at Sepulveda Basin, and the LA River to meet baseline needs for habitat.

AR0070983

Water Conservation

- Direct DWP to continue conservation efforts, including programs to reduce outdoor water usage, including using smart irrigation devices on City properties, schools, and large developments (those with 50 dwelling units or 50,000 gross square feet or larger), and to increase incentives to residential properties

- Direct LADWP to work with Building and Safety in continued conservation efforts, including evaluating and considering new water conservation technologies, including no-flush urinal technology

- Direct LADWP to continue conservation efforts, including working with Building and Safety to evaluate and develop a policy that requires developers to implement individual water meters for all new apartment buildings

- Direct LADWP to continue conservation awareness efforts, including increasing education programs on the benefits of using climate-appropriate plants with an emphasis on California friendly plants for landscaping or landscaped areas developed in coordination with the LA River Revitalization Master Plan, and to develop a program of incentives for implementation.

- Direct the Planning Department to consider development of a City Directive to require use of California friendly plants in all City projects where feasible and not in conflict with other facilities usage

Runoff Management – Wet Weather Runoff

- Direct Public Works to review SUSMP (Standard Urban Stormwater Management Plan) requirements to determine ways to require, where feasible, on-site filtration and/or treat/reuse, rather than treat and discharge, including in-lieu fees for projects where infiltration in infeasible

- Direct Building and Safety to evaluate and modify applicable codes to encourage all feasible Best Management Practices (BMPs) for maximizing on-site capture and retention and/or infiltration of stormwater instead of discharge to the street and storm drain, including using porous pavement.

- Direct Public Works and Planning to evaluate the possibility of requiring porous pavement in all new public facilities in coordination with the LA River Revitalization Master Plan, and large developments greater than one acre. Program feasibility should consider slope and soil conditions

- Direct Planning to evaluate ordinances that would need to be changed to reduce the area of on private properties that can be paved with non-permeable pavement

- Direct Public Works to evaluate and implement integration of porous pavements into sidewalks and street programs where feasible.

- Direct Public Works, LADWP, and Recreation and Parks to prepare a concept report and determine the feasibility of developing a powerline easement demonstration project for greening, public access, stormwater management, and groundwater replenishment.

- Direct Public Works and LADWP to work with the Los Angeles Unified School District to determine the feasibility of developing projects for both new and retrofitted schools, as well as for government/city-owned facilities, with

AR0070984

stormwater management BMPs (cisterns to store runoff for irrigation, reduce paving and hardscapes, add infiltration basins).

- Direct Public Works, General Services, and Recreation and Parks, to identify sites that can provide on-site percolation of wet-weather runoff in surplus properties, vacant lots, parks/open spaces, abandoned alleys in the East Valley area, and along the LA River in the East Valley where feasible. Program feasibility should consider slope and soil conditions.

- Direct Public Works, General Services, and the Department of Transportation to maximize unpaved open space in City-owned properties and parking medians using all feasible BMPs and by removing all unnecessary pavement.

- In the context of developing Total Maximum Daily Load implementation plans, direct Public Works to consider diversion of dry weather runoff from Ballona Creek to constructed wetlands, wastewater system, or urban runoff plants for treatment and/or beneficial use. For inland creeks and storm drains tributary to the LA River, direct Public Works to consider diversion of dry weather runoff to the wastewater system or constructed wetlands or treatment/retention/infiltration basins.

- Direct General Services, in coordination with Planning and Public Works, to evaluate feasibility of all City properties identified as surplus for potential development of multiple-benefit projects to improve stormwater management, water quality, and groundwater recharge.

Los Angeles River

The IRP planning effort included the Los Angeles River (River). The Los Angeles River is a valuable resource to the City providing habitat as well as recreational and economic opportunities. Since the City's water reclamation plants were built, recycled water has been released to the River resulting in the development of significant environmental benefits from riparian habitat in the unlined portions of the River near Glendale, to regionally significant migratory shore bird habitat in Long Beach. As a result many efforts have been developed to protect existing habitat and interest in habitat restoration and river revitalization.

The IRP established that treated wastewater is needed for the operation of Lake Balboa, the Japanese Gardens, and the Wildlife Lake in the Sepulveda Basin. Treated wastewater flows through these features and ultimately is released to the River from the Donald C. Tillman Water Reclamation Plant. The remainder of the treated wastewater produced by the City's water reclamation plants is available for recycled water use and distribution to LADWP customers.

Shortly after work on the IRP began, the Los Angeles City Council Ad Hoc Committee on the Los Angeles River (Ad Hoc Committee) was formed to address River revitalization. LADWP staff routinely attends Ad Hoc Committee meetings and functions, and monitors River-related activities.

LADWP also funded the preparation of a Los Angeles River Revitalization Master Plan which was approved in 2007. This plan addresses economic development opportunities, water quality, water resources, flood control, and recreation along the Los Angeles River. The plan also discusses opportunities to improve access to the Los Angeles River and increase community awareness and pride.

In addition, LADWP staff also actively participates on the City Department Los Angeles River Task Force, which was formed in response to instructions by the Ad Hoc Committee to:

AR0070985

- inventory all current and future City Department projects, studies, and programs along the River;
- assess opportunities for future funding, projects, and studies; and
- coordinate River related activities of City Departments and other agencies.
- partner with the United States Army Corps of Engineers for a Habitat Restoration Project Study

LADWP recognizes the importance of the Los Angeles River as a resource that provides multiple benefits to the City.

Agency Coordination

LADWP was a partner with the Bureau of Sanitation (BOS) in developing the IRP along with public stakeholders and other agencies. As with any integrated plan that extends beyond traditional departmental boundaries and government jurisdictions, close coordination is required with multiple City, state, and federal agencies including but not limited to, the Cities of Burbank and Glendale, County of Los Angeles, Caltrans, United States Army Corps of Engineers, United States Bureau of Reclamation, and City Parks and Recreation Department. Since approval of the IRP, ongoing project implementation and "Go-Policy Directions" continue to require close coordination with City departments and with the agencies listed above.

IRP Implications for City's Urban Water Management Plan

One of the primary purposes for developing the IRP was to explicitly consider the relationship between wastewater facility planning and other water resources issues, such as water supply and urban runoff. Implementation of the IRP has and will continue to result in increased beneficial reuse of water, water conservation, and groundwater supplies. IRP alternatives examined ways in which to decrease potable water needs by expanding the City's recycled water program; increase water efficiency by installing smart irrigation and other water efficient devices that reduce irrigation and indoor water demands; and increase groundwater resources by using wet weather runoff to recharge the aquifer. All of these options will have to be tested from a technical, institutional, and public acceptance perspective. Ongoing work on programmatic elements identified in the "Go-Policy Directions" applicable to LADWP will continue to investigate means of increasing local water supplies, water conservation, and groundwater recharge opportunities in an integrated manner. The IRP has demonstrated that by integrating water resources planning for the City, more opportunities for water supply development can be identified.

10.2 Greater Los Angeles County Integrated Regional Water Management Plan (IRWMP)

Description and Purpose

The Los Angeles County Department of Public Works led efforts to develop an Integrated Regional Water Management Plan (IRWMP) for the Greater Los Angeles County Region. Water quality, resource, and supply issues within the region are complex and managed by a myriad of government agencies subjected to a plethora of regulations. Exponential growth over the last century has required water managers to develop creative solutions to meet growing demands. Previously projects addressing water issues were designed to appease single-focused visions and solutions of organizations operating independently in silos. At the core of the plan a clear vision and direction for the sustainable management of water resources within the region for the next twenty years was formulated. Over 1,600 projects were collected and synthesized for inclusion in the plan bringing together hundreds of local government agencies all working cooperatively to develop cost-effective, sensible, and economically feasible solutions to address regional water issues. New partnerships were forged joining together potential funding partners from within and outside the region. An innovative partnership between agencies was formed

AR0070986

creating a new model of integrated regional planning to address competing water demands, water supply reliability, and project financing.

An Interim Draft of the IRWMP was adopted by the Leadership Committee on June 28, 2006 with a final plan adopted on December 16, 2006. To date the plan has received $25 million from the Department of Water Resources (DWR) under Proposition 50, Chapter 8, for implementation of fourteen priority projects identified in the plan and $1.5 million from DWR for development of the IRWMP. Since completion of the document a revised Memorandum of Understanding (MOU) was executed by each of the sixteen agencies serving on the Leadership Committee for the purpose of developing, administering, updating, and implementing the IRWMP.

Region

The IRWMP region encompasses 92 cities, portions of four counties, and hundreds of government agencies and districts spread over 2,058 square miles. Approximately 10.2 million residents, or equivalent to roughly 28% of the population of California, reside within the region. To facilitate input, variations in geographic and water management strategies, and effective planning the region was further subdivided into five sub-regions:

- Lower San Gabriel and Los Angeles River Watersheds
- North Santa Monica Bay Watersheds
- South Bay Watersheds
- Upper Los Angeles River Watersheds
- Upper San Gabriel River and Rio Hondo Watersheds.

Mission and Purpose

A collaborative process resulted in the following mission statement of the IRWMP, "[T]o address the water resources needs of the Region in an integrated and collaborative manner." The IRWMP recognizes that in order to meet future needs water supply planning must be integrated with other resource strategies. Additionally, in a region with significant urban challenges, including population growth, densification, traffic congestion, poor air quality, and quality of life issues, it is imperative to consider water resources management in conjunction with other urban planning issues. The IRWMP's purpose is to proactively:

- Improve water supplies
- Enhance water supply reliability
- Improve surface water quality
- Preserve flood protection
- Conserve habitat
- Expand recreational access.

DRAFT

AR0070987

Stakeholder Involvement

Over 1,400 invitations to participate in the IRWMP process were sent out to cities, counties, agencies, districts, disadvantaged communities, and community organizations. Stakeholders participated in workshops, project identification, and development of the IRWMP. Stakeholders were involved in plan development and through development of technical memorandums and participation in regional workshops, subregional workshops, and the Leadership Committee. Stakeholders assisted in the development of the following:

- Development of the IRWMP mission and objectives
- Refinement of procedures for incorporation of projects into the IRWM
- Identification of implementation strategies
- Recommendation of stakeholder workshop improvements.

Recommended Projects

Over 1,600 projects were submitted and analyzed for inclusion in the IRWMP. This list was narrowed down to fourteen priority projects that met the objectives and priorities established by the IRWMP process and assist in meeting the targets established for the planning region. Objectives and priorities were established to guide the project selection process. The IRWMP is a living document and will be updated as needed. Projects can continuously be submitted as they are identified by stakeholders.

Objectives and Priorities

Six objectives and six long-term priorities were developed through the stakeholder process to guide project selection based on stakeholder input and previously completed documents, including UWMPs, MWD's IRP, Common Ground, Santa Monica Bay Restoration Plan, and watershed plans for the major tributaries in the region. The objectives are:

- Optimize local water resources to reduce the Region's reliance on imported water
- Comply with water quality regulations (including TMDLs) by improving the quality of urban runoff, runoff, stormwater, and wastewater
- Protect and improve groundwater and drinking water quality
- Protect, restore, and enhance natural processes and habitats
- Increase watershed friendly recreational space for all communities
- Maintain and enhance public infrastructure related to flood protection, water resources, and water quality.

Long term regional priorities are:

- Maintain a regional and subregional structure to oversee plan implementation and assure continued stakeholder input
- Optimize use of recycled water, groundwater, desalination, and stormwater to enhance water supply reliability
- Reduce demand on imported water sources

AR0070988

- Protect groundwater supplies
- Improve surface water quality to meet applicable water quality regulations, including TMDLs
- Preserve open space, conserve and restore functional habitats, and protect special-status species.

Targets

Targets for the region were developed to assist in prioritizing projects. Targets include:

- Increase water supply reliability by providing 800,000 AFY of additional water supply and demand reduction through conservation, including infiltration or reuse of 130,000 AFY of reclaimed water
- Reduce and reuse 150,000 AFY (40%) of dry weather urban runoff and capture and treat an additional 170,000 AFY (50%) for a total target of 90%
- Reduce and reuse 220,000 AFY (40%) of stormwater runoff from developed areas and capture and treat an additional 270,000 AFY (50%) for a total of 90%
- Treat 91,000 AFY of contaminated groundwater
- Restore 100+ linear miles of functional riparian habitat and associated buffer habitat
- Restore 1,400 acres of functional wetland habitat
- Develop 30,000 acres of recreational open space focused in under-served communities
- Repair/Replace 40% of aging water resources infrastructure.

Projects

Fourteen priority projects were developed for the greater Los Angeles County region. As a regional plan encompassing an area larger that LADWP's service area, many of the IRWMP projects do not directly benefit LADWP's service area, but rather provide benefits towards improving water resources in the region as a whole. However, for projects not within LADWP's service area LADWP can utilize the results of other projects and apply the knowledge to potentially develop similar programs within the service area. Brief descriptions of the priority projects are provided below.

Southeast Water Reliability Project

The Southeast Water Reliability Project consists of an 11.4 mile recycled water transmission pipeline from the City of Pico Rivera to the City of Vernon to complete Central Basin Municipal Water District's recycled water transmission system. Recycled water will be mainly provided by the County Sanitation Districts of Los Angeles County via the San Jose Creek Water Reclamation Plant.

Joint Water Pollution Control Plant Marshland Enhancement

The Joint Water Pollution Control Plant Marshland Enhancement Project is designed to improve and maintain plant and wildlife habitat at the seventeen acre freshwater marshland located at the Joint Water Pollution Control Plant (JWPCP) in

DRAFT

AR0070989

Carson. As proposed the project will serve as a mitigation measure for upgrading the JWPCP to full secondary wastewater treatment. The JWPCP is operated by the County Sanitation Districts of Los Angeles County.

Large Landscape Water Conservation, Runoff Reduction, and Educational Program (Central Basin)

The Large Landscape Water Conservation, Runoff Reduction, and Education Program is an end use water management program to reduce runoff and address water/energy management associated with large landscapes, residential land uses, and street medians within the Central Basin Municipal Water District's Service Area. Weather-based irrigation controllers coupled with GIS to monitor runoff and two-way communication technologies will provide necessary information to address emergency, drought, and end use management challenges.

Large Landscape Water Conservation, Runoff Reduction, and Educational Program (West Basin)

West Basin Municipal Water District's Large Landscape Water Conservation, Runoff Reduction, and Educational Program is a four component project. The first component targets large landscape sites of 1 acre or more by providing centralized weather-based irrigation controllers with the goal of conserving 1 AFY per acre of land. The second component will provide 1,350 rebates for the purchase of smart irrigation controllers for the top residential water users. A third component will consist developing and offering classes on residential landscaping for residences and businesses. The last component involves installing ten "Ocean Friendly" demonstration gardens throughout watersheds in the service area.

Las Virgenes Creek Restoration Project

The City of Calabasas is initiating the Las Virgenes Creek Restoration Project to restore 450 linear feet of a concrete-lined section of the creek to a natural function. Native vegetation will be planted in place of the concrete liner to establish connectivity between riparian habitat north and south of the existing liner.

Malibu Creek Watershed Urban Water Conservation and Runoff Reduction Project

As proposed the Malibu Creek Watershed Urban Water Conservation and Runoff Reduction Project seeks to conserve water and reduce runoff in the City of Westlake Village and within the Las Virgenes Municipal Water District (LVMWD) service areas. Irrigation controllers on city-owned land in Westlake Village will be replaced with weather-based irrigation controllers. Within the LVWMD service area indoor conservation will be addressed by continuing rebates for residential and multi-family customers to install water saving devices. This project will also continue existing efforts to reduce urban runoff and outdoor conservation in the LVMWD service area by targeting customers with persistent and substantial irrigation runoff in the vicinity of stormdrains. These customers are offered water efficient equipment rebates and free on-site assistance to upgrade irrigation systems to eliminate runoff.

Morris Dam Water Supply Enhancement Project

The Morris Dam Water Supply Enhancement Project would allow the capture of additional local runoff (5,720 AF) for groundwater recharge and extraction in the San Gabriel River watershed. This project would reduce the minimum pool required by the Los Angeles County Flood Control District to prevent sediment damage to the outlet works of the dam by modifying the dam valves and control systems.

Pacoima Wash Greenway Project

The Pacoima Wash Greenway will treat storm runoff from neighborhoods adjacent to the wash in a series of parks incorporating stormwater treatment best management practices along the wash. Project development will be a joint effort between the City of San Fernando and the Mountains Recreation and Conservation Authority.

AR0070990

San Gabriel Valley Riparian Habitat Arundo Removal Project

Arundo donax a non-native plant classified federally and by California as noxious weed will be removed from approximately 30 acres of riparian habitat in the San Gabriel Watershed. Removal will increase surface water flows to the Rio Hondo percolation basins and improve native habitat.

Solstice Creek Restoration Project

The Solstice Creek Restoration Project will restore side drainages of Solstice Creek and areas negatively impacting riparian habitat through sediment and invasive species introduction. This project is part of an overall larger project to restore Solstice Creek.

South Los Angeles Wetlands Park

The South Los Angeles Wetlands Park project will involve purchasing a 9 acre parcel in Los Angeles on Avalon Boulevard for conversion to a wetlands park. As proposed, the wetlands park will treat urban runoff from a 520 acre area through a series of best management practices. Park vegetation will consist of plants not requiring supplemental irrigation.

Whittier Narrows Water Reclamation Plant UV Disinfection

The Whittier Narrows Water Reclamation Plant UV Disinfection project will convert current disinfection processes at the 15 mgd plant to a UV disinfection process. Currently, tertiary-treated water is disinfected to Title 22 recycled water standards using chloramination resulting in the production of NDMA byproducts.

Wilmington Drain Restoration Multiuse

As proposed, the Wilmington Drain Restoration Multiuse Project involves restoration of the Wilmington Drain. Restoration will involve creation of a public park, improved public access, native revegetation, stormwater treatment, and educational signage. The drain is within the City of Los Angeles on an easement held by the Los Angeles County Flood Control District.

North Atwater Creek Restoration

As a component of the overall Los Angeles River Revitalization efforts, the North Atwater Creek Restoration Project will restore North Atwater Creek at North Atwater Park by providing stormwater runoff capture and treatment and the provision of habitat linkage to the Los Angeles River. Additionally, the project will provide an educational component and provide BMP implementation at adjacent horse stables and riding trails.

Implications of IRWMP for LADWP's Urban Water Management Plan

LADWP is a member of the IRWMP Leadership Committee and additionally serves as the chair of the of the Upper Los Angeles River Watersheds sub-region for the IRWMP region. As member of the Leadership Committee, LADWP is a signatory to the MOU for the IRWMP approved by the Board of Water and Power Commissioners on July 15, 2008.

Participating agencies in the IRWMP coordinate and share information concerning water resources management planning programs and projects, share grant funding information, and improve and maintain overall communication among the participants. Coordination and information sharing assists LADWP and other agencies in achieving their respective missions and contribute to overall IRWMP goals.

AR0070991

10.3 MWD's Integrated Resources Plan

In 1993, MWD and its member agencies embarked on a three year process to develop Southern California's first IRP. Six main objectives for this plan were defined as:

- Supply and System Reliability
- Affordability
- Water Quality
- Diversity
- Environmental Issues
- Institutional Constraints

In order to meet these objectives, supply and conservation options that included everything from groundwater desalination, water transfers, Colorado River and SWP improvements, and new surface storage were evaluated. Complete portfolios, representing different combinations of supply and conservation options, were assembled. Based on extensive participation from water providers and other stakeholders as well as detailed evaluations, a "preferred resource mix" was recommended. The preferred resource mix balanced local and imported water supply projects with significant water conservation in order to best meet the needs of the region. This preferred resource mix also established regional targets for the development of water supply to be made by MWD, its member agencies, and retail water providers.

The 20-year plan was designed so that MWD and its member agencies would be able to meet their full service demands through 2020. MWD's Board of Directors formally adopted the IRP in January 1996.

MWD IRP 2004 Update

In 2001, the MWD Board of Directors developed a work plan to update the 1996 IRP in order to accommodate changed conditions and extend the targets through 2025. Specifically, the IRP Update has three main objectives: (1) review the resource development targets and implementation achievements of the 1996 IRP; (2) identify significant changed conditions for water resource development since the adoption of the 1996 IRP; and (3) evaluate the reliability of the IRP Preferred Resource Mix through 2020, adjust targets as needed to reflect changed conditions, and extend resource targets through 2025.

The results of the IRP Update analysis demonstrate that the resource targets of the 1996 IRP, factored in with the changed conditions discussed in this report, provide for 100 percent reliability in 2020 and up to 2025 (MWD, 2004). Although the current targets provide 100 percent reliability in 2020 and up to 2025, the IRP Update recommends a 10 percent supply buffer. The "planning buffer" identified additional supplies, both imported and locally developed, that could be implemented to address uncertainty in future supplies and demands. The most significant changed conditions include:

- Lower projected retail demands due primarily to conservation savings.
- Higher projected local water resource development.
- Lower projected dry-year MWD demands.
- Board revised targets for the SWP and Colorado River Aqueduct (CRA).

AR0070992

- More stringent water quality regulations.
- Recognition of implementation risks.

MWD IRP 2010 Update

In 2008, the MWD and its member agencies updated the 2004 IRP in order to accommodate changed conditions and extend the targets through 2035. The 2010 IRP Update has three main objectives: (1) develop an Emergency Response Plan for hydrologic, regulatory, and other types of uncertainties in the Sacramento-San Joaquin Delta; (2) identify energy-efficient and cost-effective energy management initiatives; and (3) evaluate the reliability of the IRP Preferred Resource Mix through 2035, adjust targets as needed to reflect changed conditions, and extend resource targets through 2035.

The IRP Update modified the resource targets to take into account the changed conditions and recommended buffer. A summary of the 2004 IRP Update and 2010 Update targets are shown in Exhibit 10A.

Exhibit 10A

MWD's IRP Resource Targets

IRP Resource Targets	2004 IRP Update 2025	2010 IRP Update 2025	Change	2010 IRP Update 2035
Conservation	1,107,000	1,412,000	305,000	1,538,000
Local Projects*	750,000	905,000	155,000	926,000
Colorado River Aqueduct **	1,250,000	1,250,000	0	1,250,000
State Water Project	650,000	713,000	63,000	713,000
Groundwater Conjunctive Use	300,000	300,000	0	300,000
Central Valley/State Water Project Storage and Transfers	550,000	1,070,000	520,000	1,092,000
MWD Surface Water Storage***	620,000	620,000	0	620,000

* Includes recycled water, brackish groundwater desalination, and seawater desalination

** Target for specific year types, the CRA is not intended to be full at all times

*** Represents the total amount that can be withdrawn from surface reservoirs

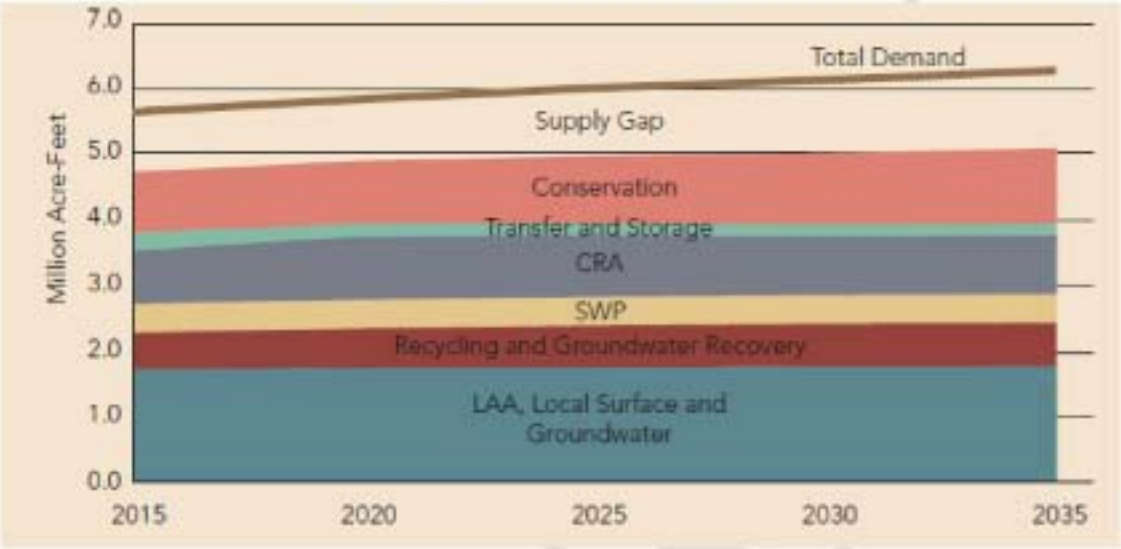
DRAFT

AR0070993

Exhibit 10B shows regional water demands without conservation from 2015 to 2035 under dry weather. The graph also depicts the supply sources and water conservation identified in MWD's 2010 IRP Update.

Exhibit 10B
Meeting Regional Water Needs Through MWD's IRP



Stakeholder Participation

MWD's 1996 IRP was developed in concert with its member agencies. A technical workgroup was established that consisted of MWD staff, member agency and local retail agency managers, and groundwater basin managers. This workgroup met frequently and spent hundreds of hours reviewing analyses and providing guidance. LADWP was an active participant in this workgroup.

To provide more direct involvement of MWD in the IRP Process, the IRP Steering Committee was created. The IRP Steering Committee, consisting of five MWD directors who are also members of the Water Planning and Stewardship Committee, recommended policy options, reviewed proposed resource strategies, and managed public forums.

In addition, regional assemblies were held at critical milestones of the IRP development that provided a platform to collectively discuss strategic direction and regional water solutions. Participants of these assemblies included Board members, water agency managers, local retail water providers, groundwater basin managers, and invited public stakeholders. Public forums and several member agency sponsored workshops attended by stakeholders from business, environmental, agricultural, and water interests were held throughout the IRP process. Finally, findings of the IRP 2010 Update were adopted in October 2010 to a diverse group of stakeholders including elected officials, environmental groups, and the general public.

Agency Coordination

In preparation of MWD's IRP, all member agencies were closely involved, including LADWP. LADWP was involved with providing data and reviewing documents. Additionally, LADWP was an active member of the technical workgroup.

AR0070994

Funding MWD's IRP

In accordance with MWD's Board adoption of the IRP Update, a revised Long-Range Finance Plan (LRP) was developed and approved by MWD's Board. The LRP (2010) identifies MWD's planned capital improvement program (CIP) and operating expenses from 2015 to 2035.

The following summarizes the MWD's CIP and operating expenses needed to implement the IRP:

- **Core Resources (Fixed costs to maintain Delta habitat conservation and conveyance program, LRP contracts, CRA programs, and conservations funding)** – costs for water supply will increase from the current $853/AF in 2015 to $1,484/AF in 2035.
- **Water Use Efficiency** – costs for water supply will increase from the current $892/AF in 2015 to $1,608/AF in 2035.
- **Capital Expenditures** – costs for water supply will increase from $919/AF in 2015 to $1,844/AF in 2035.
- **Demand Management & Local Projects** – costs from water supply will increase from $953/AF to $2,021/AF in 2035.

IRP Implications for City's Urban Water Management Plan

As LADWP evaluates its water supply options, it is important to understand the significance of a reliable and cost-effective water supply from MWD. The City's water supply reliability is directly linked to MWD's reliability, and LADWP's local supply development uses the cost of MWD water as one of the benchmarks for feasibility evaluation. Through the IRP Update, MWD has shown that it will be able to meet the supplemental needs of all its member agencies reliably through 2035, even during prolonged drought events. MWD has also developed a plan to implement and finance the approved IRP targets.

DRAFT

AR0070995

DRAFT Chapter Eleven
Water Supply Reliability and Financial Integrity

11.0 Overview

Providing for a reliable water supply in a semiarid climate with wet and dry years is challenging. This is mainly due to the fact that surface water supplies are imported from the LAA and MWD and vary substantially due to hydrology. LADWP has made significant investments in groundwater, recycled water, stormwater capture and water conservation. These supplies provide local water supplies that are more reliable due to variability of imported supply sources.

11.1 Unit Cost and Funding of Supplies

11.1.1 Unit Cost Summary of Supplies

Unit costs play an important role in planning future water supply sources and determining where supply investments provide the greatest benefits to LADWP. Unit costs vary dramatically by water supply sources. Exhibit 11A summarizes the unit cost for each water supply source.

Costs per acre-foot ranged from a high of $1,500 for certain recycled water projects to a low of $215 for locally produced groundwater among LA's existing and planned water supplies. Los Angeles Aqueduct supply has required operation and maintenance costs regardless of water availability. Therefore, hydrology and increased water for environmental commitments in the Eastern Sierras result in unit cost fluctuations year to year. Local groundwater supply is the least expensive source. However, its production is limited by contamination. Unit costs for MWD purchased water vary based on tier allocations. MWD's water rates vary from $484 per AF of tier 1 untreated water to $811 per AF of tier 2 treated water in 2010. LADWP has a Tier 1 allocation of 304,970 AF. Any purchases above this amount will be at the Tier 2 rates. Conservation is relatively inexpensive to offset water supplies that may otherwise be required to meet water demand. Conservation unit costs are based on costs of conservation rebate and incentive programs and their potential water use reduction. Recycled water cost is project specific and varies widely depending on the infrastructure requirements of each project. Water transfers using a future connection between the LAA and the California Aqueduct is planned. Its costs include the purchase price of water and conveyance fees.

Unit costs for potential water supplies including stormwater reuse (harvesting) and increased groundwater production (stormwater recharge) are highly variable based on factors such as the magnitude of the overall program, project locations, etc. Centralized stormwater capture unit cost is based on LADWP's current planned centralized stormwater capture projects and distributed stormwater capture unit costs are from various sources as referenced in Chapter 7, Watershed Management. These projects are joint efforts among agencies, city departments, stakeholders and community groups and yield additional benefits beyond water supply.

Seawater desalination unit costs are based on the estimate from MWD's 2010 IRP. Seawater desalination was a planned supply identified in the 2005 UWMP but is excluded from this 2010 UWMP. Its impacts to marine habitats and high energy consumption make seawater desalination less desirable comparing to options such as recycled water, conservation, and stormwater capture.

AR0070996

Exhibit 11A
Unit Costs of Supplies

Exhibit 11A		
Water Source	**Chapter Reference**	**Average Unit Cost ($/AF)**
Los Angeles Aqueduct[1]	**Chapter 5 - Los Angeles Aqueduct System**	$563
Groundwater[1]	**Chapter 6 - Local Groundwater**	$215
Metropolitan Water District[2]	**Chapter 8 - Metropolitan Water District Supplies**	$484 - $811
Conservation	**Chapter 3 - Conservation**	$325 - $400
Recycled Water	**Chapter 4 - Recycled Water**	$600 - $1,500
Water Transfer	**Chapter 9 - Other Potential Supplies**	$440 - $540
Stormwater Capture	**Chapter 7 - Watershed Management**	
- Centralized Stormwater Capture		$60 - $200
- Distributed Stormwater Capture		
Urban Runoff Plants		$4,044
Rain Barrels		$701 - $1,875
Cisterns		$2,426
Rain Gardens		$308 - $5,000
Neighborhood Recharge		$3,351
Seawater Desalination	**Chapter 9 - Other Potential Supplies**	$1,300 - $2,000

[1] Los Angeles Aqueduct supply and groundwater supply are based on FY2005-06 to FY2009-10 five-year average.
[2] MWD Water Rates effective on January 1, 2010.

11.1.2 Funding of Supplies

Funding for water resource programs and projects are primarily provided through LADWP water rates, with supplemental funding provided by the Metropolitan Water District (MWD), and state and federal grants. Funding for water conservation, water recycling, and stormwater capture projects has increased significantly in recent years. Currently, approximately $100 million is collected annually through water rates for these initiatives. The current level of annual expenditures is believed to be sufficient to achieve projected goals.

Funding for groundwater cleanup will require water rate increases. LADWP will also seek reimbursement from potential responsible parties to assist with cleanup program costs.

AR0070997

Water Resource Project Funding

- Water Rates – currently provides approximately $100 million annually for water conservation, water recycling, and stormwater capture programs.
- MWD – Currently provides funding up to $250 per AF for water recycling through their Local Resources Program. MWD also provides some water conservation incentive funding.
- State Funds – Funds for recycling, conservation, and stormwater capture have been available on a competitive basis though voter approved initiatives, such as Propositions 50 and 84. The proposed 2010 Water Bond, approved by the Legislature but not yet placed on the ballot, also includes potential funding for groundwater cleanup. Occasionally low or zero-interest loans are available though State Revolving Fund programs.
- Federal Funds – Funding for recycling may be obtained through periodic Water Resource Development Act legislation. Also, LADWP has received recycled water funds through the Bureau of Reclamation Title XVI program.
- Potentially Responsible Parties – LADWP may be able to recover some costs for groundwater cleanup through potentially responsible parties.

Receipt of state or federal funding will allow water resource goals to be achieved sooner than projected, or allow for increased local supply development.

11.2 Reliability Assessment Under Different Hydrologic Conditions

11.2.1 Los Angeles Aqueducts

Water supply from the LAA can vary substantially from year to year due to hydrology. In very wet years, LAA supply can exceed 500,000 AFY. During average year weather conditions the LAA supply is projected to gradually decrease from 254,000 AFY to 244,000 AFY by 2035 due to climate change impact. Critical dry year (defined as a repeat of a 1990/91 drought) supplies can be as low as 48,520 AFY.

11.2.2 Groundwater

Groundwater is also affected by local hydrology. However, with conjunctive use management of groundwater—storing imported water in the groundwater basins during wet and average years - groundwater production can actually be increased during dry years. During average weather conditions, LADWP projects it will pump approximately between 40,500 AFY and 111,500 AFY of groundwater during the projection period to fiscal year 2035. These projections are based on the Purification Complex in operation in 2018-19 and storage credit of 5,000 AFY is used to maximize the groundwater production thereafter. Although in dry years LADWP can pump larger quantities of groundwater, a more conservative approach was adopted by assuming the same level of projected groundwater production for both single dry year and multi dry year analysis.

11.2.3 Conservation

LADWP has developed conservation goals in the Water Supply Action Plan to decrease water use in the City and to comply with the new State 20 percent by 2020 requirements. Multiple actions will be taken to increase water conservation including education, targeting the CII sector, reducing outdoor water use, and continuing participation in MWD's rebate programs.

AR0070998

LADWP is planning to increase water conservation levels during the projection period with an increase of over 60,000 AFY between 2010 and 2035, assuming average weather conditions.

11.2.4 Recycled Water

Recycled water is based on wastewater effluent flows, which do not vary significantly due to hydrology. Therefore, recycled water use is mainly limited by system capacities and demands. This makes recycled water a more reliable supply than imported water. As outlined in Chapter 4 on Recycled Water, LADWP is planning an extensive expansion of its recycled water system to not only include expansion of irrigation and industrial uses, but also groundwater replenishment. Under average weather conditions recycled water supply for irrigation and industrial purposes is projected to increase from 20,000 AFY in 2015 to 29,000 AFY in 2035. Groundwater replenishment with recycled water is projected at 30,000 AFY in 2035. For a critical dry year available supplies would not change.

11.2.5 Water Transfers

Water transfers are being developed to replace a portion of the City's Los Angeles Aqueduct water that has been dedicated for environmental enhancement uses in the eastern Sierra Nevada. Water acquired through transfers helps increase water supply reliability for the City. The Los Angeles Aqueduct and California Aqueduct interconnection is under construction and estimated to be completed in January 2013. LADWP is expected to enter into agreements to obtain 40,000 AF per year under average weather conditions beginning in FY2013-14 and continuing throughout the projection period.

11.2.6 MWD Imported Supplies

Historically, water from MWD (like supplies from the LAA) has been subject to severe variability (i.e., 1976/77, 1987-1992, and the current water shortage). This is due to the fact that MWD's core sources of water supply are the Colorado River and SWP, both of which are highly affected by hydrology. More recently restrictions to protect threatened fish species have further decreased pumping from the Bay-Delta, and limiting SWP supplies available to MWD. After the 1987-1992 drought, MWD started to diversify its water supplies. Partnering with its member agencies, MWD launched the IRP in 1993 and most recently updated it in 2010. As a result of the resource targets in the IRP, MWD implemented a variety of projects and programs designed to reduce its dependency on imported water during water shortages and environmental related SWP pumping restrictions. Efforts have included: (1) providing financial incentives for local projects and conservation; (2) increased surface storage via Diamond Valley Lake and use of the SWP terminus reservoirs; (3) groundwater storage programs in the Central Valley, Imperial Valley, and Coachella Valley; (4) short- and long-term water transfers; and (5) contracted groundwater storage programs with participating member agencies.

In the 2010 IRP Update MWD developed a three-part adaptive resource strategy: (1) meet demands by building on existing core resources to provide reliability under foreseen conditions; (2) implement a supply buffer of 10 percent of retail demand through multiple actions to adapt to short-term uncertainty; and (3) implement adaptive management through low-regret foundation actions, monitoring key vulnerabilities and bringing adaptive resources online, if required, and using a comprehensive approach to meet specific needs and degrees of shortages. The 2010 IRP adaptive management concept seeks to mitigate against supply uncertainty to further increase reliability.

The 2010 IRP Update concluded that the resource targets identified in previous updates, taking into consideration changed conditions identified since that time, will continue to provide for 100 percent reliability through 2035. The 2010 RUWMP also concluded the same full reliability through 2035 during average (1922 – 2004 hydrology), single dry (1977 hydrology), and

AR0070999

multiple dry years (1990 - 1992 hydrology). For each of the scenarios there is a surplus in every forecast year (see Exhibit 11B).

Exhibit 11B
MWD Supply Capability and Projected Demands (in AFY)

Single Dry-Year MWD Supply Capability and Projected Demands					
Fiscal Year	2015	2020	2025	2030	2035
Capability of Current Supplies	2,457,000	2,782,000	2,977,000	2,823,000	2,690,000
Projected Demands	2,171,000	2,162,000	2,201,000	2,254,000	2,319,000
Surplus	286,000	620,000	776,000	569,000	371,000

Source: MWD 2010 Regional Urban Water Management Plan Tables 2-9 to 2-11

As part of the implementation of MWD's IRP, MWD and its member agencies worked together to develop MWD's Water Surplus and Drought Management Plan (WSDM Plan) in 1999. The WSDM Plan established broad water resource management strategies to ensure MWD's ability to meet full service demands at all times and provides principles for supply allocation if the need should ever arise. The WSDM Plan splits MWD's resource actions into two major categories: Surplus Actions and Shortage Actions. The Shortage Actions of the WSDM Plan are split into three sub-categories: Shortage, Severe Shortage, and Extreme Shortage. Under Shortage conditions, MWD will make withdrawals from storage and interrupt long-term groundwater basin replenishment deliveries. Under Severe Shortage conditions, MWD will call for extraordinary drought conservation in the form of voluntary savings from retail customers, interrupt 30 percent of deliveries to Agricultural Water Program users, call on its option transfer water, and purchase water on the spot market. Under Extreme Shortage conditions, MWD will equitably allocate supplies to its member agencies on the basis of agencies' needs. The overall objective of MWD's IRP and WSDM Plan is to ensure that shortage allocations of MWD water supplies are not required.

If shortage allocations are required, MWD will rely on the calculations established in its Water Supply Allocation Plan (WSAP) adopted in 2008. The plan equitably allocates shortages among its member agencies based on growth, local investments, changes in supply conditions, demand hardening, and water conservation programs for each of its member agencies.

AR0071000

11.2.7 Potential Supplies

Other planned and potential water supplies that LADWP is exploring include capturing stormwater for reuse and infiltration leading to increased groundwater production (see Chapter 7). Development of these supplies will offset water purchased from MWD. The beneficial reuse of stormwater presents significant opportunity. The City must reduce pollutants in impaired receiving waters (rivers, creeks, and beaches in the Santa Monica and Los Angeles watersheds) as required by the Clean Water Act. By managing urban runoff during dry and wet periods, pollution will be reduced. Traditional ways of managing urban runoff would be to divert the runoff into existing wastewater treatment plants and/or build satellite treatment plants specifically designed to treat urban runoff.

During the City's IRP process, stakeholders expressed the desire to examine other ways to manage runoff that would reduce pollution and provide for other benefits such as water supply and open space. These methods involve local and regional storage of wet weather runoff for groundwater infiltration, on-site storage and recovery of wet weather runoff for irrigation using cisterns and other devices, and reuse of treated dry weather effluent for irrigation (much like recycled water). As an outgrowth of the IRP, neighborhood recharge concept efforts are moving from the conceptual stage visualized in the IRP to actual projects in the City to infiltrate wet weather runoff as close as possible to the point of origin with multiple projects either complete, under construction, or in final design.

Under average weather conditions LADWP is projecting stormwater capture and reuse in 2015 will potentially be 2,000 AFY increasing to 10,000 AFY by 2035. Increased groundwater production as a result of stormwater infiltration will potentially be 15,000 AFY in 2035. This potential is contingent on modifying the court judgment. If these resources reach fruition, LADWP will be able to reduce imported demands on MWD by 25,000 AFY in 2035 under average weather conditions.

11.2.8 Service Area Reliability Assessment

To determine the overall service area reliability, LADWP defined three hydrologic conditions: average (or normal weather); single dry year (such as a repeat of the 1990/91 drought); and multi-dry year period (such as a repeat of FY1988-89 to FY1992-93).

The water supply reliability summaries are shown in Exhibit 11C for the 5-year average from FY 2005-06 to FY 2009-10 and in Exhibit 11 D for FY 2034-35 under average weather conditions with new water conservation shown as a supply source. The exhibits show that the City's reliance on MWD supply will decrease from 52 percent to 24 percent by FY 2034-35 while the combined imported supplies of LAA and MWD water will decrease from 88 percent to 57 percent by FY 2034-35. The locally-developed supplies will increase from 12 percent to 43 percent by FY 2034-35.

Exhibit 11C
LADWP Supply Reliability FYE 2006-2010 Average

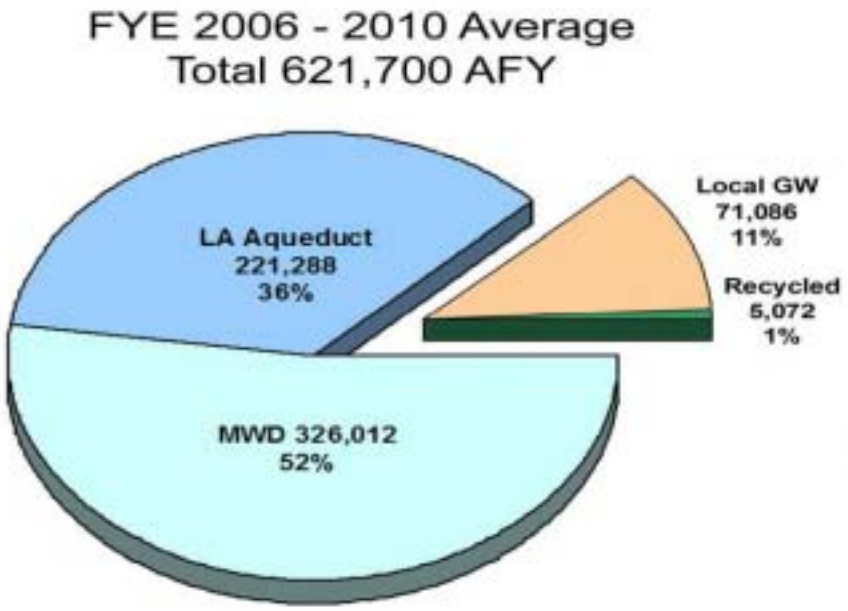

Exhibit 11D
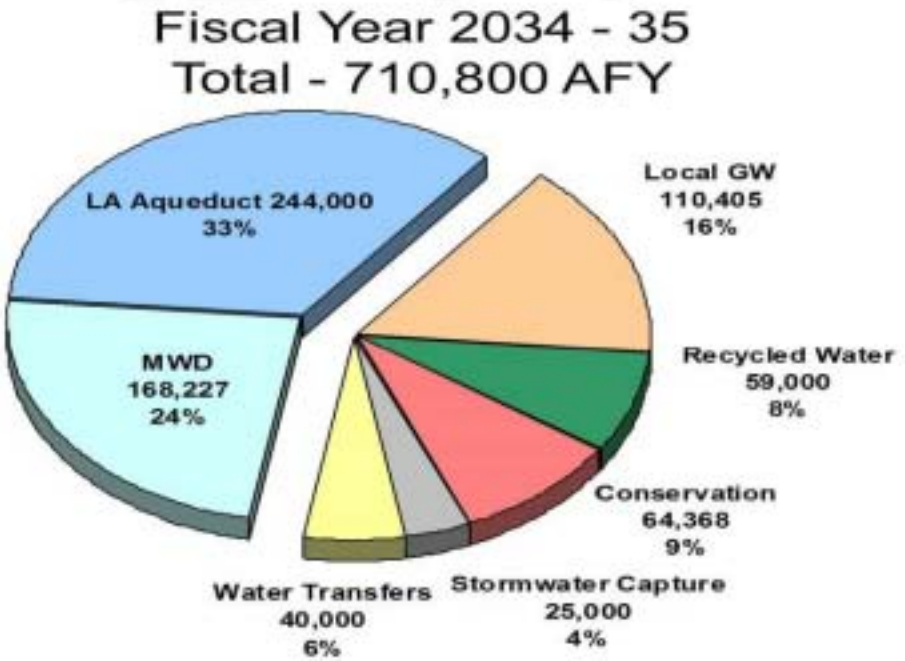
LADWP Supply Reliability Under Average Weather Conditions in Fiscal Year 2034-35



AR0071002

Exhibits 11E and 11F tabulate the service reliability assessment for normal and single dry year conditions, respectively. Exhibits 11G through 11K show reliability assessments in five year increments from 2010 to 2035 with each five year period assuming that a multiple dry year condition occurs. For these reliability tables, existing water conservation has been already subtracted from projected demands, but new water conservation is included as a supply source. Under all scenarios all demands are met by the available supplies.

AR0071009

11.3 Water Shortage Contingency Plan

The Los Angeles City Municipal Code Chapter XII, Article I, Emergency Water Conservation Plan is the City's water shortage contingency plan. It was developed to provide for a sufficient and continuous supply of water in case of a water supply shortage in the service area. There are two scenarios that can cause a water shortage: 1) a severe hydrologic drought affecting surface and groundwater supplies and 2) a catastrophic event that severs major conveyance and/or distribution pipelines serving water to the City. The following discusses LADWP's compliance with the Act as outlined in Section 10632 (a) through (i) of the California Water Code.

11.3.1 Stages of Action – 10632 (a)

As set forth in the Emergency Water Conservation Plan, the City has phases or stages of action that can be undertaken in response to water supply shortages. Phase I prohibited uses of water are in effect at all times within the City. These prohibited uses, defined in article 10632 (d) (see section 11.3.4), are intended to eliminate waste and increase public awareness of the need to conserve water. There are further stages of compounding actions in addition to the Phase I prohibited uses that might be imposed. Phase II to Phase V progressively responds to different severity of shortage with the authority to implement additional prohibited uses of water in Phase V in order to cope with up to a 50 percent reduction in water supply. They are described as follows:

Moderate Shortage, Phase II

1. Should Phase II be implemented, uses applicable to Phase I shall continue to be applicable, except as specifically provided herein.

2. No landscape irrigation shall be permitted on any day other than Monday, Wednesday, or Friday for odd-numbered street addresses and Tuesday, Thursday, or Sunday for even-numbered street addresses. Street addresses ending in ½ or any fraction shall conform to the permitted uses for the last whole number in the address. Watering times shall be limited to: (a) Non-conserving nozzles (spray head sprinklers and bubblers) – no more than eight minutes per watering day per station for a total of 24 minutes per week; (b) Conserving nozzles (standard rotors and multi-stream rotary heads) – no more than 15 minutes per cycle and up to two cycles per watering day per station for a total of 90 minutes per week.

3. Upon written notice to LADWP, irrigation of sports fields may deviate from non-watering days to maintain play areas and accommodate event schedules; however, to be eligible for this means of compliance, a customer must reduce his overall monthly water use by LADWP's Board of Water and Power Commissioner's (Board) adopted degree of shortage plus an additional 5 percent from the customer baseline water usage within 30 days.

4. Upon written notice to LADWP, large landscape areas may deviate from the non-watering days by meeting the following requirements (1) must have approved weather-based irrigation controllers registered with LADWP (eligible weather-based irrigation controllers are those approved by MWD or the Irrigation Association Smart Water Application Technologies (SWAT) initiative (2) must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus an additional 5 percent from the customer baseline water usage within 30 days; and (3) must use recycled water if it is available from LADWP.

5. These provisions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase II except between the hours of 9:00 am and 4:00 pm.

Severe Shortage, Phase III

1. Should Phase III be implemented, uses applicable to Phases I and II shall continue to be applicable, except as specifically provided herein.

AR0071010

2. No landscape irrigation shall be permitted on any day other than Monday for odd-numbered street addresses and Tuesday for even-numbered street addresses. Street addresses ending in ½ or any fraction shall conform to the permitted uses for the last whole number in the address.

3. No washing of vehicles allowed except at commercial car wash facilities.

4. No filling of residential swimming pools and spas with potable water.

5. Upon written notice to LADWP, irrigation of sports fields may deviate from the specific non-watering days and be granted one additional water day (for a total of two watering days allowed). To be eligible for this means of compliance, a customer must reduce his overall monthly water use by LADWP's Board's adopted degree of shortage plus an additional 10 percent from the customer baseline water usage within 30 days.

6. Upon written notice to LADWP, large landscape areas may deviate from the specific non-watering days and be granted one additional watering day (for a total of two watering days allowed) by meeting the following requirements (1) must have approved weather-based irrigation controllers registered with LADWP (eligible weather-based irrigation controllers are those approved by MWD or the Irrigation Association Smart Water Application Technologies (SWAT) initiative (2) must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus an additional 10 percent from the customer baseline water usage within 30 days; and (3) must use recycled water if it is available from LADWP.

7. These provisions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase III except between the hours of 9:00 am and 4:00 pm.

Critical Shortage, Phase IV

1. Should Phase IV be implemented, uses applicable to Phases I, II, and III shall continue to be applicable, except as specifically provided herein.

2. No landscape irrigation allowed.

Super Critical Shortage, Phase V

1. Phase I, II, III, and IV shall continue to remain in effect.

2. The Board is hereby authorized to implement additional prohibited uses of water based on the water supply situation. Any additional prohibitions shall be published at least once in a daily newspaper of general circulation and shall become effective immediately upon such publication and shall remain in effect until cancelled.

11.3.2 Driest Three-Year Supply – 10632 (b)

In the event that three consecutive dry-years curtailing the City's LAA System deliveries should follow the 2010 water supply conditions, LADWP will rely on increased groundwater pumping and purchases from MWD to meet City water demands. This particular sequence is quantified in Exhibit 11L, including relevant assumptions.

AR0071011

Exhibit 11L
Driest Three-Year Water Supply Sequence

Demand and Supply Projections (in acre-feet)	FY2009-10 Actual	Followed by Repeat of Driest Three Consecutive Years FY1958-59 to 1960-61 Hydrology Fiscal Year Ending on June 30		
		2011	2012	2013
Total Demand	**554,140**	**588,900**	**607,300**	**626,000**
Existing / Planned Supplies				
Los Angeles Aqueduct[1]	199,739	104,530	50,849	59,382
Groundwater[2]	76,982	61,090	53,660	46,260
Conservation	8,178	5,670	7,310	8,950
Recycled Water				
- Irrigation and Industrial Use	6,703	7,500	8,300	9,000
- Groundwater Replenishment	0	0	0	0
Water Transfers	0	0	0	40,000
Subtotal	291,602	178,790	120,119	163,592
MWD Water Purchases				
With Existing/Planned Supplies	262,538	410,110	487,181	462,408
Total Supplies	**554,140**	**588,900**	**607,300**	**626,000**

1. Driest three consecutive years on record in LAA watershed (FY1958-59 to FY1960-61) averaged 28 percent of normal runoff.
2. LAA deliveries reflect increased releases for environmental restoration in the Owens Valley and Mono Basin.
3. Dry year demands are 5 percent greater than normal year demands
4. MWD's Water Surplus and Drought Management Plan actions sufficient to meet LADWP demands.

During such severe drought periods, the City's supplemental water supplier, MWD, may use an allocation strategy that is consistent with the framework developed in its Water Surplus and Drought Management (WSDM) Plan. Developed by MWD with substantial input from its member agencies, the WSDM Plan provides for a needs-based allocation strategy, and establishes priorities for the use of MWD's water supplies to achieve 100 percent retail reliability.

Following are actions that could be taken by MWD in accordance with their WSDM Plan to augment its water supplies prior to implementation of any drought allocation action:

1. Draw on Diamond Valley Lake storage
2. Draw on out-of-region storage in Semitropic and Arvin-Edison Groundwater Banks
3. Reduce/suspend local groundwater replenishment deliveries
4. Draw on contractual groundwater storage programs in MWD's service area

AR0071012

5. Draw on State Water Project terminal reservoir storage (per Monterey Agreement)
6. Call for voluntary conservation and public education
7. Reduce deliveries from MWD's Interim Agricultural Water Program
8. Call on water transfer options contracts
9. Purchase transfers on the spot market
10. Allocate imported water if necessary

In 2008 MWD adopted the Water Supply Allocation Plan (WSAP) designed to allocate supplies among its member agencies in a fair and efficient manner. The WSAP establishes the formula for calculating member agency allocations if MWD cannot meet firm demands in a given year.

11.3.3 Catastrophic Supply Interruption Plan – 10632 (c)

LADWP has Emergency Response Plans (ERPs revised January 2010) in place to restore water service for essential use in the City if a disaster should result in the temporary interruption of water supply. Department personnel responsible for water transportation, distribution, and treatment have established ERPs to guide the assessment, prioritization, and repair process of City facilities that have incurred damage during a disaster. Citywide, an Emergency Operations Center (EOC) serves as a centralized point for citywide management of information about disasters and for coordination of all available resources. The EOC supports the City's Emergency Operations Organization to achieve its mission of saving lives, protecting property, and returning the City to normal operations in the event of a disaster. LADWP coordinates its efforts with the EOC and will utilize the EOC to resume water supply service after a catastrophic event.

11.3.4 Mandatory Water Use Prohibitions – 10632 (d)

Phase I prohibited uses of the Emergency Water Conservation Plan contain 13 wasteful water use practices that are permanently prohibited for all City of Los Angeles customers. These prohibited uses are intended to eliminate waste and increase public awareness of the need to conserve water. During times of shortage, education and enforcement of the following provisions will be increased:

1. No customer shall use a water hose to wash any paved surfaces including, but not limited to, sidewalks, walkways, driveways, and parking areas, except to alleviate immediate safety or sanitation hazards. This section shall not apply to LADWP approved water conserving spray cleaning devices. Use of water pressure devices for graffiti removal is exempt. A simple spray nozzle does not qualify as a water conserving spray cleaning device.
2. No customer shall use water to clean, fill, or maintain levels in decorative fountains, ponds, lakes, or similar structures used for aesthetic purposes unless such water is part of a recirculating system.
3. No restaurant, hotel, cafe, cafeteria, or other public place where food is sold, served, or offered for sale shall serve drinking water to any person unless expressly requested.
4. No customer shall permit water to leak from any pipe or fixture on the customer's premises; failure or refusal to affect a timely repair of any leak of which the customer knows or has reason to know shall subject said customer to all penalties

AR0071013

for a prohibited use of water.

5. No customer shall wash a vehicle with a hose if the hose does not have a self-closing water shut-off device or device attached to it, or otherwise to allow a hose to run continuously while washing a vehicle.

6. No customer shall irrigate during periods of rain.

7. No customer shall water or irrigate lawn, landscape, or other vegetated areas between the hours of 9:00 a.m. and 4:00 p.m. During these hours, public and private golf courses greens and tees and professional sports fields may be irrigated in order to maintain play areas and accommodate event schedules. Supervised testing or repairing of irrigation systems is allowed anytime with proper signage.

8. All irrigating of landscape with potable water using spray head sprinklers and bubblers shall be limited to no more than ten minutes per watering station per day. All irrigating of landscape with potable water using standard rotors and multi-stream rotary heads shall be limited to no more than fifteen minutes per cycle and up to two cycles per watering day per station. Exempt from these irrigation restrictions are irrigation systems using very low drip type irrigation when no emitter produces more than four gallons of water per hour and micro-sprinklers using less than fourteen gallons per hour. This provision does not apply to Schedule F water customers or water service water service that has been granted the General Provision M rate adjustment under the City's Water Rates Ordinance, subject to the Customer having complied with best management practices for irrigation approved by the Department. The 9:00 a.m. to 4:00 p.m. irrigation restriction shall apply unless specifically exempt as stated in subsection 7 of the Emergency Water Conservation Ordinance.

9. No customer shall water or irrigate any lawn, landscape, or other vegetated area in a manner that causes or allows excess or continuous flow or runoff onto an adjoining sidewalk, driveway, street, gutter, or ditch.

10. No installation of single pass cooling systems shall be permitted in buildings requesting new water service.

11. No installation of non-recirculating systems shall be permitted in new conveyor car wash and new commercial laundry systems.

12. Operators of hotels and motels shall provide guests with the option of choosing not to have towels and linens laundered daily. The hotel or motel shall prominently display notice of this option in each bathroom using clear and easily understood language. LADWP shall make suitable displays available.

13. No large landscape areas shall have irrigation systems without rain sensors that shut-off the irrigation systems. Large landscape areas with approved weather-based irrigation controllers registered with LADWP are in compliance with this requirement.

11.3.5 Consumption Reduction Methods during Water Shortages – 10632 (e)

Short-Term Actions

During a water shortage or emergency condition, LADWP's existing rate structure (enacted in 1993) serves as a basis for further reducing consumption. First tier water allotments are reduced during shortages by the degree of the shortage. For single-family residential users, the adjusted first tier allotments apply for the entire year. For other users, the adjusted first tier allotments apply only during the high season (June 1 through October 31). Details of LADWP's water rate structure are provided in Appendix X – Water Rate Ordinance.

AR0071014

Additional measures can be phased in as the dry cycle continues to provide some immediate demand reductions and increase public awareness of the need to conserve water. Included among these measures are water conservation public service announcements (through television and/or radio), billboard ads, flyer distributions, and conservation workshops. LADWP also actively participates in public exhibits to disseminate water conservation information within its service area. Conservation is a permanent and long-term application used within the City to counter the potentially adverse impacts of water supply shortages.

State law further regulates distribution of water in extreme water shortage conditions. Section 350-354 of the California Water Code states that when a governing body of a distributor of a public water supply declares a water shortage emergency within its service area, water will be allocated to meet needs for domestic use, sanitation, fire protection, and other priorities. This will be done equitably and without discrimination between customers using water for the same purpose(s).

Long-Term Actions

LADWP's long-range water conservation program is driven by the need to continuously increase water use efficiency. This will reduce demand, extend supply, and therefore, provide greater reliability. Dry cycle experiences, public trust responsibilities, and regulatory mandates have raised the level of awareness within the City of Los Angeles of the need to approach demand reduction from a permanent and long-term perspective.

LADWP will continue to maintain and increase its existing conservation programs and pursue the development of new and innovative programs as outlined in Chapter 3, Water Conservation with the goal of reducing potable water demands by 60,000 AFY by 2035. Emphasis continues to be placed on structural conservation for the residential and CII sectors (HETs, high-efficiency washing machine rebates, etc.) which result in permanent per capita water use reduction. Substantial efforts are also being placed on landscape water use efficiency and CII conservation opportunities. It should, however, be recognized that the ability to achieve water reduction during shortages by requesting additional voluntary measures is likely to be more difficult in the future. As customers adjust to a conservation ethic and adopt permanent measures to reduce water use, their water demands harden and become less susceptible to voluntary conservation.

11.3.6 Penalties for Excessive Use (Non-Compliance to Prohibited Use) – 10632 (f)

The Emergency Water Conservation Plan sets penalties for violations of prohibited uses outlined in Sections 10632 (a) and (d). The penalties vary by water meter size. For water meters smaller than two inches the following penalties shall apply:

1. The first violation consists of a written warning

2. The second violation within the preceding 12 month period will result in a surcharge in the amount of $100 added to the customer's water bill.

3. The third violation within the preceding 12 month period will result in a surcharge in the amount of $200 added to the customer's water bill.

4. The fourth violation within the preceding 12 month period will result in a surcharge in the amount of $300 added to the customer's water bill.

5. After a fifth violation or subsequent violation within the preceding 12 month period, LADWP may install a flow-restricting device of 1 gpm capacity for services up to 1 ½ inches in size and comparatively sized restrictors for larger services or

AR0071015

terminate a customer's service, in addition to the aforementioned financial surcharges. Such action shall only be taken after a hearing held by LADWP.

For water meters two inches and larger the following penalties shall apply:

1. The first violation consists of a written warning
2. The second violation within the preceding 12 month period will result in a surcharge in the amount of $200 added to the customer's water bill.
3. The third violation within the preceding 12 month period will result in a surcharge in the amount of $400 added to the customer's water bill.
4. The fourth violation within the preceding 12 month period will result in a surcharge in the amount of $600 added to the customer's water bill.
5. After a fifth violation or subsequent violation within the preceding 12 month period, LADWP may install a flow-restricting device or terminate a customer's service, in addition to the aforementioned financial surcharges. Such action shall only be taken after a hearing held by LADWP.

11.3.7 Analysis and Effects on Revenues and Expenditures of Reduced Sales during Shortages – 10632 (g)

The City's Water Rate Ordinance, adopted in June 1995 and last amended in June 2008, provides a remedy to the impact of reduced water sales on revenues in the form of a Water Revenue Adjustment Factor (Adjustment). The Adjustment recovers any shortage in revenue due to variation in water sales. It is intended to support a fiscal year revenue target that is deemed sufficient to cover LADWP's essential expenses. The formula takes into account target and actual revenues as well as projected water sales to determine the appropriate Adjustment.

The Adjustment is currently limited to $.18 per hundred-cubic-feet. It cannot exceed this limit unless the Board determines that a surcharge in excess of $0.18 per hundred-cubic-feet is financially required and approval from the Los Angeles City Council is obtained. The Board also has the authority to reduce the factor to less than the formula-calculated amount.

A billing factor is calculated annually on January 1 and is added to the standard commodity charge. The factor is set to zero if a negative value is calculated. A Water Revenue Adjustment Account is maintained and updated each month by LADWP. This account is adjusted annually on July 1.

The City's Water Revenue Adjustment Factor ensures that the required funds are available to fund Department activities aimed at providing continuous water service to Los Angeles water users, even during periods of low water sales.

11.3.8 Water Shortage Contingency Resolution or Ordinance – 10632 (h)

A draft water shortage contingency resolution is shown in Exhibit 11M. Moreover, the City's Emergency Water Conservation Plan Section 121.07.B has the following conservation phase implementation procedures:

AR0071016

"The Department (LADWP) shall monitor and evaluate the projected supply and demand for water by its Customers monthly, and shall recommend to the Mayor and Council by concurrent written notice the extent of the conservation required by the Customers of the Department in order for the Department to prudently plan for and supply water to its Customers. The Mayor shall, in turn, independently evaluate such recommendation and notify the Council of the Mayor's determination as to the particular phase of water conservation, Phase I through Phase V, that should be implemented. Thereafter, the Mayor may, with the concurrence of the Council, order that the appropriate phase of water conservation be implemented in accordance with the applicable provisions of this Article. Said order shall be made by public proclamation and shall be published one time only in a daily newspaper of general circulation and shall become effective immediately upon such publication. The prohibited water uses for each phase shall take effect with the first full billing period commencing on or after the effective date of the public proclamation by the Mayor. In the event the Mayor independently recommends to the Council a phase of conservation different from that recommended by the Department, the Mayor shall include detailed supporting data and the reasons for the independent recommendation in the notification to the Council of the Mayor's determination as to the appropriate phase of conservation to be implemented."

The City's Water Rate Ordinance No. 170435 also has specific provisions for LADWP's Board, through a resolution, to determine the degree of shortage and apply corresponding commodity charges in case of a water shortage (see Section 11.3.5 and Appendix X – Water Rate Ordinance). If a water shortage is declared, certified copies of the resolution will be transmitted to the offices of the Mayor and of the Los Angeles City Clerk, and the Los Angeles City Council for final approval. This particular water shortage act is included under Section 3 – General Provisions, Article R – Shortage Year Rates of the City's Water Rate Ordinance.

DRAFT

AR0071017

Exhibit 11M
Draft Water Shortage Contingency Resolution

BE IT RESOLVED that the Board of Water and Power Commissioners (Board) recognizes that a Water Shortage Contingency Plan has been prepared and incorporated into the City of Los Angeles 2010 Urban Water Management Plan pursuant to the Urban Water Management Planning Act; the Urban Water Management Plan is on file with the Secretary of the Board; this Board has reviewed and considered the information and recommendations contained in this document, and makes the following findings and determinations:

1. The water supply available to the City of Los Angeles is insufficient to meet the City's normal water supply needs; and
2. The Department of Water and Power has developed a Water Shortage Contingency Plan for the City of Los Angeles that compiles with all the requirements of the Urban Water Management Planning Act; and
3. The Urban Water Management Plan has been developed, adopted, and implemented pursuant to Article 3, Sections 10640 through 10645 of the Urban Water Management Planning Act; and
4. The Water Shortage Contingency Plan includes stages of action that can be taken in response to water supply shortages, including up to a 50 percent reduction in water supply, a driest three-year water supply scenario, mandatory water use prohibitions, and penalties for non-compliance; and
5. The Water Shortage Contingency Plan identifies both short-term and long-term actions to maximize water use efficiency and minimize the effects of the current water shortage as well as future water supply shortages.

BE IT FURTHER RESOLVED that this Board has adopted the Water Shortage Contingency Plan as incorporated in the Urban Water Management Plan, and declares the provisions of the Water Shortage Contingency Plan in full force and effect during the duration of this period of water shortage.

I HEREBY CERTIFY that the foregoing is a full, true, and correct copy of the resolution adopted by the Board of Water and Power Commissioners of the City of Los Angeles at its meeting held

11.3.9 Methodology to Determine Actual Water Use Reductions during Shortages – 10632 (i)

Water use is monitored closely by LADWP throughout its service area regardless of the supply conditions. With 100 percent of its over 700,000 service connections metered, there is a high degree of accountability on the quantity of water used within the Los Angeles service area. Information from meter reads is collected for billing and accounting purposes, with reports prepared on a monthly basis from the data compiled.

LADWP also used a conservation model to estimate conservation efforts within the City since the early 1990s. The model estimated City water demand without conservation efforts using population and weather variables. A new conservation model was developed in 2010 to account for additional factors such as economic recession and drought conservation is discussed in Chapter 2, Water Demand. The conservation effort is derived by comparing estimated pre-conservation demand with actual demand. Conservation efforts derived from this model are shown in Chapter 3, Water Conservation.

AR0071018

11.4 Water Supply Assessments

Background

In 1994, the California Legislature enacted Water Code section 10910 (Senate Bill 901), which requires cities and counties, as part of the California Environmental Quality Act (CEQA) review, to request the applicable public water system to assess whether the system's projected water supplies were sufficient to meet a proposed development's anticipated water demand. The intent was to link the land use and water supply planning processes to ensure that developers and water supply agencies communicate early in the planning process. However, a study of projects approved by local planning agencies revealed that numerous projects were exempted due to loopholes in the statute, and that the intent of the legislation has largely gone unfulfilled.

Subsequently, California Senate Bill (SB) 610 and SB 221, modeled after SB 901, amended State law effective January 1, 2002, to ensure that the original intent of the legislation is fulfilled. SB 610 and 221 are companion measures which seek to promote more collaborative planning between local water suppliers and cities and counties. These bills improve the link between information on water supply availability and certain land use decisions made by cities and counties. Both statutes require detailed information regarding water availability to be provided to the city and county decision-makers prior to approval of specified large development projects. Both statutes also require this detailed information be included in the administrative record that serves as the evidentiary basis for an approval action by the city or county on such projects. Both measures recognize local control and decision making regarding the availability of water for projects and the approval of projects.

Under SB 610 a water supply assessment (WSA) must be furnished to local governments for inclusion in any environmental documentation for certain development projects subject to the CEQA. Specifically, SB 610 requires that for certain projects, the CEQA lead agency must identify any public water system that may supply water to the proposed project and request the public water system to determine the water demand associated with the project and whether such demand was included as part of the most recently adopted UWMP. If the projected water demand associated with the proposed project was accounted for in the most recently adopted UWMP, the public water system may incorporate the supporting information from the UWMP in preparing the elements of the assessment. If the proposed project's water demand was not accounted for in the most recently adopted UWMP, the WSA for the project shall include a discussion with regard to whether the public water system's total projected water supplies available in normal, single dry, and multiple dry water years during a 20-year projection will meet the proposed project's water demand.

Per Section 10912 of the California Water Code, a project which is subject to the requirements of SB 610 includes: (1) a proposed residential development of more than 500 dwelling units; (2) a proposed shopping center or business establishment employing more than 1,000 persons or having more than 500,000 square feet of floor space; (3) a proposed commercial office building employing more than 1,000 persons or having more than 250,000 square feet of floor space; (4) a proposed hotel or motel, or both, having more than 500 rooms; (5) a proposed industrial, manufacturing, or processing plant, or industrial park planned to house more than 1,000 persons, occupying more than 40 acres of land, or having more than 650,000 square feet of floor area; (6) a mixed-use project that includes one or more of the projects specified in this subdivision; or (7) a project that would demand an amount of water equivalent to, or greater than, the amount of water required by a 500 dwelling unit project.

The assessment would include an identification of existing water supply entitlements, water rights, or water service contracts relevant to the identified water supply for the proposed project and water received in prior years pursuant to those

AR0071019

entitlements, rights, and contracts. If the assessment concludes that water supplies will be insufficient, plans for acquiring additional water supplies would need to be presented.

Under SB 221, approval by a city or county of certain developments requires an affirmative written verification of sufficient water supply; which is a "fail safe" mechanism to ensure collaboration on finding the needed water supplies to serve a new large development occurs before construction begins.

Methodology

During the years from 2005 to 2010, LADWP has been requested to develop over 40 WSAs. Each WSA performed by LADWP is carefully evaluated within the context of the current adopted UWMP and current conditions, such as restrictions on State Water Project (SWP) pumping from the Sacramento-San Joaquin Delta imposed by a Federal Court. The Metropolitan Water District of Southern California (MWD), from whom the City purchases its State Water Project and Colorado River water supplies, has also been actively developing plans and making efforts to provide additional water supply reliability for the entire Southern California region. LADWP coordinates closely with MWD to ensure implementation of MWD's water resource development plans and supplemental water reliability report prepared by MWD.

LADWP's UWMP uses a service area-wide method in developing City water demand projections. This methodology does not rely on individual development demands to determine area-wide growth. Rather, the growth in water use for the entire service area was considered in developing long-term water projections for the City to the Year 2035. The driving factors for this growth are demographics, weather, and conservation. LADWP used anticipated growth in the various customer class sectors as provided by MWD who reallocated projected demographic data from the Southern California Association of Governments (SCAG) into member agencies' service areas. The data used was based on SCAG's 2008 Regional Transportation Plan Forecast.

As governed by City Charter Sections 673 and 677, LADWP can serve surplus water supplies to areas outside of the City boundaries. There are approximately 4,500 services for customers outside of the City, with a combined annual water use less than 1 percent of all water delivered. Water served outside of the City includes a surcharge to account for the increased MWD purchased water.

The water demand forecast model in the UWMP was developed using LADWP total water use, including the water served by LADWP for use outside of the City. The service area reliability assessment was performed for three hydrologic conditions: average year, single dry year, and multiple-dry years; and a Shortage Contingency Plan was developed to provide for a sufficient and continuous supply in LADWP's service area. This Shortage Contingency Plan included water provided for use outside of the City.

An important part of the water planning process is for LADWP to work collaboratively with MWD to ensure that anticipated water demands are incorporated into MWD's long-term water resources development plan and water supply allocation plan. The City's allotment of MWD water supplies under MWD's water supply allocation plan is based on the City's total water demand which includes services to areas outside the City. The ongoing collaboration between LADWP and MWD is critical in ensuring that the City's anticipated water demands are incorporated into the development of MWD's long-term Integrated Resources Plan (IRP). MWD's IRP directs a continuous regional effort to develop regional water resources involving all of MWD's member agencies. Successful implementation of MWD's IRP has resulted in reliable supplemental water supplies for the City from MWD.

AR0071020

In summary, the WSAs are performed to ensure that adequate water supplies would be available to meet the estimated water demands of the proposed developments during normal, single-dry, and multiple-dry water years, as well as existing and planned future uses of the City's water system. LADWP will continue to perform WSAs as part of its long-term water supply planning efforts for its service area.

WSA Procedure

The CEQA lead agency, such as the Department of City Planning or the Community Redevelopment Agency of the City of Los Angeles, evaluates the proposed project against the requirements for a WSA in accordance with the Water Code. If the proposed project falls within the requirements for a WSA, a formal request is submitted to LADWP to perform a WSA.

In evaluating the proposed project's water demand, LADWP applies the Sewer Generation Factors (published by City of Los Angeles Bureau of Sanitation) to the development's project description for calculating indoor water use. Outdoor landscape water demand is calculated by using computer software which takes into account various factors such as landscape area square footage, location, and plant types. Historical billing records are used to establish existing baseline water demand on the property.

LADWP also encourages all projects to implement additional water conservation measures above and beyond the current water conservation ordinance requirements. As an example, if the proposed development is near an existing or future recycled water pipeline system, commitment to use recycled water for irrigation, toilet flushing and cooling towers is highly recommended as part of the additional conservation measures for the proposed development.

The net increase/decrease in water demand, which is the projected additional water demand of the development, is calculated by subtracting the existing baseline water demand and water saving amount from the total proposed water demand.

The net increase/decrease in water demand, which is the projected additional water demand of the development, is calculated by subtracting the existing baseline water demand and water saving amount from the total proposed water demand. If the land use of the proposed development is consistent with the City's General Plan, the projected water demand of the development is considered to be accounted for in the most recently adopted UWMP. The City incorporates the projected demographic data from the SCAG in its General Plan. MWD utilizes a land use based planning tool that allocates SCAG's projected demographic data into water service areas for their member agencies, which was adopted for water demand projection in the UWMP.

If the proposed land use is not consistent with the City's General Plan, the WSA will further evaluate if the projected supplies from the UWMP are able to accommodate the proposed project's water demand, which may include other resource options to offset the projected water demand.

All WSAs are subject to approval by the Board of Water and Power Commissioners. Upon approval, the lead agency is responsible for enforcing the requirements of the WSA as part of the approval for the project.

AR0071021

DRAFT Chapter Twelve
Climate Change

12.0 Overview

LADWP is considering impacts of climate change during development of its long-term water supply plan. Climate change is a global-scale concern, but is particularly important in the western United States where potential impacts on water resources can be significant to supplies for water agencies. Climate change can impact surface supplies from the LAA, imported supplies from MWD, and local demands. As a result, LADWP is completing a study to analyze the operational and water supply impacts of potential shifts in the timing and quantity of runoff along the LAA system due to climate change. Such potential shifts may require LADWP to develop, enhance, and modify management of local water resources. Projected changes in climate are expected to alter hydrologic patterns in the Eastern Sierra through changes in precipitation, snowmelt, relative ratios of rain and snow, winter storm patterns, and evapotranspiration.

To understand some of the key issues surrounding climate change impacts, it is important to put it into the context of LADWP's water supplies. California lies within multiple climate zones. Therefore, each region will experience unique impacts to climate change. Because LADWP relies on both local and imported water sources, it is necessary to consider the potential impacts climate change could have on the local watershed as well as the western and eastern Sierra Nevada watersheds where a portion of MWD's imported water originates and LADWP's imported LAA supplies originate, respectively, and the Colorado River Basin where the remainder of MWD's imported supplies originate.

Generally speaking, any water supplies that are dependent on natural hydrology are vulnerable to climate change, especially if the water source originates from mountain snow pack. For LADWP, the most vulnerable water sources subject to climate change impacts are imported water supplies from MWD and the LAA. However, local sources can expect to see some changes in the future as well. In addition to water supply impacts, changes in local temperature and precipitation are expected to alter water demand patterns. However, there is still general uncertainty within the scientific community regarding the potential impacts of climate change for the City of Los Angeles. LADWP will continue to stay abreast of developments in climate change to better understand its potential implications to the City's water supplies.

12.1 Potential Impacts of Climate Change on Water Service Reliability

Scientists predict future climate change scenarios using highly complex computer global climate models (GCMs) to simulate climate systems. Although most of the scientific community agrees that climate change is occurring and, as a result, mean temperatures for the planet will increase, the specific degree of this temperature increase cannot be accurately predicted. Predictions of changes in precipitation are even more speculative, with some scenarios showing precipitation increasing in the future and others showing the opposite.

It is important to acknowledge that the predictions of the GCMs lack the desired precision due to the presence of uncertainties inherent in the analyses. The uncertainty to future emissions of greenhouse gases and the chaotic nature of the climate system leads to uncertain response of the global climate system to the increases in greenhouse gases. In addition, the science of climate change still lacks the complete understanding of regional manifestations that will result from global changes, thus restraining the projecting capacity of these models. However, these projections are consistent with the state of science today, and they help predict the manner of which hydrologic variables are likely to respond to a range of possible future climate conditions, and thus provide invaluable insight to water managers in their decisions pertaining to water supply reliability.

AR0071022

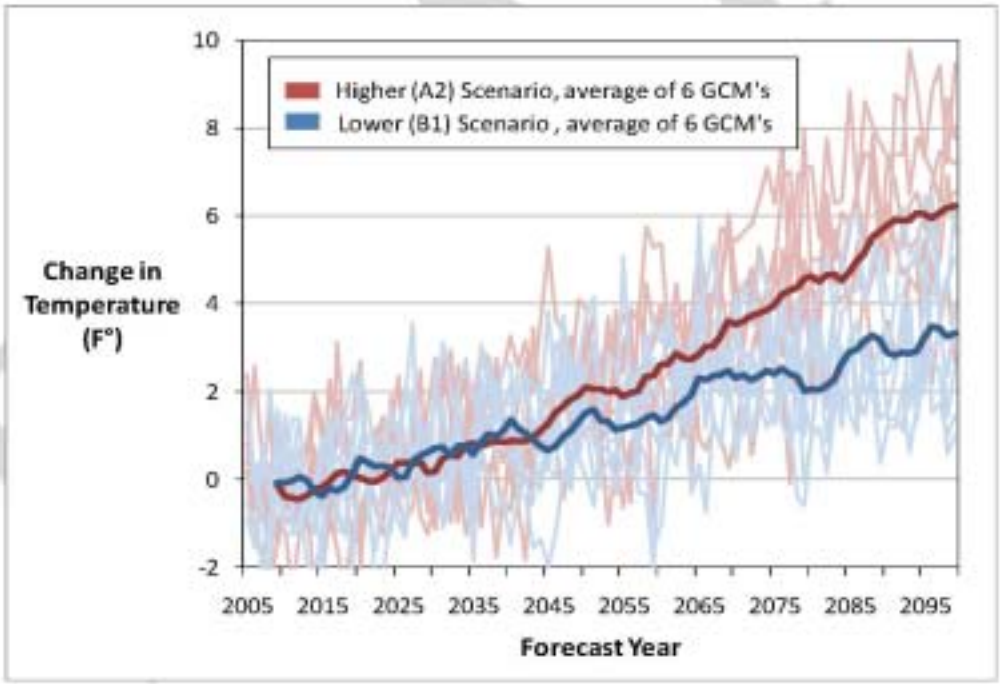
The regional areas of interest in assessing climate change impacts to LADWP include the local service area and sources of origination for imported water supplies in northern California, eastern Sierra Nevada Mountains, and the Colorado River Basin. Data regarding climate change impacts for the various regions of interest is provided in this section.

12.1.1 Local Impacts

Most scientific experts believe that because of the uncertainty involved with each model, several models should be used to test the potential impact of climate change. To downsize the global coarse-scale climate projections to a regional level incorporating local weather and topography, the GCMs are "downscaled". Future projections of precipitation and temperature were obtained for six GCMs under two greenhouse gas emission scenarios (A2 - higher and B1 - lower) for Los Angeles County.[1,2] Exhibits 12A and 12B plot the changes in projected average annual mean temperature and precipitation, respectively for the model scenarios. The bold line represents the running average of all six models for each emission scenario. The six models were also used in the preparation of the 2008 California Climate Change Scenarios assessment.

Note Exhibits 12X and 12X are placeholders and are for illustrative purposes only of the type of data that will be presented for Los Angeles. The data in the figures represent data obtained from the Scripps Institute of Oceanography for the Pasadena area. Similar data has been requested for Los Angeles.

Exhibit 12A
Climate Change Impacts to Local Temperatures for Los Angeles (Placeholder)



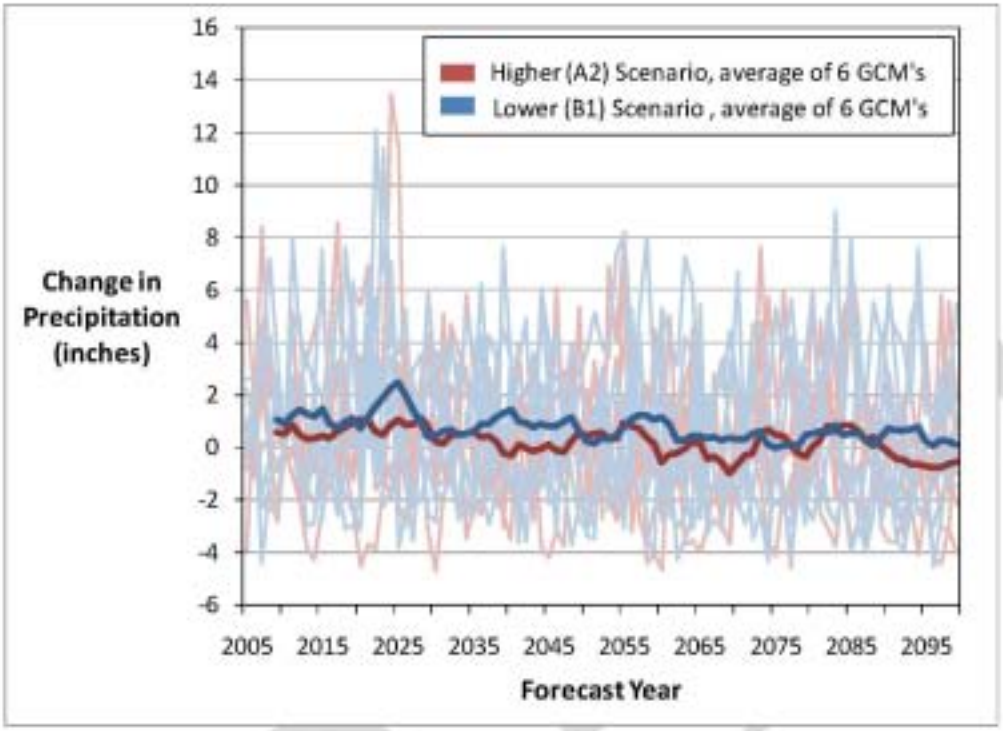
[1] Dan Cayan and Mary Tyree (University of California, San Diego, Scripps Institute of Oceanography) provided downscaled data for Pasadena under two emissions scenarios from six climate models: CNRM CM3, GFDL CM2.1, Miroc3.2 (medium resolution), MPI ECHAM5, NCAR CCSM3, NCAR PCM1.

[2] Note: These scenarios do not bracket the highest and lowest emission futures possible, but represent a status quo approach (A2) and a pro-active mitigation (B1) approach to reduce carbon emissions.

AR0071023

Exhibit 12B

Climate Change Impacts to Local Precipitation for Los Angeles (Placeholder)



Local climate changes within the vicinity of the LADWP service area are expected to include:

- An increase in average temperatures that will be more pronounced in the summer than in the winter with annual mean temperatures in 2100 increasing greater than 3°Fwhen lower greenhouse gas emission scenarios are used and may exceed 7°F when high higher emissions scenarios are used dependent upon the GCM utilized
- An increase in extreme temperatures
- An increase in heat waves and droughts that will extend for a longer duration
- A decrease in precipitation with the potential for 30 year deficits of more than 10% below historical levels that, coupled with higher temperatures, will increase evaporation/transpiration
- An increase in short-duration/high volume intense storm events during the winter

The impact of these climate effects will likely be increased water demands for irrigation and cooling purposes earlier in the year and for extended periods coupled with decreased local surface runoff available to recharge groundwater basins. Other impacts might include increased fire events that could impact water quality and sedimentation, decreased groundwater recharge due to lower soil moisture, and sea level rise increasing seawater intrusion into coastal groundwater basins.

AR0071024

12.1.2 Los Angeles Aqueduct Impacts

The LAA is one of the major imported water sources delivering a reliable water supply to the City of Los Angeles. The LAA originates approximately 340 miles away from snowmelt runoff in the eastern Sierra Nevada; hence LAA is subject to hydrologic variability associated with climate change. Since the majority of precipitation occurs during winter in the eastern Sierra Nevada watershed, water is stored in natural reservoirs in the form of snowpacks, and is gradually released into streams that feed into the LAA during spring and summer. More detailed information regarding the LAA is presented in Chapter 5, Los Angeles Aqueduct Systems.

Higher concentrations of greenhouse gases in the atmosphere are often indications of pending climate change. These changes threaten the hydrologic stability of the eastern Sierra Nevada watershed through alterations in precipitation, snowmelt, relative ratios of rain and snow, winter storm patterns, and evapotranspiration, all of which have major potential impacts on the LAA water supply and deliveries.

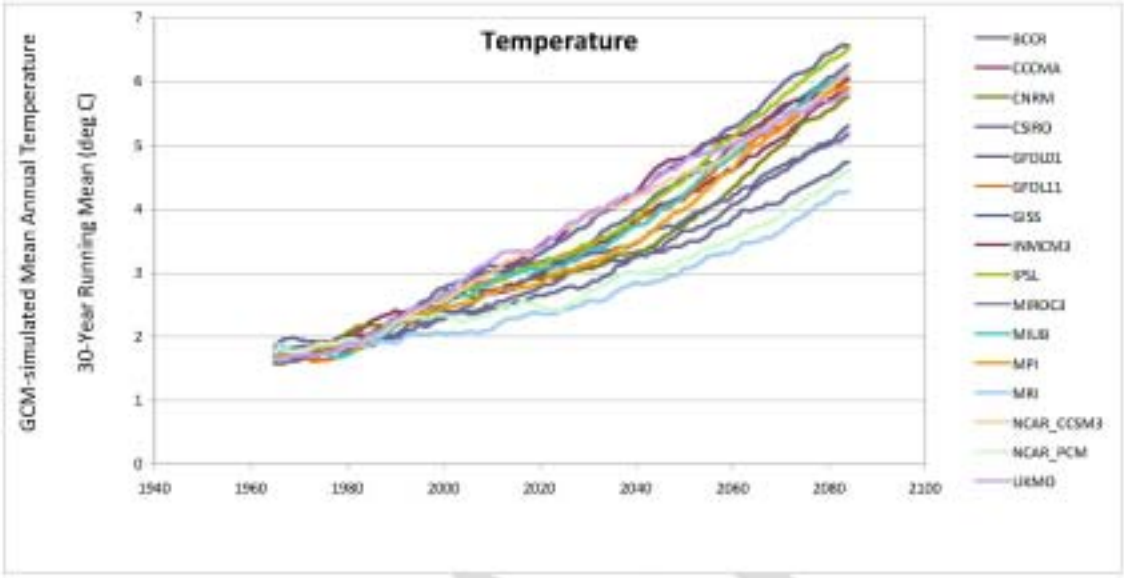
To address the possible challenges posed by climate change on the LAA, LADWP commenced a climate change study in 2009 to evaluate the potential impacts of climate change on the eastern Sierra Nevada watershed and the LAA water supply and deliveries, and investigate opportunities to improve the LAA system as a result of these impacts over the next hundred years. In this study, future climate conditions are predicted using a set of sixteen GCMs and two greenhouse gas emission scenarios.

The impacts of these climate change scenarios and the associated hydrology on the LAA's eastern Sierra Watershed includes an analysis of historical temperature, precipitation, water quality, and runoff records. Hydrologic modeling will be performed to estimate runoff changes from current conditions and an evaluation will be provided to determine their effects on the performance of the existing infrastructure with regards to storage and conveyance capacity to Los Angeles. As part of the evaluation of potential adaptation measures if existing infrastructures are inadequate, recommendations will be provided to modify the existing infrastructure and operations to accommodate these impacts.

Preliminary results of the study are showing steady temperature increases throughout the 21st century and are consistent with other prior studies performed in the scientific community. Exhibit 12C displays the time series of 30-year running means of the projected temperature of one of the greenhouse gas emission scenarios considered in the study, A2 (higher greenhouse gas emissions), averaged over the simulation area for each of the sixteen GCMs. All GCMs project temperature increases throughout the 21st century.

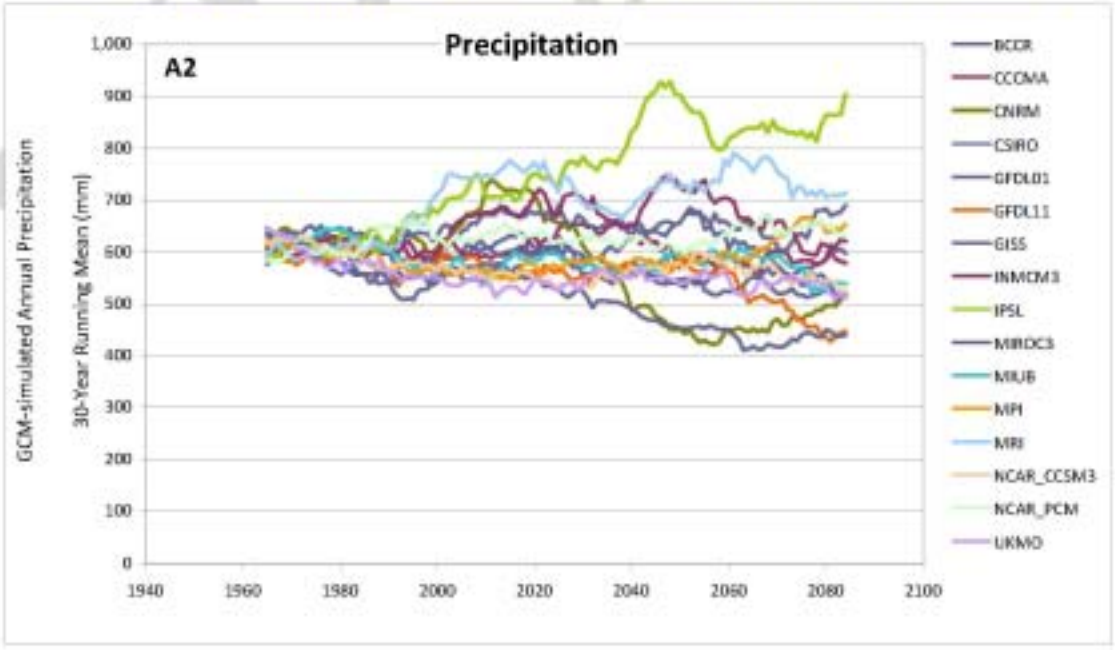
AR0071025

Exhibit 12C
30-Year Time Series Projected Temperature Means for Eastern Sierra Nevada Watershed



On the other hand, forecasts for precipitation differ greatly between the GCMs. Some GCMs are projecting increases, but the majority of the model outputs are projecting decreases in precipitation over the study period. Exhibit 12D displays the time series of 30-year running means of the projected precipitation using the A2 greenhouse gas emission scenario (higher greenhouse gas emissions) averaged over the simulation area for each of the sixteen GCM models.

Exhibit 12D
30-Year Time Series Projected Precipitation Means for Eastern Sierra Nevada Watershed



AR0071026

Temperature is the main climate variable that is projected to rise significantly in the coming years and decades. The rise in temperature directly affects several variables including:

- Whether precipitation falls as snow or rain;
- The ground-level temperature determines the timing and rate of snowmelt; and
- The temperature profile in the canopy that determines the rate of evapotranspiration.

Preliminary results have shown that future predictions for the early-21st century suggested a warming trend of 0.9 to 2.7 °F and almost no change in average precipitation. Mid-21st century projections suggested a warming trend of 3.6 to 5.4 °F and a small average decrease in precipitation, approximately 5 percent. This warming trend is expected to increase by the end of 21st century, as the results suggest further warming of 4.5 to 8.1 °F and a decrease in precipitation of approximately 10 percent. In addition, preliminary results indicate an increase in the frequency and length of droughts in the end-of-century period.

Projected changes in temperature (warmer winters) will change precipitation patterns to rain with larger fractions than historically encountered. Consequently, peak Snow Water Equivalent (SWE) and runoff are projected to undergo a shift in timing to earlier dates.

At elevations of up to about 9,800 feet, the snowpack of the eastern Sierras is susceptible to earlier melt and less accumulation with a long term-shift in mean temperature of 3.6°F, especially in the southern Sierras. On average, mean temperature rises are in the range of 3.6 to 10.8 °F resulting in about a 17 to 50 percent loss in snowpack storage, respectively. This vulnerability shows up in average to warm winters and will directly affect the stream levels and stream discharge. This raises potential concerns for LADWP in the areas of adequate storage and operations, especially the capacity of the LAA system to store the early runoff in surface reservoirs.

The projected temperature and precipitation dataset form the basis of the hydrologic model projections for runoff, snow-water equivalent (SWE), and rain-to-snow ratio. To compare the future projections of these variables, the trends that dominated the second half of the 20th century are considered baselines for future trends. The baseline values for runoff, SWE, and rain-to-snow ratio are 0.6 million acre-feet (MAF), 15 inches, and 0.2, respectively. By Early 21st century (2010 – 2039), preliminary results illustrate runoff is projected to undergo increases and decreases averaging between 0.5 to 0.85 MAF; SWE is projected to undergo decreases and increases ranging between 10.6 to 19.0 inches, and the rain-to-snow ratio is projected to increase between 0.24 to 0.33. By mid-century (2040 – 2069), the same trends are expected to dominate, with runoff ranging between 0.34 to 0.9 MAF, SWE ranging between 7.0 to 19.7 inches, and the rain-to-snow ratio increasing between 0.25 to 0.43. These trends are expected to govern until the end-of-century (2070 -2099) with runoff ranging between 0.35 to 1.1 MAF, SWE ranging between 5.0 to 16.0 inches, and rain-to-snow ratio increasing between 0.28 to 0.54. Exhibit 12E summarizes the projections for runoff, SWE, and rain-to-snow ratio for the 21st century.

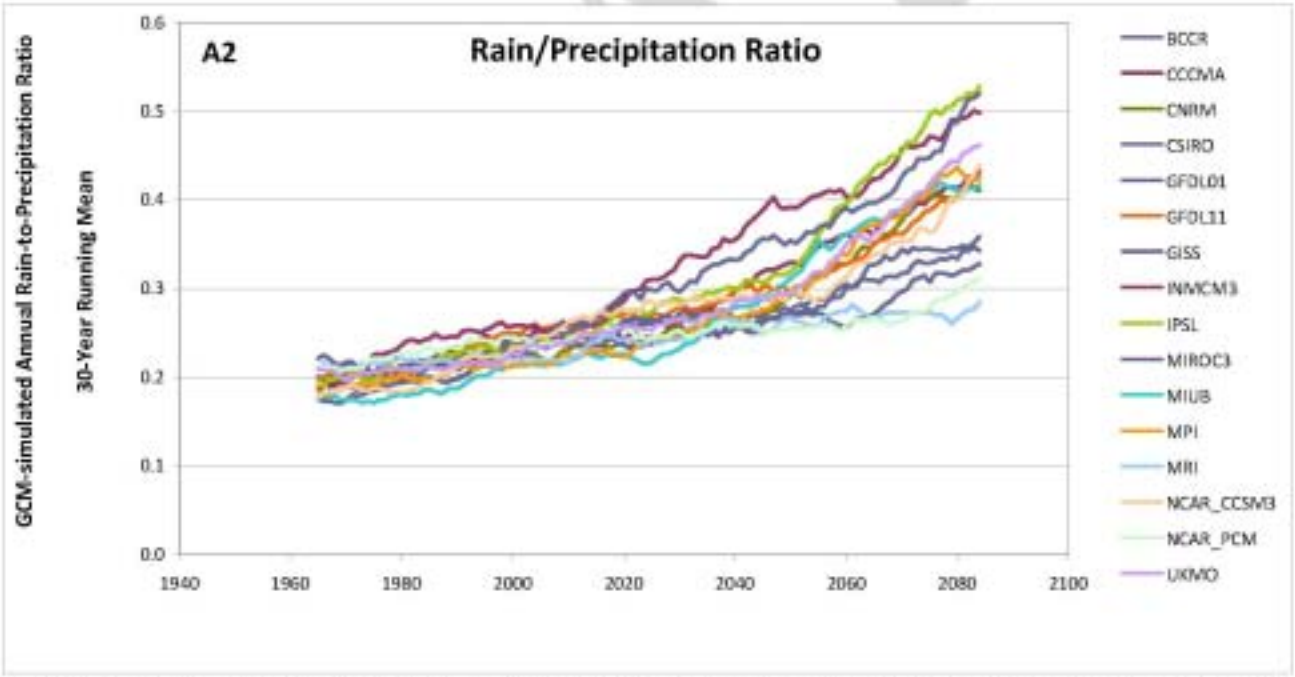
AR0071027

Exhibit 12E
Projected Runoff, Snow-Water Equivalent, and Rain-to-Snow Ratio for Eastern Sierra Nevada Watershed

	Runoff (MAF)	April 1 SWE (Inches)	Rain/Snow Ratio
Baseline (Second Half of 20th Century)	**0.6**	**15.0**	**0.2**
Early 21st-century (2010-2039)	0.5 - 0.85	10.6 - 19.0	0.24 - 0.33
Mid-century (2040-2069)	0.34 - 0.9	7.0 - 19.7	0.25 - 0.43
End-of-century (2070-2099)	0.35 – 1.1	5.0 - 16.0	0.28 - 0.54

Exhibit 12F displays the rain-to-snow ratio based on the projected precipitation and temperature for the 16 GCMs. The rain-to-snow ratio is projected to increase throughout the 21st century, ranging between 0.24 to 0.33 by early 21st century, between 0.25 to 0.43 by mid-century, and between 0.28 to 0.54 by the end-of-century.

Exhibit 12F
Projected Rain to Precipitation Ratio Based on Projected Precipitation and Temperature



The increase of rain-to-snow ratio indicates the shift from snowfall to rainfall, specifically at low to moderate elevations, where the temperature tends to be warmer. This shift indicates more precipitation as liquid, and in turn, leads to loss of the snowpack. The snowpack is critical in providing seasonal storage for water that releases winter precipitation in spring and summer to provide the soil moisture and stream flow needed to sustain both ecosystems and human populations. The climate change study work is still ongoing with remaining analyses to be performed on potential climate change impacts to existing infrastructures, water quality, and recommended adaptation measures.

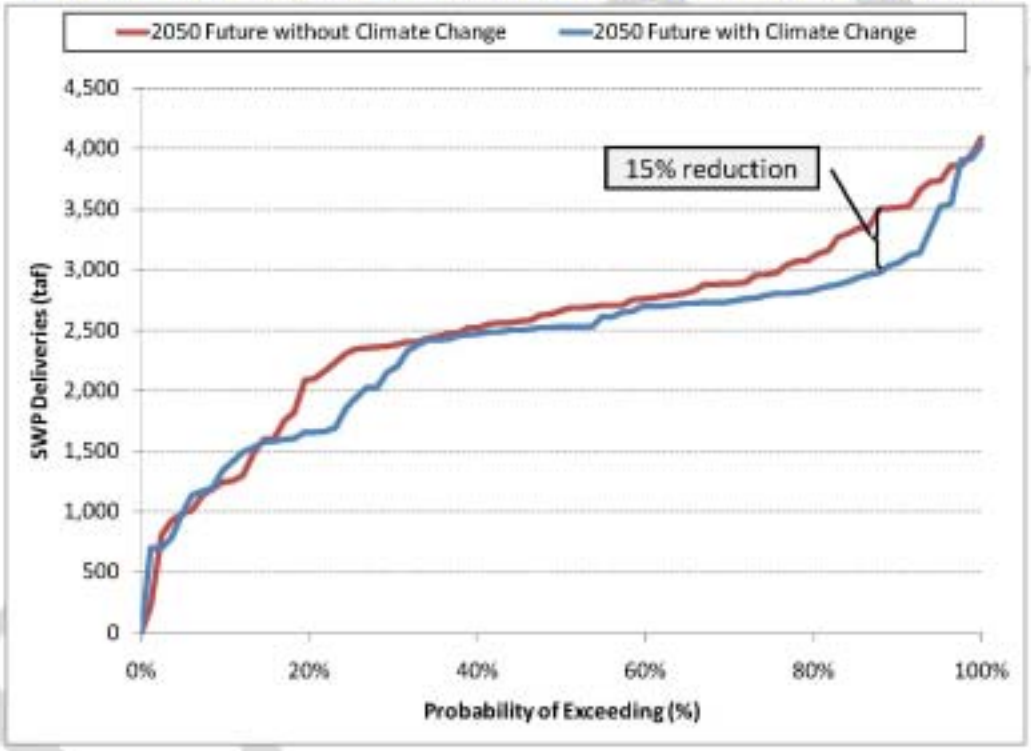
AR0071028

Although the results above are quantitative in nature, it is important to account for the uncertainties inherent in these predictions. The results of this study will help guide the water managers in planning and developing water supply and infrastructure to ensure the reliability and sustainability of adequate water supply and delivery.

12.1.3 State Water Project Impacts

To date, most studies on climate change impacts to California's water supply have been conducted for the Northern California region. In August 2010, DWR released the 2009 State Water Project Delivery Reliability Report, which specifically analyzes changes in volume of water available under various climate change scenarios. DWR projected that SWP deliveries could be reduced by as much as 15 percent in some cases as illustrated in Exhibit 12G.

Exhibit 12G
Projected Rain to Precipitation Ratio Based on Projected Precipitation and Temperature



To incorporate climate change into its reliability reports, DWR reviewed 6 GCMs for year 2050 projections using lower emission and higher emission scenarios contained in *Using Future Climate Projections to Support Water Resources Decision Making in California* prepared in April 2009 by DWR. DWR selected the model most representing median effects on the SWP, the MPI-ECHAM5 model run with a higher greenhouse gas scenario.

Climate change has the potential to disrupt SWP source supplies, impact conveyance, and alter storage levels in reservoir carryover storage. Annual Bay-Delta exports to areas south of the Delta are expected to decline 7 percent for the lower greenhouse gas emissions scenario and 10 percent for the higher emissions scenario. However, it should be noted that for the six GCMs under the lower and higher emission scenarios the range varies from a 2 percent increase to a 19 percent decrease illustrating the variability in the various GCMs.

AR0071029

By 2050, median reservoir carryover storage is projected to decline by 15 percent for the lower emissions scenario and 19 percent for the higher emissions scenario thereby reducing operational options if water shortages were to occur. Furthermore, by 2050 it is projected a water shortage worse than the 1977 drought could potentially occur in 1 out of every 6 to 8 years requiring acquisition of other supplies, reductions in water demands, or a combination. An additional 575 to 850 TAF would be needed to maintain minimum SWP operation requirements and meet regulatory requirements. The main supply reservoirs on the SWP must maintain minimum water levels to allow water to pass through their lower release outlets in the dams. However, the April 2009 report does not consider the SWP vulnerable to a system interruption such as this under current conditions.

The primary effects of climate change on the SWP identified in the 2009 Reliability Report include, among others:

- More precipitation will fall as rain than snow
- Reductions in Sierra snowpack
- Sea level rise threatening the Bay-Delta levee system
- Increased salinity in the Bay-Delta due to sea level rise requiring releases of freshwater from upstream reservoirs to maintain water quality standards
- Shifted timing of snowmelt runoff into streams – spring runoff comes earlier resulting in increased winter flows and decreased spring flows
- Increased flood events

The most severe climate impacts in California are expected to occur in the Sierra watershed, where the SWP supply originates. Therefore, imported SWP water is extremely vulnerable to climate change.

12.1.4 Colorado River Aqueduct Impacts

Although many research efforts are underway, there have not yet been any reports quantifying potential changes in supply to California from the Colorado River via the CRA. At this time, the assumption is that there would be similar patterns as the SWP impacts.

12.2 Water and Energy Nexus

It is widely believed in the scientific community that the increase in concentrations of greenhouse gases (GHG) in the atmosphere is a major contributing factor to climate change. As such, California is leading the way with laws that require reductions in greenhouse gas emissions and requirements to incorporate climate change impacts into long range water resource planning.

Carbon dioxide emissions into the atmosphere and the emissions of other GHGs are often associated with the burning of fossil fuels like crude oil and coal in the generation of energy. As a significant amount of energy is required for the movement of water over long distances and elevations, a link was subsequently realized between water supply conveyance and corresponding GHG emissions through its energy consumption. An assessment of the GHG emissions, sometimes also known as **carbon footprint expressed in units of tons CO_2, could be estimated for water.** Once the size of a carbon footprint is known, a strategy can be developed to better manage and reduce its impact on climate change.

AR0071030

LADWP has taken the initiative to study the nexus between water and energy consumption and to evaluate the associated carbon footprint of its water system. The most energy intensive source of water for LADWP is water purchased from MWD, which imports SWP supplies via the California Aqueduct and Colorado River supplies via the CRA. LADWP also imports water via the LAA, which is a net producer of energy. Local sources of water for LADWP include groundwater and recycled water. Exhibit 12H outlines the sources of LADWP's water supply as well as the energy profiles of each facility that provides water to LADWP. For those sources of water operated by LADWP, the energy intensity has been computed by dividing the total energy consumed/generated by the total water produced or processed by that source.

12.2.1 State Water Project Supplies

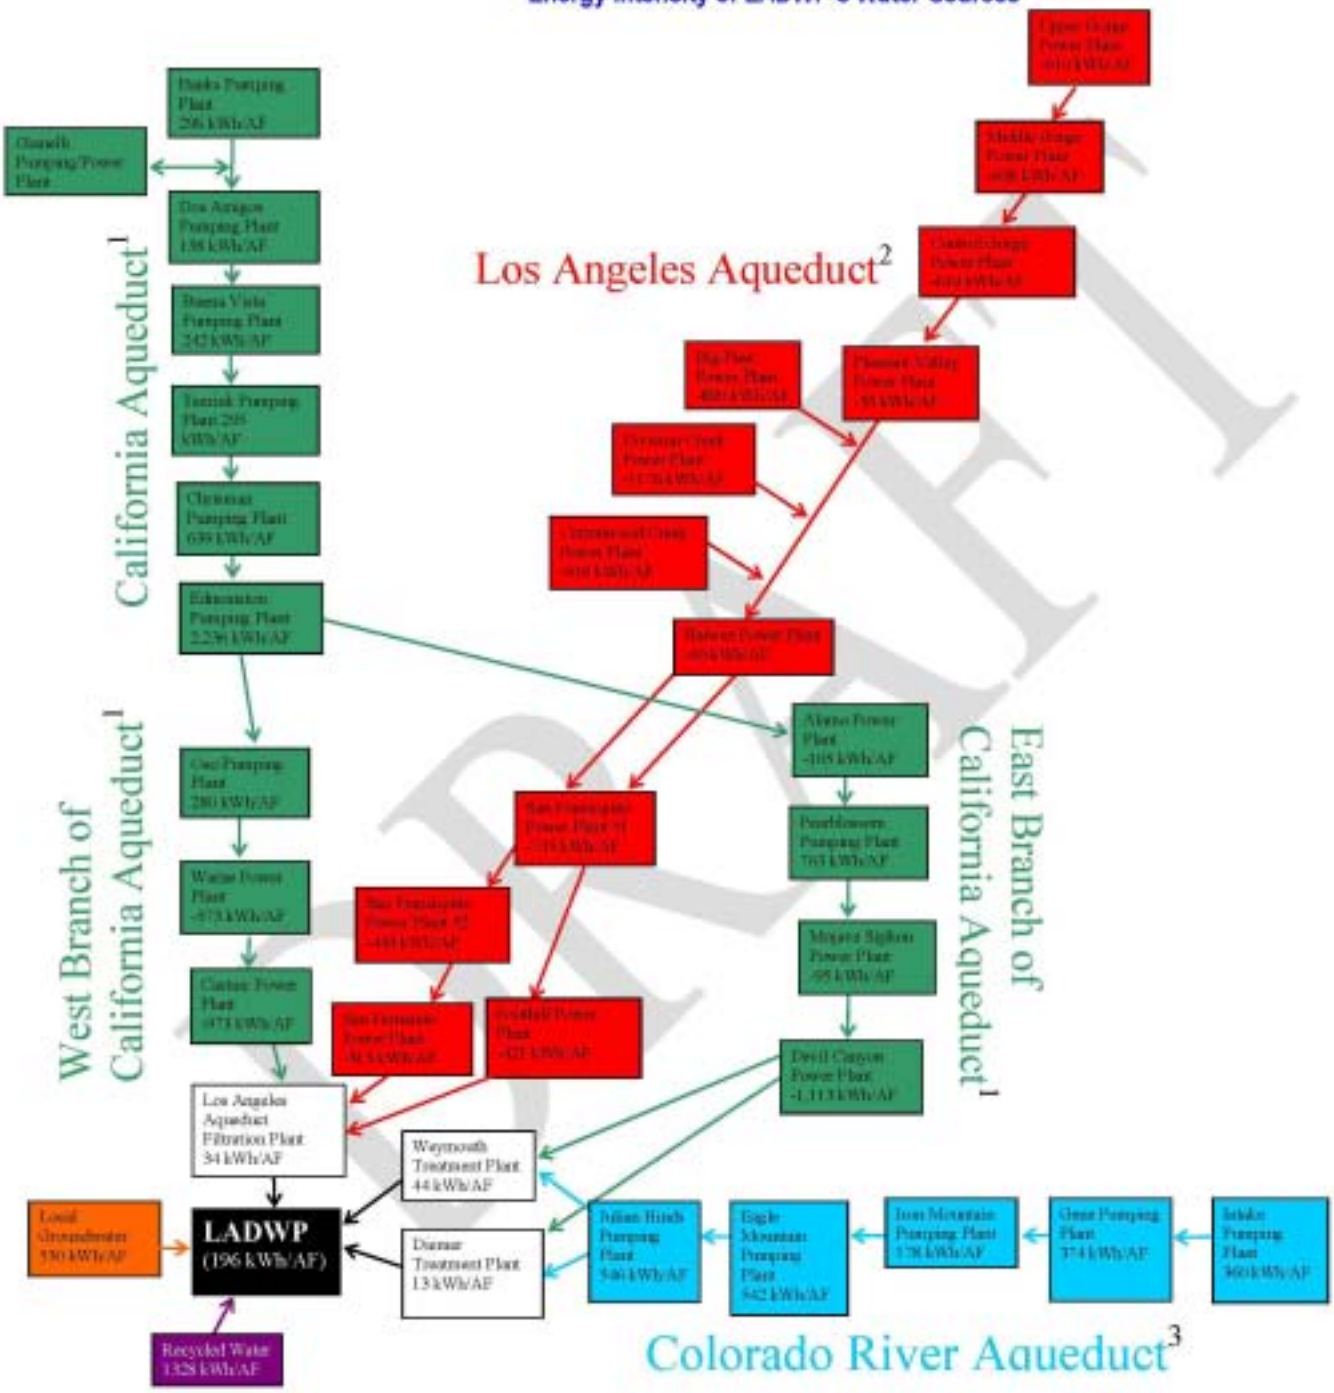
Water Supplied to Los Angeles via the SWP originates from Northern California and the Bay-Delta and is conveyed along the 444-mile long California Aqueduct to southern California. Six pump stations are required to lift the water to the point at which the California Aqueduct splits into two branches. At the zenith of the California Aqueduct in the Tehachapi Mountains, approximately 3,846 kilowatt hours per acre foot (kWh/AF) is required to lift the water from the start of the aqueduct. After the water passes through Edmonston Pumping Plant, the California Aqueduct separates into two branches, the West Branch and the East Branch. Along the West Branch, the water is lifted once more at the Oso Pumping Plant and then energy is recovered through hydro-electric generation at the Warne and Castaic Power Plants. By the time the West Branch reaches its terminus at Lake Castaic, the net energy consumed in transporting the water from the Bay-Delta is approximately 2,580 kWh/AF. Water supplied through the West Branch is provided to the San Fernando Valley, Western Los Angeles, and Central Los Angeles communities.

Along the East Branch, the water generates power at the Alamo Power Plant, is lifted once more at Pearblossom Pumping Plant, and then used for generation at Mojave Siphon and Devil Canyon Power Plants. At the East Branch terminus at Lake Perris, approximately 3,236 kWh/AF of energy has been expended in the transport. Water conveyed through the East Branch is provided to the Eastern Los Angeles and Harbor communities. The water supplied from the SWP is the most energy intensive source of water available to LADWP.

DRAFT

AR0071031

Exhibit 12H
Energy Intensity of LADWP's Water Sources



1. Source: *Methodology for Analysis of the Energy Intensity of California's Water Systems*, p. 27.
2. Generation on the Los Angeles Aqueduct is not considered in LADWP's total energy intensity.
3. Energy intensities for the Colorado River Aqueduct pumping stations were derived by multiplying the total energy intensity for the aqueduct by the proportion of load for each individual pumping station in relation to the total load for all five pump stations.
4. Positive numbers indicate power consumption due to pumping and negative numbers indicate power generation.

AR0071032

12.2.2 Colorado River Aqueduct Supplies

Water supplied from the Colorado River is imported via the 242 mile CRA operated by MWD. From the start of the aqueduct at Lake Havasu to its terminus at Lake Mathews, the water is lifted approximately 1,617 feet. Five pumping stations along the aqueduct lift the water to MWD's service area requiring approximately 2,000 kWh/AF. CRA water is the second most energy intensive water source for Los Angeles and is supplied to the eastern Los Angeles and Harbor communities. Together SWP water and CRA water comprise the total imported provided by MWD to LADWP. MWD imported water is the most expensive water source for LADWP in terms of both cost and energy.

12.2.3 Los Angeles Aqueduct Supplies

The LAA provides water from the Eastern Sierra watershed and is entirely gravity fed. As a result, no energy is required to import LAA water, making it the most desirable source of water in terms of energy intensity. There are twelve power generation facilities along the aqueduct system. On average, the LAA generates approximately 6,848 kWh/AF from water directly used to generate power. This number was determined using the same methodology as was used to determine the energy intensity for the two branches of the SWP. The individual energy intensities for each individual generating facility were summed up to arrive at the total energy intensity for the water used to generate power. However, when considered from the perspective of total amount of water delivered to Los Angeles via the LAA, the energy generated along the aqueduct is approximately 2,456 kWh/AF. The variance between the numbers can be attributed to the fact that not all water wheeled through the aqueduct is used to generate power and the fact that a portion of the water is introduced into the aqueduct system at a point downstream of several of the power plants. For the purposes of determining LADWP's total energy intensity, the energy intensity of the LAA is considered to be zero since the power generated does not directly offset the energy required for other sources of water. However, in terms of supply the LAA is able to offset the more energy intensive sources of water, consequently reducing the overall energy intensity of LADWP's water supplies. As LAA flows to Los Angeles are decreased due to environmental enhancement efforts in the Owens Valley and Mono Basin, LADWP is forced to increasingly rely on energy intensive water purchased from MWD. LAA water currently supplies approximately 37 percent of the demand for Los Angeles.

12.2.4 Local Groundwater Supplies

Groundwater currently accounts for approximately 11 percent of LADWP's water supply and has an average energy intensity of approximately 530 kWh/AF. As LADWP continues with its cleanup of the contaminated water in the San Fernando Basin, groundwater will play an increasingly important role in Los Angeles' water supply. Although there is potential for a future increase in the energy required to produce groundwater due to the introduction of new treatment technologies, groundwater is expected to remain a low energy source of water when compared to imported supplies purchased from MWD. Increasing groundwater production will allow LADWP to offset the energy intensive MWD sources and reduce its overall energy intensity..

12.2.5 Recycled Water Supplies

Recycled water is currently the smallest component of LADWP's water supply portfolio, with municipal and industrial uses accounting for less than 1-percent of total supplies. Currently, LADWP directly receives recycled water from three wastewater treatment plants operated by Bureau of Sanitation (BOS), two of which provide recycled water treated to a tertiary level: LAG and DCT. The TITP performs advanced treatment of recycled water in addition to tertiary treatment. LADWP also directly receives a small portion of recycled water from the West Basin Municipal Water District (WBMWD), which provides additional treatment of wastewater from the Hyperion Treatment Plant (HTP) in El Segundo. Since all water at the plants directly supplying recycled water to LADWP is treated to at least a tertiary level regardless of disposal or reuse, the energy cost to

AR0071033

treat the water to this level is considered a sunk cost because the water would be treated whether it offsets potable use or not. The advanced treatment process at the Terminal Island Treatment Plant (TITP) is beyond the requirements for discharge and is therefore not considered a sunk cost. The incremental energy required to treat water from tertiary levels to advanced treatment levels at TITP requires approximately 2,200 kWh/AF. Since the treatment energy at the other two plants is not considered additional energy, only the pumping energy is included in the overall LADWP recycled water energy intensity. For the Los Angeles Glendale (LAG) Treatment Plant, the pumping requires approximately 690 kWh/AF, and for the Donald C. Tillman (DCT) Treatment Plant, the pumping requires approximately 450 kWh/AF. A weighted average of these values gives recycled water an energy intensity of approximately 1,139 kWh/AF. In the future this number will likely change as the recycled water infrastructure is expanded. In addition to the municipal and industrial recycled water that is considered in LADWP's total supplies, the plants produce significant additional volumes of recycled water that is beneficially used. Beneficial uses include the seawater barrier for the Dominquez Gap using recycled water from TITP and the Japanese Garden and Los Angeles River from DCT.

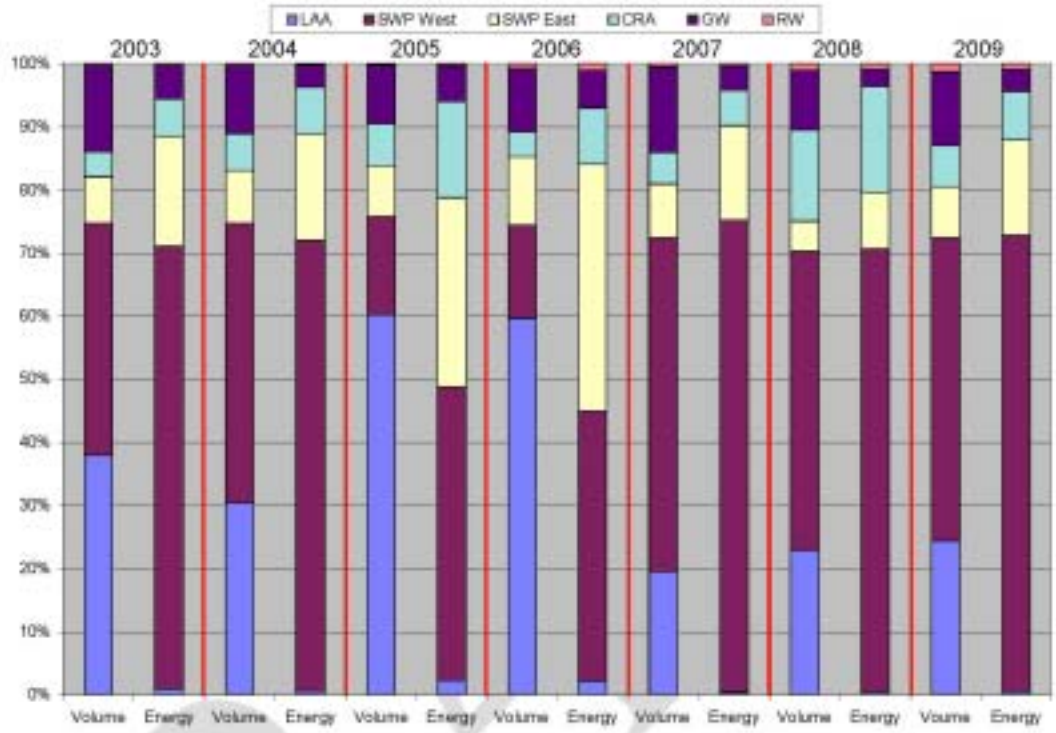
12.2.6 Treatment Energy

Another factor in determining the energy intensity of LADWP's water is the energy required to treat water. All LAA water and nearly all West Branch SWP water purchased by LADWP are treated at the Los Angeles Aqueduct Filtration Plant (LAAFP). For the LAAFP, the average treatment energy intensity is approximately 34 kWh/AF. The East Branch SWP water and the CRA water are primarily treated at the Weymouth Treatment Plant in the San Gabriel Valley and the Diemer Treatment Plant in Orange County. Both of these treatment plants are operated by MWD. The average energy intensity for Weymouth Treatment Plant is approximately 42 kWh/AF and supplies water to the East Los Angeles Community. The average energy intensity for the Diemer Treatment Plant is 13 kWh/AF and supplies water to the Harbor Community. The mix of SWP East Branch water and CRA water that flows through these two treatment plants varies depending on the regional hydrology of the two sources, but on average approximately 55 percent SWP East Branch water and 45 percent CRA water flows through each of these MWD treatment plants.

The proportion that each of the above mentioned sources contributes to the LADWP's total supplies is displayed below in Exhibit 12I. Of note is the relationship that the volume of LAA flow has to the amount of SWP water imported into the system. In this case, the energy free LAA water is replaced by the energy intensive SWP water resulting in an increase in the overall energy intensity.

AR0071034

Exhibit 12I
Proportion of Volume Delivered and Total Energy Intensity (Inclusive of Treatment)



12.2.7 Distribution Energy

LADWP benefits from the topography of its service area in that much of the hydraulic head required for water distribution is provided by gravity. With the major sources of LADWP's water entering the service area at higher elevation than the rest of the City, the energy required for distribution is lower than much of the region. The average energy intensity for LADWP water distribution is approximately 196 kWh/AF.

Exhibit 12J shows the sum of the energy intensities for LADWP from each of the individual sources between 2003 and 2009. Exhibit 12K shows a graphical representation of the total energy intensity for LADWP for the same time period. An important detail is the influence that LAA water has on the total energy intensity for a given year. For those years with large volumes of LAA water, such as 2005 and 2006, the total energy intensity was correspondingly low. Alternatively, those years with low volumes of LAA water have high total energy intensity as a result of the energy requirements for imported MWD supplies

AR0071035

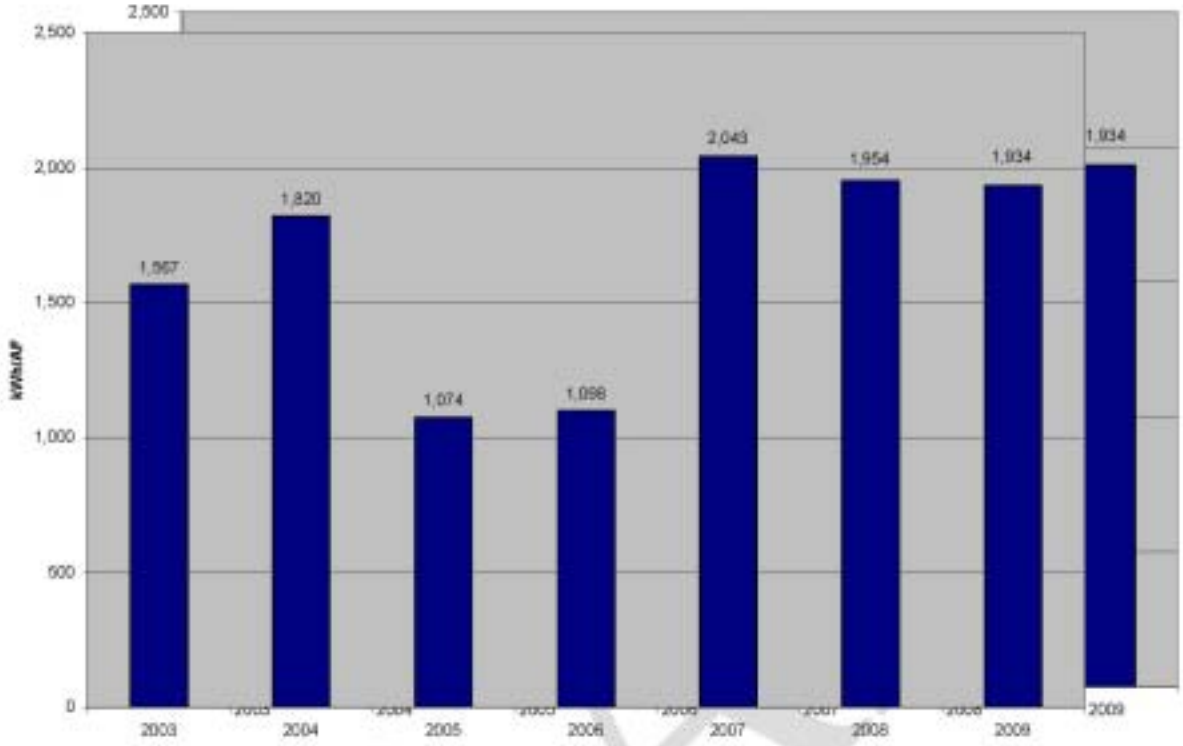
1. Los Angeles Aqueduct and State Water Project West Branch supplies are treated at the Los Angeles Aqueduct Filtration Plant
2. Colorado River Aqueduct and State Water Project East Branch supplies are treated at Weymouth and Diemer Filtration Plants operated by Metropolitan Water District of Southern California. The listed energy intensity is based on an average of the energy intensity for the two plants.
3. Amount of SWP water and CRA water delivered is based on the reported average ratio of the two sources in Weymouth Treatment Plant and Diemer Treatment Plant effluent from MWD annual Water Quality Report
4. Recycled water volume is based on use for municipal and industrial uses, not all beneficial uses. Energy intensity is a weighted average of energy used for pumping to customers and the incremental energy to treat from tertiary to advanced treatment.

AR0071036

Exhibit 12K
LADWP Annual Energy Intensity



12.2.8 Carbon Footprint

All of LADWP's water supply sources have an associated carbon footprint related to the energy required to pump the water. Exhibit 12L provides the annual carbon footprint by water source. Exhibit 12M shows a graphical representation of the total annual carbon footprint for the same time period. For imported sources, the 2007 CAMX California average carbon emission of 0.72412 lbs CO2/kWh was used to estimate the amount of carbon emissions produced per acre-foot of water imported. For local sources the CO2 metric reported to the California Climate Action Registry in 2007 was used to estimate the carbon emissions released in the production of this water. LAA is a net producer of energy and produces only green hydropower. There are no carbon emissions associated with water imported through the LAA.

AR0071037

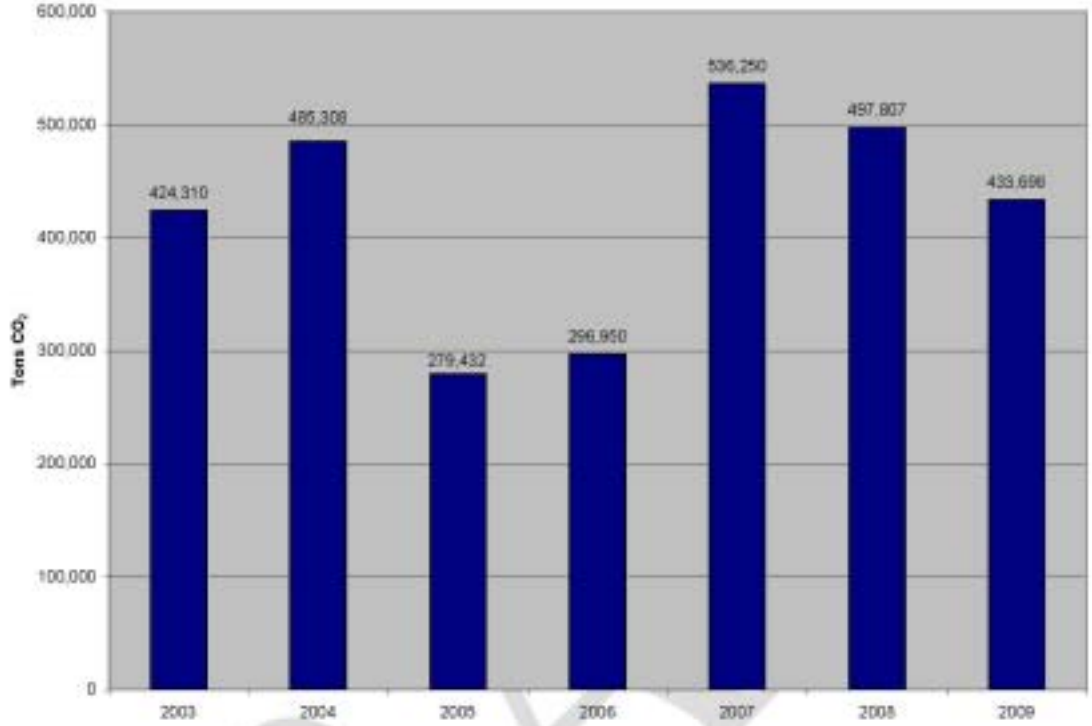
1. Amount of SWP water and CRA water delivered is based on average of the proportion of the two sources delivered to MWD Weymouth Treatment Plant and Diemer Treatment Plant for the calendar year

2. Based on 2007 CO_2 metric of 1.22789 lbs CO_2/kWh reported to the California Climate Action Registry

3. Based on eGRID 2007 CAMX (California Average) of 0.72412 lbs CO_2/kWh

AR0071038

Exhibit 12M
Total Annual Carbon Footprint for Water Supply Portfolio



As Los Angeles increases its reliance on energy intensive imported supplies from MWD, its overall energy intensity will increase. Reductions in LAA flows due to environmental mitigation have the consequence of increasing Los Angeles' reliance on supplies imported through the SWP via the California Aqueduct, and Colorado River through the CRA.

12.3 Climate Change Adaption and Mitigation

Climate change strategies fall under two main categories: adaptation and mitigation. For water resources planning, a climate change adaptation strategy involves taking steps to effectively manage the impacts of climate change by making water demands more efficient and relying on supply sources that are less vulnerable to climate change. A mitigation strategy involves proactive measures that reduce greenhouse gas emissions, such as placing a stronger emphasis on using water resources requiring less greenhouse gas emissions. Both LADWP and its wholesale supplier for imported water, MWD, are implementing adaption and mitigation strategies as they become aware of potential climate change impacts.

It is imperative that supply options are carefully vetted and evaluated against both adaptation and mitigation goals, as they may conflict and work against each other. For example, desalination is a typical supply option that performs quite well in adapting to climate change impacts; however, due to the energy necessary to draw from and manage the supply source, it could result in higher greenhouse gas emissions if conventional energy sources are utilized.

12.3.1 LADWP Adaption and Mitigation

In the 2008 City of Los Angeles Water Supply Action Plan, LADWP and the City have outlined strategies to dramatically increase conservation and water recycling. Increasing conservation and water recycling encompasses both adaption and mitigation goals to address climate change. The Plan calls for reducing potable demands by an additional 50,000 AFY through

AR0071039

conservation by fiscal year 2030 and 50,000 AFY through recycled water use. Additional adaption strategies under investigation by LADWP and the City includes beneficial reuse of stormwater as discussed in Chapters Seven and Nine, Watershed Management and Other Potential Water Supplies, respectively.

Conservation has a double savings in terms of energy intensity because not only does it save energy in importing or producing the water, but it also saves energy through reduction of end use, such as heating water for a shower or for a dishwasher and wastewater treatment. The anticipated conservation savings will not only help to provide Los Angeles a secure and dependable water supply, but it will also reduce the energy footprint of the water supply, and consequently the carbon footprint. A further discussion regarding conservation is provided in Chapter Three, Conservation.

Recycled water use reduces reliance on potable water imported through MWD and provides a year round drought resistant water supply source. While the energy consumption requirements to produce recycled water are greater than local and LAA supply sources, recycled water assists LADWP in bolstering its supply portfolio to address potential supply changes related to climate change. A further discussion regarding recycled water is provided in Chapter 4, Recycled Water.

The climate change study work for the LAA is still ongoing with remaining analyses to be performed on potential climate change impacts to existing infrastructures, water quality, and recommended adaptation measures. Hydraulic models will be performed to determine impacts to the LAA conveyance capacity. Adaptation measures may include upgrades to treatment processes in order to address degradation in water runoff quality, and/or changes in operational procedures to address shifts in runoff timing and quantity.

There is still general uncertainty within the scientific community regarding the potential impacts of climate change for the City of Los Angeles. LADWP will continue to stay abreast of developments in climate change to better understand its potential implications to the City's water supplies to assist in further developing adaption and mitigation strategies.

12.3.2 MWD Adaption and Mitigation

MWD is taking an active approach to adapt and mitigate against climate changes in its operations. Adaption and mitigation measures include:

- Investments in local resources to diversify MWD's water supply portfolio
- Tracking climate change legislation – MWD provides input and direction on legislation
- Collaborating on climate change with state, federal, and non-governmental agencies
- Monitoring state and local climate change actions
- Investigating the water supply and energy nexus
- Coordinating with large water retailers
- Integrating climate change into integrated resource planning as discussed in Chapter 10, Integrated Resource Planning

AR0071040

- Sharing climate change knowledge and providing support – founding member of Water Utility Climate Alliance,
- Adopting energy management policies to support cost-effective and environmentally responsible programs, projects, and initiative

MWD has also taken structural adaption measures including construction of the Inland Feeder. The Inland Feeder completed in 2009 connects SWP supplies with MWD's CRA supplies and allows delivery of SWP supplies to MWD's major reservoir, Diamond Valley Lake. In relation to climate change, the project will increase conveyance capacity allowing more rain to be conveyed as projected snowpack levels decrease and allow MWD to capture rain associated with projected short duration high intensity storms.

About This Report 15

A Quality Partnership

In 2010, LADWP collected over 25,000 water samples across the city, and performed more than 240,000 water quality tests—not just for compliance, but also for research and operational improvements. We tested for over 200 different contaminants throughout the year including both, regulated contaminants such as arsenic, chromium, lead, and disinfection by-products, as well as unregulated contaminants such as sodium and boron. Every day, hundreds of LADWP employees work diligently to ensure that you receive the high-quality, low cost drinking water you've come to expect. This is our commitment to you.

After water completes multiple treatment processes, it is distributed throughout the City via trunk lines, distribution lines and ultimately service lines that feed the water to your meter. In 2010, LADWP delivered more than 200 billion gallons of water to 4.1 million residents that met or surpassed all health-based drinking water standards. However, in spite of all our efforts, some of our customers do not get to enjoy this high quality water within their home because degraded in-house plumbing negatively affects the ultimate quality of the tap water.

LADWP would like to invite you to partner with us by learning more about what we do to provide high quality drinking water and what you can do to get the best possible glass of water from your tap (See pages 3-4). Because, at the end of the day, we all want the same thing—the best!

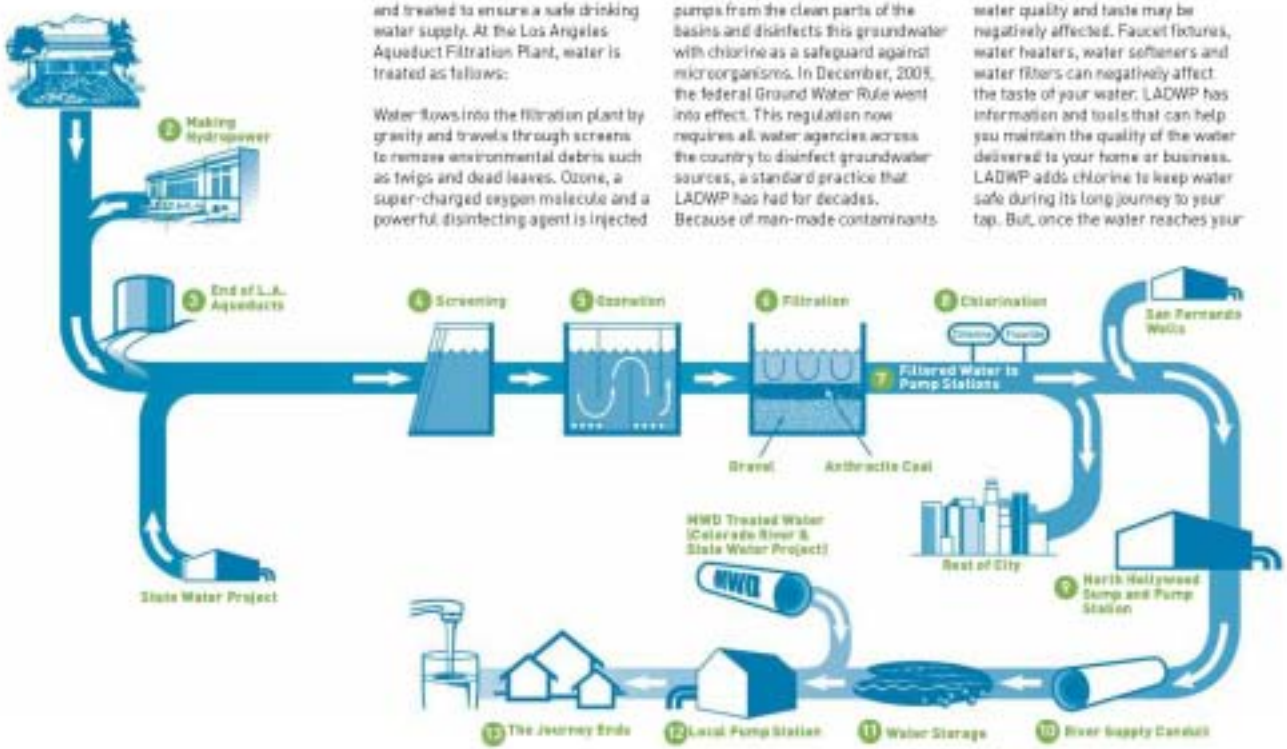
James B. McDaniel
Senior Assistant General Manager - Water

Dr. Pankaj Parekh
Director of Water Quality

Beginning of L.A. Aqueducts

The Journey Begins: Lee Vining Intake

The beginning of the Los Angeles Aqueducts. Water is collected from creeks in the Mono Basin and the Owens River in the Owens Valley and then carried to the City of Los Angeles by the Los Angeles Aqueducts, which operate completely by gravity, making clean hydroelectric energy along the way.



Water Treatment Processes

Surface Water Treatment

LADWP water comes from four very different water sources—three are from surface water sources like lakes and rivers, and the other is groundwater from local wells and springs. The taste and appearance of surface water can vary seasonally and groundwater generally contains more minerals. All these factors make for different tasting water. Despite these variations, LADWP water meets all drinking water standards for health and aesthetics.

All water coming from the Los Angeles Aqueducts, the California Aqueduct (a.k.a. State Water Project), and the Colorado River Aqueduct is filtered and treated to ensure a safe drinking water supply. At the Los Angeles Aqueduct Filtration Plant, water is treated as follows:

Water flows into the filtration plant by gravity and travels through screens to remove environmental debris such as twigs and dead leaves. Ozone, a super-charged oxygen molecule and a powerful disinfecting agent is injected into the water to destroy bacteria and other impurities that affect taste, odor and color. Treatment chemicals are quickly dispersed into the water to make fine particles called floc. A six-foot-deep filter (crushed coal over gravel) removes the floc and previously added chemicals. Chlorine added during the final step ensures lasting disinfection and protects the water as it travels through the City's distribution system to your tap. Fluoride is optimized to promote oral health by strengthening tooth enamel.

Groundwater Treatment

The City's vast groundwater supply in the San Fernando and Central Basins are generally clean. LADWP pumps from the clean parts of the basins and disinfects this groundwater with chlorine as a safeguard against microorganisms. In December, 2009, the federal Ground Water Rule went into effect. This regulation now requires all water agencies across the country to disinfect groundwater sources, a standard practice that LADWP has had for decades. Because of man-made contaminants found in San Fernando Valley groundwater wells, LADWP continuously monitors and ensures that all well water meets water quality standards and results are far below the maximum contaminant levels permitted by federal or state regulations. LADWP is formulating a comprehensive long term groundwater treatment plan for the San Fernando Basin that will allow us to extract more water and treat it so we can safely increase our local supply of water.

Improving Water Quality At Home

It is common for the integrity of pipes on the customer-side of the meter to degrade to the point that water quality and taste may be negatively affected. Faucet fixtures, water heaters, water softeners and water filters can negatively affect the taste of your water. LADWP has information and tools that can help you maintain the quality of the water delivered to your home or business. LADWP adds chlorine to keep water safe during its long journey to your tap. But, once the water reaches your

AR0071045

7 Making Hydropower

San Francisquito Power Plant 1

Water generates electricity as it passes through the hydroelectric plant.

3 End of LA Aqueducts

The Cascades

Seen along Interstate 5, this is the terminus (end) of the Aqueducts. Water flows over the "steps" to release some of the water's energy.

tap, the chlorine is no longer needed. There are numerous home treatment options that can be implemented to improve the smell and taste of your water. To remove any objectionable chlorine odors, simply chill the water in the refrigerator. This alone can significantly improve the taste. You can also use a filter specific for the removal of chlorine or chloramine. Once filtered, be sure to keep the water in the refrigerator to prevent any new growth of bacteria.

If you intend to buy a water filter to improve the taste, odor, or appearance of your tap water, be sure to purchase one that is certified by the National Sanitation Foundation (NSF), an independent testing organization whose certification is the industry's seal of approval.

If you need a more comprehensive home water treatment device due to a health condition, such as a weakened immune system or chemical allergy, be sure the treatment device is certified by the California Department of Public Health (CDPH).

Purchasing and installing a faucet-mounted or under-the-sink filter is another way to improve the taste of your water. As with any filter, be sure to change the filter cartridges regularly according to the manufacturer's recommendation.

To learn more about water quality in your home visit www.ladwp.com, or call (213) 367-3182 Monday through Friday 8 a.m. – 4 p.m.

Water Quality News & Updates

Safeguarding Our Surface Water

The Surface Water Treatment Rule (SWTR), administered by CDPH, is a drinking water regulation that safeguards reservoir supplies from microbiological contamination that may occur when rain runoff from nearby hillsides and slopes enters the water. In Los Angeles, SWTR applied to four open water reservoirs – Lower Stone Canyon, Encino, and Upper and Lower Hollywood.

LADWP successfully met the compliance deadlines and treatment requirements for all four open reservoirs that were subject to SWTR. Upper and Lower Hollywood Reservoirs were successfully removed in July 2001 and replaced with two 33 million-gallon buried tanks. New support facilities were successfully commissioned to serve filtered water from Encino Reservoir in January 2006 and Lower Stone Canyon Reservoir in September 2008.

The latest drinking water regulation related to the treatment of surface water is the Long Term 2 Enhanced Surface Water Treatment Rule (LT2). This rule requires

4 Screening

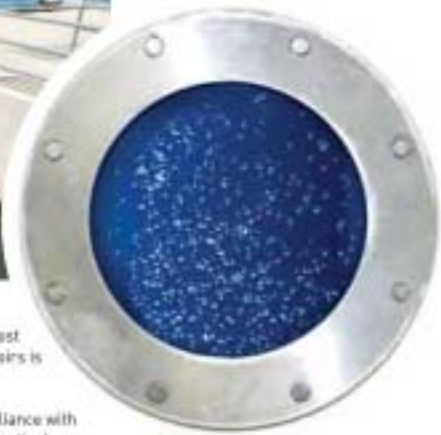
Los Angeles Aqueduct Filtration Plant (LAAFP) Inlet Structure

Water flows through the inlet of the LAAFP, where large pieces of debris or algae are removed by screens.

5 Ozonation

Ozone Contact Chamber, LAAFP

Water is exposed to ozone gas, a disinfectant that prepares the water for filtration.



6 Filtration

Anthracite Coal Filters, LAAFP

Water passes through 40 inches of anthracite coal filters, which remove particles smaller than can be seen through a microscope.

that LADWP cover or remove from service the remaining six uncovered distribution reservoirs, or provide additional treatment to achieve prescribed inactivation or removal of viruses, Cryptosporidium, and Giardia by April 1, 2009 or be in compliance with a state-approved schedule to meet the same requirements. The six reservoirs are Los Angeles, Upper Stone Canyon, Santa Ynez, Ivanhoe, Silver Lake, and Elysian Reservoirs. Santa Ynez Reservoir was removed from service in November 2010. It will be put back in service after a floating cover is installed in 2011.

On April 1, 2008, LADWP notified CDPH that it is fully committed to complying with the new regulations and requested an extension of the April 1, 2009 deadline. LADWP submitted an interim operations plan, a schedule for the required reservoir improvements, and executed a Compliance Agreement with CDPH on March 31, 2009. LADWP is working diligently to bring all reservoirs into compliance as quickly as possible and will provide the public with project updates in the annual water quality report. The estimated cost to modify the six reservoirs is $1.65 billion.

In preparation for compliance with LT2, LADWP has been routinely monitoring its water sources for microbial pathogens since 2005. Cryptosporidium and Giardia are occasionally detected in very low numbers in some of our reservoirs and in the L.A. Aqueduct and we are fully committed to achieving compliance with the LT2. To further inform our customers on this topic, below is a generic statement from CDPH regarding Cryptosporidium.

"Cryptosporidium is a microbial pathogen found in surface water throughout the U.S. Although filtration removes Cryptosporidium, the most commonly used filtration methods cannot guarantee 100 percent removal. Our monitoring indicates the presence of these organisms in our source water and finished water. Current test methods do not allow us to determine if the organisms are dead or if they are capable of causing disease. Ingestion of Cryptosporidium

may cause cryptosporidiosis, an abdominal infection. Symptoms of infection include nausea, diarrhea, and abdominal cramps. Most healthy individuals can overcome the disease within a few weeks. However, immunocompromised persons are at greater risk of developing life-threatening illness. We encourage immunocompromised individuals to consult their doctor regarding appropriate precautions to take to avoid infection. Cryptosporidium must be ingested to cause disease, and it may be spread through means other than drinking water." (source: CDPH)

Special Population Precautions

There are certain health conditions for which customers may need specially treated water. Customers with weakened immune systems who may have undergone chemotherapy treatment, received organ transplants, suffer from HIV/AIDS, or other immune system disorders. Some elderly and infants can be particularly at risk from infection. Customers with these types of health challenges should seek advice about drinking water from their health care providers. Contact the EPA's Safe Drinking Water Hotline at (800) 426-4791, or visit www.epa.gov, for free guidelines on how to lessen the risk of infection by Cryptosporidium and other microbial contaminants.

Chlorine and Chloramine

LADWP is gradually switching from chlorine to chloramine to disinfect the water we serve. This will take several more years and, in the meantime, customers should expect to receive either type of disinfectant in their water at any time.

Both chlorine and chloramine are effective killers of bacteria and other microorganisms, but chloramine forms less by-products and does not have a chlorinous odor. Customers in the Harbor area of the City have received water treated with chloramine for more than 25 years. Customers in Eastern Los Angeles and the Sunland-Tujunga area are also receiving water treated with chloramine.

Since chlorine and chloramine are different chemicals, certain types of water users must adjust their additional treatment to handle either disinfectant. Operators of kidney dialysis machines should monitor their equipment more frequently for both "free" and "total" chlorine. The Southern California Renal Disease Council supports this recommendation.

Customers who maintain fish ponds, tanks, or aquaria should also make necessary adjustments in water quality treatment, as both chlorine and chloramine are toxic to fish. For further information, please visit www.ladwp.com or call our Water Quality Customer Services group at (213) 367-3182.

2010 Drinking Water Quality Monitoring Results

Tables I-IV list the results of water tests performed by LADWP and MWD from January to December 2010. LADWP tests for over 200 contaminants. These tables include only contaminants with values that are detected.

How to Read the Tables

The constituents/contaminants found in the water served in your area are listed as follows:

- For San Fernando Valley Area – water test results are under the Los Angeles Aqueduct Filtration Plant, the Northern Combined Wells, and MWD Jensen Filtration Plant columns
- For Western Los Angeles Area – water test results are under the Los Angeles Aqueduct Filtration Plant column
- For Central Los Angeles Area – water test results are under the Los Angeles Aqueduct Filtration Plant and the Southern Combined Wells columns
- For Harbor/Eastern Los Angeles Area – water test results are under the MWD Jensen, Weymouth, and Diemer Filtration Plants columns

Some constituents/contaminants are reported on a citywide basis as required by the California Department of Public Health.
The unregulated contaminants reported on an area-wide basis are included for additional information on the water served in your area.

continued from page 7

A Better Understanding of Radon

Radon is a naturally occurring radioactive gas that is not a significant issue in most of California. In 2010, very low levels of radon were detected in some of our ground water supplies (see Table II on page 12). There is no established drinking water standard or monitoring requirement for radon. In general, radon entering a home through tap water is a very small contributor to radon in indoor air. Although the radon levels were well below what the EPA is currently considering for a standard, the EPA has asked us to share the following general information with you to help you better understand radon.

"Radon is a radioactive gas that you can't see, taste, or smell. It is found throughout the U.S. Radon can move up through the ground and into a home through cracks and holes in the foundation. Radon can build up to high levels in all types of homes. Radon can also get into indoor air when released from tap water from showering, washing dishes, and other household activities. Compared to radon entering the home through soil, radon entering the home through tap

Abbreviations and Footnotes

mg/L = milligrams per liter (equivalent to ppm)
µg/L = micrograms per liter (equivalent to ppb)
ng/L = nanograms per liter (equivalent to ppt)
pCi/L = picoCuries per liter
% = percentage
µS/cm = microSiemens per centimeter
NTU = nephelometric turbidity unit
TON = threshold odor number
CFU = colony-forming unit
ACU = apparent color unit
< = less than
NA = not applicable
NT = not tested
HRAA = highest running annual average

(a) Values reflect Highest Running Annual Average (HRAA). HRAA is the highest of all Running Annual Averages (RAAs). RAA is a calculated average of all the samples collected within twelve months period.

(c) Bromate is tested in water treated with ozone. Bromate has also been found in chloramated treated water at some LADWP reservoirs exposed to sunlight. Metropolitan Water District of Southern California (MWD) only tests bromate at Jensen Filtration Plant.

(c) Radiological monitoring is performed in cycles of various periods of time. LADWP performed Gross Alpha testing in 2006 – 2009 and all other radiological testing in 2005 - 2010 for samples collected at Los Angeles Aqueduct Filtration Plant, Northern Combined Wells blend points, and Southern Combined Wells blend points. MWD performed all radiological testing in 2008 for samples collected at Weymouth, Diemer, and Jensen Plants.

(d) Turbidity is a measure of the cloudiness of the water and is a good indicator of water quality and filtration performance. High turbidity can hinder the effectiveness of disinfectants.

The Primary Drinking Water Standard for turbidity level at water filtration plants is less than or equal to 0.3 NTU in at least 95% of the measurements taken in any month and shall not exceed 1.0 NTU at any time. The reporting requirement for treatment plant turbidity is report the highest single measurement in the calendar year and the lowest monthly percentage of measurements that are less than or equal to 0.3 NTU.

(e) The highest turbidity at the Los Angeles Filtration Plant effluent was 2.4 NTU on December 30, 2010. This high turbidity reading reflects a single reading taken out of some 35,000 readings. Turbidity is monitored in 15 minute intervals all year round.

(f) Values reflect annual range and average of samples collected from six open reservoirs: Elysian, Ivanhoe, Los Angeles, Santa Ynez, Silver Lake, and Upper Stone Canyon.

(g) At-the-tap monitoring of lead and copper is conducted every three years as required by the Lead and Copper Rule. A system is out of compliance if the Regulatory Action Level is exceeded in the 90th percentile of all samples at the customers' tap. Although the City's treated water has little, if any, detectable lead, studies were conducted and corrosion control is scheduled for implementation.

(h) Values reflect testing at entry to the distribution system.

(i) NDMA was tested in 2009 – 2010 for compliance to Unregulated Contaminant Monitoring Rule (UCMR3).

10 **River Supply Conduit**

Water Travels through the City

Water from the pump station is carried through a 78" water main to Ivanhoe Reservoir in the Silver Lake area of the City.

continued from page 9

water is, in most cases, a small source of radon in indoor air. Radon is a known human carcinogen. Breathing air containing radon can lead to lung cancer. Drinking water containing radon may also cause increased risk of stomach cancer. If you are concerned about radon in your home, test the air in your home. Testing is inexpensive and easy. Fix your home if the level of radon in your air is 4 picoCuries per liter of air (pCi/L) or higher. There are simple ways to fix a radon problem that aren't too costly. For additional information, call your State radon program or call EPA's Radon Hotline (800-SOS-RADON)."

Terms Used In The Tables

Compliance: A drinking water standard based on the health risk (primary standards) and aesthetics (secondary standards) exposure of a contaminant to consumers. For example, bacteria and nitrate have strict limits that must be met at all times due to the acute effects they can cause. Other standards, like small amounts of disinfection by-products and man-made chemicals, have standards that are based on a lifetime of exposure because the risk to consumers is very low. Compliance with most standards is based on an average of samples collected within a year. This allows for some fluctuation above and below the numerical standard, while still protecting public health.

Detection Limit for Reporting Purpose (DLR): DLR means the designated minimum level at or above which any analytical finding of a contaminant in drinking water resulting from monitoring required under Title 22 Code of Regulations shall be reported to the California Department of Public Health (CDPH).

Maximum Contaminant Level (MCL): MCL is the highest level of a contaminant that is allowed in drinking water. Primary MCLs are set as close to the Public Health Goals (PHGs) or Maximum Contaminant Level Goals (MCLGs) as is economically and technologically feasible. Secondary MCLs are set to protect odor, taste, and appearance of drinking water. For certain contaminants, compliance with the MCL is based on the average of all samples collected throughout the year.

Maximum Contaminant Level Goal (MCLG): MCLG is the level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs are set by the U.S. Environmental Protection Agency (USEPA).

Maximum Residual Disinfectant Level (MRDL): MRDL is the highest level of a disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.

Maximum Residual Disinfectant Level Goal (MRDLG): MRDLG is the level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs do not reflect the benefits of the use of disinfectants to control microbial contaminants. MRDLGs are set by the USEPA.

Notification Level (NL): NL is the health-based advisory levels established by CDPH for chemicals in drinking water that lack maximum contaminant levels (MCLs).

Primary Drinking Water Standard (PDWS): MCLs and MRDLs for contaminants that affect health along with their monitoring and reporting requirements, and water treatment requirements.

Public Health Goal (PHG): PHG is the level of a contaminant in drinking water below which there is no known or expected risk to health. PHGs are set by the California Environmental Protection Agency, Office of Environmental Health Hazard Assessment (OEHHA).

Regulatory Action Level (AL): AL is the concentration of a contaminant which, if exceeded, triggers treatment or other requirements that a water system must follow. ALs are set by the USEPA.

Secondary Drinking Water Standard (SDWS): SMCL is for contaminants that may affect the taste, odor or appearance for drinking water.

Treatment Technique (TT): TT is a required process intended to reduce the level of a contaminant in drinking water. For example, the filtration process is a treatment technique used to reduce turbidity (the cloudiness in water) and microbial contaminants from surface water. High turbidities may be indicative of poor or inadequate filtration.

Table IV Calendar Year 2010 Water Quality Monitoring Results

Drinking Water Disinfection By-Products Reported on Area-Wide Basis

Shade Balls Minimize Bromate in City Reservoirs

LADWP continues to minimize bromate levels in open reservoirs, keeping them within regulatory requirements. A creative short-term intervention LADWP recently implemented was the use of "shade balls" to decrease the formation of Bromate. In 2008, shade balls were used to shade the water surfaces of Elysian and Ivanhoe Reservoirs. As a result, bromate levels have been consistently well below the current drinking water standard of 10 parts per billion.

In the long term, LADWP intends to permanently cover or replace all remaining uncovered reservoirs by 2022 as required by the LT2 regulation (please see Safeguarding our Surface Water, page 4). Meanwhile, all water served to our customers continues to meet all public health standards.

Lead Exposure from Plumbing Materials

LADWP monitors lead contents in source water and the distribution system and has not found detectable amounts. If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with home plumbing. The LADWP is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting in the pipes for several hours, you can minimize the potential for lead exposure by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. This water can be collected and used to water plants. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at http://www.epa.gov/safewater/lead.

Pharmaceutical and Personal Care Products

Very low levels of pharmaceutical and personal care products (PPCPs) are increasingly being detected in U.S. drinking water supplies. PPCPs include medicines, shampoos, soaps, detergents, lotions, and perfumes. Currently, neither the state or federal government require LADWP to test for PPCPs. However, as a forward looking utility, LADWP conducts its own monitoring for these compounds.

In 2009, LADWP tested its source and treated waters for PPCPs. The amount of PPCPs detected was so minute that no adverse health effect from exposure has been reported. LADWP continues to study the issue with several other utilities and the Water Research Foundation. Customers can do their part by disposing of unwanted medications into a waste receptacle or by returning to a pharmacy—not down a toilet or drain.

12 Local Pump Station

Fletcher Pump Station
Additional chlorine is added before large pumps send the water to L.A. neighborhoods, east of Ivanhoe Reservoir.

13 The Journey Ends

At Home Treatment
Customers can further improve the taste of drinking water through chilling, filtration or by replacing older pipes, faucet fixtures, water heaters, water softeners and water filters.

CITY OF LOS ANGELES
BOARD OF WATER AND POWER COMMISSIONERS
Thomas S. Sayles, President
Eric Holoman, Vice President
Richard Moss, Commissioner
Christina Noonan, Commissioner
Jonathan Parfrey, Commissioner

EXECUTIVE TEAM
Ronald O. Nichols, General Manager
James B. McDaniel, Senior Assistant General Manager, Water Systems

Ann M. Santilli, Chief Financial Officer
Lorraine A. Paskett, Senior Assistant General Manager, Customer Service, Programs and External Affairs

About This Report

The 2010 Drinking Water Quality Report was prepared by the Los Angeles Department of Water and Power (LADWP). This report is required by the California Department of Public Health (CDPH) and was prepared in accordance with CDPH guidelines. It was prepared, printed and mailed to you at a cost of 35 cents.

Contact Information

LADWP, the largest municipal utility in the nation, was established more than 100 years ago to provide a reliable and safe water and electric supply to the City's 4 million residents and businesses.

LADWP is governed by a five-member Board of Water and Power Commissioners, appointed by the Mayor and confirmed by the City Council. The Board meets regularly on the first and third Tuesdays of each month at 1:30 p.m. Meetings are held at:

Los Angeles Department of Water and Power
111 North Hope Street, Room 1555H
Los Angeles, CA 90012-2694

The meeting agenda is available to the public on the Thursday prior to the week of the meeting. You can access the Board agenda at www.ladwp.com or by calling (213) 367-1351.

For general information about LADWP, call 1-800-DIAL DWP (1-800-342-5397) or visit www.ladwp.com.

For questions regarding water quality, call the LADWP Water Quality Customer Services Group at (213) 367-3182.

For questions regarding this report, please call Mr. Nathan Aguayo at (213) 367-4561.

Want to know more about your drinking water and related regulations?

For more information about the NSF certification, call (800) 673-8010 or visit www.nsf.org.

For more information about CDPH certification, call (916) 449-5577 or visit www.cdph.ca.gov.

Preface

This 2011 IRP represents an update of last year's 2010 IRP document, and addresses, among other things, updated renewable energy requirements, the latest load forecast, early divestiture of the Navajo coal plant, revenue and rate impacts, and the incorporation of public input.

The recent passage of legislation SB 2 (1X) establishes specific renewable energy requirements, enabling more near-term certainty on the near-term need and the associated plan for renewable energy resources. As a result, the strategic case options evaluated in this IRP reflect updated quantities and mix of renewables based on the recent load forecast and availability of renewable resources and their related transmission.

The current load forecast used in this IRP is lower than the one used in 2010. Compared to the prior forecast, electricity sales for year 2020 decreased by approximately 7 percent mostly due to updated econometric studies that indicate a more prolonged recovery from the recession. The lower load forecast results in less electricity demand and fewer replacement resources when compared to last year.

This IRP update recommends divestiture of the Navajo coal power plant by 2015, 4 years ahead of the 2019 end date. Regarding early Navajo coal divestiture, the analysis and findings of this IRP update are generally consistent with conclusions developed from last year's 2010 IRP process with more details of specific replacement resources and costs. Early divestiture of LADWP's other coal source—the Intermountain Power Project—while analyzed in greater detail in this IRP, will be subjected to further investigation and analysis in next year's 2012 IRP.

Also included in this 2011 IRP is an assessment of the revenue requirements and rate effects that support the recommended plan through 2020. The rate process which began earlier in 2011 is expected to conclude in 2012, from which a final budget and rate schedule will result. LADWP supports the City Council's efforts towards this process, and looks forward to the appointment of the Ratepayer Advocate so that these budget and revenue issues can be properly addressed in a collaborative and expeditious manner. Establishing the proper rate structure will allow LADWP to implement its plan and stay on track towards meeting its long-term goals and obligations.

Lastly, many of the recommendations contained in this IRP update address concerns raised during last year's IRP public outreach process, as well as from the summer 2011 rate process. Accelerating coal replacement, emphasizing energy efficiency, and expanding local solar were among the major issues that emerged from the public processes; these and others have been incorporated into the case analysis and long-term recommendations. Next year's 2012 IRP process will include a new outreach program that will build upon these themes, as well as identify any new concerns or issues that may emerge.

AR0071063

(This page intentionally left blank)

I INTRODUCTION AND PURPOSE

The Los Angeles Department of Water and Power (LADWP) is currently facing some of the most serious environmental, regulatory, and economic challenges in its 100-year plus history. LADWP finds itself at a crossroads in terms of how the utility operates that will require revamping its power generation portfolio to continue providing the same reliable, low-cost electricity to the residents and businesses of Los Angeles. As the largest municipally owned utility in the nation, LADWP must continue to ensure reliable electricity service as it reduces greenhouse gas (CO_2) emissions and transitions from energy sources based on fossil fuels to sustainable forms of renewable energy.

This 2011 Power Integrated Resources Plan (IRP) is an update of last year's 2010 IRP, and reflects evolving environmental, regulatory, and economic developments since 2010. The purpose of this IRP remains as before—to provide a framework to assure the future energy needs of LADWP customers are met in a manner that balances the key objectives of:

- Maintain a high level of electric service reliability
- Maintain competitive rates
- Exercise environmental stewardship, including a reduced carbon footprint

In balancing these key objectives, LADWP's integrated resource planning efforts must be deliberate, comprehensive, and clear to our ratepayers as well as all other City stakeholders. LADWP's goal—and primary challenge—is to develop a long-term resource plan that is informative, sensitive to the local and regional economy, and adaptable to changes in state and federal regulations, fuel prices, and advances in power generation technologies.

This IRP presents several potential strategies for meeting LADWP's regulatory requirements and policy objectives, maintaining electric power service reliability, and minimizing any financial impact on ratepayers. LADWP rigorously evaluated each potential strategy to identify and recommend the best overall plan to meet its key objectives at the least cost.

This IRP is not a technical plan nor a compact to pursue all of the initiatives identified in this document. Instead, this plan establishes the overall vision for the power system and a broad discussion of the finances necessary to support that vision. LADWP needs to be free to react to market conditions and make corrections in its shorter term tactical plans. Additionally, short-term budgets will be refined and financial analysis published as they are recommended for approval by LADWP's Governing Board and the City Council.

AR0071065

II PUBLIC OUTREACH

LADWP conducts a public review process on their IRP every other year. A review process was held last year in support of the 2010 IRP, and the results of that process are considered applicable to the 2011 IRP. A full scale public outreach program, similar to the one held in 2010, is planned for next year's 2012 IRP. In summary, following are the themes that emerged.

LADWP should:

- Emphasize a variety of energy resources
- Maximize energy efficiency and conservation
- Eliminate coal from its generation portfolio
- Emphasize local solar generation
- Avoid adverse impacts to vulnerable communities
- Clarify costs of IRP implementation and potential impacts to ratepayers
- Reduce environmental impacts
- Provide proactive leadership and transparency

For details regarding the 2010 Public Outreach effort, refer to Appendix N. The recommended strategy for addressing these themes is presented in Section 5.2.

AR0071066

III 2011 IRP DEVELOPMENT PROCESS

The IRP is prepared by a group of engineers dedicated to LADWP resource planning and preparation of the IRP. This group is managed by a Supervising Engineer, with a direct reporting staff of four. While this group performs the production model and report preparation for the IRP, the bulk of the work is collaborative across the different work groups and functional areas of the Power System.

The IRP is developed in multiple stages, including:

1. Identifying and approving key assumptions
2. Establishing clear goals and objectives
3. Establishing strategic case alternatives
4. Completing computer modeling of power system operations
5. Recommending and approving a preferred case

Each of these stages includes coordination between multiple LADWP organizations responsible for different aspects of power system operations, preparing recommended positions for each stage, presenting recommendations to LADWP's leadership team, including Division and Section Heads, and ultimately presenting recommendations to the General Manager. At each of these presentations, modifications to recommendations are noted. The approval process for recommendations is based on consensus from the managers of each area of responsibility.

AR0071067

IV RECENT ACCOMPLISHMENTS

A summary of recent LADWP accomplishments consistent with the objectives of this IRP are presented below in Table ES-1. These accomplishments promote the goals of maintaining high reliability and exercising environmental stewardship, while keeping rates competitive. See Section 1.5 for more details.

Table ES-1. LADWP RECENT ACCOMPLISHED PROJECTS/PROGRAMS

Project/Program	Time Period	Accomplishment
Milford II Wind Project	2011	Supply over 100 MW of wind energy
Electric Vehicles Incentive	2011	Provide a $2000 rebate for home EV charging systems
Southern Transmission System Upgrade	2011	Increased capacity of 480 MW was added to the existing transmission line
Navajo Generation Station Retrofits	2011	Retrofit burners reduce NO_X emission by 40% or 14,000 tons per year
Energy Efficiency Program	2000 to 2011	Reduced long-term peak period demand by 303 MW, 1,256 GWh of energy savings
Renewable Portfolio Standard	2003 to 2010	Increased renewable energy percentage from 3% to 20%
Castaic Upgrade	2004 to 2014	Project adds up to 80 MW renewable capacity
Green Power Program	1999 to 2011	Participants receive 104 GWh of renewable energy annually
Power Reliability Program	Ongoing	Improve reliability of Power System infrastructure
Solar Incentive Program	1999 to 2011	Provided funding that has enabled the installation of 41 MW of solar
CO_2 Emissions Reduction	1990 to 2010	CO_2 emission 23% lower than 1990 level
Once-through Cooling	1990 to 2011	OTC reduced by 17% from 1990 level

AR0071068

V CHALLENGES AND CRITICAL ISSUES

LADWP faces a number of concurrent issues and challenges that require careful assessment. Long term strategies must focus on these issues so they can be addressed in the most cost effective manner without compromising reliability compliance and environmental stewardship. The major issues around which the strategies of this IRP are centered include: adequate funding to support initiatives, programs and projects; ensuring reliability; greenhouse gas emission reduction; increasing the amounts of renewable generation resources; and addressing once-through cooling.

Adequate Multi-year Funding to Support Programs

Based on last year's 2010 IRP, a multi-year rate increase was recommended beginning fiscal year 2011-12. The rate increase would have supported elements of last year's IRP, all of which remain as the foundation for LADWP's short and long term plans. Because the rate increase was not realized in July 2011, many of the programs that required funding were scaled down, delayed or deferred.

A multi-year funding plan is necessary to provide consistent and sustainable project and program development. Funding that is based on annual budgets are subject to year-to-year fluctuations which introduces uncertainty for our customers and the inefficient use of staff and financial resources that are necessary to meet LADWP's objectives and compliance requirements.

Properly funded programs will enable LADWP to achieve the following objectives:

- Modernize its coastal generation units to replace aging equipment and to satisfy once-through cooling regulatory requirements.
- Implement early coal divestiture.
- Secure the state-mandated amounts of renewable energy.
- Through the Power Reliability Program, reduce the number of distribution outages and improve system reliability.
- Implement necessary transmission improvements to maintain reliability.
- Achieve energy efficiency target levels.
- Implement Smart Grid initiatives.
- Comply with FERC-approved reliability standards.

A rate process that began earlier this year is addressing the revenue needs for LADWP. A proposed 3-year rate adjustment that would support the programs listed above is being considered. The expectation is that the rate process will conclude sometime in 2012. Securing adequate multi-year funding is crucial to ensure LADWP's ability to stay on track towards meeting its future long term goals and obligations.

AR0071069

Ensuring Reliability

Challenges to ensuring continued reliable electric service include the replacement of aging generation facilities, maintaining grid reliability, the integration of intermittent renewable energy resources, and the replacement of poles, power cables, transformers and other elements of the local distribution system.

LADWP's Repowering Program, which began in 1994, is a long term program to upgrade LADWP's in-basin generating units. The program is a sequence of projects that extends to 2029, and will provide modern units that are more reliable than the units they are replacing.

To maintain grid reliability, LADWP's Ten-Year Transmission Assessment Plan has identified a number of necessary improvements. In addition, a recently completed Reactive Power Management Study recommends improvements to optimize grid performance and reduce system losses. More information can be found in Section 2.1.4.

The integration of renewable energy into the grid poses major reliability challenges. Because renewable resources like wind and solar produce electricity variably and intermittently (i.e., only when the wind is blowing or when the sun is shining), integration of these resources requires additional generator units to compensate for significant and often rapid swings in energy production. These swings present operational challenges and must be leveled by controllable generation capable of equally rapid changes of generation in the opposite direction. This stabilization is known as "regulation." A preferred solution would use energy storage to regulate delivery of energy and reduce the severity of integration problems. LADWP currently uses, among other resources, pumped water storage and hydro resources for regulation.

Between 2003 and 2005, LADWP experienced a growing number of distribution outages due to, among other things, aging infrastructure (poles, lines, transformers, etc.), and deferred maintenance and asset replacement.[1] In response, LADWP established a comprehensive Power Reliability Program (PRP) in 2006 which provided increased funding to address the growing maintenance backlog. The goals of the program include: (1) mitigating problem circuits and stations based on the types of outages specific to a given facility, (2) implementing proactive maintenance and capital improvements to avert problems before they occur, and (3) establishing replacement cycles for facilities that are in alignment with equipment life cycle.

Greenhouse Gas Emissions Reduction

LADWP's CO_2 emissions reduction strategy must comply with state and federal regulations. At the time of this writing, key legislation and regulations either promulgated or proposed include:

[1] To illustrate the age of the distribution system, over 50 percent of the City's 298,106 distribution poles are greater than 50 years old.

AR0071070

- Assembly Bill (AB) 32, the California Global Warming Solutions Act of 2006, calls for reducing the state's CO_2 emissions to 1990 levels by 2020. The regulations for implementing a greenhouse gas emissions trading program under AB 32 were finalized and adopted on October 20, 2011 by the California Air Resources Board (ARB). Enforcement and compliance with the trading program will begin January 1, 2013. Electric distribution utilities, including LADWP, will receive an administrative allocation of emission allowances that reflects their respective annual emissions as they implement aggressive energy efficiency measures and the 33 percent Renewable Portfolio Standard. The ARB will continue to work with stakeholders to monitor the impacts of the regulation on all sectors, including the electricity sector.
- SB 1368, the California Greenhouse Gas Emissions Performance Standard Act, also enacted in 2006, prohibits LADWP and other California utilities from entering into long-term financial commitments for base load generation unless it complies with the CO_2 emissions performance standard. The CO_2 emissions level must be equal, or below, that of a gas-fired combined cycle units (i.e., 1,100 lbs. per MWh). This standard also applies to existing power plants for any long-term investments or contractual extensions.

LADWP has historically relied upon coal for base load generation. Currently, 39 percent of the energy delivered to LADWP customers is generated from two coal-fired generating stations: the Intermountain Power Project (IPP), located in Utah, and the Navajo Generating Station (NGS), located in Arizona. The NGS's land lease expires in 2019 but has a stipulation for a 25-year extension. IPP's contract is in effect until 2027. These stations provide dependable, low cost base load generation to Los Angeles. Coal-fired generation, however, emits about twice as much CO_2 as energy generated with natural gas. Accordingly, this 2011 IRP focuses on early coal divestiture options as a means to comply with AB 32 and lower LADWP's CO_2 emission levels. Sections 3 and 4 discuss the alternative strategic case options in detail.

Increasing Renewable Resources

Initiatives to utilize renewable resources to generate electricity support the goal of reducing CO_2 emissions and lessen our reliance on fossil fuels.

State legislation – SB 2 (1X) – which was passed in April 2011 and became effective on December 10, 2011, will subject all utilities to procurement of eligible renewable energy resources of 33 percent by 2020, including the following interim targets:

- Maintain at least an average of 20 percent renewables between 2011 and 2013
- Achieve 25 percent renewables by 2016

The legislation allows for the California Energy Commission to issue a notice of violation and correction, and to refer all violations to the California Air Resources Board. Failure to achieve the targets may result in significant penalties.

AR0071071

Once Through Cooling

Once-through cooling (OTC) is the process of drawing water from a river, lake, or ocean, pumping it through a generating station's cooling system, and discharging it back to the original body of water. OTC is a major regulatory issue, stemming from the Federal Clean Water Act Section 316(b) and administered locally by the State Water Resources Control Board (SWRCB).

OTC regulations affect LADWP's three coastal generating stations – Scattergood, Haynes, and Harbor. To comply with OTC regulations, generation units at those stations that utilize ocean water for cooling will be repowered with new units that do not use ocean water. The total generation capacity affected by OTC is significant – approximately 2,162 MW, or roughly 35 percent of LADWP's annual peak demand in 2010. The total expenditures required are also significant, on the order of $2.4 billion. Because of the size and scope of the effort required, the work to comply with OTC regulation is a long term program, extending to 2029. Figure ES-1 is a timeline of the program target dates. More information regarding OTC is provided in Section 1.6.5.

Figure ES-1. Timeline for OTC compliance.

AR0071072

VI STRATEGIC CASE ALTERNATIVES

IRP planning is an on-going process and as such, the development of the 2011 IRP strategic cases incorporates the latest changes that have occurred in the regulatory landscape, and tactical plans developed by the power system. This 2011 IRP also includes many updated assumptions that have been developed over the past year. These assumptions have influenced the composition of potential resource portfolios that can fulfill LADWP's goals of reliability, competitive rates and environmental stewardship.

Last year's 2010 IRP analyzed 6 strategic cases representing different potential renewable resource portfolio mixes, with and without the early divestiture of IPP, and recommended a comprehensive strategy that adopted elements of a number of the cases analyzed. The 2011-12 fiscal-year financial planning process included many of the assumptions and recommendations set forth in the 2010 IRP.

This year's IRP analyzes a focused set of strategic cases, expanding on the results from the 2010 IRP process. Cases from last year that included a variety of renewable percentage targets were eliminated, mostly due to the recent approval of SB 2(1X) which mandates a fixed set of renewable targets. Because the key remaining discretionary decision involves coal divestiture, a streamlined set of 3 new coal divestiture cases were analyzed. These cases are designed to assist policymakers and ratepayers to make informed decisions regarding accelerated coal divestiture, particularly with regard to the environmental benefits and resulting resource and electricity rate impacts. The time frames for coal divestiture for each strategic case are as follows:

- Case #1 provides a baseline without any early coal divestiture. Navajo Generating Station continues until 12/1/2019 and the Intermountain Power Project (IPP) until 6/15/2027.

- Case #2 considers an early divestiture of NGS, by 12/31/2015, with IPP until 6/15/2027.

- Case #3 considers early divestiture of both coal plants – NGS by 12/31/2015 and IPP by 12/31/2020.

Section 3 provides more information surrounding the development of the cases, including resource adequacy and net-short considerations. Table ES-2 provides a more detailed description of each strategic case. For comparison purposes, the recommended case from last year's IRP is included in the table.

AR0071073

Table ES-2. CANDIDATE RESOURCE PORTFOLIOS FOR 2011 IRP

		2020	CO_2 or SB 1368 Compliance Date		New Renewables Installed Capacity (MW) 2011 – 2020					New Renewables Installed Capacity (MW) 2011 – 2030				
Case ID	Resource Strategy	RPS Target	Navajo Replacement	IPP Replacement[1]	Geo-thermal	Bio-mass	Wind	Non-DG Solar	Dist. Solar	Geothermal/ Biomass	Wind	Non-DG Solar	Dist. Solar	Generic
1 (Base Case)	No Early Coal Divestiture	33%	12/1/2019	6/15/2027	183	60	492	401	325	308	492	451	466	162
2	Navajo Early Replacement	33%	12/31/2015	6/15/2027	183	60	492	401	325	308	492	451	466	162
3	Navajo and IPP Early Replacement	33%	12/31/2015	12/31/2020	183	60	492	401	325	308	492	451	466	162
Rec. Case 2010 IRP	33% RPS Balanced	33%	1/1/2014	6/15/2027	320	0	580	315	315	320	680	485	485	160

[1] Early replacement for IPP will be further evaluated in the 2012 IRP

VII EVALUATION OF STRATEGIC CASE OPTIONS

Key results for each model run were tabulated and compared against each other. Each strategy was ranked on average dollars per megawatt hour generation cost and the total million metric tons of CO_2 emissions. The selection of the best case for LADWP ratepayers hinges mainly upon the load forecast, price of natural gas, and CO_2 emission levels. All cases meet the mandated RPS percentage targets and reliability standards. The analytics performed for this IRP examined the associated costs of each strategic case.

The key modeling results are summarized below:

CO_2 Emissions Considerations

The reductions of CO_2 emissions are reflected in the production cost model simulations. Figure ES-2 illustrates a comparison of the resulting CO_2 emission levels of the three cases. Divestiture of Navajo results in an average 1.86 Million Metric Tons (MMT) reduction in CO_2 each year while IPP results in an average 3.26 MMT reduction each year. CO_2 reductions are accelerated in Cases 2 and 3 with the divestiture of Navajo and IPP prior to the expiration of existing power contracts with these facilities. Case 1 represents the normal course of emissions reductions with no early divestiture. Reduction levels are eventually reached in all cases in 2019 and then again in 2027 when SB 1368 essentially prohibits the importation of energy produced from coal when the existing power contracts expire.

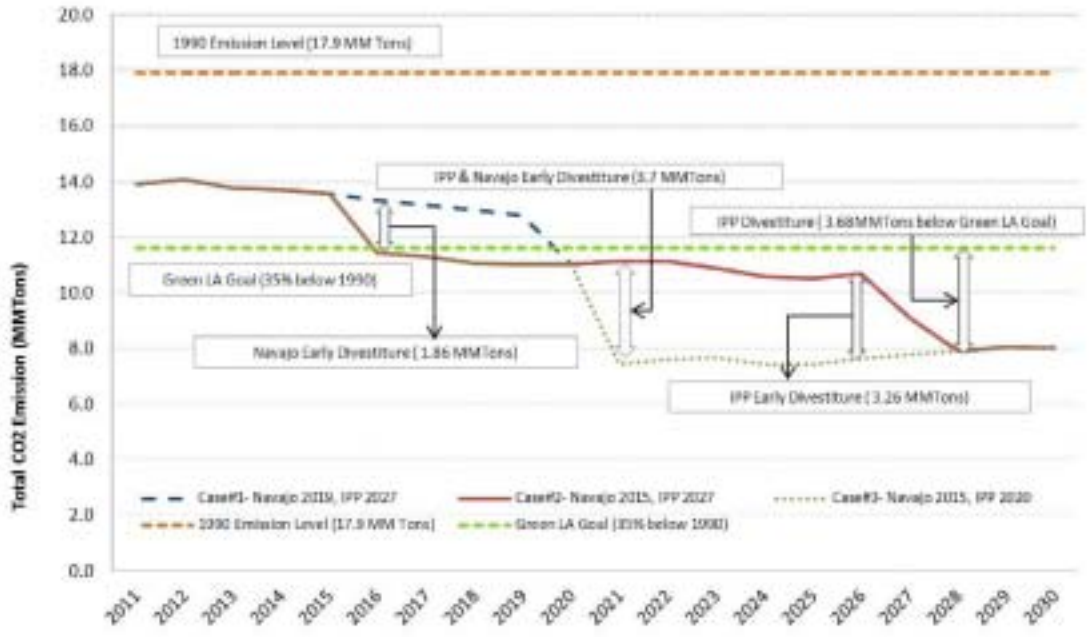

Figure ES-2. CO_2 emissions comparison by calendar year.

AR0071075

Current CO_2 emissions levels are approximately 14.1 MMT which is 21 percent below 1990 levels due to the elimination of Mojave and Colstrip Coal, completed repowering of units at Haynes and Valley generating stations with cleaner gas-fired replacements, and increased renewable generation from 3% in 2003 to 20% in 2010. Early divestiture of Navajo shown in Cases 2 and 3 results in approximately 7.5 MMT less CO_2 emissions between 2016 and 2019 and early divestiture of IPP shown in Case 3 results in a reduction of CO_2 emissions of 21.1 MMT between 2020 and 2027.

Total Power System Cost Comparisons

The total power system cost for each case includes bulk power costs, depreciation costs related to transmission, distribution, and generation, bond debt-service, and city transfer costs. These costs assume full funding of the Power System programs including the Power Reliability Program and Energy Efficiency programs, among others. The Power System costs shown below in Figure ES-3 reflect short-term spending reductions through 2011-12 fiscal year with subsequent years reflecting a restoration of funding levels to insure that the IRP recommendations can be realized. The illustrated costs and rates presented below do not attempt to represent a thorough analysis of Power System finances. The main goal of this section is to illustrate the general trend of Power System costs relative to the 3 cases analyzed.

Figure ES-3 summarizes the total annual power system costs.

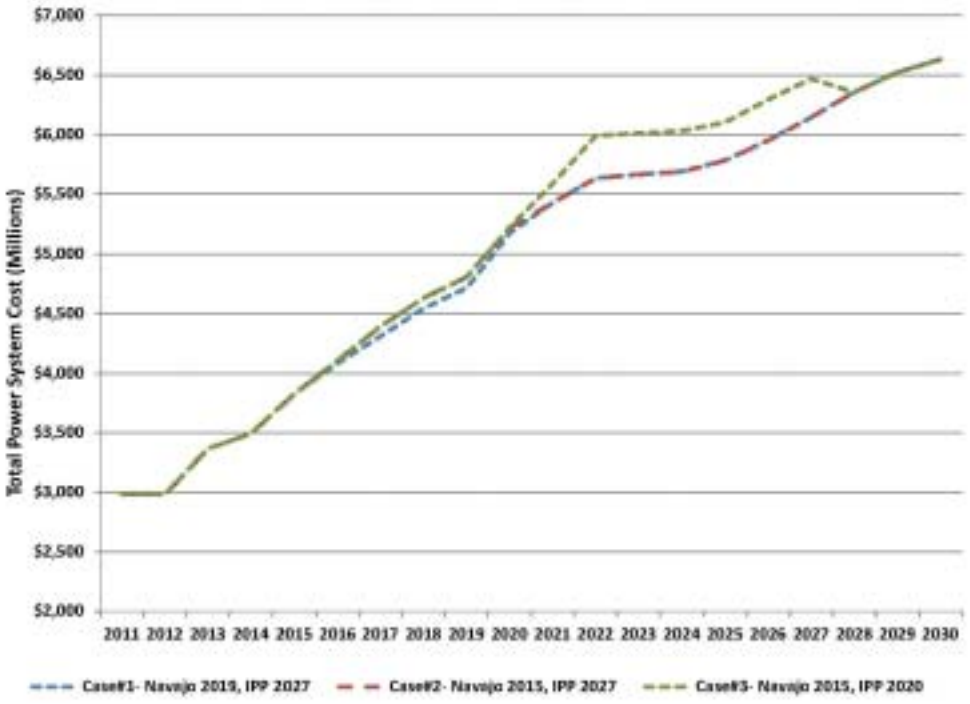

Figure ES-3. Comparison of annual power system costs over next 20 fiscal years.

AR0071076

Sensitivity Analyses on the Recommended Cases

With the early divestiture of Navajo in 2015 and the IPP coal contract ending in June 2027, increased bulk power costs are expected to rise with the divestiture of each of these resources as shown on Figure ES-4. It is important to note that bulk power costs shown in Figure ES-4 include fuel, renewable and other purchase power costs in addition to coal divestiture related costs which are shown in Table 4-4. Applying high and low fuel prices to these bulk power costs, the divestiture of these resources could result in large cost increases should fuel prices remain at higher than expected levels. Conversely, lower than expected fuel prices could have the opposite effect on bulk power costs.

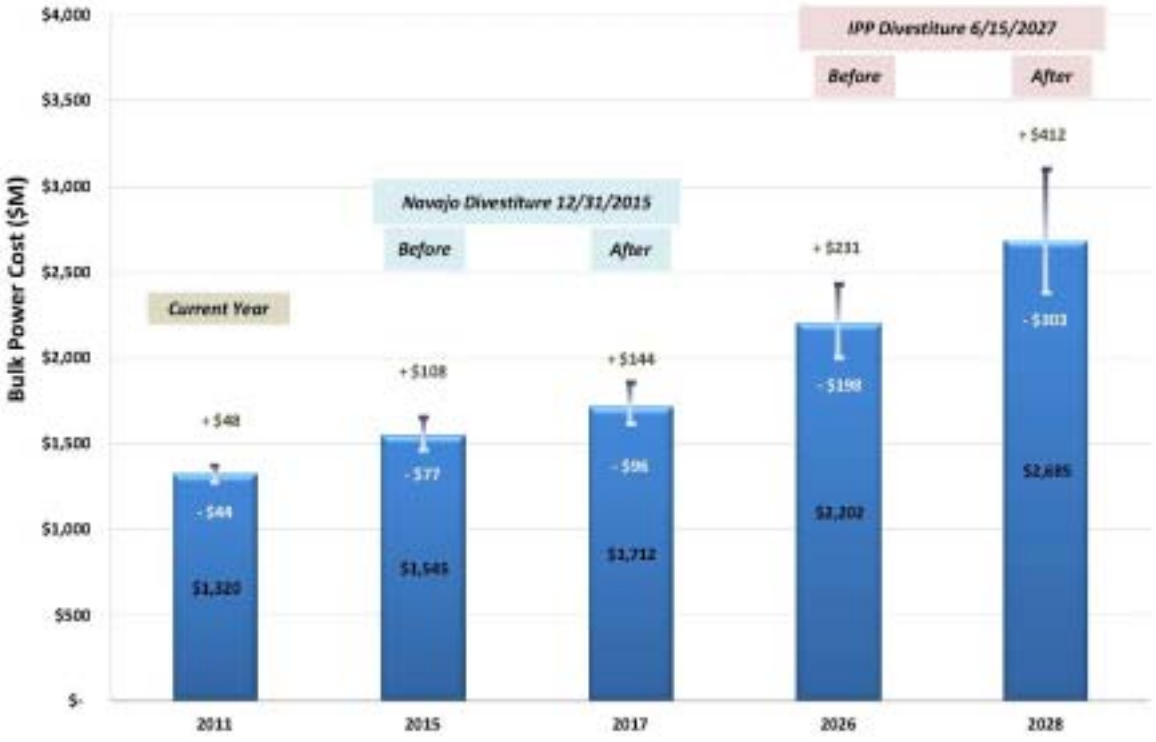

Figure ES-4. Recommended case - bulk power cost before and after coal divestitures with potential cost impacts from high and low fuel prices.

AR0071077

Rate Contributions from Environmental and Reliability Programs

Summarized in Figure ES-5 is the cost contribution from various environmental and reliability programs towards the retail rates. One can draw the conclusion that there is a significant cost to comply with various reliability and regulatory requirements while divesting of Navajo in 2015 and IPP in 2027.

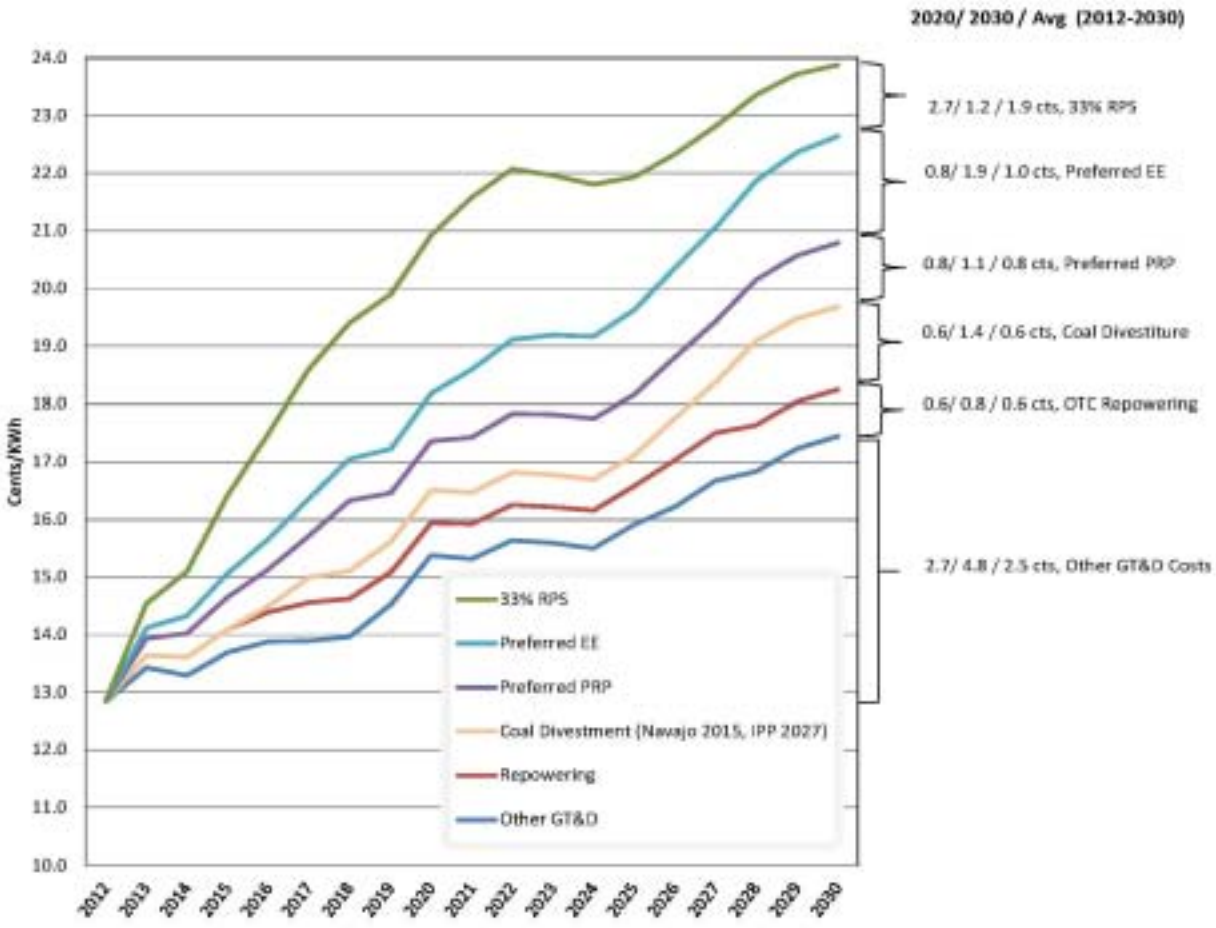

Figure ES-5. Electric rate contributions of environmental and reliability programs by fiscal year based on the 2011-12 budget forecast (preferred case).

A few observations from Figure ES-5 can be made regarding the RPS and EE program. Firstly, the influence of the RPS program on rates increases substantially through 2020 when the RPS percentage of sales reaches 33%. Beyond 2020, the RPS component of rates begins to decline as fuel savings increases over time with escalating fuel prices. Secondly, the EE program component of rates increases over time as power system fixed costs are distributed over the reduced energy sales attributable to the EE program.

Figures ES-6 and ES-7 further illustrate the effect that costs related to environmental and reliability programs will have on average residential and commercial/industrial customer

AR0071078

monthly bills from these environmental and reliability programs.

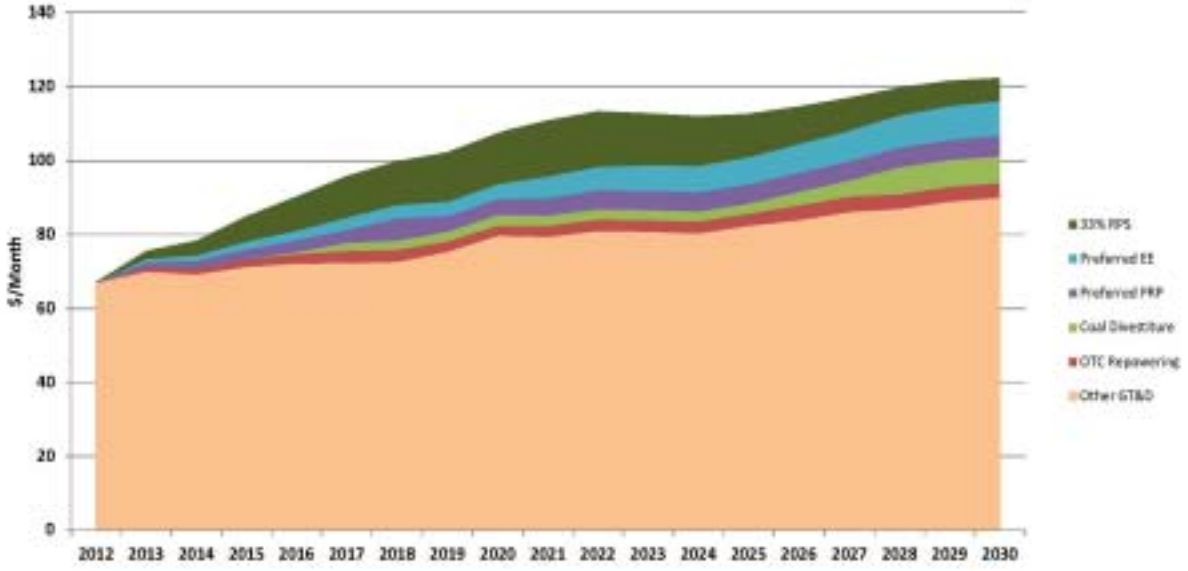

Figure ES-6. Average residential customer bill (500 kWh/month) with environmental and reliability programs by fiscal year based on the 2011-12 budget forecast (preferred case).

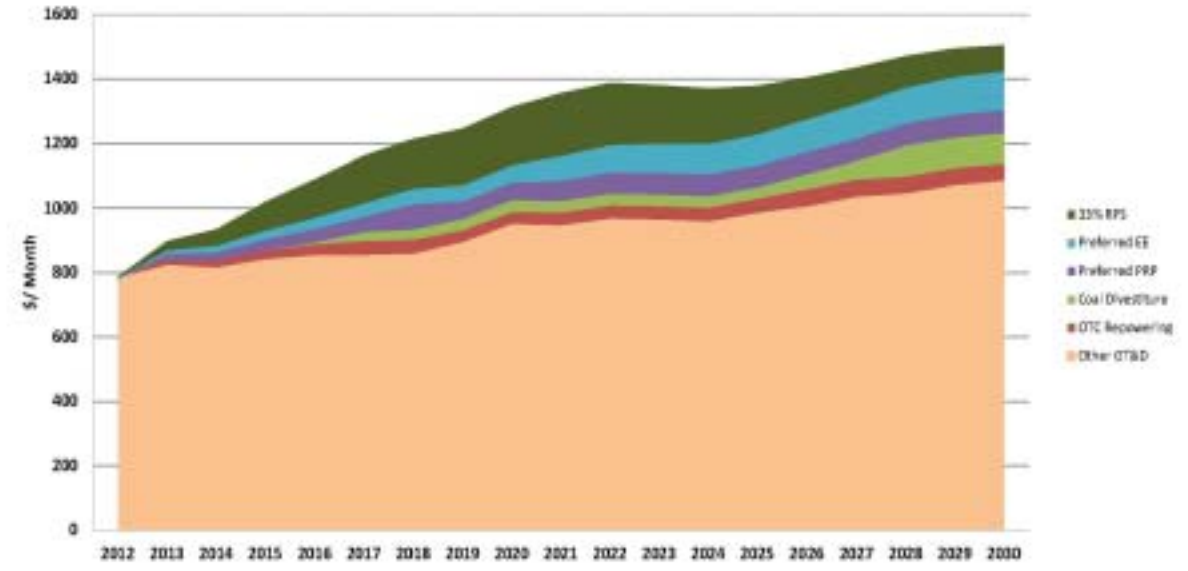

Figure ES-7. Average commercial/industrial customer bill (6,500 kWh/month) with environmental and reliability programs by fiscal year based on the 2011-12 budget forecast (preferred case).

AR0071079

Recommended Strategic Case

Decisions to fund coal divestiture strategies cannot take place independent of other power system programs. Maintaining reliability and meeting regulatory requirements are primary considerations before any coal divestiture cases can be considered. However, this IRP presupposes funding of these programs so that the recommended coal divestiture case can be implemented.

Achieving the goals of reliability and environmental stewardship, while maintaining competitive rates, requires that costs be closely managed. Considering these factors, Case 2 (see Table ES-3 below) with early Navajo coal divestiture in 2015 becomes the recommended case for the 2011 IRP. Although Case 2 represents additional cost as compared to Case 1, the additional costs to rate payers appears to be reasonable in light of the environmental benefit of reducing CO_2 emissions by 7.5 MMT. Early divestiture of Navajo also provides additional time to insure a smooth transition in acquiring and implementing replacement resources. The 2010 IRP included the same recommendation to accelerate divestiture of Navajo and this IRP further clarifies and supports this prior recommendation. This recommended case presents a reasonable approach to achieving environmental goals without excessive costs to our ratepayers while limiting potential exposure to possible fuel price volatility to within manageable limits.

Table ES-3. 2011 IRP RECOMMENDED CASE

	2020	SB 1368 Compliance Date		New Renewables Installed (MW) 2011-2020			New Renewables Installed (MW) 2011-2030			
Case ID	RPS Target	Navajo Replacement	IPP Replacement	Geo/ Biomass	Wind	Solar	Geo/ Biomass	Wind	Solar	Generic
Case 2	33%	12/31/2015	6/15/2027	243	492	726	308	492	917	162

The changing generation energy mix for 2010, 2020, and 2030 based on the Recommended Case is illustrated in Table ES-4.

Table ES-4. ENERGY MIX FOR RECOMMENDED CASE

Year	2010	2020	2030
Coal	39%	26%	0%
Natural Gas	22%	21%	45%
Nuclear	11%	9%	8%
Hydro	3%	4%	4%
Renewable	20%	33%	33%
Energy Efficiency [1]	0%	7%	10%
Generic Purchase/ Other	5%	0%	0%

[1] Forward-looking, does not include 3% existing as of 2010.

AR0071080

VIII CONCLUSIONS/RECOMMENDATION

LADWP's recommended strategy set forth in this IRP for meeting its key objectives can be separated into two areas: (1) Regulatory and Reliability Initiatives, and (2) Strategic Initiatives. Regulatory and Reliability Initiatives are required actions to ensure system reliability and compliance with regulatory and legislative mandates. Strategic Initiatives are policy actions to achieve objectives established by the LADWP Board of Water and Power Commissioners and the Los Angeles City Council, and reflect their vision and leadership.

The analysis performed in Section 4 to identify the 2011 IRP recommended case closely mirrors the same recommended strategy put forth in the 2010 IRP which incorporated feedback from LADWP's 2010 community outreach efforts (See Section 5.2 and Appendix N for details). The 2011 IRP recommended strategy differs slightly from the 2010 IRP in the timing of the Navajo coal divestiture which is now planned for 2015 instead of 2013. Another difference is in the renewable installed capacity by technology type (e.g. geothermal, wind, and solar). The reasons for these changes are further explained in Section 3.2.1.

Regulatory and Reliability Initiatives

- SB 2 (1X) - RPS Percentage

  LADWP must increase its percentage of renewable energy per recently enacted state law, from the current 20 percent at the end of 2010, to 33 percent by the end of 2020. SB 2 1(X) also establishes interim targets to ensure progress towards the 33 percent goal. Addressing this mandate requires the continued diligence LADWP has demonstrated in raising its renewable portfolio from 3 percent in 2003 to 20 percent in 2010.

- Power Reliability Program and System Infrastructure Investment

  LADWP must re-establish sustained funding to invest in replacing aging transmission and distribution infrastructure to ensure system reliability, especially during significant weather events. Recent funding shortfalls have resulted in an increase in system outages. Section 1.6.2 of this IRP discusses the negative consequences that continued underfunding poses to the city.

- Repowering for Reliability and to Address OTC

  LADWP will continue to repower older, gas-fired generating units at its coastal generating station for the reasons discussed previously. The repowering program is a long term series of projects that will increase reliability and eliminate the need for once-through ocean cooling.

- AB 32 – CO_2 Cap and Trade

  LADWP will participate in the mandated green house cap-and-trade system which is scheduled to start January 1, 2013. During the next year, LADWP will participate in the regulatory process that will clarify some outstanding details of the proposed program.

AR0071081

- SB 1368 Compliance

  Navajo and IPP must be compliant with the mandates established in SB 1368 by 2019 and 2027, respectively. IRP modeling determined that these units will be replaced with a combination of renewable energy, demand response, EE, short term market purchases, and conventional gas-fired generation.

- Energy Efficiency

  LADWP will continue to pursue and implement energy efficiency programs per AB 2021 standards, including recommendations contained in its latest Market Potential Study.

- Castaic FERC Re-licensing Program

  On January 31, 2022, the Federal Energy Regulatory Commission's (FERC) license to operate Castaic Pumped-storage Hydroelectric Plant will expire. In 2016, LADWP expects to file a notice of intent (NOI) and initiate the formal studies and applications for re-license. Based on reviews of re-licensing activity for similar projects, LADWP could expect cumulative expenditures of approximately $10 million prior to filing the NOI and approximately $80 million before the license expires.

- Transmission

  LADWP should implement those recommendations of the latest Ten-Year Transmission Assessment Plan in order to maintain reliability in accordance with regulatory guidelines.

Strategic Initiatives

- Early Compliance with SB 1368

  Comments from the public workshops indicated the desire to comply with SB 1368 as early as possible. Navajo must be compliant with SB 1368 by 2019. LADWP recommends divestiture from Navajo by 2015. This will reduce LADWP's CO_2 emissions by 7.5 million metric tons and required additional revenue of about $343 million.

  In this 2011 IRP, LADWP recommends no change in IPP until 2027 at which time the site would be reconfigured, providing LADWP with firm transmission capacity for potential renewable projects. However, LADWP is actively investigating potential options in coordination with the Intermountain Power Agency (IPA) Board and the other participants, and will further address this issue in next year's 2012 IRP.

- Local Solar

  Comments received at the public workshops indicate local solar development should be a priority in LADWP's renewables procurement strategy. LADWP is recommending a policy action to allow approximately 40-50 percent of its solar resources be sited locally through initiatives including the Solar Incentive Program, feed-in tariffs, and installation of solar on City-owned properties. Local solar costs an estimated additional $50/MWh

AR0071082

over utility-scale solar located outside the Los Angeles Basin, estimated to cost $120/MWh, primarily due to economies of scale and about 30% better solar insolation, even when considering transmission and distribution costs.

- Public Benefits

  LADWP should continue to pursue public benefit initiatives, including low-income and lifeline programs, refrigerator exchange, conservation, public outreach and education.

- Advanced Reliability Improvements

  LADWP is looking ahead to technologies that will enhance the reliability of its system, including smart grid technologies, enhanced information systems, automation of system functions, and advanced methods of outage management. These enhancements will also better integrate local generation such as solar into the distribution network, enable smart charging of electric vehicles, and advance demand-side management technologies.

- System Losses

  To reduce system losses, LADWP should implement the recommendations of the recently completed Reactive Power Management Study, including the installation of shunt capacitors and shunt inductors at appropriate locations within the system grid.

- Demand Response

  LADWP should begin the development of a formal Demand Response program that will initially provide 5 MW of peak demand capacity beginning in 2013 and gradually build to 200 MW by 2020 and 500 MW by 2026. Ramping the program in this manner will provide the development of in-house expertise, and will also allow time to deploy the supporting information systems necessary to implement these systems successfully.

Revenue Requirements

The reliability, regulatory, and strategic initiatives discussed above require revenue funding as shown in Table ES-5. In addition to funding for basic generation, transmission, and distribution, revenue is required to fund the Power Reliability Program, increase renewable energy, address OTC, energy efficiency and demand reduction, fund local solar programs, and transition away from coal.

AR0071083

Table ES-5. RECOMMENDED REVENUE REQUIRED TO FUND PROGRAM INITIATIVES, 2011-2020

PROGRAM INITIATIVE	Revenue Requirement ($ Billion)
Power Reliability	$6.8
OTC Repowering of Power Plants	$1.2
Transition from Coal (Navajo GS)	$0.4
Increasing Renewable Energy	$6.0
Expand Renewable Transmission	$0.5
Expand Local Solar	$0.7
Increasing Energy Efficiency	$0.7
Smart Grid Investments	$0.3
SUBTOTAL	$16.6
Basic Generation, Transmission and Distribution	$23.4
TOTAL	$39.9

Some elements of the plan will take five to ten years to implement. It is important to commit to a direction so that critical time and resources are not lost. Subsequent IRPs will refine the direction as additional information becomes available. The recommended plan allows for flexibility to incorporate necessary adjustments over time. It is also important to set a steady course and pace to allow for reasoned and deliberate action by LADWP staff, Board, or City Council to avoid situations leading to unfavorable pricing or adverse rate impacts. The IRP implementation must be viable from a technical and financial perspective to best balance all the priorities of reliability, environmental stewardship, and cost.

AR0071084

1.0 INTRODUCTION

1.1 Overview of the 2011 Integrated Resource Plan

This document represents the Los Angeles Department of Water and Power (LADWP) Integrated Resource Plan (IRP) for 2011. The goal of this IRP is to identify a portfolio of generation resources that meets the city's future energy needs at the lowest cost and risk consistent with LADWP's environmental priorities and reliability standards. The IRP is an important planning document for electric utilities, and many states and regulatory agencies require development of an IRP prior to approval of procurement programs or electric rate increases.

This IRP considers a 20 year planning horizon to guide LADWP as it executes major new projects and programs. The overriding purpose is to provide a framework to assure the future energy needs of LADWP customers are met in a manner that balances the key objectives of:

- High reliability of electric service
- Competitive electric rates consistent with sound business principles
- Responsible environmental stewardship meeting all regulatory obligations

In balancing these key objectives, LADWP's strategic planning efforts must ensure a high level of system reliability, consider impacts to the local and regional economy, allow for volatility in fuel and other cost factors, comply with federal, state, and local regulations, and guarantee fiscal responsibility.

The 2011 integrated resource planning process developed alternative strategic cases that assess different options of divestiture from coal-fired generation. These cases are modeled to determine their respective operational and fiscal impacts, as well as their effects on greenhouse gas emission levels. This document presents the results of this analysis and recommends the appropriate near-term actions and long-term plan to best meet the future electrical needs of Los Angeles.

AR0071085

1.2 Organization of the IRP

This document begins with a brief discussion of the objectives of this IRP (Section 1.3).

Section 1.4 provides a brief overview of the current Power System—LADWP's electricity generation, transmission and distribution infrastructure. Power System upgrades are also addressed.

Section 1.5 summarizes LADWP's major recent accomplishments, underscoring LADWP's commitment to environmental leadership, maintaining a high level of electric service reliability, and competitive energy rates.

Section 1.6 summarizes the key issues and challenges facing LADWP. As the largest municipal utility in the U.S., LADWP faces unique challenges that are expected to become more complex and demanding over the timeframe considered in this IRP.

Section 1.7 summarizes the Public Outreach effort conducted in as part of the 2010 IRP process. The 2010 public outreach conclusions are considered applicable to this 2010 IRP. Next year's 2012 IRP process will include a new public outreach program.

Section 1.8 discusses the 2011 IRP development process that resulted in this document.

The remainder of this IRP is organized as follows:

- Section 2, "Load Forecast and Resources," provides forecasts of electricity demand, discusses the resources available or needed to meet that demand, and addresses the issues associated with each resource.
- Section 3, "Strategic Case Development," establishes potential alternatives available to LADWP to meet its projected electricity demand.
- Section 4, "Strategic Case Analysis," addresses the operational modeling used to assess the impact of each alternative on cost, energy rates, and levels of greenhouse gas emissions.
- Section 5, "Recommendations," provides an overview of recommendations, including near-term actions and long-term goals.

AR0071086

1.3 Objectives of the IRP

This 2011 IRP documents the long term planning efforts for LADWP's power system. It includes a review of the various issues and considerations that LADWP must address moving forward, and summarizes the planning process used to identify future energy resource requirements. The recommended long term plan is presented, as are the actions and initiatives LADWP must undertake over the next several years. The key objectives of LADWP's long term planning efforts are: (1) maintaining a high level of electric service reliability, (2) exercising environmental stewardship, and (3) keeping its energy rates competitive.

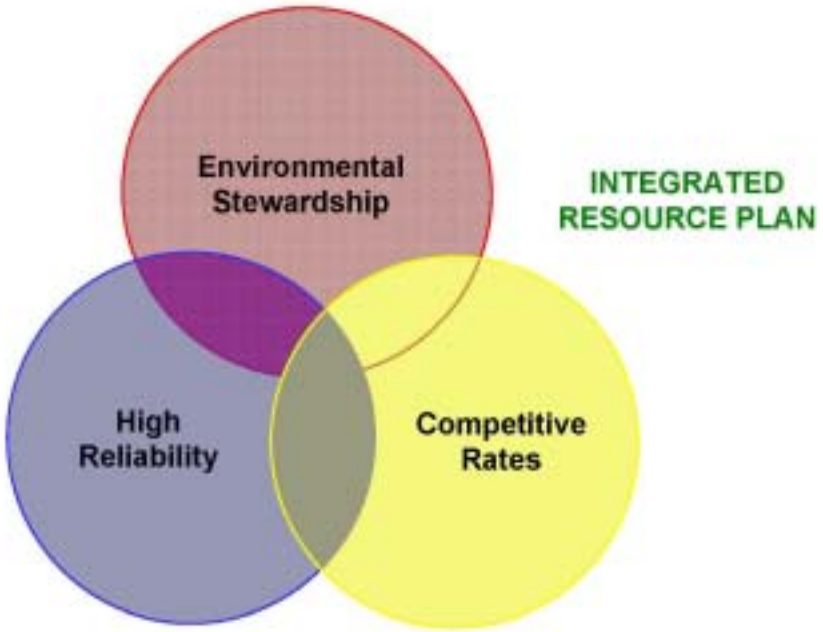

Figure 1-1. Objectives of this IRP.

1.3.1 Reliable Electric Service

Providing reliable electric service to the residents and businesses of Los Angeles has always been a cornerstone of LADWP. Some of the key principles, policies and program areas related to reliability are listed here:

- Reliability Standards

  LADWP will comply with all Federal Energy Regulatory Commission (FERC), North American Electric Reliability Corporation (NERC) and Western Electric Coordinating Council (WECC) standards regarding system reliability. NERC and WECC are electric utility organizations that enforce reliability standards on owners, operators and users of the bulk power system.

AR0071087

- CAISO-RTO

  The California Independent System Operator or CAISO was established in 1998 as part of California's electric utility restructuring effort. CAISO was established as a non-profit corporation to provide an impartial link between power plants and utilities. LADWP is not a member of the CAISO but has recently been certified by the CAISO to be a scheduling coordinator which will authorize LADWP to buy and sell energy and/or ancillary services in the CAISO market. The ability to interface with CAISO increases the reliable operation of the bulk power system.

- Balancing Authority

  LADWP is a registered Balancing Authority with NERC and is responsible for coordinating and balancing the generation and delivery of electricity through its system. LADWP will continue to maintain its presence as a balancing authority.

- Self Sufficiency

  LADWP maintains a policy of owning or controlling its transmission and generation resources to serve its native load customers. This policy serves the City of Los Angeles well. However, in consideration of economic and environmental factors involved with the coal divestiture options discussed in Section 3 and 4, a limited amount of generation capacity is proposed to come from 3rd quarter purchases acquired in the wholesale electricity market. These purchases will be temporary in the 2015 to 2030 timeframe, will be called upon only in the third quarter of a given year, and will amount to less than 4% of the total system capacity needs.

- Coastal Power Plants

  LADWP operates three coastal natural gas fired power plants that are critical to its operations. These plants were built from the 1940s up to the 1970s. One of these plants was modernized in the 1990s, resulting in increased efficiency and reliability while reducing emissions and maintenance costs. The modernization of the remaining generation units is a long term program that is targeted for completion in 2029. LADWP must modernize these plants to comply with environmental regulations, improve efficiency, better integrate renewable resources, and provide for transmission import capability. See Section 1.6.3 and Appendix C for more details.

- Power Reliability Program.

  In response to an increasing frequency of power outages between 2003-2005, LADWP established the Power Reliability Program. The goals of the program include: (1) mitigating problem circuits and stations based on the types of outages specific to a given facility, (2) implementing proactive maintenance and capital improvements to avert/prevent problems before they occur, and (3) establishing replacement cycles for facilities that are in alignment with the equipment's life cycle. See Section 1.6.2 and Appendix E for more details.

AR0071088

- Smart Grid

  Smart Grid refers to the application of advanced information-based technologies that will improve system operations in a variety of areas. Smart Grid technologies provide information that allows the implementation of real-time, self-monitoring communication networks that are predictive rather than reactive to system disturbances, and will enable LADWP and its customers to make decisions to optimize the use of energy, improve reliability, and reduce the consumption of fossil fuels. See Appendix L for more information.

- Distributed Generation

  Distributed Generation (DG) refers to the installation and operation of small-scale electric generators that are located at or near the electrical load. Cogeneration, solar photovoltaic, and fuel cells are examples of DG applications. As more DG is added within the city of Los Angeles, it is important that these generation sources be managed in a manner that does not reduce grid reliability. More information on DG is provided in Section 2.3.3 and Appendix G.

1.3.2 Competitive Rates Consistent With Sound Business Principles

Historically, LADWP's electric rates have been consistently among the lowest in California. As utilities throughout the industry address renewable energy, greenhouse gas emissions, ocean water cooling and other issues, it can be expected that rates for most, if not all utilities, will rise. By continuing its strategic planning and implementation activities, LADWP hopes to maintain its rates as among the lowest in the region.

Energy rates

As shown in Figure 1-2, LADWP's rates for Fiscal Year 2010/2011 were lower than other utilities in Southern California.

AR0071089

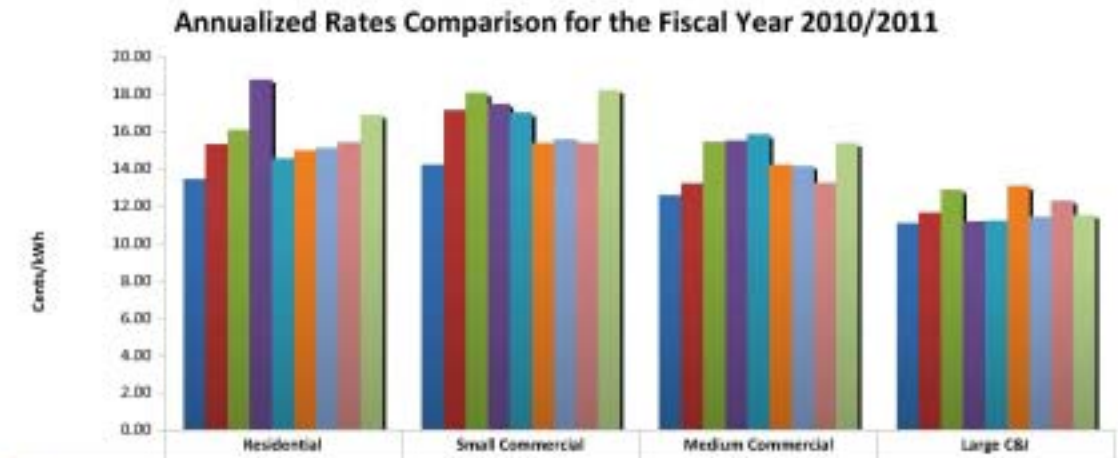

Figure 1-2. LADWP rate comparison among other electric utilities.

While LADWP provides electricity at competitively low rates, several factors challenge the current rate structure. These factors include new regulatory requirements for renewable energy, the reduction of greenhouse gas emissions and ocean water for power plant cooling, the costs to replace aging infrastructure, and the potential volatility of natural gas and coal prices. Transmission capacity upgrades, energy efficiency and demand response programs, and projects to implement coal divestiture will also exert upward pressure on energy rates. Because of these and other initiatives, it is expected that structural rate adjustments and amendments to the Energy Cost Adjustment Factor will be necessary to maintain appropriate debt ratios and bond ratings.

Financial Metrics

Since LADWP sells substantial amounts of bonds to sustain its capital expenditures, maintaining its high credit rating is essential to minimizing financial costs. To maintain its high credit rating, LADWP adheres to the following policies:

- Bond rating

  Maintain LADWP's current "AA" bond credit rating to keep financing costs as low as possible.

AR0071090

- Debt service coverage

  Maintain a debt service coverage ratio of at least 2.25

- Adjusted debt service coverage

  Maintain an adjusted debt service coverage ratio of at least 1.75

- Full obligation coverage

  Maintain a full obligation coverage ratio of 1.5

- City transfer

  Maintain a level of net income sufficient to ensure stable transfer of funds to the City.

- Cash on hand

  110 days of operating cash or $300 million, whichever is greater.

- Capitalization ratio

  Maintain a capitalization ratio of 65% percent or less.

These financial parameters are used in the electric rates analysis, discussed in Section 5.5.

1.3.3 Environmental Stewardship

LADWP's mission includes a role as an environmentally responsible public agency. Programs and subject areas related to improving the environment include:

- Renewable energy

  LADWP will continue efforts to increase its use of renewable energy resources to provide electricity to Los Angeles. LADWP will, at a minimum, comply with local, state and federal mandates for levels of renewable energy as a percentage of electricity sales. Senate Bill SB 2 (1X) sets renewable energy targets of 20% for years 2011-2013, 25% by 2016 and 33% by 2020. For more information, see Sections 1.5, 1.6.4, 2.4, 3.4.2, and Appendix D.

- Carbon dioxide (CO_2) emissions

  LADWP will continue its efforts to reduce CO_2 emissions. The potential early divestiture from coal-fired generation, a key strategic focal point of this 2011 IRP, is one means of achieving reductions of CO_2 emissions. Additional recommended means of reducing CO_2 emissions include the continuation and expansion of energy efficiency programs, and the transition towards increasing amounts of energy generated from renewable resources. For further information, see Section 1.6.3 and Appendix C.

AR0071091

- Once-Through Cooling

  LADWP has embarked on a series of repowering projects that are reducing the use of ocean water for cooling at its coastal generating stations. Completed projects to date have already reduced ocean water use by 17% from 1990 levels. The Haynes 5 & 6 repowering project, currently in construction and scheduled for completion in 2013, will further reduce ocean water use by another 25%. Within the 20-year planning horizon of this IRP, five additional repowering projects will totally eliminate the use of ocean water. More information on OTC can be found in Sections 1.6.5.

- Energy efficiency

  Since 2008, LADWP has spent approximately $282 million on its energy efficiency programs, and these programs have reduced long-term peak period demand and consumption by approximately 303 MW and 1,256 GWh, respectively. LADWP is committed to developing comprehensive programs with measurable, verifiable goals as well as implementing robust, cost effective energy efficiency programs. Further information regarding LADWP's EE Program can be found in Section 2.3.1 and Appendix B.

- Solar Incentive Program and Feed-in Tariff

  To date, LADWP has encouraged the installation of more than 41 MW of solar installations at over 4,500 customer locations through its ratepayer-funded Solar Incentive Program. Additionally, LADWP is developing a feed-in tariff program that will further promote solar development across the city. Solar energy will help LADWP achieve its environmental goals of increased energy generated from renewable resources and the reduction of greenhouse gas emissions.

- Demand Response Program

  This IRP recommends the development of a Demand Response (DR) program, which will lessen environmental impacts by deferring the need to build additional generation facilities and infrastructure, as well as reducing energy usage and the associated greenhouse gas emissions. Details regarding the proposed DR program are included in Section 2.3.2.

AR0071092

1.4 LADWP's Power System

"Capacity" is an electric utility term referring to how much power a system can generate at a given instant in time, while "energy" refers to how much power the system generates over a given period of time. Capacity is expressed in megawatts (MW) or gigawatts (GW), while energy is expressed in megawatt-hours (MWh) or gigawatt-hours (GWh).

LADWP's Power System serves approximately 4.1 million people and is the nation's largest municipal electric utility. LADWP experienced an all-time peak demand of 6,142 megawatts (MW), which occurred on September 27, 2010, and has an installed net dependable generation capacity greater than 7,125 MW. Its service territory covers the City and many areas of the Owens Valley, with annual sales exceeding 23 million megawatt-hours (MWh). LADWP is the third largest California electric utility in terms of consumption, behind Southern California Edison and Pacific Gas & Electric—see Figure 1-3 below. Projected future demand growth for LADWP is less than one percent per year. The current economic recession has reduced energy demand slightly over the preceding three years.

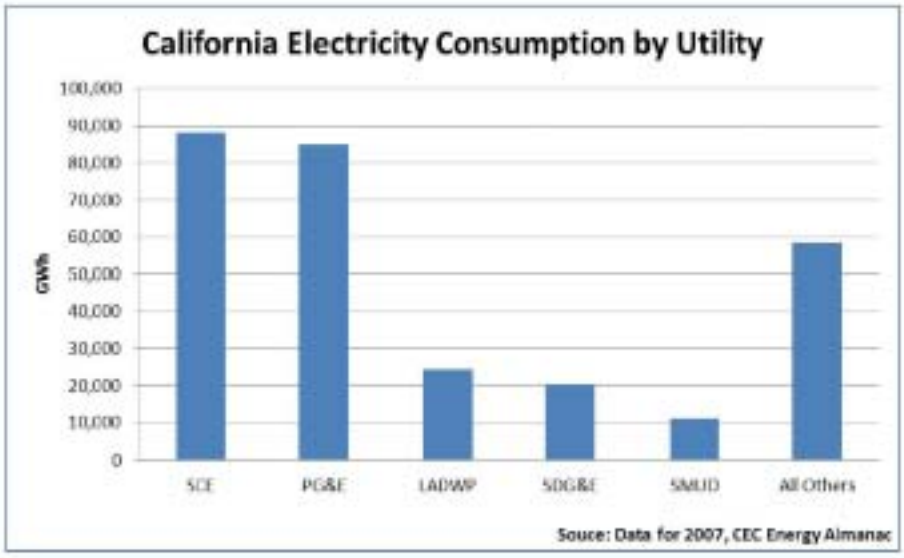

Figure 1-3. Comparison of California utilities by consumption.

LADWP is a "vertically integrated" utility—both owning and operating the majority of its generation, transmission, and distribution systems. LADWP is currently fully resourced to meet peak demand but maintains transmission and wholesale marketing operations to keep production costs low and increase system reliability.

While LADWP customers represent roughly 10 percent of California's electrical load, approximately 25 percent of the state's total transmission capacity is owned by LADWP. LADWP's transmission reach also extends beyond California, and enables the transport of power from a diversified set of generation resources from across the Western United States.

Additional information on the Power System's generation and transmission assets can be found in Section 2.4 and Appendices F and I.

AR0071093

1.5 Recent Accomplishments

A summary of recent LADWP accomplishments consistent with the objectives of this IRP are presented below. These accomplishments promote the goals of maintaining high reliability and exercising environmental stewardship, while keeping rates competitive.

- Renewable portfolio standard

  Through the active procurement of renewable resources, LADWP has increased the renewable energy component of its resource mix from 3% in 2003 to 20% in 2010.

- Energy efficiency

  LADWP continues its commitment to energy efficiency through numerous programs and services to customers, encouraging the adoption of energy-saving practices and installation of energy-efficient equipment. Since 2000, LADWP energy efficiency programs have reduced long-term peak period demand by approximately 303 MWs, resulting in 1,256 GWh of energy savings.

- Emissions reduction

  As of 2010, CO_2 emissions from power generation are 23% lower than 1990 levels. The lower emissions are attributed to the respective sales of the Colstrip and Mohave Generation Stations, increased generation from renewable resources, and the ongoing repowering of the in-basin natural gas units.

  Due to the installation of advanced pollution control equipment at all of its in-basin generating stations, NO_X emissions from LADWP's local generating plants are at least 90 percent lower than 1990 level,

- Once-through cooling

  As a result of completed repowering projects, LADWP has reduced the use of once-through ocean water cooling by 17% from 1990 levels. The current plan calls for a complete phase-out of ocean water cooling by 2029.

- Haynes 5 & 6

  The September 2011 groundbreaking ceremony signified the start of construction for the replacement of Haynes Units 5 and 6. The original units, which date back to the mid 1960's, will be replaced with efficient modern units that can facilitate the integration of intermittent renewable energy. This project is also one of many that that will eliminate the use of ocean water for cooling by 2029.

- Castaic

  The seven units of the Castaic Hydroelectric Plant are currently being rotated out of service for modernization. This multi-phase process began in 2004 and is expected to continue through 2014. To date, five units have been completed. The associated increase in efficiency is projected to add up to 80 MW of renewable qualifying capacity to Castaic. The increased capacity also results in more reserves available to reliably meet peak system demands.

AR0071094

- Power Reliability Program (PRP)

  The PRP is a comprehensive, long-term power reliability program developed by LADWP to replace aging infrastructure and make permanent repairs to generation, transmission, and distribution infrastructure. Through the program LADWP successfully reduced the number of distribution outages by 28% between 2006 and 2009, by accelerating the replacement of transformers, poles, underground cables, and other equipment. See Section 1.6.2 and Appendix E for more information.

- Green Power Program

  LADWP offers its customers an opportunity to participate in the Green Power Program. "Green Power" is produced from renewable resources such as wind energy, geothermal, or other renewable resources, rather than conventional generating plants. Over 17,100 LADWP customers participated in the program during 2010. These participants receive approximately 104,000 MWh of renewable energy annually. Since program inception, in 1999, to the end of 2010, 818,768 MWh of renewable energy was procured, making it one of the largest voluntary green pricing programs in the nation.

- Solar Incentive Program

  To date, LADWP has encouraged the installation of 41 MW of solar at approximately 4,500 customer locations through its ratepayer-funded Solar Incentive Program.

- Upgraded capacity on the Southern Transmission System (STS)

  In May 2011, 480 MW of additional capacity was added to the existing transmission line from Utah, of which LADWP's share is 288 MW. The increased capacity allows LADWP to increase procurement of renewable energy.

- Navajo Generating Station retrofitted with low NO_x burners

  In March 2011, Navajo completed a three year project that retrofitted the boilers of all three units with low NO_x burners and separated over-fire air systems. This project was successful in reducing NO_x emissions by 30% which represents an annual NO_x emission reduction of 14,000 tons per year.

- Barren Ridge Switching Station

  The Barren Ridge Switching Station, located 15 miles north of Mohave, was completed in 2009. This substation is a key component of the Barren Ridge Renewable Transmission Project, which will enable LADWP to interconnect approximately 1,400 MW of wind, solar, and other renewable resources that will be available in the next several years, from the Mohave Desert and Tehachapi Mountain areas. The next step for the project is to upgrade and build a new transmission line from the new substation to a new Haskell Canyon Station near Santa Clarita.

AR0071095

- Milford II Wind Project

  In May 2011, LADWP began receiving over 100 MW of new wind energy. Milford II is an expansion of the 209 MW Milford I wind farm project. Together, Milford I and II are providing 2.6% of LADWP's total energy sales.

- Electric Vehicles Incentive for Home Chargers

  To encourage the transition towards electric vehicles, LADWP launched a demonstration program in April 2011 providing a $2,000 rebate for home charging systems. LADWP also worked with other City agencies to streamline the process time for permitting and installation of these systems.

AR0071096

1.6 Key Issues and Challenges

LADWP faces a number of concurrent issues and challenges that require careful assessment. Long term strategies must focus on these issues so they can be addressed in the most cost effective manner without compromising reliability compliance and environmental stewardship. The major issues around which the strategies of this IRP are centered include: ensuring reliability, greenhouse gas emission reduction, increasing the amounts of renewable generation resources, and addressing once-through cooling.

However, the inability to fund the programs designed to address these issues warrants some discussion. Current budget constraints are deferring a number of initiatives and programs. The delays surrounding resolution of the Power System budget have the potential of impeding LADWP's ability to meet its long term plans and obligations.

1.6.1 Adequate Multi-year Funding to Support Programs

Based on last year's 2010 IRP, a multi-year rate increase was recommended beginning fiscal year 2011-12. The rate increase would have supported elements of last year's IRP, all of which remain as the foundation for LADWP's short and long term plans. Because the rate increase was not realized in July 2011, many of the programs that required funding were scaled down, delayed or deferred.

A multi-year funding plan is necessary to provide consistent and sustainable project and program development. Funding that is based on annual budgets are subject year-to-year fluctuations which introduces uncertainty for our customers and the inefficient use of staff and financial resources that are necessary to meet LADWP's objectives and compliance requirements.

Properly funded programs will enable LADWP to achieve the following objectives:

- Modernize its coastal generation units to replace aging equipment and to satisfy once-through cooling regulatory requirements.
- Implement early coal divestiture.
- Secure the state-mandated amounts of renewable energy.
- Through the Power Reliability Program, reduce the number of distribution outages and improve system reliability.
- Implement necessary transmission improvements to maintain reliability.
- Achieve energy efficiency target levels.
- Implement Smart Grid initiatives.
- Comply with FERC-approved reliability standards.

AR0071097

A rate process that began earlier this year is addressing the revenue needs for LADWP. A proposed 3-year rate adjustment that would support the programs listed above is being considered. The expectation is that the rate process will conclude sometime in 2012. Securing adequate multi-year funding is crucial to ensure LADWP's ability to stay on track towards meeting its future long term goals and obligations.

1.6.2 Ensuring Reliability

Challenges to ensuring continued reliable electric service include the replacement of aging generation facilities, maintaining grid reliability, the integration of intermittent renewable energy resources, and the replacement of poles, power cables, transformers and other elements of the local distribution system.

Aging Facilities and Infrastructure

LADWP's generating units sited within the Los Angeles Basin were primarily built in the late 1950s and early 1960s. While these units have undergone extensive upgrades, they are approaching the end of their service lives. Repowering of these units began in 1994, and refurbishment is approximately one-third complete. Repowered units will be substantially cleaner, more efficient, and more reliable than the units they are replacing. Repowering LADWP's gas-fired units will also assist in integrating intermittent renewable resources into LADWP's energy mix by providing quick–response, back-up generation capacity.

LADWP's local transmission system cannot be reliably operated without generation from local thermal generating plants. The amount of generation required to provide transmission reliability is termed Reliability Must Run (RMR) generation. Repowering these local units will maintain transmission reliability by maintaining the reliability of RMR generation.

Historically, LADWP's local generation has provided voltage control for the basin transmission system. Over the years, as imports into the basin transmission system have increased, fewer local generators are on-line. No other means of voltage control, such as static capacitors and reactors, have been installed. As a result, LADWP's ability to control voltage has decreased. As more renewables become available, even fewer local generating units are likely to be on-line, and the ability to control nighttime voltage may become unmanageable.

Grid Reliability

LADWP's latest Ten-Year Transmission Assessment Plan has identified a number of infrastructure improvements that are needed to avoid potential overloads on key segments of the Basin transmission system. These overload conditions, if encountered, could lead to load shedding events (intentional power outages) to minimize the overall impact on the power system. LADWP has also investigated the system's reactive power needs, and

AR0071098

recommends further improvements to reduce system losses and optimize performance. More information can be found in Section 2.4.4.

Integration of Intermittent Renewable Energy

The integration of renewable energy into the grid poses major challenges. Integrating renewables may, paradoxically, require additional gas fired generation. Because renewable resources like wind and solar produce electricity variably and intermittently (i.e., only when the wind is blowing or when the sun is shining), integration of these resources requires additional generation units to compensate for significant and often rapid swings in energy production. These swings present operational challenges and must be leveled by controllable generation capable of equally rapid changes of generation in the opposite direction. This stabilization is known as "regulation." A preferred solution would use energy storage to regulate delivery of energy and reduce the severity of integration problems. LADWP currently uses, among other resources, pumped water storage and hydro resources for regulation. Batteries and compressed air offer alternative storage solutions, but these technologies are still in development and have not yet been proven as commercially viable.

LADWP is conducting studies to determine the maximum levels of intermittent energy resources that can be integrated reliably and the investments necessary to maintain power grid reliability.

Power Reliability Program (PRP)

Between 2003 and 2005, LADWP experienced a growing number of distribution outages due to, among other things, aging infrastructure (poles, lines, transformers, etc.), and deferred maintenance and asset replacement.[1] In response, LADWP established a comprehensive Power Reliability Program (PRP) in 2006 which provided increased funding to address the growing maintenance backlog. The goals of the program include (1) mitigating problem circuits and stations based on the types of outages specific to a given facility, (2) implementing proactive maintenance and capital improvements to avert problems before they occur, and (3) establishing replacement cycles for facilities that are in alignment with equipment life cycle.

The PRP has clearly defined annual targets for various distribution, substation, and transmission assets. While cable replacements consistently reached ideal replacement rates, the overall number of underground related outages has been falling. However, the overhead distribution replacements did not reached their ideal replacement rates, and the number of overhead outages has continued to rise. This has also contributed to the overall aging of the overhead system. Overhead outages have increased and are expected to continue to degrade with less replacements moving forward. Since 72% of the distribution system is overhead, we can expect the overall distribution outage rate to continue to increase unless replacements are increased dramatically.

[1] To illustrate the age of the City's distribution system, over 50 percent of the 308,000 distribution poles are at least 50 years old.

AR0071099

In the years since the program was implemented, a clear correlation has been established between the amount of funding for PRP and the successful reduction of outages. As shown on Figure 1-4, during the initial 3 years of the PRP, when the program was fully funded, total outages declined by 28%. Budget constraints since then, however, have resulted in program underfunding. As a consequence, outage frequency has flattened out and is on the up rise. The projected outage levels shown in Figure 1-4 reflect current budget shortfalls. Adequate funding is necessary to get the PRP back on track towards its goal of reducing outage levels.

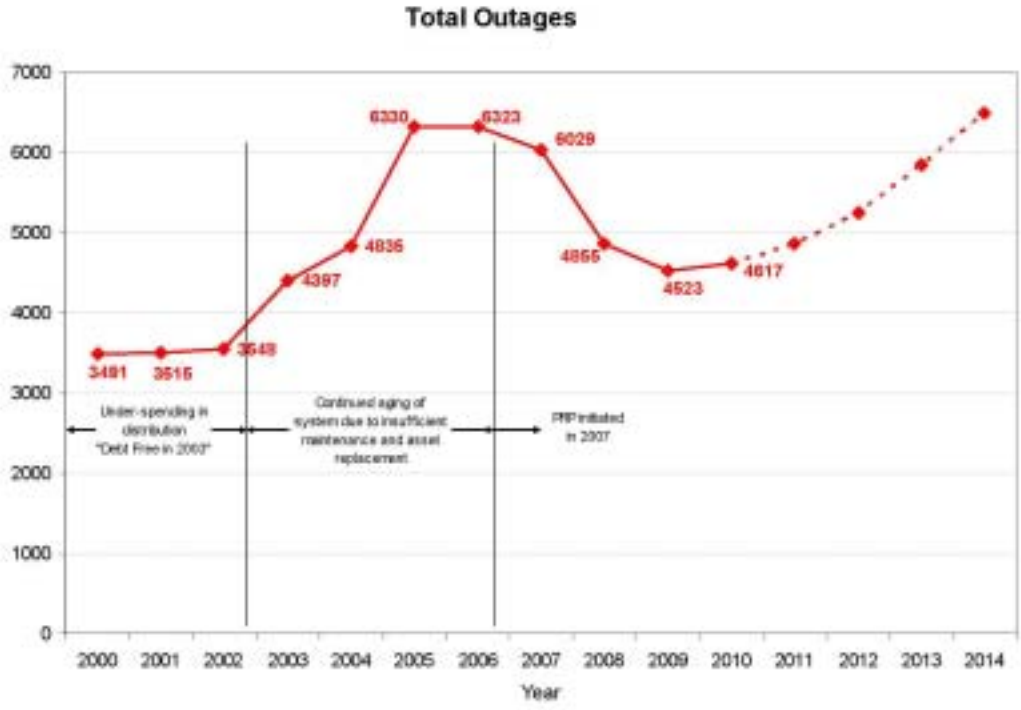

Figure 1-4. Total outages between 2000-2010, and projected to 2014.

Additional information on LADWP's PRP can be found in Appendix E.

1.6.3 GHG Emissions Reduction

LADWP's GHG emissions reduction strategy must comply with state and federal regulations. At the time of this writing, key legislation and regulations either promulgated or proposed include:

- Assembly Bill (AB) 32, the California Global Warming Solutions Act of 2006, calls for reducing the state's GHG emissions to 1990 levels by 2020. The regulations for implementing a greenhouse gas emissions trading program under AB 32 were finalized and adopted on October 20, 2011 by the California Air Resources Board (ARB). Enforcement and compliance with the trading program will begin January 1, 2013. Electric distribution utilities, including LADWP, will

AR0071100

receive an administrative allocation of emission allowances that reflects their respective annual emissions as they implement aggressive energy efficiency measures and the 33 percent Renewable Portfolio Standard. The ARB will continue to work with stakeholders to monitor the impacts of the regulation on all sectors, including the electricity sector.

- SB 1368, the California Greenhouse Gas Emissions Performance Standard Act, also enacted in 2006, prohibits LADWP and other California utilities from entering into long-term financial commitments for base load generation unless it complies with the GHG emissions performance standard. The GHG emissions level must be equal, or below, that of a gas-fired combined cycle units (i.e., 1,100 lbs. per MWh). This standard also applies to existing power plants for any long-term investments or contractual extensions.

In the absence of comprehensive federal climate legislation, the U.S. Environmental Protection Agency (EPA) has taken steps toward regulating GHG emissions from electric power plants under authority of the federal Clean Air Act, and will be issuing a new revised schedule for regulations in the coming months.

LADWP has historically relied upon coal for base load generation. Currently, 39 percent of the energy delivered to LADWP customers is generated from two coal-fired generating stations: the Intermountain Power Project (IPP), located in Utah, and the Navajo Generating Station (NGS), located in Arizona. The NGS's land lease expires in 2019 but has a stipulation for a 25-year extension. IPP's contract is in effect until 2027. These stations provide dependable, low cost base load generation to Los Angeles. Coal-fired generation, however, emits about twice as much CO_2 as energy generated with natural gas. Accordingly, this 2011 IRP focuses on early coal divestiture options as a means to comply with AB 32 and lower LADWP's GHG emission levels. Sections 3 and 4 discuss the alternative strategic case options in detail.

1.6.4 Increasing Renewable Resources

Initiatives to utilize renewable resources to generate electricity support the goal of reducing GHG emissions and lessen our reliance on fossil fuels.

- The LADWP Board of Commissioners has adopted a policy to achieve 20 percent renewables by 2010, and 33 percent by 2020. The Board and City Council have approved projects and long-term power purchase agreements that achieved the 20 percent RPS goal in 2010. The policy has been revised to incorporate SB 2 (1X) requirements, and is included as Reference D-2 of Appendix D.

- State legislation – SB 2 (1X) – which was passed in April 2011 and became effective December 10, 2011, will subject all utilities to procurement of eligible renewable energy resources of 33 percent by 2020, including the following interim targets:

AR0071101

- Maintain at least an average of 20 percent renewables between 2011 and 2013
- Achieve 25 percent renewables by 2016
- Achieve 33 percent renewables by 2020 and maintain this level in all subsequent years.

In addition, SB 2 (1X) sets certain conditions regarding renewable energy contracts entered into on or after 6/1/2010, as shown in Table 1-1.

Table 1-1. SB 2 (1X) CATEGORY REQUIREMENTS FOR RPS ENERGY CONTRACTS

Category[1]	RPS % Target		
	Compliance Period 1 (1/1/2011 – 12/31/2013)	Compliance Period 2 (1/1/2014 – 12/31/2016)	Compliance Period 3 (1/1/2017 – 12/31/2020)
A	Minimum 50%	Minimum 65%	Minimum 75%
B	See footnote 2	See footnote 2	See footnote 2
C	Maximum 25%	Maximum 15%	Maximum 10%

[1]Categories are defined as follows:

Category A = Energy and RECs from eligible resources that

- Have the first point of interconnection with a CA balancing authority or with distribution facilities used to serve end users within a CA balancing authority area; or
- Are scheduled into a CA balancing authority without substituting electricity from another source. If another source provides real-time ancillary services to maintain an hourly import schedule into CA, only the fraction of the schedule actually generated by the renewable resource will count; or
- Have an agreement to dynamically transfer electricity to a CA balancing authority.

Category B = Firmed and shaped energy or RECs from eligible resources providing incremental electricity and scheduled into a CA balancing authority.

Category C = Energy or RECs from eligible resources that do not meet the requirements of category A or B, including unbundled RECs.

[2]Remainder % of resources which are neither in Category A nor Category C.

The legislation allows for the California Energy Commission to issue a notice of violation and correction, and to refer all violations to the California Air Resources Board. Failure to achieve the targets may result in significant penalties.

The challenges of adopting more renewable resources such as wind, solar and geothermal, are: (i) obtaining local and environmental rights and permits for renewable projects and the associated transmission lines needed to deliver energy to Los Angeles; (ii) establishing reliable and cost-effective integration of large scale wind and/or solar farms into the LADWP power grid through the addition of regulation-capable generation; and (iii) developing geothermal sites which are potentially scarce, require large capital

AR0071102

costs, impose exploration risks, and have limited transmission line access. In addition, energy from renewable resources is generally more expensive than energy from conventional fossil fuel resources.

1.6.5 Once-through Cooling

Once-through cooling (OTC) is the process of drawing water from a river, lake, or ocean, pumping it through a generating station's cooling system, and discharging it back to the original body of water. OTC is a major regulatory issue, stemming from the Federal Clean Water Act Section 316(b) and administered locally by the State Water Resources Control Board (SWRCB). The interpretation of rules and development of guidelines for OTC have been several years in the making. See Appendix C for details.

OTC regulations affect LADWP's three coastal generating stations – Scattergood, Haynes, and Harbor. To comply with OTC regulations, generation units at those stations that utilize ocean water for cooling will be repowered with new units that do not use ocean water. The total generation capacity affected by OTC is significant – approximately 2,162 MW, or roughly 35 percent of LADWP's annual peak demand in 2010. The total expenditures required are also significant, on the order of $2.4 billion. Because of the size and scope of the work required, and for various reasons discussed below, the work to comply with OTC is a long term program, extending to 2029.

It should be noted here that many of the units being replaced are older units that would have been replaced even without the OTC requirement. However, the OTC mandate requires some units to be replaced sooner than what may have been otherwise.

Discussions between LADWP and the SWRCB have resulted in the following timeline for OTC compliance (Figure 1-5).

Figure 1-5. Timeline for OTC compliance.

AR0071103

There are many constraints and considerations that were factored into the development of the OTC compliance timeline. Because the LADWP power system relies on the in-basin units to provide transmission system reliability, as well as local sources of power generation, it is important to keep all of the units available to meet the peak summer demand. An older existing unit cannot be decommissioned (shut down) until the new replacement unit is built, tested, and ready to go on-line. This requires a strict sequencing of the separate repowering projects, as shown on Figure 1-5.

There are many challenges to meeting the target dates. The limited space available within some of the generating station property boundaries presents planning and construction difficulties. Other issues include the long lead times required for environmental permitting, engineering design, and equipment procurement. Any unforeseen delay – for example, a delay in acquiring an environmental permit or a delay in delivery of new plant components – will adversely affect the schedule. The timeline shown in Figure 1-5 represents LADWP's best effort to comply with the mandated compliance deadlines while also meeting its reliability responsibilities.

The effects of the repowering program on ocean water use are shown in Figure 1-6. As individual units are replaced with new units that do not use ocean water, OTC levels decrease. The overall goal of the program is the total elimination of OTC by 2029. Additional discussion regarding LADWP's compliance with OTC regulations can be found in Appendix C.

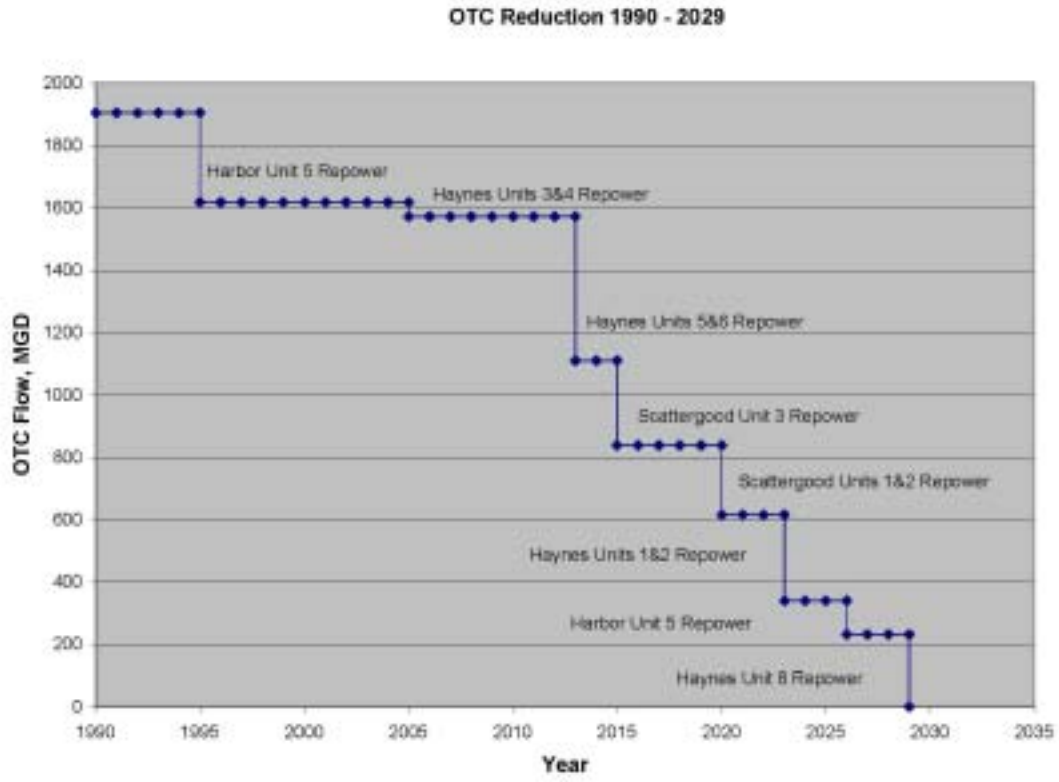

Figure 1-6. LADWP's reduction in once-through cooling from 1990 to 2029.

AR0071104

1.6.6 Additional Challenges

Additional challenges that LADWP must address include an increased risk from natural gas price volatility, cyber security legislation, hydro-plant re-licensing, and improving system load factor:

- Natural Gas Price Volatility

  To the extent that LADWP seeks to reduce its GHG footprint, but cannot meet all its future needs through renewable resources and EE/DSM programs, a greater percentage of generation utilizing natural gas will be forthcoming. The energy profiles of all strategic cases analyzed in this IRP are composed of approximately 45 percent gas-fired generation by 2030. To reduce the price risk inherit when relying so much on a single fuel type, LADWP will need to continue to develop and implement strategies to hedge against natural gas price volatility. These strategies are designed to protect LADWP from potential future price fluctuations, and include financial hedging products, ownership of gas reserves to supply a portion of its fuel needs, and other potential products and contractual arrangements.

- Cyber Security Legislation

  Cyber security legislation which provides additional authority to the federal government, has been pending for several years. The Grid Reliability and Infrastructure Defense Act (GRID Act) of 2011 would grant new authority to the Federal Energy Regulatory Commission (FERC) to determine power system vulnerabilities and required actions by the power industry, and additional authority related to physical security and other threats. Public power is working with House and Senate representatives to develop a bill that focuses more on information sharing and which would allow a utility to take voluntary actions as they see best for their organization.

- Castaic FERC Re-licensing Program

  On January 31, 2022, the Federal Energy Regulatory Commission's (FERC) license to operate Castaic Pumped-storage Hydroelectric Plant will expire. The license is a co-license between LADWP and the Department of Water Resources (DWR) and includes a number of hydro power plants along the California Aqueduct. Both parties have initiated the joint re-licensing process that, on average, requires ten years to complete. Through 2015, LADWP expects to complete preliminary studies, contract negotiations, and prepare a filing strategy. In 2016, LADWP expects to file a notice-of-intent (NOI) and initiate the formal studies and applications. Based on reviews of re-licensing activity for similar projects, LADWP could expect cumulative expenditures of approximately $10

AR0071105

million prior to firing the NOI and approximately $80 million before the license expires. From DWR's recent experience at re-licensing of Oroville Dam, they have informed LADWP that future mitigation cost could exceed $1 billion dollars for a new 50-year license period.

- Load Factor Improvement:

  Load factor represents how constant energy usage is over a given day. A 100 percent load factor means that the same amount of power is used off peak as on peak, so the system is getting full use of its generation, transmission, and distribution resources. A low load factor results in generators being started more often to serve load for a few hours a day, which is not optimum. As an analogy, a car traveling at constant speed will get the best gas mileage and reduced wear and tear than a car in stop-and-go traffic.

  From the 1990s through 2005, annual system load factors were trending slowly upward, which is a positive movement. Since 2006, however, system load factors are trending down. Some of this decline is due to the fact that much of the historic energy efficiency effort is directed at lighting, which has higher impact on sales when compared to peak. Also, most customers are making greater efforts to conserve energy but during extreme weather events safety and comfort predominate over conservation causing the peak to spike. It is imperative that LADWP implement tools to shift load from peak hours to off peak hours to reverse this trend and improve system performance.

AR0071106

1.7 Public Process

LADWP conducts a public review process on their IRP every other year. A public review process was held in the fall of last year in support of the 2010 IRP. The review process included a series of public workshops and stakeholder meetings with representatives from neighborhood councils, environmental groups, and local business associations. The 2010 public review process is relatively recent, and the input gathered and the conclusions that emerged from that process remain mainly intact. A full scale public outreach program, similar to the one held in 2010, is planned for next year's 2012 IRP.

Therefore, this 2011 IRP relies on the findings from last year's public outreach effort (for details see Appendix N). In summary, following are the themes that emerged.

LADWP should:

- Emphasize a variety of energy resources
- Maximize energy efficiency and conservation
- Eliminate coal from its generation portfolio
- Emphasize local solar generation
- Avoid adverse impacts to vulnerable communities
- Clarify costs of IRP implementation and potential impacts to ratepayers
- Reduce environmental impacts
- Provide proactive leadership and transparency

Section 5 includes a discussion on how LADWP incorporated these ideas into its recommended strategy.

AR0071107

1.8 2011 IRP Development Process

Note: The 2011 IRP process did not include public review. Next year's 2012 IRP process will include a public outreach program similar to the one conducted as part of the 2010 IRP.

The IRP is prepared by a group of engineers dedicated to LADWP resource planning and preparation of the IRP. This group is managed by a Supervising Engineer, with a direct reporting staff of four. While this group performs the production model and report preparation for the IRP, the bulk of the work is collaborative across the different work groups and functional areas of the Power System.

The IRP is developed in multiple stages, including:

1. Identifying and approving key assumptions

   The assumptions form the basis for subsequent analysis, and include such factors as load and fuel price forecasts, renewable resource percentages targets, CO_2 allowances and pricing, projected energy efficiency implementations, repowering schedules, etc. Assumptions are prepared and approved by the internal LADWP organizations responsible for the respective subject areas. The assumptions are then presented to LADWP management for comments and acceptance.

2. Establishing clear goals and objectives

   The overarching goal of LADWP's IRP planning efforts is to produce a long term plan that ensures the future supply of electricity that is reliable, competitively priced, and is secured in a manner consistent with environmental stewardship. Through the planning and development process, specific initiatives, programs and projects (many which are in progress) are identified and assessed. The planning effort is collaborative among cross functional organizations within LADWP. Each initiative, program and project will have its own appropriate set of goals and objectives, which in turn supports the collective goal of reliable, affordable electricity that is sensitive to the environment.

3. Establishing strategic case alternatives

   Each of the strategic cases is developed by IRP staff with input from each of the internal LADWP organizations. The strategic cases are designed to consider alternative future resource portfolios, and reflect real decision points and plans that LADWP will have to implement. The current major decision area for LADWP is coal divestiture; therefore, this IRP considers three alternative options for reducing coal-fired energy (whereas last year a decision area was the amount of renewable energy to adopt, it is no longer discretionary due to regulatory mandates, and is not a distinguishing feature among the current alternatives). Each case is vetted through LADWP management and working meetings are held to agree on final cases to be assessed.

AR0071108

4 Completing computer modeling of power system operations

Simulations of the case alternatives are made using the Planning and Risk (PAR) software. PAR is a widely used hourly production cost model that commits and dispatches resources to minimize the cost of serving electric load. PAR is used by many utilities across the US and the world. The modeling results are vetted for quality, including a third party consultant review. Post model analysis is then conducted to account for non-generation system costs, including transmission and distribution. The final results compare each case in terms of reliability, costs, and CO_2 emissions reduction. The results are reviewed by management for comments and acceptance. If needed, modifications are made to the model input assumptions for new computer runs.

5 Recommending and approving a preferred case

Based on the results of the case alternative analysis, a recommended case is identified. The recommended case is presented to management for review and acceptance.

Each of these stages includes coordination between multiple LADWP organizations responsible for different aspects of power system operations, preparing recommended positions for each stage, presenting recommendations to LADWP's leadership team including Division and Section Heads, and ultimately presenting recommendations to the General Manager. At each of these presentations, modifications to recommendations are noted. The approval process for recommendations is based on consensus from the managers of each area of responsibility.

AR0071109

1.9 Conclusions

Addressing all of these challenges requires considerable amounts of labor and capital resources, which applies upward pressure on LADWP's electric rates. It is important to note that LADWP cannot compromise on its responsibility to ensure adequate reliability of its power system. As facilities age, they must be repaired and eventually replaced.

LADWP is focusing on both near-term and long-term solutions. Attainment of the objectives and goals documented in this 2011 IRP will require the continued implementation of existing programs and projects, as well as the introduction and expansion of new initiatives and program areas. The following list shows the major activities that require action over the next 3-5 years (for more information, see the referenced IRP sections).

Major Power System Activities 2011-2016

Program Areas in Progress

- **Haynes 5&6 Repowering** (Sections 1.6.5, 2.4, 3.2.1, and 3.3; Tables 4-5, 5-3, and 5-4; Appendix F)
- **Scattergood Repowering** (same as Haynes 5&6 references)
- **Coal Divestiture Planning and Implementation** (Sections 1.6.3, 2.4, 3.2.1, 3.3, 3.5, 4, and 5)
- **Replacing aging distribution infrastructure** (Sections 1.6.2; Appendix E)
- **RPS procurement** (Sections 2.4, 3,4, and 5; Appendices D and M)
- **Solar Program Development** (Sections 2.4, 3.2, and 5; Appendices D, G, and M)
- **Existing EE program elements** (Section 2.3; Appendix B)

New Program Areas

- **Demand Response Program** (Sections 2.3.2, 3.2.1, 5.3, and 5.6; Table 4-3)
- **New EE program elements** (Section 2.3; Appendix B)
- **Smart Grid Implementation** (Section 2.3.4; Appendix L)
- **Transmission Line Improvements** (Sections 2.4.4 and 5; Appendix I; Tables 4-5 and 5-3)
- **Grid Reliability Improvements** (Sections 2.4.4 and 5)
- **Haynes 1&2 Repowering** (Sections 1.6.5 and 3.3)

AR0071110

2.0 LOAD FORECAST AND RESOURCES

2.1 Overview

Through an IRP, utilities forecast the demand for energy and determine how that demand will be met. Meeting forecasted demand is accomplished by the planning and delivery of electric power generating ("supply-side") resources through transmission and distribution systems. Another key element of IRP planning is to determine how to reduce energy demand and increase the efficiency of the utility customer's use of electricity, known as "demand-side resources."

This section of the IRP addresses the following:

- Forecasting of future energy demand
- Demand-side Resources (DSR), including Energy Efficiency and Demand Response
- Supply-side Resources
- Transmission/Distribution
- Reserve requirements

The discussions include the technical, regulatory, and economic factors that affect LADWP's planning and execution of programs and projects.

Data for this analysis comes from publicly available reports from organizations like the California Energy Commission (CEC), California Public Utilities Commission (CPUC), the North American Electric Reliability Corporation (NERC), the Federal Energy Regulatory Commission (FERC), industry forecasts, and internal LADWP sources. Also highlighted in this IRP are additional studies that are either underway or will be performed in the near future to provide additional clarity regarding the boundaries and needs of the system.

AR0071111

2.2 Forecast of Future Energy Needs

For this IRP, LADWP developed a forecast of customer demand for energy over the next 20 years (the complete 2011 load forecast is included in Appendix A). Econometric models are used to forecast retail sales and peak demand. Net Energy for Load (NEL) is defined as the production necessary to serve retail sales. NEL, and its allocation across various times of the day, are functions of the retail sales and peak demand forecasts. The retail sales forecast is the sum of seven separate customer class forecasts. The classes are residential, commercial, industrial, plug-in electric vehicle (PEV), intradepartmental, streetlight, and Owens Valley. The drivers in the retail sales models include normalized weather, population, employment, construction activity, and personal consumption. The NEL forecast is derived from the retail sales forecast by applying a normalized loss factor of 11.5 percent. Losses can vary depending on the sources of energy production. NEL load growth becomes a driver of the peak demand forecast. Peak demand is also a function of temperature, heat buildup, and time of year. The NEL forecast is allocated using the Loadfarm algorithm developed by Global Energy. The inputs into the algorithm are NEL, peak demand, minimum demand, and system load shape.

2.2.1 2011 Retail Electrical Sales and Demand Forecast

The effect of the recent recession and slower than normal recovery combined with cooler than normal weather depressed electricity sales by approximately 6 percent off their fiscal year 2007-08 peak. Losses in commercial sectors such as construction, real estate, retail, and leisure are forecasted to recover as the economy expands.

The electricity consumption within LADWP's service territory is forecasted to remain flat over the next three years. The load forecast predicts an increase of 1.6 percent in 2014-15 due to the expected completion of large mixed-use projects. The growth in annual peak demand over the next twenty years is predicted to be about 1.1 percent—approximately 65 MW per year—with less growth over the next few years due to the current recession. After 2016, some of the growth will not be realized at the meter depending on the adoption of energy efficiency and distributed generation technologies.

The 2011 Forecast is LADWP's official power system forecast. This forecast is used as the basis for LADWP power system planning activities including, but not limited to, integrated resource planning, transmission and distribution planning, and wholesale marketing. The forecast is a public document that uses only publically available information.

Table 2-1 summarizes the data sources used to develop the forecast and where these data sources have been updated from previously published forecasts.

AR0071112

Table 2-1: LOAD FORECAST DATA SOURCES

Data Sources	*Updates*
1. Historical Sales through September 2010 are reconciled to the General Accountings Consumption and Earnings Report.	*Historical Sales, Net Energy for Load and weather data is updated through September 2010.*
2. Historical NEL, peak demand and losses through September 2010 are reconciled to energy accounting data.	
3. Historical weather data is provided by the National Weather Service and Los Angeles Pierce College.	*Weather is updated through March 2010.*
4. Historical Los Angeles County employment data is provided by the State of California Economic Development Division using the March 2009 benchmark.	*Employment data is updated through September 2010 using the March 2009 benchmark.*
5. Historical population and forecasts is provided by the State of California Department of Finance.	Population data is updated through January 2010.
6. The long-term Los Angeles County economic forecast is provided by UCLA Anderson Forecast.	
7. The construction activity forecast is provided by McGraw-Hill Construction.	*Building permit data is updated through September 2010.*
8. The plug-in electric vehicle (PEV) forecast is based on the CEC statewide PEV forecast.	
9. The port electrification forecast is provided by the Port of Los Angeles.	
10. The housing forecast is informed by the City of Los Angeles "Housing that Works" plan.	

2.2.2 Five-year Sales Forecast

The Retail Sales Forecast through 2016 represents sales that will be realized at the meter. In the forecast, energy efficiency and solar savings are expected to occur uniformly throughout the year as a simplifying assumption. Installation schedules are difficult to prepare because they rely on the customers allowing the installation to occur.

Energy efficiency and customer solar installations cause about a two percent drop in retail electricity sales. The remaining decreases in the next two years are attributed to economic conditions. Personal consumption should decrease as personal income flattens and savings and tax rates increase. Vacancy rates in the commercial sector are expected to increase short term. Manufacturing jobs are forecast to continue to decline. Retail electricity growth will lag growth in the economy somewhat. Businesses will become more efficient and begin to increase their operating margins as the economy improves. As shown in Figure 2-1, once the operating margins increase, new hiring will begin again and then retail electricity sales will begin to grow.

AR0071113

Figure 2-1. Retail sales net of energy efficiency and distributed generation.

Table 2-2 shows projections of short-term retail sales growth:

Table 2-2. SHORT-TERM GROWTH

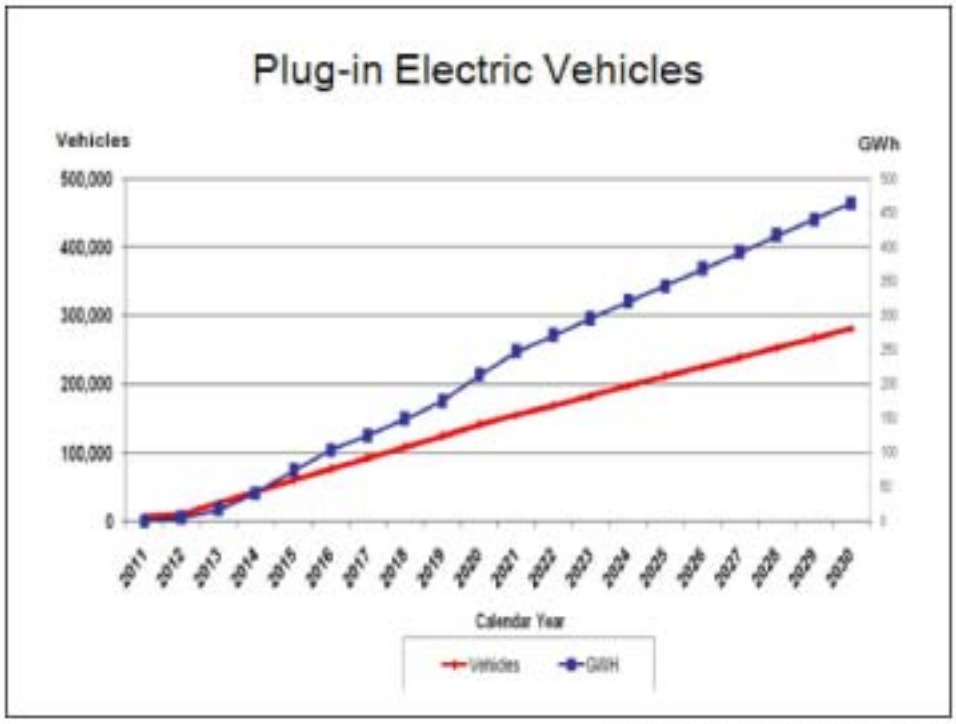
Fiscal Year	Retail Sales		Additional Load if not for EE & Solar Savings
Ending June 30	(GWH)	YOY Growth Rate	(GWH)
2009-10	23,491	-4.2%	10
2010-11	23,051	-1.40%	176
2011-12	23,221	0.7%	383
2012-13	23,175	-0.2%	676
2013-14	23,258	0.4%	928

AR0071114

2.2.3 Electrification

A result of AB 32 will be to encourage increased electrification as a means to reduce GHG emissions. This has added a degree of uncertainty to the forecast of future electricity needs in terms of both additional resulting load and the speed of implementation of electrification programs.

In the transportation sector, fuel switching from diesel and gasoline to electric power can result in air quality improvements if the sources of electric power are clean. Figure 2-2 shows the forecasted number of plug-in electric vehicles (PEVs) within the LADWP service area over the next 20 years. To support the adoption of electric vehicles, LADWP launched a pilot program in May 2011 that provides 1000 customer rebates of up to $2,000 towards the purchase and installation of electric vehicle home charging systems. Supporting the City's electric vehicle infrastructure, LADWP is also in the process of retrofitting 117 vintage chargers on City property.



Based on 2009 CEC Forecast

Figure 2-2. Forecasted number of plug-in electric vehicles.

Other agencies in the LA air basin have initiatives underway for "electrification" to replace existing diesel fueled trucks and gasoline powered cars with electric power. In addition, planned expansions to light railway and the metro system would add additional electric load to the system.

AR0071115

Another example of transportation sector electrification is the Clean Air Action Plan developed jointly by the Port of Los Angeles and the Port of Long Beach to reduce air pollution from their many mobile sources as well as some fixed sources. This includes trucks, locomotives, ships, harbor craft, cranes, and various types of yard equipment. One of the programs, Alternative Marine Power (AMP), allows AMP-equipped container vessels docked in port to "plug-in" to shore-side electrical power instead of running on diesel power while at berth.

Plug-in Electrical Vehicles (PEVs)

Large scale deployment of electric vehicles will significantly affect the way electricity is consumed. It is estimated that by 2015, the United States will have one million EVs in deployment, 10% of which is expected to be in California. The introduction of electric vehicles in Southern California brings a challenging set of planning, regulatory and cost issues. Because EVs require a unique infrastructure, including specialized charging equipment and adequate electric service, it is essential to anticipate and predict the grid impact in Southern California from the EV deployment.

Regulated utilities in California are now responding to regulatory direction to submit plans for large-scale EV initiative with full delineation of costs and benefits. This regulatory initiative is an aggressive step, seeking to promote accelerated adoption of EVs. The EV deployments and the associated utility customer features are proceeding throughout the State of California. Energy needed for PEVs will come partially from the utility electric grid. It is expected that the "fuel shift" from traditional transportation fuels will increase customers' demand for electricity from the electric grid.

PEVs also present an opportunity to influence charging patterns by incentivizing charging during off-peak time periods, resulting in better system load factor. Currently 80% of PEV charging in Los Angeles occurs during off peak hours (per US DOE)

LADWP will use a part of the $120 million Smart Grid demonstration grant award from DOE to demonstrate the integration of electric vehicles into the LADWP-managed electric system. The demonstration will use internal fleet equipment, privately owned EV chargers, and will include electric vehicle fleets from both UCLA and USC. These complementary fleets provide the opportunity to test EVs in both the controlled environment of a corporate fleet and the "real world" usage of individuals. These opportunities will test the integration of EVs into the grid, along with acquisition of EV communications to the grid management.

AR0071116

2.2.4 Peak Demand Forecast

Growth in annual peak demand over the next ten years is 1.0 percent as shown in Table 2-3.

Table 2-3: FORECASTED GROWTH IN ANNUAL PEAK DEMAND

Fiscal Year End June 30	Base Case Peak Demand (MW)	Growth rate Base Year 2010-11	One-in-Ten Peak Demand (MW)
2010-11	5589[1]		6042
Forecast			
2015-16	5809	0.8%	6277
2020-21	6211	1.0%	6710
2030-31	7000	1.1%	7560
2040-41	7780	1.1%	8403

[1] Weather-normalized. Actual peak was 6142 MW

In 2010, the System set its all-time annual net energy for load peak at 6142 MW on September 27, 2010 on a day that was a one-in-thirty-five year weather event. The weather-adjusted one-in-two peak for 2009 is 5589 MW. Figure 2-3 presents the one-in-ten peak demand forecast, which is used for integrated resource planning. In the 1990s through 2005, annual system load factors were trending slowly upward. Since 2006, system load factors are trending down. Two factors are generally thought to be contributing to this effect. Most customers are making greater efforts to conserve energy but during extreme weather events safety and comfort predominate over conservation causing the peak to spike. Much of the historical and forecasted energy efficiency effort is lighting which has a greater impact on consumption rather than peak which lowers the load factor.

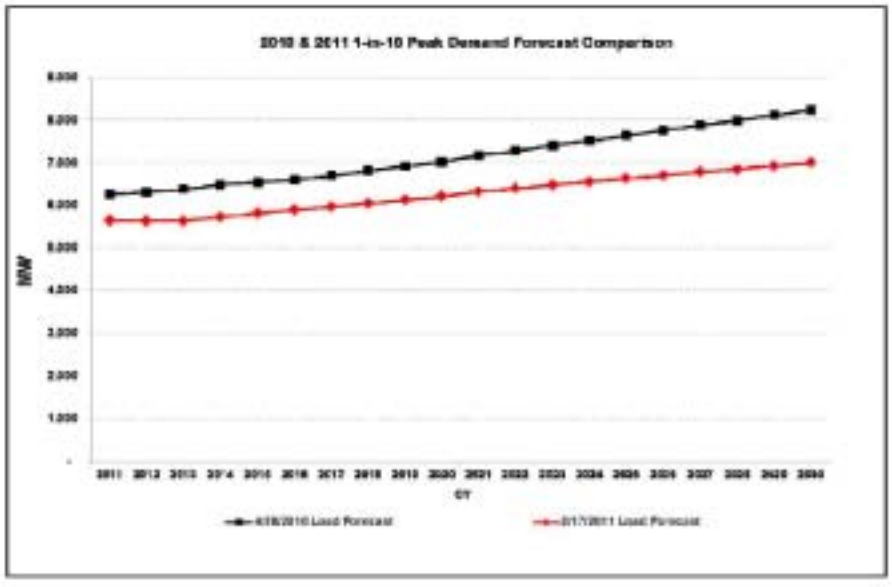


Figure 2-3. One-in-ten peak demand forecast comparison.

AR0071117

2.3 Demand-Side Resources

Demand Side Resources (DSR) programs, including energy efficiency, have become important elements of IRP planning. Also known as Demand Side Management, DSR programs help to counter or minimize energy demand growth and thereby lessen the need to build more physical generation assets and improve load factor. This section discusses the following DSR initiatives and related support areas:

- Energy Efficiency (EE)
- Demand Response (DR)
- Distributed Generation (DG)
- Smart Grid

Key DSR data assembled for this IRP included:

- The energy efficiency forecast, which was based on the Board-approved AB 2021 objectives, the City of Los Angeles Green Plan, and Demand Forecast Energy Efficiency Quantification Project working papers. Historical installation rates were referenced as part of the forecast.
- An estimate of the amount of solar rooftop and other distributed generation.
- An assessment of existing and developing technological improvements in large scale battery systems for energy storage.
- Information regarding the impact of "Smart Grid" technology on customer load profile and resource requirement.

2.3.1 Energy Efficiency

Energy Efficiency (EE) is a key strategic element in LADWP IRP planning. EE is a very cost-effective resource in LADWP's supply portfolio, and serves an important and multi-faceted role in meeting customer demand. One of the most widely recognized examples of EE is the replacement of incandescent lights with compact fluorescent lamp (CFL) bulbs. CFLs consume up to 75 percent less energy than incandescent bulbs while producing an equivalent amount of illumination and last up to 10 times longer.

LADWP offers numerous EE programs and services for residential, commercial, industrial, governmental, and institutional customers to promote the efficient use of energy through the installation of energy efficient equipment. Examples include:

- The Commercial Lighting Efficiency Offer (CLEO), which provides rebates for a variety of high efficiency lighting measures to retrofit existing buildings. The CLEO program enjoys sustained high rates of participation and has achieved 433 GWh of energy savings since 2000.

AR0071118

- The Chiller Efficiency Program, which provides incentives for customers to replace old electric chillers with new, high-efficiency units. Chillers provide space conditioning for larger buildings and the program has reduced associated peak electrical demand by more than 52 MW since 2001.
- The Small Business Direct Install (SBDI) Program, which assists eligible small businesses (A1 rate customers) in Los Angeles in becoming more energy efficient through free lighting assessments and free lighting retrofits (up to $2,500 in cost). SBDI began in 2008 and has achieved 149 GWh of energy savings since its inception.
- The Custom Performance Program, which provides performance-based incentives for energy efficiency measures not included in LADWP's menu-based EE programs. Measures supported include controls and control systems, high efficiency motors, and data server virtualization. The Custom Performance Program has achieved 200 GWh of energy savings since 2008.
- The Refrigerator Exchange Program, which delivers new Energy Star refrigerators to eligible residential customers, and picks-up/recycles customers' old, inefficient refrigerators. This program has replaced and recycled more than 53,000 refrigerators since 2007, achieving an energy savings of 49 GWh.
- A recent program, which distributed two free CFLs to LADWP's 1.2 million residential customers through direct-to-door distribution. The intent of the one-time direct-to-door distribution was to achieve cost effective energy savings and increase customer awareness of this inexpensive, yet effective, EE measure. CFLs were also distributed at events and in connection with other energy efficiency programs.

Since 2000, LADWP has spent approximately $282 million on its energy efficiency programs, and these programs have reduced long-term peak period demand and consumption by approximately 303 MW and 1,256 GWh, respectively. LADWP is committed to developing comprehensive programs with measurable, verifiable goals as well as implementing robust, cost-effective energy efficiency programs.

Per Assembly Bill 2021 (AB 2021), publically owned utilities such as LADWP, must identify and develop all potential achievable, cost-effective EE savings and establish annual targets. Furthermore, utilities are required to conduct periodic "Market Potential" studies to update their forecasts and targets. The most recent study was carried out in late 2010 and is the basis for the EE recommendations contained in this 2011 IRP.

AR0071119

The study evaluated a multitude of measures for potential inclusion into LADWP's EE program; including:

- LADWP's existing program elements
- High-efficiency air conditioners (higher efficiency levels, variable refrigerant flow systems)
- High-efficiency lighting (CFLs, LED lamps)
- Upgraded insulation in buildings
- Retro-commissioning and routine maintenance
- Programmable communicating thermostats and energy management systems

The following recommendations resulted from the 2011 potential study:

Residential Sector

- LADWP should keep its existing programs, with the exception of CFL Distribution, which should be replaced with a broader Energy Efficient Lighting Program.
- Two new programs should be adopted: (1) Low-Income Energy Efficiency and (2) Whole House Performance.
- Continue public outreach to maintain and broaden public awareness of available EE benefits, and to promote participation.

Commercial and Industrial Sector

- LADWP should keep its existing program elements, but should modify its lighting program to educate customers on expanded choices that will comply with new lighting standards.

The ten-year EE plan, incorporating budget, capitalization, and driver considerations is shown in Table 2-4. These projections have been incorporated into the IRP production model and are factored into the case analysis described in Section 3 of this IRP.

Table 2-4. RECOMMENDED EE PROGRAM PLAN

FY Ending	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
Program Cost ($Million)	50	50	67	87	100	100	100	100	100	100
Annual Net Savings (GWh)	118	224	164	182	217	183	96	98	99	63
Cumulative Net Savings (GWh)	118	362	526	708	925	1,108	1,204	1,302	1,400	1,463
Savings as a % of Baseline	0.5%	1.6%	2.3%	3.0%	3.9%	4.6%	5.0%	5.3%	5.6%	5.8%

Further information regarding LADWP's EE program is included in Appendix B.

AR0071120

2.3.2 Demand Response

Demand Response (DR) is an important energy management tool that facilitates the reduction in energy use over a given time period, in response to a price signal, financial incentive, or other mechanism. The objective of DR is to lower energy usage at critical peak demand periods, which will lower overall system costs. DR programs are voluntary; customers that choose to participate are compensated through lower rates, rebates, or other financial incentive.

The benefits of demand response are many:

Increased Reliability. The ability to strategically lower energy consumption is one way to help overcome supply-demand constraints and reduce the chance of overload and power failure. This is especially important at those few critical peak times each year when demand is at its highest, as well as those times when generation units are off-line, whether due to a forced outage or scheduled maintenance.

Lower System Costs. DR eliminates or defers the need to build additional power plants and the associated transmission and distribution infrastructure. Additionally, DR reduces wholesale energy costs by reducing the amount of energy that would otherwise be purchased to meet load. The overall effect is to save money which helps keeps rates low.

Less Environmental Impact. By eliminating or deferring the need to build additional infrastructure, the associated construction and operational impacts are also eliminated or deferred. Furthermore, the reduction in energy usage results in less operational impacts, including less fuel consumption, less carbon emissions, and less transmission use.

Help Integrate Renewables. Under certain circumstances, DR can enable customer loads to respond to fluctuations in generation from wind and solar power.

DR is a relatively new demand-side resource, and LADWP plans to develop an active program over the next several years. As discussed in Section 5, one of the recommendations of this 2011 IRP is to provide funds to develop and implement DR. The analysis of all strategic cases considered in this 2011 IRP (discussed in more detail in Section 4) calls for a small 5 MW DR program beginning in 2013 that gradually builds to 200 MW by 2020 and 300 MW by 2030. This will provide adequate learning that will ensure a sound DR program by the end of this decade, and will also allow time to deploy the supporting IT infrastructure and to implement required IT systems and processes.

A variety of program elements are being considered for LADWP's DR program. The following are some of the offerings that are currently common in the industry. Depending on the circumstances of how energy is used, certain programs will be more suitable to particular customer segments than others.

AR0071121

Direct Load Control Customers sign up and agree to be subjected to demand reductions as needed based on power system constraints. The typical example is a customer's central air conditioning system may be remotely shut down by the utility during high peak conditions. In exchange, the customer gets an incentive payment or bill credit.

Critical Peak Pricing Retail electric rates are temporarily adjusted up, typically as a response to events or conditions such as extreme high peak loads. Customers who participate are notified in advance of the event and can avoid the higher prices by decreasing their energy use during this time period. The customer incentive is a lower base rate throughout the year.

Peak Rebate Pricing Similar to Critical Peak Pricing, but instead of raising the customer's rate during an event (which creates a disincentive), a positive incentive is created where the customer receives a rebate for reducing or shifting their load during the peak load event.

Real Time Pricing Retail rates are varied on an hourly basis or other short term basis and are typically tied to variations in the commodity market prices for wholesale power supplies. Consumers are aware of the changing market prices on a continual basis, and can change their usage patterns accordingly to lower their energy costs. The premise is that customers will reduce usage during the expensive high peak periods.

Demand Bidding Commercial/Industrial customers are given the opportunity to receive a credit for voluntarily reducing load when an event is called. The customer is not penalized if they are unable to meet their reduction target.

Curtailable/Interruptible Commercial Industrial customers who sign up are on-call for curtailment of power, and are provided credit even if an event is not triggered. However, curtailments are firm and mandatory; penalties are assessed for under performance or non-performance.

Aggregation Programs DR aggregators are third party contractors who work with groups of customers to make combined loads available for reduction or interruption. The aggregator works with LADWP and the combined load is assigned to the appropriate DR program. Customers work directly with the aggregator. Terms, conditions and payment may vary per aggregator.

In designing the overall program, a number of parameters need to be established, such as the specific program elements to offer, and for each program element, customer eligibility, the type and size of incentives, contract duration, event duration, number of events, notification lead times, automation, billing requirements, etc.

This 2011 IRP recommends funding to initiate a formal DR program with the capacity targets as shown in Table 2-5.

AR0071122

Table 2-5. DEMAND RESPONSE TARGET SCHEDULE (MW CAPACITY)

Yr.	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026
Target	5	10	20	40	75	100	150	200	250	300	350	400	450	500

DR will play a significant long-term role in securing adequate system capacity, especially in the case of early coal divestiture. Section 4 discusses the strategic cases in detail. As shown in the case analysis, DR is a key part of LADWP's future resource portfolio.

2.3.3 Distributed Generation

Distributed Generation (DG) is the concept of installing and operating small-scale electric generators located at or near the electrical load. These numerous small generators are "distributed" across the service area, as opposed to the traditional configuration of a few large centralized generating stations. DG sources can be utility-owned or customer owned. A large subset of DG is combined heat and power systems, also known as cogeneration, which are primarily owned and operated by industrial and commercial customers.

Many categories of electrical generation fall under the DG definition, with the key characteristic being that they are located at or near the service load. The most common technologies used today for DG are turbines and internal combustion engines. Solar PV is a newer technology that is forecasted to account for an increasing percentage of DG. Other DG technologies are microturbines and fuel cells. Under a pilot project, LADWP installed a total of four 200-250 kW fuel cell power plants in various locations in Los Angeles that have provided considerable experience and data. LADWP is closely monitoring fuel cell development.

More details regarding DG can be found in Appendix G.

2.3.4 Smart Grid

"Smart Grid" is a term used to describe a variety of advanced information-based utility improvements. Smart Grid refers to intelligent data gathering and advanced two-way digital communication capabilities overlaid on electric distribution networks to provide real-time data that enhances the utility's ability to optimize energy use. Smart Grid is a national policy evolving from the Energy Policy Act of 2005, and is a major enabler for many existing and potentially new DSR/EE programs.

Smart Grid technologies can turn every point in the existing network—including every meter, switch and transformer—into a potential information source, able to feed performance data back to the utility instantly. Smart Grid Technologies will provide utilities with the information required to implement real-time, self-monitoring networks that are predictive rather than reactive

AR0071123

to instantaneous system disruptions. It can enable the utility and consumer to make decisions to optimize the use of energy, improve reliability, and reduce the consumption of fossil fuels.

LADWP is implementing eleven Smart Grid initiatives:

A smart grid has the following characteristics:

- *Enables new products, services and markets*
- *Enables active participation by consumers through self-monitoring and more responsible consumption decisions*
- *Auto-selects safest and most efficient forms of storage and generation based on real-time energy needs and concerns*
- *Provides power quality for the digital economy*
- *Optimizes asset utilization and operates efficiently*
- *Anticipates and responds to system disturbances (self-heals)*
- *Operates resiliently against attacks and natural disasters*

1. Renewable Integration
2. Transmission Automation
3. Substation Automation
4. Distribution Automation
5. Advanced Metering Infrastructure
6. Demand Response
7. Advance Telecommunications
8. System and Data Integration
9. Cyber Security
10. Feed-in Tariff
11. Solar Incentives

Through a US Department of Energy grant in 2009, LADWP is leading a group of local research institutions in a regional demonstration program. The program includes pilot projects in four interrelated areas – Demand Response, Consumer Behavior, Cyber Security and Electric Vehicle Integration.

More information on this demonstration program and all of LADWP's Smart Grid initiatives can be found in Appendix L.

AR0071124

2.4 Generation Resources and Transmission Assets

The Supply-Side Resources discussed in this section include

- Existing Generation Resources
  - Natural Gas
  - Coal
  - Nuclear
  - Large Hydro
  - Existing Renewable energy resources (small hydro, wind, solar, biogas, and geothermal)
- Spot Purchases
- Spot Sales

The major issues affecting generation are then presented, including the need to repower the in-basin natural gas units and the future disposition of coal-fired generation.

This section concludes with:

- Future Renewable Resources
- Transmission and Distribution/Grid Reliability
- Reserve Requirements

The LADWP Power System has a diverse mix of generating resources. Figure 2-4 shows LADWP's Power System capacity and energy breakdown as of December 31, 2010 as well as what the capacity and energy mix was at the end of 2006.[1] The largest change between these two periods is the decrease in coal-fired energy from 47 percent in 2006 to 39 percent in 2010, and the corresponding increase in energy from renewable resources, from 7 percent in 2006 to 20 percent in 2010.

[1] "Capacity" and "Energy" are electric utility terms that distinguish between how much power the system is capable of generating at a given instant in time (capacity; in megawatts) and how much power the system generates over a given period of time (energy; in megawatt-hours). Capacity numbers are expressed in MW, and energy numbers are expressed in MWh.

AR0071125

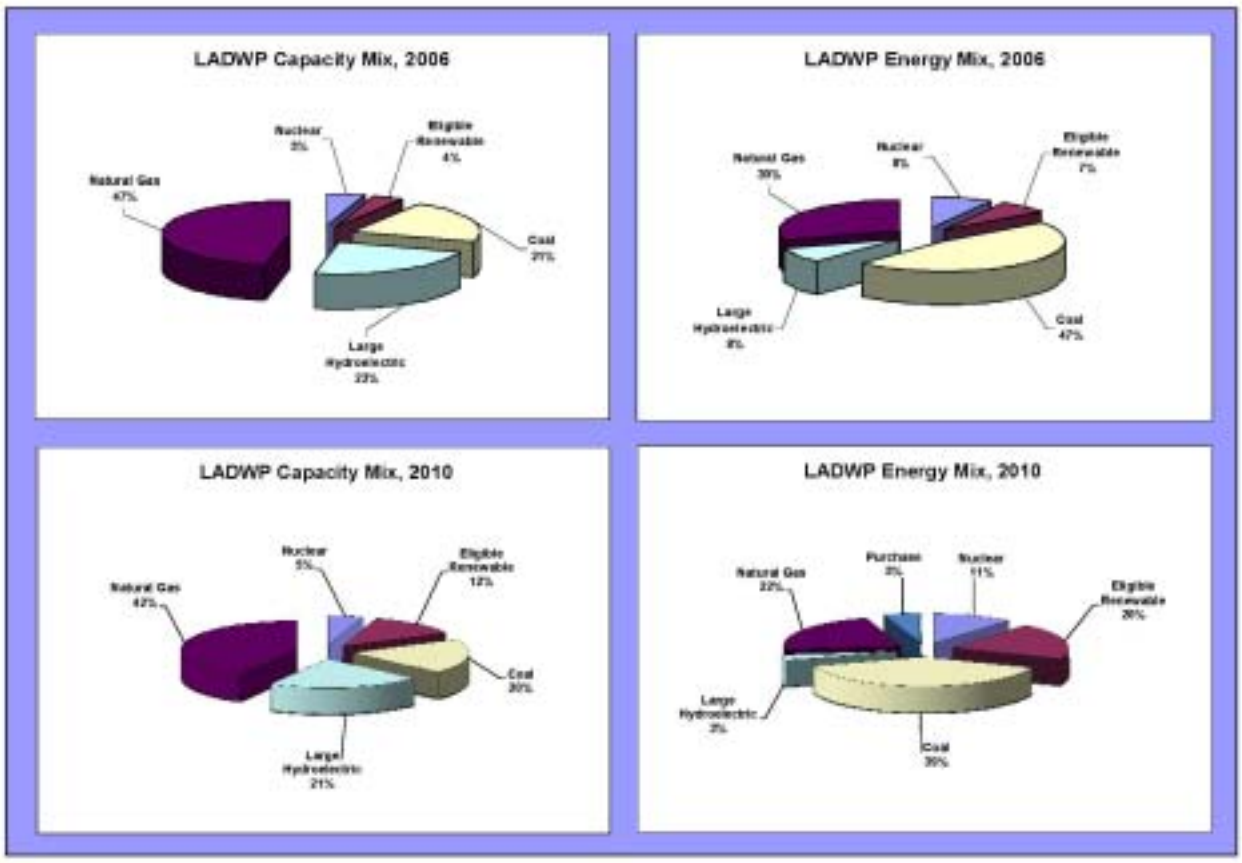

Figure 2-4: LADWP capacity and energy mix for 2006 and 2010.

2.4.1 Generation Resources

LADWP is vertically integrated, both owning and operating the majority of its generation, transmission and distribution systems. Generation resources that are not wholly owned by LADWP are available as entitlement rights resulting from undivided ownership interests in facilities that are jointly-owned with other utilities. Table 2-6 lists existing LADWP generation resources.

AR0071126

Table 2-6: Capability of existing LADWP generating resources (as of September 2011)

Name of Plant	Fuel Source	Unit No.	In Service Date	Age (Years)	Net Maximum Unit Capability (MW) [2]	Net Maximum Plant Capability (MW) [3]	Net Dependable Plant Capability (MW) [4]	Comments

State's Capacity Entitlement (See Note[6])						-120	-55	
Total Net Capability of LADWP System						**8346**	**7329**	Note [7]

Notes:

1. Power source data are based on Power System Engineering Division's January 2011 Generation Ratings and Capabilities Sheet and power purchase agreements for contract sources.
2. All units can attain maximum capability only when the weather and equipment are simultaneously at optimum conditions.
3. Reflects: water flow limits at hydro plants, sum of unit output at in-basin thermal or renewable plants, or LADWP contract entitlement of external thermal plants.
4. Reflects: year- round outputs adjusted for low-generation season. For hydro plants, winter is the low-generation season.
5. Owned or contracted renewable projects in wind, solar, hydro, landfill gas, biomass, and distributed generation in-service as of September 2011.
6. The maximum State (CDWR) Capacity Entitlement from Castaic Power Plant is 120 MW. The average for FY 09-10 was approximately 55 MW. The actual amount varies weekly.
7. Total Net Capability of LADWP System may vary due to unit outages, de-ratings and sales obligations.

AR0071127

Natural Gas

LADWP is the sole owner and operator of the following four electric generating stations in the Los Angeles Basin (the "In-basin stations"):

- Haynes Generating Station, located in Long Beach
- Harbor Generating Station, located in Wilmington
- Scattergood Generating Station, located in Playa del Rey
- Valley Generating Station, located in the San Fernando Valley

A map of the in-basin stations is shown in Figure 2-5.

Figure 2-5. LADWP in-basin generating stations.

Each station consists of multiple generating units, with each unit ranging is size between 43 MW and 450 MW. A summary of each station's capabilities is shown in Table 2-5. Detailed information on each generating station is included in Appendix F.

AR0071128

While all of these stations utilize natural gas as a fuel source, a special arrangement has been made that enables the Scattergood Generating Station to also use digester gas from the adjacent Hyperion Sewage Treatment Plant. The digester gas currently accounts for 16 MW of Scattergood's generation output. The agreement enabling this arrangement will end by 2015.

Securing continued local generation capacity is important for grid reliability. LADWP's local transmission system cannot be reliably operated without generation from local thermal generating plants. The amount of generation required to provide transmission reliability is termed Reliability Must Run (RMR) generation. RMR generation is incorporated into all of the strategic cases considered in this IRP.

The major issues facing the in-basin stations include the need to replace some of the older units that are approaching the end of their service life, compliance with regulations related to ocean water cooling and NO_x emissions, and fuel price volatility. Natural gas fuel prices and procurement issues are presented in detail in Appendix H.

Natural gas will continue to be the essential fuel for LADWP's generation due to abundant supply levels. Natural gas will be used to supply base load (as is currently used), and will also provide for the integration of intermittent renewable generation. Natural gas is also a major component of LADWP's coal replacement strategy.

Coal

LADWP's coal generating capacity comes from the Navajo Generating Station (NGS) and the Intermountain Generating Station (IGS). IGS is also referred to as the Intermountain Power Project (IPP). The amount of capacity available to LADWP's from these stations is 477 MW from NGS and approximately 1,200 from IPP. A summary of each station is included in Table 2-5. Further details and discussion is provided in Appendix F.

Contractual arrangements for power from IPP will expire on June 15, 2027 while NGS operates under a co-tenancy agreement that shall remain effective throughout the initial term of its land lease until December 31, 2019 and throughout the lease extension thereafter.

Nuclear

LADWP has contractual entitlements totaling approximately 387 MW of capacity from the Palo Verde Nuclear Generating Station (PVNGS). PVNGS, located approximately 50 miles west of Phoenix, Arizona, consists of three generating units. Of the 387 MW capacity available to LADWP, approximately 159 MW is available through a power sales agreement with the Southern California Public Power Authority (SCPPA). Further details are provided in Appendix F.

Large Hydro

LADWP's large hydroelectric facilities include the Castaic Pumped-storage Hydroelectric Plant and an entitlement portion of the capacity of Hoover Dam. The Castaic Pumped-storage

AR0071129

Hydroelectric Plant, located in Castaic, California, is LADWP's largest source of hydroelectric capacity and consists of seven units. Hoover Dam, located on the Arizona-Nevada border, consists of seventeen units. Details of these plants are provided in Appendix F.

A distinction is made between "large hydro" and "small hydro". Small hydro consists of generating units with less than 40 MW of capacity generally located along the Los Angeles Aqueduct. They also qualify as a renewable resource for electricity generation. For discussion purposes they are grouped within renewable resources.

Current Renewable Energy Projects

Existing secured renewable resources total over 1200 MW of capacity, and consist of wind, small hydro, solar, biogas, and geothermal resources. More detailed information is presented in Section F.2.5 of Appendix F. A listing of existing renewable projects by resource type is as follows.

- Wind Resources
  - Linden
  - Pebble Springs
  - Pine Tree
  - PPM Wyoming
  - Willow Creek

Additional renewable energy (including geothermal) comes from market purchases.

Figure 2-6 presents the current energy profile for renewable resources in LADWP's portfolio.

AR0071130

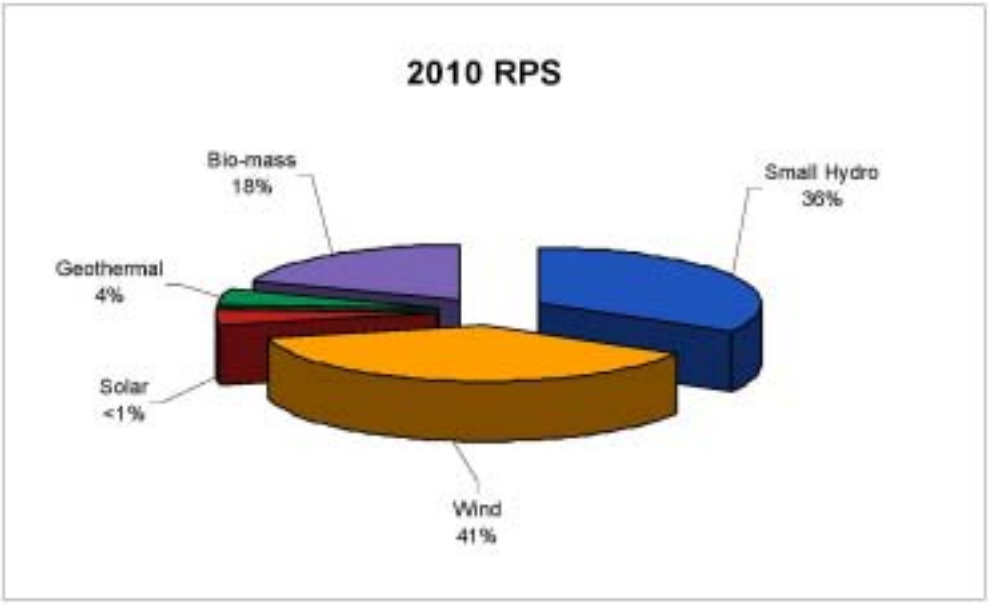

Figure 2-6: 2010 IRP renewable energy mix.

Spot Purchases

Although LADWP's policy has been to be self-sufficient and capable of generating all of its energy needs from resources it owns or controls, it also participates in energy markets if it is in the City's best economic interest. This happens when energy can be acquired from the wholesale market for a cost which is less than which LADWP can produce such energy. Periodically, capacity and energy is purchased from providers within the Western Electricity Coordinating Council (WECC) jurisdiction under short-term "spot" arrangements to be delivered to the LADWP transmission system. These purchases are used by LADWP in conjunction with other resources for economical Power System operation.

The cost and availability of economical energy on the spot market has fluctuated greatly in recent years. While LADWP currently continues to execute economical spot purchase opportunities, it cannot guarantee the future availability of economic energy from either the Pacific Northwest or the Southwest at prices below LADWP's costs for producing power from its own resources.

Spot Sales

LADWP often has a surplus of generating capacity and energy. Consistent with prudent utility practice, LADWP offers this surplus into wholesale electricity markets within the WECC at prices above LADWP's production costs. This way, LADWP's ratepayers benefit both by receiving the lowest cost energy in the Power System and from economic purchases, in addition to economic benefits resulting from wholesale revenue generated from sales.

AR0071131

2.4.2 Major Issues Affecting Existing Generation Resources

Three major issues affecting LADWP's existing generation fleet are: (1) the need to rebuild or "repower" some of its in-basin generating units, (2) compliance with state and local regulations regarding once-through cooling and NO_X emissions, and (3) strategies for early divestiture from coal-fired energy to accelerate GHG reductions.

2.4.2.1 Repowering Program to Replace Aging Infrastructure

There is an urgent need to modify or replace some of LADWP's older gas-fired generation facilities located at the Haynes and Scattergood generating stations. These units were primarily built in the late 1950s and the early 1960s and are approaching the end of their service lives. LADWP must modernize these plants to maintain system reliability, improve efficiency, and better integrate renewable resources.

- System reliability
  As facilities age, they require more maintenance and become more susceptible to operational problems and outages. The units to be replaced at the Scattergood and Haynes generating stations are between 44 and 53 years old, and are among the oldest remaining units in LADWP's generation fleet. Minimizing outages at these locations close to the system load center is especially important for the reliable operation of the in-basin electrical network, including the transmission and distribution systems. Variable resources, such as solar or wind power, can augment existing in-basin gas-fired generation, but do not serve as adequate replacements for purposes of voltage support. LADWP's local transmission system cannot be reliably operated without generation from local generating plants. The amount of generation required to provide transmission reliability is termed Reliability Must Run (RMR) generation. Repowering these local units will maintain transmission reliability by maintaining the reliability of RMR generation.

- Increased efficiencies
  New units will operate more efficiently, generating more energy and less emissions with the same amount of fuel. Operational costs per energy output will decrease.

- Integrating renewables
  The new units will incorporate new technologies which will enable faster start-up and faster ramping of generation output. This ability to increase or decrease generation on short notice, measured by what is termed "ramp rate," is an important requirement for integrating renewable resources. Wind resources produce power when the wind is blowing. When the wind suddenly begins blowing or stops blowing, the energy being delivered also changes but the customer load (the amount of energy the power system requires) remains substantially the same. Solar photovoltaic resources are subject to even greater output variability as clouds pass overhead and vary the intensity of available sunlight. To compensate for these fluctuations, natural gas "peaker" units (which are included in the new unit configurations) are able to quickly start, stop, and ramp up and down so that the total energy generated continuously matches customer load. Integrating significant amounts of intermittent

AR0071132

renewable resources, such as wind and solar photovoltaic, will not be possible without the fast load-following capability that the repowering program will provide.

2.4.2.2 Repowering Program to Comply With Regulatory Requirements

In addition to the reasons stated in Section 2.4.2.1, the repowering program is necessary to comply with local regulations related to once through cooling and NO_X emissions.

- Once-through cooling
  Once-through cooling (OTC) is the process where water is drawn from the ocean, is pumped through equipment at a power plant to provide cooling, and then is discharged back to the receiving water source. A cooling process is necessary for nearly every type of conventional electrical generating station and an OTC process utilizing ocean water is a major reason why many electrical generating stations were sited along the coastline. Typically, the water used for cooling is not chemically changed in the cooling process; however, the temperature of the water increases before it is returned to the ocean.

  LADWP operates three coastal generating stations – Scattergood, Harbor, and Haynes – that utilize OTC. The combined net capacity of these stations is 2,839 MW. Further information regarding repowering can be found in Section 1.6.5. Table 3-3 contains a listing of specific repowering projects.

  In addition to repowering, OTC interim mitigation measures will be required until a facility is fully compliant. These measures include the funding into projects to alleviate impacts, such as the installation of alternative technologies to reduce impingement and/or entrainment. These issues are discussed in more detail in Appendix C.

- NO_X compliance
  In mid-2000, during the statewide energy crisis, LADWP predicted that NO_X emissions from the in-basin generating units would exceed the available supply of NO_X RECLAIM Trading Credits issued by the South Coast Air Quality Management District (SCAQMD). Although LADWP's NO_X emissions ultimately did not exceed its allocation in 2000,on August 29, 2000 the SCAQMD Hearing Board issued a "Stipulated Order for Abatement" to the LADWP. Under the terms of the Order, LADWP was required to perform a series of repowering projects at its in-basin generating stations. The Stipulated Order was later superseded by a Settlement Agreement to accommodate scheduling and other issues. This agreement was revised in September 2011 and addresses the current repowering projects at the Haynes and Scattergood Generating Stations.

2.4.2.3 Coal-Fired Generation

SB 1368, the California Greenhouse Gas Emissions Performance Standard Act, enacted in 2006, prohibits California utilities from entering into long-term financial commitments for base load

AR0071133

generation unless it complies with the GHG emissions performance standard. As this standard also applies to existing power plants for any long-term investments or contractual extensions, it affects LADWP's coal-fired generation resources.

- SB 1368 Compliant Coal-Fired Generation

  As presented in Section 5, the analysis of future potential resource portfolios includes a set of strategic cases that accelerate compliance with SB 1368 for coal-fired generation by year 2020. The feasibility of adopting and implementing this will depend on a number of factors, including: (1) resolving contractual issues, (2) the cost of alternatives (and LADWP's ability to cover its costs) and (3) regulatory factors that today are uncertain.

  SB 1368 compliant power will reduce the GHG emissions for LADWP, reduce regulatory compliance costs, and spur development of renewable resources in the western United States. SB 1368 established a greenhouse gas emissions performance standard that limits long term investments in baseload generation by the state's utilities to power plants that meet an emissions performance standard, which was jointly established by the California Energy Commission and the California Public Utilities Commission. Subsequently, the Energy Commission designed regulations that establish a standard for baseload generation owned by, or under long-term contract to publicly owned utilities, of 1,100 lbs CO2 per megawatt-hour (MWh).

  There are several methods to achieve SB 1368 compliance, for example, replace coal generation with natural gas-fired generation, carbon sequestration, coal gasification, or the application of other potentially emerging technologies. Since coal generation operates as a base load resource for LADWP, any replacement option would also need to provide base load generation around the clock while reducing GHG emissions.

- Intermountain Power Project

  The Intermountain Power Project (IPP) is a coal-fired generating station located near Delta, Utah. IPP consists of two generating units with a combined capacity of 1800 MW. LADWP is the operating agent. LADWP is also the largest single purchaser and has a power purchase agreement for 47.617 percent (803 MW) of IPP's total output. LADWP has additional purchase obligations for up to 22.368 percent (400 MW) of additional output. These additional obligations are dependent on the power usage of the Utah and Nevada participants. The power sales contract for IPP expires in 2027.

  In addition to the generating units, IPP includes four important transmission lines, a 500-kV DC transmission line from the generating station to Adelanto, California (a distance of 490 miles), two parallel 345-kV AC transmission lines from the generating station to Mona, Utah (50 miles away), and a single 230-kV AC transmission line from the generating station to the Gonder Switchyard near Ely, Nevada (about 144 miles away).

  At IPP, LADWP has no ownership rights. Rather, LADWP has a long-term power purchase contract which expires in 2027 and which also includes renewal option rights. With firm

AR0071134

"take or pay" IPP contract obligations extending to 2027, LADWP has committed to continue to fulfill all contractual obligations. At the same time, LADWP is investigating ways to maintain compliance with SB 1368. LADWP is reviewing several options.

LADWP has called for a strategic business plan to be developed for IPP. This effort, which is currently underway, involves IPA as owners of the IPP assets and the 36 participants that have power sales contracts. This effort is seen as a way to focus on the current and future needs of the project owners and those with power contracts and seek ways to find mutually beneficial solutions. Many of the participants, including LADWP, would like to settle on solutions that can be implemented in the next few years thereby reducing uncertainty with regard to the future use of IPP.

The work product that was approved in 2010 directed the subcommittee to continue work in 5 strategic areas.

- An energy trading hub at the site
- Generation development (A plan for future generation)
- Asset optimization
- Transmission
- Communications (Preparing advocacy efforts to assure future success)

The Energy Trading Hub Subcommittee has completed the majority of its work and is launching a 1 year trial of the program starting February 1, 2012. The Generation Subcommittee has considered a number of alternatives using natural gas and has determined that several of these are possible. Currently, this subcommittee is directing its efforts at the various contracts and governances that oversee the project and is drafting language that will facilitate options for future generation. The other three committees are meeting on as needed basis.

- Navajo Generating Station

The Navajo Generating Station (NGS) is a coal-fired generation station located near Page, Arizona. It consists of three units with a combined capacity of 2,250 MW. Salt River Project is the Operating Agent. As one of six owners, LADWP has a 21.2 percent ownership share in the station's generation. NGS operates under a co-tenancy agreement which shall remain effective throughout the initial term of the land lease with the Navajo Nation and throughout the lease extension thereafter.

Replacement options for NGS are discussed in Section 3.5.

AR0071135

2.4.3 Future Renewables for LADWP

The increase of renewables, as a percentage of electricity sales, from the current 20% to the regulatory mandated 33% by year 2020 requires the continued diligence of LADWP to pursue renewable projects and power purchase contracts. The development of a solar feed-in tariff and continued encouragement for rooftop solar is also necessary to support increased solar capacity. Because the acquisition of additional renewables is mandated by law, all of the strategic cases analyzed in this IRP include portfolios with the required amount of renewable resources. All strategic case alternatives include the following targets for new renewable acquisitions between 2011 and 2020:

New Renewable Installed Capacity (MW) 2011-2020			
Geothermal & Biomass	Wind	Non-DG Solar	Distributed Solar
243	492	401	325

Furthermore, maintaining at least 33% of renewables beyond 2020 requires additional renewables to account for load growth, project turnover, and output degradation as projects age. All strategic case alternatives include the following additional targets for new renewable acquisitions between 2021 and 2030:

New Renewable Installed Capacity (MW) 2021-2030			
Geothermal & Biomass	Generic	Non-DG Solar	Distributed Solar
65	162	50	141

Details regarding future renewables can be found in Appendices F and M.

2.4.4 Transmission and Distribution Facilities/Grid Reliability

Electricity from LADWP's power generation sources is delivered to customers over an extensive transmission and distribution system. To deliver energy from generating plants to customers, LADWP owns and/or operates approximately 20,000 miles of alternating current (AC) and direct current (DC) transmission and distribution circuits operating at voltages ranging from 120 volts to 500 kilovolts (kV). Major transmission lines connecting to out-of-basin generating resources are shown in Figure 2-8. Appendix I provides more details regarding LADWP's transmission system.

In addition to using its transmission system to deliver electricity from its power generation resources, LADWP arranges for the transmission of energy for others through its Open Access Same-Time Information System (OASIS) when surplus transmission capacity is available and saleable. LADWP uses its extensive transmission network to sell its excess energy and capacity in the California, Northwest, and Southwest energy markets. Revenues from these excess energy sales are used to reduce costs to ratepayers and for capital improvements. In the near future,

AR0071136

LADWP anticipates that revenue from excess energy sales may be less due to aging facilities, anticipated load growth, and GHG emission regulations.

Transmission for Renewable Energy

Transmission infrastructure improvements to access renewable energy are in various phases of development or construction:

- Barren Ridge Renewable Transmission Project. Up-to-date information is available for this project at http://www.ladwp.com/ladwp/cms/ladwp009508.jsp. This project, scheduled to be completed in 2016, will increase the capacity of the existing 230kV Barren Ridge—Rinaldi transmission segment. As of August 2011, approximately 2800MW from a combination of wind and solar projects are being investigated for potential interconnection. Castaic Power Plant, with its flexibility as a pump storage facility, stores surplus variable energy for optimal dispatch.

  Important components of the Barren Ridge Renewable Transmission Project are as follows:

  - New Haskell Canyon Switching Station
  - New double-circuit 230kV transmission line from Barren Ridge Switching Station to new Haskell Canyon Switching Station
  - New 230kV circuit on existing structures from Haskell Canyon to the Castaic Power Plant
  - Reconductor the existing 230kV transmission line from Barren Ridge Switching Station to existing Rinaldi Substation, through Haskell Canyon Switching Station
  - Expand existing Barren Ridge Switching Station

- Pacific Direct Current Intertie (PDCI) Upgrade. LADWP and its PDCI partners are considering increasing the capacity of the PDCI from 3100MW to as much as 3650MW. The benefit of such an undertaking would be a higher-capacity corridor for renewable wind and hydro energy from the Pacific Northwest to Los Angeles. LADWP, as PDCI operator, is currently developing a cost estimate for the project that considers transmission and station upgrades and the increased dispatch and energy costs during construction to cover the reserve margin. Toward that end, preliminary estimates based on a recently commissioned and completed Light Detection and Ranging study indicate the transmission portion of the project may cost up to $150 million and require as much as six years to construct. Less aggressive options with lower capacity benefits are also being investigated to facilitate an informed decision by the PDCI partners.

AR0071137

Regional transmission plans have shown that in order for LADWP and its Western counterparts to meet their renewable energy goals at the lowest cost, additional transmission improvements will be needed. While the projects listed here have a high priority and a high likelihood of construction, they may not be sufficient to meet future needs. LADWP will continue to evaluate transmission needs and opportunities as necessary.

AR0071138

Grid Reliability

LADWP annually performs a Ten-Year Transmission Assessment Plan, in compliance with the North American Electricity Reliability Corporation (NERC) Compliance Enforcement Program. LADWP's 2011 plan has identified a number of transmission improvements that are needed to maintain reliability. These projects include:

- Installation of a new Scattergood Olympic 230kV Line 1.
- An upgrade of the existing Northridge-Tarzana 230 kV Line 1.
- Transmission upgrades between the Haskell, Olive, and Sylmar Switching Station
- Construction of a new Cottonwood 230 kV substation with a new 100 MVAR capacitor bank

These infrastructure improvements are critical to avoid potential overloads on key segments of the Basin transmission system. Certain of these overload conditions would require load shedding events (intentional power outages) to minimize the impact on the power system as a whole.

System Losses

LADWP Power System transmission and distribution losses are approximately 11.5 percent, and are higher than the industry average of 6-8 percent partly due to its long transmission reach to external generation from Utah, the Desert Southwest, and the Pacific Northwest. However, there may be opportunities to reduce some losses by addressing the system's reactive power needs. To optimize performance and reduce these system losses, LADWP commissioned a 2011 Reactive Power Management Study, which arrived at the following recommendations:

- Retire 9 synchronous condensers which are beyond their useful lives and in subpar operating condition
- Install shunt compensation to replace the retired synchronous condensers and to enhance system security

  Shunt capacitors totaling 1565MVAR with consideration given to dynamic devices at Rinaldi and Hollywood Stations. The capacitors would be located at receiving and distributing stations and distribution feeders

  Shunt inductors totaling 930MVAR, with consideration given to dynamic devices at Rinaldi and Hollywood Stations. The inductors would be located at receiving and distributing stations and distribution feeders
- Implement a customer power factor improvement program as the current aggregate customer power factor is less than 0.75, lagging.
- Install and implement a real-time MVAR reserve margin monitoring and alarm system to alert power system operators of decaying operating margins so outages might be averted

AR0071139

FERC Order 1000 - The California Transmission Planning Group

With the release of Federal Energy Regulatory Commission (FERC) Order 1000 in July 2011, which directs regional and interregional transmission planning and cost allocation, FERC-jurisdictional (investor-owned) electric utilities are now required to reorganize transmission planning functions to collectively achieve state and federal public policy goals. Order 1000 builds upon the directives of FERC Order 890, issued in February 2007, to open regional and local planning to stakeholders to ensure transparency and non-discriminatory access to transmission service.

LADWP has a longstanding history of working with its Western Electricity Coordinating Council counterparts on regional transmission planning to ensure bulk power reliability and to leverage economies of scale; regional transmission plans are reviewed and approved through a formal process. Since the California Transmission Planning Group (CTPG) was formed in 2009, LADWP has been active in that transmission planning forum. CTPG was formed to comply with Order 890 by providing the increased coordination and public participation mandated while ensuring the electric needs and goals of Californians are reliably and efficiently met. In February 2011, the 2010 California Transmission Plan (California Plan) was released http://www.ctpg.us/images/stories/ctpg-plan-development/2011/02-Feb/2011-02-09_final_statewide_transmission_plan.pdf.

With Order 1000, CTPG must now consider reorganizing CTPG as an interregional planning organization with local and regional planning members or continue as a regional planning organization with WECC, or a yet unknown entity, serving as its interregional planner. CTPG and its members have up to eighteen months to formalize their positions with FERC. As the member utilities evaluate their options, they continue to press forward with their current transmission assessment to ensure California's electric power policy goals are reached efficiently and without undue hardship to the consumer or to the electric grid. California's electric power policy goals include:

- Attainment of renewable portfolio standard goals as promulgated by SB 2 (1X), which was signed into law on October 11, 2011
- Satisfaction of repowering/retirement deadlines of fossil-fueled Once-Through Cooling power plant units as negotiated with the State Water Resources Board to comply with Federal Clean Water Act §326(b)

As a municipal utility, LADWP is outside FERC jurisdiction, so, in a technical sense, Order 1000 is not a mandate. Consistent with its response to other FERC Orders, however, LADWP is seeking to conform to this order, with the same consideration as it would to an industry standard.

LADWP's extensive network of transmission resources is described in Appendix I; Figure 2-7 shows its major out-of-basin generation resources. Noteworthy is the fact that while LADWP customers represent roughly ten percent of California's electrical load, approximately 25 percent of the state's total transmission capacity is owned by LADWP. LADWP also differentiates itself from its counterparts by continuing to operate as a vertically integrated electric utility, owning and operating its generation, transmission, and distribution resources rather than as a parent company with subsidiaries carrying out the various functions that comprise the supply chain.

AR0071140

Figure 2-7: Major out-of-basin generating stations and major transmission lines.

AR0071141

2.4.5 Reserve Requirements

Reliability of the electric power system is dependent upon two elements: "resource adequacy" and "security." Resource adequacy refers to the availability of sufficient generation and transmission resources to meet customer's projected energy needs plus reserves for contingencies. Security refers to the ability of the system to remain intact after experiencing sudden disturbances, outages or equipment failures.

LADWP, as part of the electric power grid of the western United States and Canada (and a small section of northern Mexico), is required to meet operational, planning reserve and reliability criteria, and the resource adequacy standards of the WECC and the North American Electric Reliability Corporation (NERC). These standards define the system reserve margin requirements and other criteria for which LADWP must plan and operate and are defined as follows:

Generation Capacity Requirement = Net Power Demand + System Reserve Requirement
System Reserve Requirement = Operating Reserve + Replacement Reserve
Operating Reserve = Contingency Reserve + Regulation

The "Net Power Demand" is the total electrical power requirement for all of LADWP's customers at any time. The other reserve requirements are defined below, as well as numerically calculated.

The loss of the largest single contingency of generation or transmission, is a key reserve margin determinant for LADWP and defines the Contingency Reserve as well as the Replacement Reserve requirements. Under the current NERC Standards, at least 50 percent of the Contingency Reserves must be Spinning Reserve. The Replacement Reserve requirement is to restore Operating Reserves within 60 minutes of a contingency event. The Regulation Requirement of 25 MW is related to system load variations due to customer load changes. This regulation requirement is anticipated to increase in the future as additional amounts of intermittent renewable generation are added to the generation mix. Given LADWP's current total generation portfolio, the system reserve requirement is approximately 1,100 MW. Therefore, if the system demand is 5,000 MW, LADWP must have a total of 6,100 MW of stable and dispatchable generating capacity (and the transmission for that capacity) to meet the 5,000 MW demand.

Due to the variable and intermittent nature of some renewable resources, particularly resources such as wind and solar photovoltaic, their generation capacity cannot be depended upon to meet peak demand conditions. As LADWP acquires a larger proportion of such resources, studies on the characteristics of these variable and intermittent resources will need to be carried out to determine their effect on reserve and regulation requirements. Refer to Appendix J for additional information on issues associated with integrating intermittent energy resources.

The capacity value of a generating resource is based on its ability to provide dependable and reliable energy and capacity during peak periods when the system requires reliable resources for stable operation. Resources that can provide firm capacity will have a higher capacity value than

AR0071142

resources that cannot. For purposes of planning LADWP's reserves adequacy calculations, it was assumed that the dependable capacity of wind would be 10 percent of its nameplate capacity and the dependable capacity of solar photovoltaic would be 27 percent of its nameplate capacity.

Local Resources for Grid Stability and Contingencies

As a subset of the reserve requirements, LADWP has located a significant amount of generating resources within the Los Angeles (LA) area. The specific amount of capacity that needs to be located in the LA Basin is approximately 3,400 MW, but varies, depending on the combination of which units are operating and how much power is flowing on the transmission system at the time. LADWP's local transmission system cannot be reliably operated without generation from local thermal generating plants. The amount of generation required to provide transmission reliability is termed Reliability Must Run (RMR) generation. RMR generation is incorporated into all of the strategic cases considered in this IRP.

This local requirement is particularly important in the context of deciding how to schedule the repowering of units that use once through cooling. It is for this reason that no unit will be taken out of service before an equivalently-sized, locationally-equivalent replacement unit is constructed, tested and ready to be placed in service.

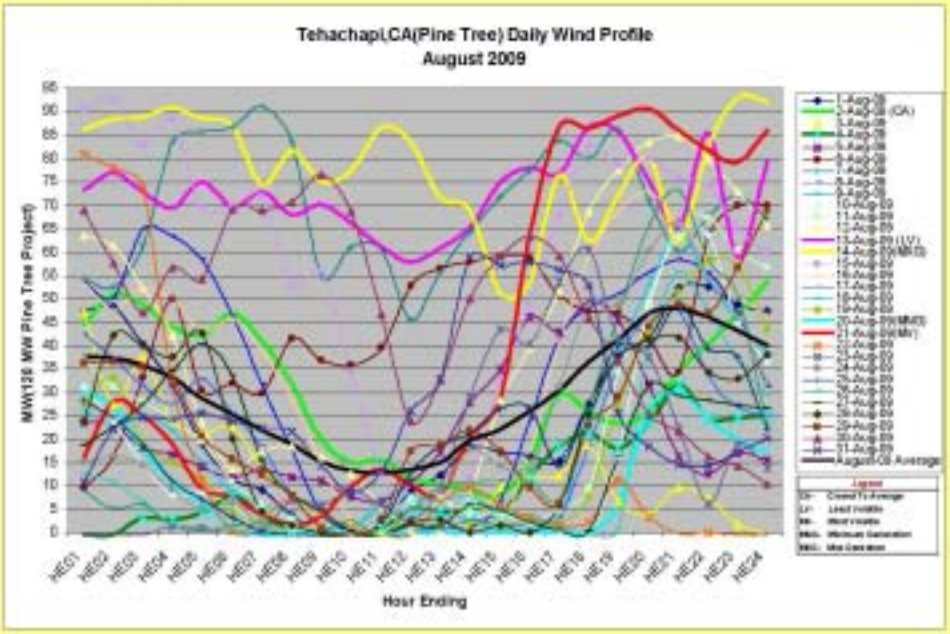
AR0071143

Integration of Intermittent Energy

One of the main responsibilities of power system operators is to maintain the balance between the total aggregate electrical demand of the power system's customers and the amount of energy generated to meet that demand on an instantaneous basis. Conventional electrical generation technologies, such as nuclear, coal, natural gas and large hydro are controllable and dispatchable by the power system operators throughout the day to maintain this instantaneous balance between demand and generation.

With the much higher percentage of renewables coming on line, a variety of modifications will need to be made to the Power System to successfully and reliably integrate these higher penetrations of renewable resources. In preparation, LADWP has conducted preliminary studies on integrating renewable resources, and has also reviewed many renewable resource integration studies published over the last several years.

Individual wind farms tend to have a high variability in the amount of energy produced (see figure below), but multiple wind farms located in diverse geographic areas are thought to reduce the overall variability in the amount of aggregated wind energy production.



Energy generated from Solar PV technology is highly sensitive to cloud cover. These PV systems can experience variations in output of ± 50 percent in 30 to 90 seconds, and ± 70 percent in five to 10 minutes. When a single large sized PV facility experiences these rapid changes in output, the Power System must also be able to react just as quickly with other generation resources to accommodate such rapid changes. The capabilities of a power system's dispatchable resources will limit the size of a single PV facility.

See Appendix J for more details regarding integrating intermittent resources.

AR0071144

3.0 STRATEGIC CASE DEVELOPMENT

3.1 Overview

IRP planning is an on-going process and as such, the development of the 2011 IRP strategic cases incorporates the latest changes that have occurred in the regulatory landscape, and tactical plans developed by the power system. This 2011 IRP also includes many updated assumptions that have been developed over the past year. These assumptions have influenced the composition of potential resource portfolios that can fulfill LADWP's goals of reliability, competitive rates and environmental stewardship.

Last year's 2010 IRP analyzed 6 strategic cases representing different potential renewable resource portfolio mixes, with and without the early divestiture of IPP, and recommended a comprehensive strategy that adopted elements of a number of the cases analyzed. The 2011-12 fiscal-year financial planning process included many of the assumptions and recommendations set forth in the 2010 IRP.

The regulatory state of affairs was far from certain at the time the 2010 IRP was prepared, and many of the state laws and major regulations affecting generation resources such as AB32, SB1368, SB 2 (1X), and US EPA 316(b), were in process, and even today are still being finalized. This 2011 IRP attempts to incorporate the latest interpretation of these major regulations and state laws as we understand them today.

Section 3.2 summarizes the major changes from last year's model assumptions. Section 3.3 discusses the key parameters that have a bearing on the resource portfolios being considered for this IRP. Section 3.4 describes the development process for the candidate strategic cases, and Section 3.5 presents the final candidate cases that were analyzed. The analyses and comparison of the case results are presented in Section 4.

AR0071145

3.2 2011 IRP Model Assumptions

At the heart of the IRP analysis effort is the computer-based production cost modeling of the LADWP Power System. In order to perform this modeling a significant amount of input data is developed. The production model and input assumptions are covered in detail in Section 3.2.2 and Appendix M. In this section, the major changes in the assumptions since last year's IRP are summarized, followed by a discussion of the general price inputs that were applied to this 2011 IRP.

3.2.1 Major Changes to 2010 IRP Assumptions

Major assumption changes from last year's IRP are summarized here. Additional detail regarding the assumptions can be found in Appendix M.

Load Forecast

As shown in Table 3-1, the new load forecast is lower than the previous forecast used in the 2010 IRP. Compared to the prior forecast, electricity sales in the calendar year 2020 decreased by 7.3 percent. The new forecast reduces the overall need for renewable energy (assuming 33% RPS) by approximately 631 GWh in 2020 and 1,309 GWh in 2030. The complete load forecast is included in Appendix A. Adjustments made to the approved load forecast to account for the latest projections of energy efficiency savings and customer-net-metered solar is shown in Appendix M.

Table 3-1. TOTAL ELECTRICITY SALES IN GWH

	2020	2030
Old Forecast – 2010 IRP	26,150	30,632
New Forecast – 2011 IRP	24,239	26,665
Difference	-1,911	-3,967

Demand Response

In the 2010 IRP, demand response (DR) started with a 50 MW program in 2011 and increased incrementally to a total of 500 MW installed by 2023. The lower load forecast used in the 2011 IRP delays the need to implement DR programs to provide added system capacity as can seen by the revised implementation schedule shown in Figure 3-1.

AR0071146

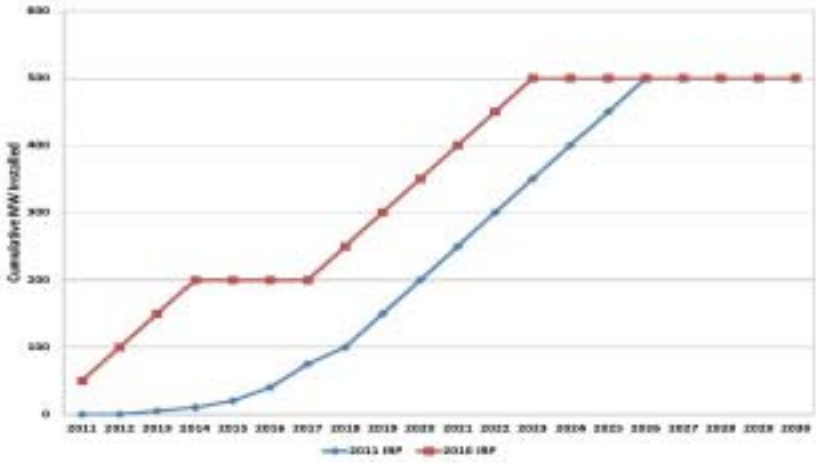


Figure 3-1. Comparison of 2010 and 2011 IRP demand response program implementation by calendar year.

Energy Efficiency

The Energy Efficiency (EE) forecast used in the 2011 IRP includes lower DSM funding levels for the 2011/12 through 2013/14 fiscal years due to short term budgetary constraints. Compared to last year, EE energy savings decrease after the 2015-16 fiscal year, even after funding levels return to normal. The main reason for this is that efficiency opportunities in lighting (which is the largest EE program component) will dissipate due to the implementation of new Federal and State lighting standards that raises the minimum efficiency level for a variety of electric products. These Federal and State efficiency standards create fewer opportunities to give financial incentives to customers to install products that exceed the higher efficiency standards and the resulting energy savings will be incrementally less. Although these standards result in fewer opportunities to provide incentives from the utility, the energy efficiency savings from these standards are nevertheless accounted for in the sales load forecast and do contribute to reducing overall sales and load growth. The cumulative EE savings incorporated in the 2011 IRP will reach 2,699 GWh in 2020 and 3,439 GWh in 2030 as shown in Figure 3-2. Efficiency savings prior to 2011 of 1,256 GWh and 303 MW from 2000 to 2010, equivalent to 5.5 percent of customer sales, are already reflected in the load forecast. The table below shows the projected cumulative savings from 2006 through 2030.

As of December 6th, 2011, the Board of Water and Power Commissioners approved an advanced EE program with a goal of 8.5 percent of sales by the end of fiscal year 2019-20 and beginning fiscal year 2010-11. The adoption of the advanced program results in approximately 920 GWh of additional gross EE savings by 2020. Due to the timing of this approval, this change could not be incorporated in the 2011 IRP, however, the advanced program will be considered in the 2012 IRP modeling results.

AR0071147

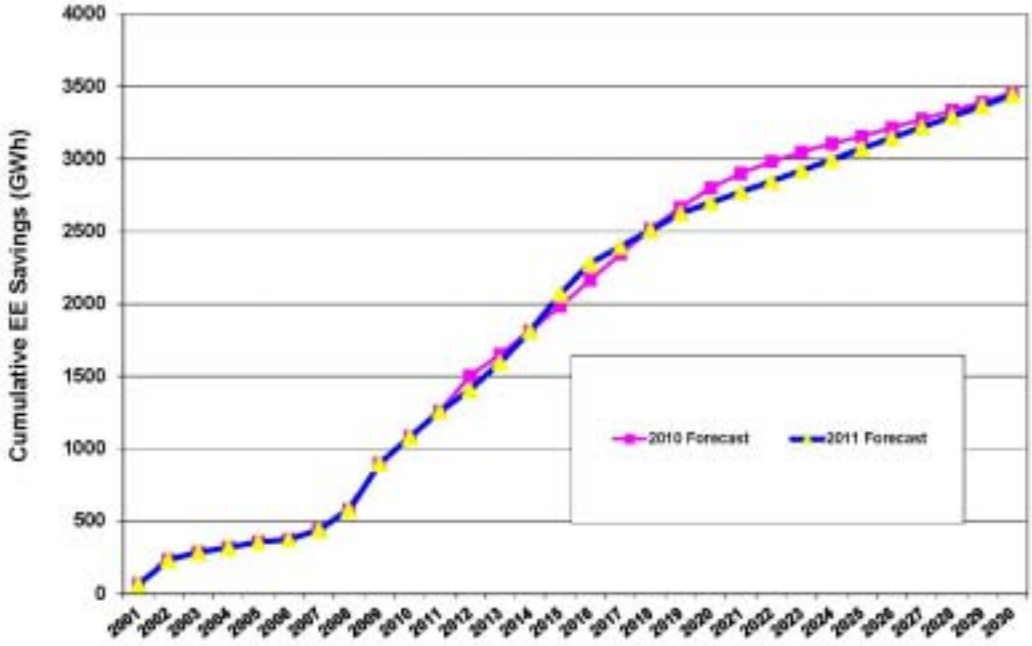

Figure 3-2. Comparison of 2010 and 2011 IRP gross energy efficiency forecasts by fiscal year.

Solar C-N-M and FIT

The solar Customer-Net-Metered (CNM) program (a.k.a. Solar Incentive Program) and Feed-In-Tariff (FIT) programs used in the 2011 IRP are based on projections dated October 2011. Figure 3-3 shows the comparison of CNM and FIT program projections used in the 2011 IRP vs. the 2010 IRP. The CNM solar is higher in years 2012-2016 primarily because of a dramatic increase in participation levels of the SIP program in 2010, and expected continued strong interest in the program given the tax benefits available and currently lower solar prices. FIT is lower in 2013-2015 due to a delay in implementation of the program due to budget constraints, but higher in 2017-2023 due to the plan to accelerate the program to take advantage of tax benefits available through 2016.

AR0071148

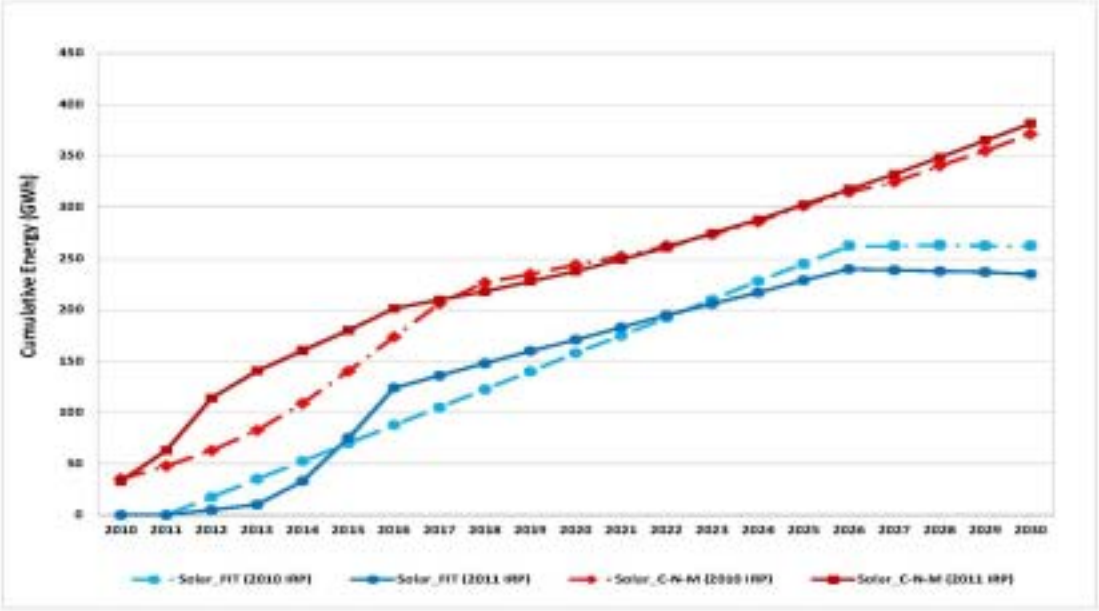

Figure 3-3. Comparison of solar projections, 2011 vs. 2010.

Renewables

Table 3-2 is a comparison of the overall renewable mix planned for the 2011 IRP vs. the 2010 IRP:

Table 3-2. RENEWABLE MIX, 2010 VS. 2011

		2020	New Renewable Installed Capacity (MW) 2011 – 2020					New Renewable Installed Capacity (MW) 2011 – 2030				
Case ID	Resource Strategy	RPS Target	Geothermal	Biomass	Wind	Non-DG Solar	Dist. Solar	Geothermal Biogas	Wind	Non-DG Solar	Dist. Solar	Generic
Recommended Case 2010 IRP	33% RPS Balanced	33%	320	0	580	315	315	320	680	485	485	160
All Cases in 2011 IRP	33% RPS SB 2 (1X) Compliant	33%	183	60	492	401	325	308	492	451	466	162

One major RPS change from the 2010 IRP was a large reduction in geothermal projects, especially in the short term. Suitable geothermal sites in accessible locations near existing transmission lines have been difficult to locate. The 2011 IRP lowers the amount of geothermal expected in 2020 by 43 percent. In the short term, increased use of low cost biogas will largely replace the energy that would have been generated by geothermal projects until more viable geothermal sites can be identified. Another change was the deferral of the Owens Valley Solar Project from 2013 to 2018 due to recent budget reductions and tax benefits for third party developed solar projects that are scheduled to end after 2016, making development of LADWP facilities that are not eligible for direct tax benefits more viable. As previously discussed, the revised load forecast decreases the need for renewables. This results in the lower overall capacity requirements in both the short term 2010 - 2020 and longer term 2020-2030 time periods as shown above.

AR0071149

Navajo Early Divestiture

Divestiture of the Navajo Generating Station (NGS) on December 31, 2013 as described in the 2010 IRP recommended case, will be extended to December 31, 2015. Member utilities of NGS have "first rights of refusal" involving the sale of other member shares. After 6-months notification of their intent to exercise "first right of refusal" rights member utilities have 3 years to complete the purchase. Although NGS participants could potentially complete the purchase sooner, the most realistic estimate of a sale being completed has been extended to December 31, 2015.

GHG Costs

Projected GHG cost impacts resulting from AB32, and as incorporated in the 2010 IRP, have been significantly reduced as a direct result of recent changes in the final regulations approved by the California Air Resources Board (CARB). Although some uncertainty still remains regarding the final regulations, the expectation of allowance prices being applied to all GHG produced, as previously assumed in the 2010 IRP, have been replaced with allowance prices being applied only to the amount exceeding the CARB allowance allocation within a compliance period. Additionally, GHG regulations are expected to begin on January 1, 2013, one year later than the assumed start date in the 2010 IRP. The net effect of the allocation changes between the 2010 and 2011 IRP was a $1.25 billion reduction in anticipated allowance costs between 2010 and 2020.

Gas Prices

Natural gas costs continue to remain stable for the near term and spot market price forecasts for gas have changed little since the 2010 IRP. The Pinedale gas reserves owned by LADWP continue to provide a low cost source of gas and estimates of gas volumes to be produced from Pinedale have risen since the 2010 IRP. These production increases have lowered the overall system gas costs. Opal and SoCal expected gas prices used in the 2011 IRP were 7 and 10 percent lower on average, respectively, in the short term (2011-2020), but were 11 and 14 percent higher on average, respectively, in the long term (2021-2030) as compared to the 2010 IRP.

Coal Prices

IPP forecasted coal prices are 22 percent lower in the short term (2011-2020) and 34 percent lower in the longer term (2021-2027) as compared to the 2010 IRP. Navajo coal prices are 10 percent lower in the short term (2011-2019) as compared to the 2010 IRP.

IPP Recall

IPP capacity is a function of the capacity recalled by Utah participants. Estimates for this recall amount, or the capacity entitlement transferred from the Utah participants to LADWP, has risen by 112 MW in the short term (2011-2020) and 44 MW in the long term (2021-2027) as compared to the 2010 IRP, thereby increasing our share of IPP capacity entitlement. This raised the energy and capacity expected from IPP generation in the 2011 IRP as compared to the 2010 IRP.

AR0071150

Once-Through Cooling

Recent OTC decisions by the State Water Resources Board have accelerated the compliance date for repowering the LA-basin coastal generation stations. Whereas December 31, 2040 was the date used in the 2010 IRP, the new "no later than" compliance date is December 31, 2029. The new repowering dates (see Table 3-3 below) and resulting efficiency improvements resulting from the more efficient replacement units have been incorporated into the 2011 IRP production model.

Table 3-3. BASIN PLANTS REPOWERING – TARGET SCHEDULE[1]

Unit	Nameplate Capability [1] (MW)	Action and Resulting Nameplate Capacity	Compliance Date (No Later Than)	LADWP Draft Target Date[3]
Haynes 1	230	Replace with 444 MW CC	12/31/2029	12/31/2023
Haynes 2	230			
Haynes 5	343	Replace with 600 MW CT	12/31/2013	6/1/2013
Haynes 6	343			
Scattergood 1	163	Replace with 367 MM CC	12/31/2024	12/31/2020
Scattergood 2	163			
Scattergood 3	497	Replace with 509 or 574 MW CC[2]	12/31/2015	12/31/2015
Harbor 1, 2 & 5	240	Repower with same MW	12/31/2029	12/31/2026
Haynes 8, 9 & 10	650	Repower with same MW	12/31/2029	12/31/2029

Notes:
1. Maximum or dependable capacity of the unit will be different based on permitting requirements as well as other constraints.
2. For Scattergood Generating Station, Unit 1 and 2 will be replaced with 300 MW (if unit 3 replaced with a 508 MW unit) or 233 MW (if unit 3 replaced with a 575 MW unit).
3. The LADWP target dates are very ambitious and based on many physical and budgetary assumptions, and are subject to change. They represent LADWP's best effort to comply with the regulations as fast as possible and assumes no unexpected complications or delays. Subject to further evaluations and studies.

AR0071151

3.2.2 General Price Inputs

General price assumptions are presented here for supply side resources, fuel, and GHG allowances. More details are provided in Appendix M.

Supply-side Resources
Table 3-4 presents a summary of the major price assumptions for supply-side resources.

Table 3-4. SUMMARY OF SUPPLY-SIDE RESOURCE ASSUMPTIONS

Resource	Levelized Cost[1] ($/MWh)	Capacity Factors	Dependable Capacity
Solar Photovoltaic – PPA	$144	23% - 31%	27%
Solar Photovoltaic - LA Solar – Public/Private Partnership In-Basin	$177	21%	27%
Solar Photovoltaic – LA Solar – Public/Private Partnership Owens	$153	24%	27%
Solar Customer-Net-Metered	$136	18%	27%
Solar Feed-In-Tariff	$179	18%	27%
Wind	$106	24% - 42%	10%
Geothermal	$138	90%	90%
New Combined Cycle Gas (310 MW)	$63	58%	100%
New Simple Cycle Gas (50/100 MW)	$302	4%	100%

[1]Net Present Value (annual costs, 2011-2030) / NPV of Energy Produced

AR0071152

Natural Gas Prices

High, low, and medium natural gas price forecasts were developed to test each portfolio against a range of potential natural gas prices. The medium or expected gas forecast originates from Platts and is the standard used by LADWP for financial and fuel procurement planning. The high and low forecast, shown on Figure 3-4, are fundamental forecasts obtained from Wood Mackenzie that consider a range of future assumptions including economic growth, supply and demand, and environmental regulations.

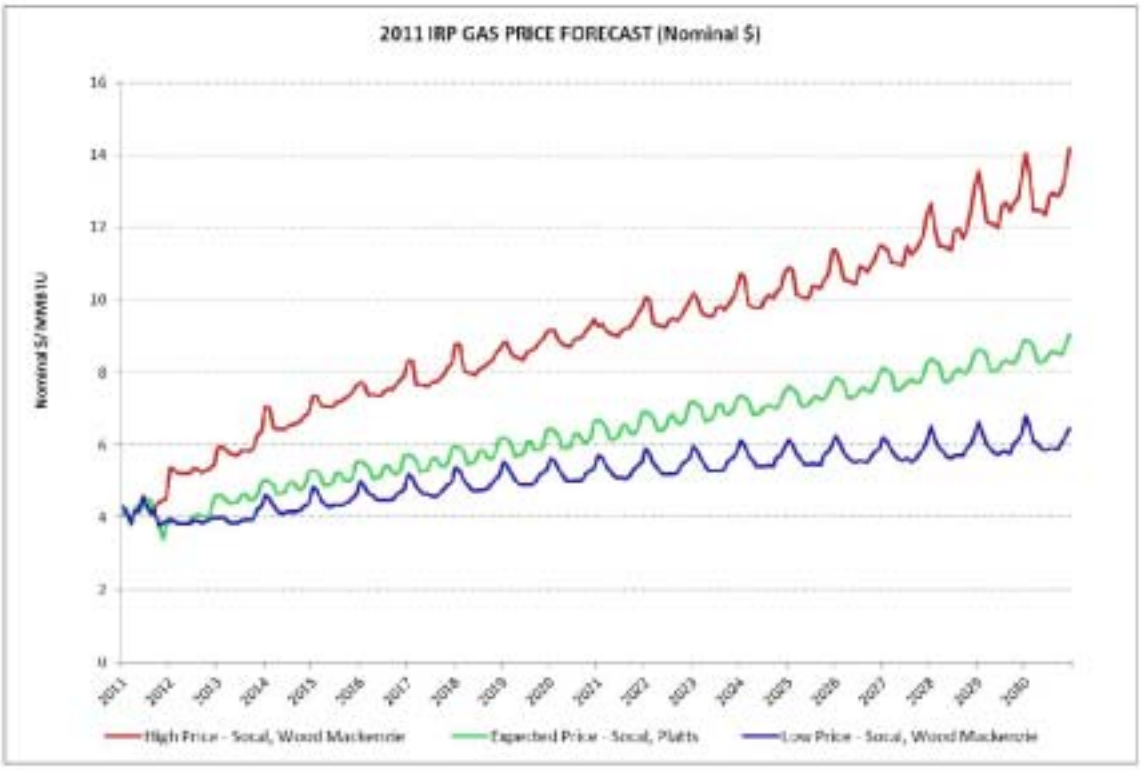

Figure 3-4. Natural gas price forecast (SoCal).

AR0071153

Coal Prices

A ±20 percent factor was applied to the expected coal fuel price, provided by LADWP's External Generation Division, to determine a high and low range for coal prices. Actual coal fuel prices have intentionally been left out of this IRP to comply with non-disclosure agreements with coal suppliers.

GHG Emissions Allowance Prices

Price scenarios were also developed and tested for GHG allowance prices using staff estimates from experience, and agency models as a template. This template assumed GHG pricing starting at $24/metric ton in 2013 escalating to $45/metric ton in 2020. Beyond the year 2020, the AB32 Cap and Trade program ends and may be replaced by another State or Federal program. Assuming that there will be another program, allowance prices beyond 2020 were assumed to remain at $45/metric ton through 2030 and the allowance allocated by CARB was assumed to remain constant. Future IRP's will consider changing this assumption as new information about future programs becomes available. Unlike the 2010 IRP where a sensitivity analysis was done using high and low GHG prices, the 2011 IRP does not include high and low GHG prices because the expected costs are not as significant as other cost drivers. Figure 3-5 depicts the GHG allowance prices used to evaluate the portfolios.

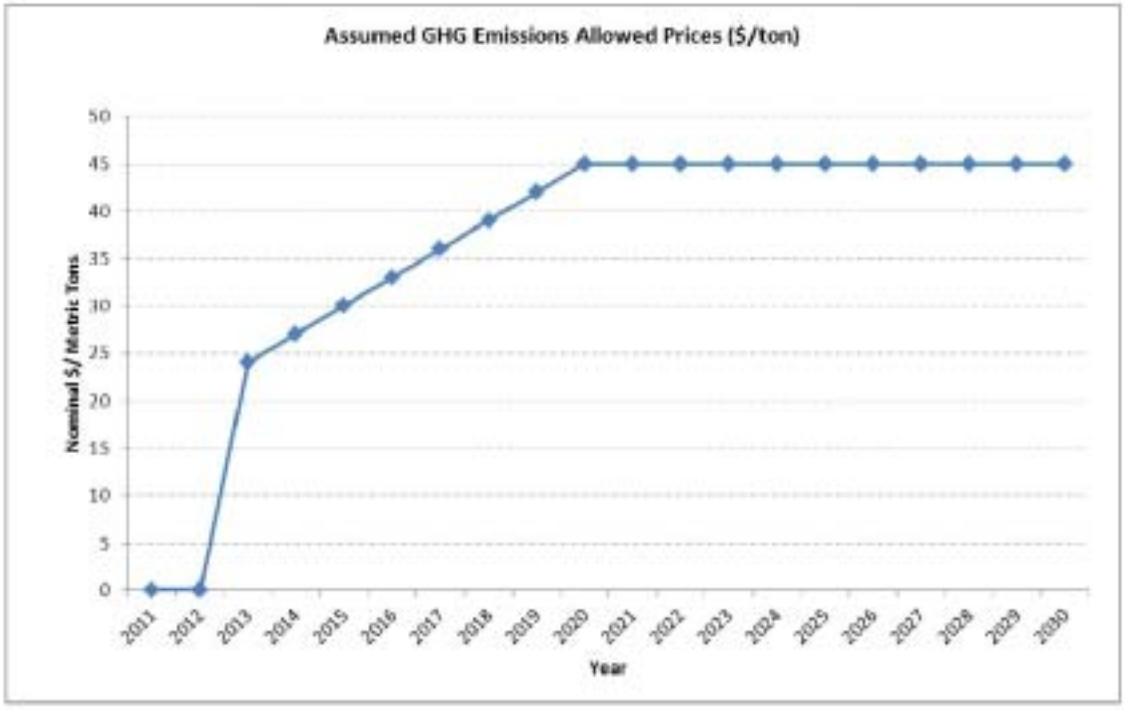

Figure 3-5. Assumed GHG emissions allowance prices.

AR0071154

3.3 Strategic Case Key Parameters

The 2011 IRP strategic cases must reflect the requirements of the most-recently implemented environmental and RPS regulations. In many cases, the regulations have predetermined a limited set of resources that can be considered to meet future generation needs. The net effect is to constrain and limit the set of alternatives that can be analyzed.

SB1368

SB1368 requires that imported energy from outside California meet a GHG emissions standard of 1,100 lbs per MWh. To comply with this requirement, all future generation outside the LA Basin will need to come from either highly efficient combined cycle gas turbines (if fossil fueled), or from renewable energy resources. This eliminates the use of coal-fired generation, at least until future coal combustion and sequestration technology improves sufficiently to make this a viable option. As a result, three Coal divestiture cases have been considered in this 2011 IRP. The three divestiture cases will further define the costs and operational impacts that divestiture of these facilities will have in meeting future energy and capacity load requirements.

OTC

Once-through cooling regulations effectively prohibits the use of ocean water cooling in all of the coastal power stations, which comprises 3 of the 4 in-basin gas-fired generation facilities, and sets specific deadlines to repower this generation prior to 2029. The limited resources available to repower virtually all in-basin generation under the accelerated time frame further limits the flexibility of altering repowering schedules based on system operation and capital requirements. Therefore, all strategic cases considered include the same repowering schedule as shown in Figure 3-6 below:

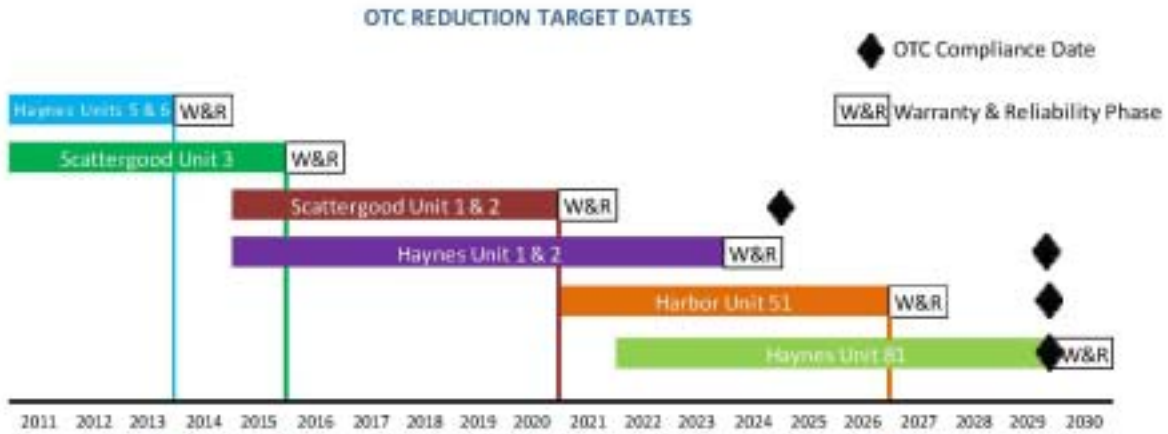

Figure 3-6. Timeline for OTC repowering projects.

AR0071155

While developing the timeline for the repowering program, LADWP had to consider a number of reliability, financial, and other contingent requirements. Because the power system relies on the in-basin units to produce energy and provide voltage support and stability, it is important to keep all of the units continuously available during summer months. This means that during summer months the total capacity available from the in-basin units remain constant. This requires a strict sequencing of the separate repowering projects. Further studies will be required to determine the impact on system reliability from the accelerated repowering schedule.

Another consideration is the cost of the program. Repowering just one unit requires a significant amount of money – on the order of $500 million or more. Spreading the program over time minimizes the need for sudden and significant infusions of capital, and helps LADWP to preserve proper cash flow and capitalization ratios to maintain its credit rating.

Other issues include the long lead times required for environmental permitting, engineering design, and equipment procurement. The limited space available within some of the generating station property boundaries also presents planning difficulties. The timeline represents LADWP's best effort to comply with the mandated compliance deadlines while also meeting its reliability and fiscal responsibilities.

SB 2 (1X)

As discussed at the end of Section 1.6.4, SB 2 (1X) defines categories with predefined percentage limitations on the amount of out-of-state renewable generation and renewable energy credits that can be used to meet renewable portfolio standards. Wind, small hydro, and biogas provide the largest contributors to LADWP's portfolio as shown in Figure 2-6. Future renewable generation will rely heavily on solar PV and wind resources located within the State to fulfill the in-state percentage requirements of SB 2 (1X). This limits the potential use of renewable resources located outside of California. The strategic cases evaluated in the 2010 IRP established a diversified resource mix for the next 20 years including goals for estimated MW's installed for each renewable technology. The 2011 IRP retains the same diversified renewable mix goals set forth in the 2010 IRP recommended case while including the latest updates based on available resources. As shown in Table 3-2, all strategic case scenarios being considered in the 2011 IRP use the same renewable resource plan. Future IRP's will likely address different renewable resource mixes as the CEC further develops specific regulations to enforce SB 2 (1X).

Accelerated Coal Divestiture

To achieve a high level of Power System reliability, minimize the impact on ratepayer energy prices, and exercise environmental stewardship while complying with federal, state, and local regulations, the 2011 IRP Strategic Cases were developed to assist policymakers and ratepayers to make informed decisions regarding the accelerated divestiture of Coal resources to promote GHG reduction prior to SB1368 compliance which occurs in 2019 for Navajo and 2027 for IPP. Accelerated Coal divestiture is discretionary, unlike other mandated regulatory requirements described previously. It is

AR0071156

important that the environmental benefits and resulting electricity rate and resource impacts be fully understood by ratepayers and policy makers.

3.4 Candidate Portfolios Development Process

A candidate portfolio is a set of renewable and non-renewable generation resources, DSR resources, regulatory constraints, policy goals, and assumptions that model strategic scenarios. Candidate portfolios are selected to cover a spectrum of possible scenarios, providing decision makers information on which portfolios are likely to be the most desirable. Additionally, each candidate portfolio must ensure resource adequacy—the ability to meet total peak demand.

3.4.1 Net Short and Resource Adequacy

The first step in developing the 2011 IRP candidate portfolios was to determine how LADWP can meet and maintain its renewable energy policy goals: 20 percent renewables in 2010 and 33 percent renewables by 2020. The net short—the gap between renewable energy policy goals and current renewable generation—was calculated, and the contribution of its renewable energy component towards resource adequacy was determined. Combined-cycle gas generation, energy efficiency, short term purchases, and demand response were then considered to supply the remaining deficiency in resource adequacy. Details regarding net short calculations and resource adequacy are included in Section 4.3.1.1 and Appendix M.

3.4.2 Renewable Resources Selection Process

Over the last ten years, LADWP has issued several requests for proposals for renewable energy and gained a thorough understanding of the nature and availability of the different renewable resource technologies. This knowledge was used in developing the candidate portfolios. Additionally, LADWP largely considered renewable resources within the Western Governors' Association's Western Renewable Energy Zones (WREZ). In the WREZ initiative, Qualified Resource Areas were defined as areas of dense, high-quality renewable energy resources, meeting various resource size, quality, environmental, and technical criteria. LADWP screened all resources to ensure they are located near available LADWP transmission infrastructure.

Assumptions were made for the cost and performance of each technology used to convert the renewable resources to electricity. A summary of the main assumptions made for biomass, geothermal, solar, and wind is presented in Appendix M.

A valuation process designed to provide a single ranking value to a resource was then applied. This step is intended to identify resources with the combination of lowest cost and highest value. The valuation approach is similar to the bid evaluation process many utilities use when procuring renewable resources. Specifics for the resource valuation methods are also covered in Appendix M.

AR0071157

After applying the appropriate constraints, resources were selected and added progressively to its renewable resource mix based on lowest rank cost and transmission availability until the net short was mitigated.

AR0071158

3.5 2011 IRP Strategic Cases

The 2011 IRP analyses a focused set of strategic cases, expanding on the results from the 2010 IRP process. Cases from last year that included a variety of renewable percentage targets were eliminated. A streamlined set of 3 coal divestiture cases where then included for the 2011 IRP. Unlike other areas that are constrained by mandated regulatory requirements (such as renewable resources), the decision to divest from coal earlier than legally required is discretionary and thus appropriate for analysis. The 2011 IRP strategic cases are designed to assist policymakers and ratepayers to make informed decisions regarding accelerated coal divestiture, particularly with regard to the environmental benefits and resulting resource and electricity rate impacts.

- Case #1 provides a baseline without any early coal divestiture. Navajo Generating Station continues until 12/1/2019 and the Intermountain Power Project (IPP) until 6/15/2027.
- Case #2 considers an early divestiture of NGS, by 12/31/2015.
- Case #3 considers early divestiture of both coal plants – NGS by 12/31/2015 and IPP by 12/31/2020.

Table 3-5 provides a more detailed description of each strategic case.

As mentioned earlier, the same renewable resource plan applies to all cases. Table 3-6 summarizes each candidate renewable portfolio. For comparison purposes, the recommended case from last year's IRP is also included.

The different cases require distinct resource strategies to replace the divested coal generation capacity and to meet future load growth. These strategies include the construction of new natural gas units, renewable generation, electricity purchases in the 3rd Qtr as needed to fill short term resource adequacy deficiencies, and the implementation of demand response and energy efficiency programs. A detailed breakdown of these strategies is discussed in Sections 4 and 5.

The candidate portfolios were modeled and the case results were compared against each other. The analysis included measurements of power costs, emissions, and fuel usage. High and low scenarios based on fuel prices were also modeled to quantify the risk associated with fuel price volatility on each case. Section 4 discusses the modeling results, and presents the 2011 IRP Recommended Case that emerged from the analysis process. Section 5 discusses in greater detail the recommended case and the resulting impact on rates as well as the actions required to implement the recommended case.

AR0071159

Table 3-5. DESCRIPTION OF STRATEGIC CASES

Case ID	Description
Case 1 (Base Case)	No Early Coal Divestiture – This case assumes coal resources will be replaced with combined cycle natural gas and renewable resources upon the expiration of coal contracts with no early compliance with SB1368. Maintains the 33 percent standard renewables mix recommended to comply with SB 2 (1X).
Case 2	Navajo Early Replacement Strategy – This case considers early replacement of Navajo on 12/31/2015, or 4 years prior to contract expiration with IPP replacement at the end of contract expiration in 2027. Maintains the recommended 33 percent standard renewables mix to comply with SB 2 (1X).
Case 3	Navajo and IPP Early Replacement Strategy – This case considers early replacement of Navajo on 12/31/2015, 4 years prior to contract expiration, and early replacement of IPP on 12/31/2020 or 7 years prior to contract expiration. Maintains the recommended 33 percent standard renewables mix to comply with SB 2 (1X).
Recommended Case 2010 IRP	33% RPS Balanced Strategy – Primarily used to compare the other strategic cases to the recommended long term strategy described in the 2010 IRP with 33 percent renewable compliance by 2020. Considers early divestiture of Navajo on 1/1/2014 or five years prior to contract expiration and assumes replacement of IPP in 2027.

AR0071160

Table 3-6. CANDIDATE RESOURCE PORTFOLIOS FOR 2011 IRP

		2020	GHG or SB 1368 Compliance Date		New Renewables Installed Capacity (MW) 2011 – 2020					New Renewables Installed Capacity (MW) 2011 – 2030				
Case ID	Resource Strategy	RPS Target	Navajo Replacement	IPP Replacement	Geo-thermal	Bio-mass	Wind	Non-DG Solar	Dist. Solar	Geothermal/ Biomass	Wind	Non-DG Solar	Dist. Solar	Generic
1 (Base Case)	No Early Coal Divestiture	33%	12/1/2019	6/15/2027	183	60	492	401	325	308	492	451	466	162
2	Navajo Early Replacement	33%	12/31/2015	6/15/2027	183	60	492	401	325	308	492	451	466	162
3	Navajo and IPP Early Replacement	33%	12/31/2015	12/31/2020	183	60	492	401	325	308	492	451	466	162
Rec. Case 2010 IRP	33% RPS Balanced	33%	1/1/2014	6/15/2027	320	0	580	315	315	320	680	485	485	160

4.0 STRATEGIC CASE ANALYSIS

4.1 Overview

The analysis was performed on the generating resources using an hourly chronological production cost model. The model simulated the operation and electric loading of the LADWP Power System over a 20-year planning horizon with different portfolios of generating resources. The objective function of the production cost model is to minimize system cost, which is achieved by finding the least cost method to meeting the electric system demand using the specified generating resource portfolios.

The resources defined in the model consist of existing LADWP generating resources and generic types of future generating resources. The resource mix of renewable generating resources and thermal generating resources must satisfy: (1) resource adequacy requirements for reliability, and (2) specific increasing targets of renewable resources as a percentage of total energy sales.

For this 2011 IRP, the key strategic consideration is the accelerated reduction of GHG emissions by way of early divestiture of coal generation. The model runs analyzed different coal divestiture scenarios for LADWP's two coal projects, the Intermountain Power Project (IPP) and Navajo Generating Station (NGS). The results for each model run were tabulated and compared against each other. Each strategy was ranked on average dollars per megawatt hour generation cost and the total million metric tons of CO_2 emissions. All of the strategic cases meet electric system reliability requirements per NERC and FERC regulations, which dictated either replacing or re-powering aged infrastructure or end-of-life generating power plants.

The selection of the best case for LADWP ratepayers hinges mainly upon the load forecast, price of natural gas and coal, GHG emission levels, capital, and O&M costs. These factors are the major cost drivers for bulk power in the cases analyzed. All cases meet the mandated RPS percentage targets and renewable resources are included in the analysis and are the same for all cases analyzed.

Section 4.2 reviews the cases that were presented in Section 3, along with the model assumptions and analysis methodology. Section 4.3 presents the modeling results, including cost comparisons and the rate impact results of the different cases. Section 4.4 presents the strategic case conclusions and the recommended case.

Section 5 includes long and short-term actions that are recommended towards implementation of the recommended case, including an estimate of the revenues requirements and electricity rate schedule needed to support it, and the consequences of funding short falls.

AR0071163

4.2 Strategic Case Runs

The cases analyzed in this 2011 IRP were introduced in Section 3.5 and are briefly reviewed here. The timing of coal divestiture (and the associated resource replacement) is the key parameter that differentiates the three strategic cases. Table 4-1 summarizes the portfolios for each case. For comparison purposes, the recommended case from last year's IRP is also included.

The following inter-related resource parameters were assumed to occur in each of the three strategies:

- OTC Repowering Schedule per Table 3-3
- Energy efficiency penetration of approximately 3071 GWh by 2030
- RPS Resource Mix, schedule per Table M-2 and M-3 of Appendix M
- GHG allowance methodology and prices on page M-17 of Appendix M
- Gas and Coal Fuel prices, as shown on Tables 4-6 and 4-7
- IPP capacity and recall schedule on Page M-16 of Appendix M

Each strategic case was also subjected to high and low scenario runs, which were based on high and low values for natural gas and coal prices. The high and low scenarios simulated production over the same 20-year horizon, and provided a measure of the level of risk due to potential future fuel price volatility.

4.2.1 Modeling Methodology

4.2.1.1 Planning & Risk (PROSYM)

Simulations were performed using Planning & Risk (PAR), a third-party software program sold and distributed by Ventyx Corporation based in Atlanta, GA. PAR is an hourly chronological production cost model that commits and dispatches resources to minimize the cost of serving electric load. It utilizes the PROSYM unit commitment and dispatch algorithm. PAR is a widely used production cost model used by many utilities across the US and the world to help plan and optimize power systems. Additional information on the model can be found in Appendix M.

4.2.1.2 Model Assumptions

To perform model simulations, a large set of input data is required. The key parameters that influence the analysis results are fuel prices, load forecast (including adjustments for energy efficiency and other demand side management programs), coal divestiture strategies, and operational inputs regarding future gas-fired units. Details regarding the model assumptions are provided in Section 3 and Appendix M

AR0071164

4.2.1.3 Net Short of Renewables

In developing the future renewable portfolio mix, the primary requirement was to meet the SB 2 (1X) goals for RPS percentage (see Section 1.6.3 for details). Other considerations included costs, resource and geographical diversity, and proximity to existing transmission. The process by which the renewable resource portfolio was constructed is described in Section 3.3.2.

4.2.1.4 Resource Adequacy

As a prerequisite for any potential future portfolio, all cases considered must satisfy Resource Adequacy (RA) requirements. RA is the ability to supply the aggregate demand and energy requirements of customers at all times, taking into consideration future load growth and planning reserve margins. In calculating RA for a given portfolio, generation resources are assigned a percentage of their nameplate capacity, known as "Net Dependable Capacity" that can be counted towards fulfillment of the RA requirement. The net dependable capacity values vary depending on the type of generation resource. Throughout the energy industry there is an on-going debate on how much variable energy resources can be relied upon during the summer system peak. Table 4-2 lists the net dependable capacities of the different resource technologies assumed for this IRP analysis.

Table 4-2: NET DEPENDABLE CAPACITY ASSUMPTIONS FOR NEW RESOURCES

Plant Technology	Net Dependable Capacity
Natural Gas Combined-Cycle	100%
Natural Gas - Gas Turbine	100%
Wind	10%
Solar PV	27%
Solar Thermal	68%
Geothermal	90%

The specific RA analyses for each of the three strategic cases are presented later in Section 4.3.1.1.

4.2.1.5 Model Runs and Scorecards

The evaluation of each strategic case yielded a tremendous amount of information about the LADWP power system. In order to organize and interpret the modeling results, a scorecard system was developed to rank and check the output results. The scorecard is a very detailed and complex Microsoft Excel based spreadsheet that summarizes all the important inputs and outputs and includes metrics such as total system power costs, plant generation, CO_2 emissions, and fuel costs.

AR0071165

4.2.1.6 Post Modeling Analysis

While the production cost modeling provides detailed information on estimated bulk power costs, reliability and mandated regulatory program revenue requirements are evaluated through analysis external to the production cost model. The results of this analysis are provided in Section 4.3.3 to provide a more complete view of the total cost components that make up total power system costs. This Section also illustrates the revenue requirements to fund these specific programs to maintain a reliable electric system while also complying with regulatory requirements for renewable portfolio standards, local solar, once-through-cooling, and energy efficiency.

AR0071166

4.3 Modeling Results

The modeling results are presented in terms of LADWP's overall goals of: (1) reliability, (2) environmental stewardship and (3) economic, or cost, considerations.

4.3.1 Reliability Considerations

Resource strategies are not designed to totally avoid the chance of a power outage due to inadequate supply resources. Such a strategy would be very expensive and would mean that some resources would be built with a small chance of ever operating, or would have an unacceptably low capacity factor. Most power outages are distribution based (e.g., a winter storm that knocks down local distribution lines) and not a result of insufficient generation resources. The NERC/WECC reliability criteria of "1 day in 10 years" attempts to quantify what is an acceptable amount of loss of load (i.e. a power outage). The generally accepted industry interpretation of the criteria is that a system is considered reliable if there are no more than a total of 24 hours of loss of load in a 10 year period (87,600 hours). This criteria translates to a 0.03 percent chance that load will not be served.

Based on the reliability calculation, no single resource strategy is significantly more or less reliable than another strategy, and all strategies meet this criteria. The economic aspects of each of the resource strategies are only valid if the resource strategy meets the NERC reliability standard of "1 day in 10 years." For this evaluation on reliability, each resource strategy was considered equal in terms of the reliability criteria.

4.3.1.1 Resource Adequacy

The process of ensuring resource adequacy for each strategic case is iterative. Initially, a model run is made for each case without any resource additions. The results indicate the amount of resource surplus or shortfall into the future. Without any resource additions, a deficit is eventually reached as a result of coal divestitures, generation unit retirements and the expiration of power purchase contracts on the supply side, as well as load growth on the demand side. Figure 4-1 present the resource shortfalls for the three strategic cases prior to any resource additions. For planning purposes, the figures focus on the most critical months of each year – July through October.

AR0071167

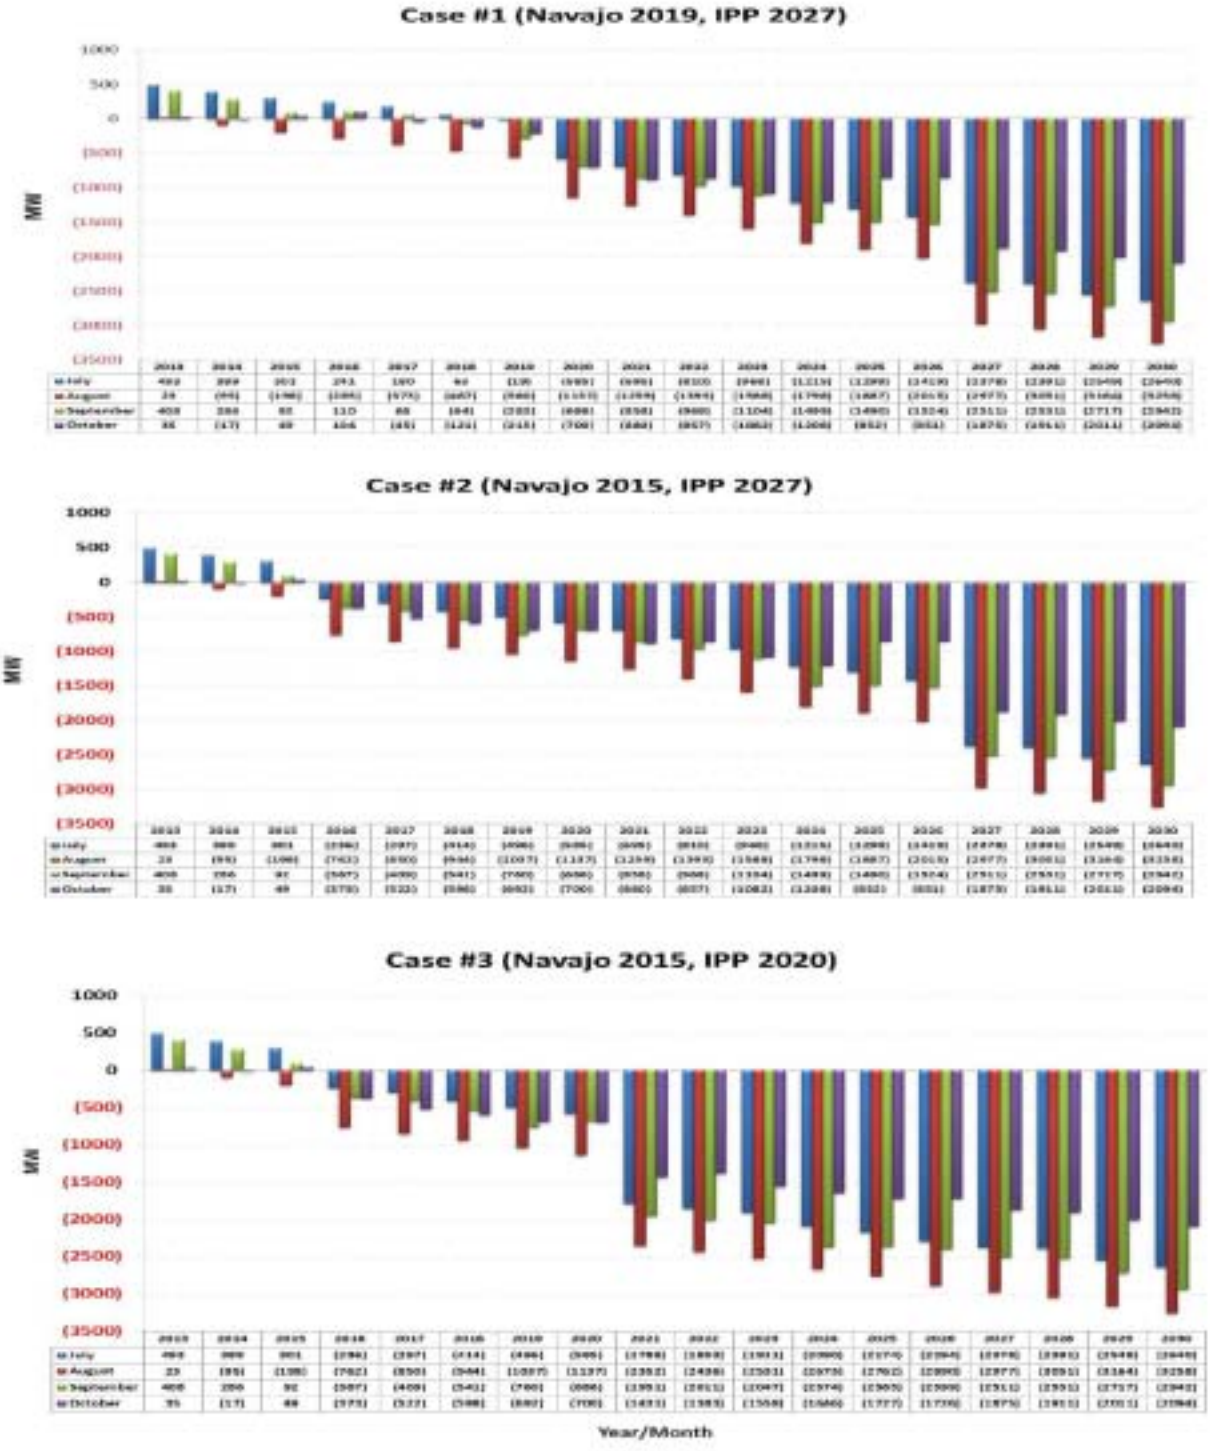

Figure 4-1. Summer months resource adequacy shortage with coal divestiture by calendar year (1 in 10)

AR0071168

Once the deficits have been quantified, the means of satisfying the shortfall is assessed. Some of the considerations that LADWP accounted for in identifying potential solutions include:

- Because the analysis already includes renewable resources expected to be in place by the end of 2011, any additional renewables added will increase LADWP's overall resource portfolio and help achieve compliance with SB 2 (1X).
- Energy efficiency, demand response, short term purchases, and replacement gas fired generation were considered to provide the most economical and well diversified blend of resources.
- The additions had to be separate and distinct from the in-basin OTC repowering projects, which are already included in the shortfall calculation.
- Large scale generation additions were located out-of-basin to take full advantage of the existing transmission infrastructure and to comply with local environmental regulations.
- Where feasible, the new generation sites should make use of existing transmission and fuel supply infrastructure.
- As with all planning activities, the solution must address reliability, costs, and environmental stewardship.

After careful consideration, LADWP's IRP team consisting of the IRP staff, Power System Management, Environmental Affairs, and the Energy Efficiency Group, developed a recommended resource replacement strategy for each case and briefed the General Manager and Financial Services Organization. The recommended solution employs a mix of new renewable generation, energy efficiency, demand response, new gas-fired combined cycle units, and short term 3rd quarter energy purchases to replace Navajo and IPP Coal and to supplement load growth. Table 4-3 shows the breakdown of the replacement resources recommended for the three cases.

AR0071169

Figure 4-2 shows the net dependable capacity profiles for the 3 cases after including the recommended resources to satisfy resource adequacy requirements. In each case, Navajo is replaced with new renewable generation and a 300 MW replacement combined cycle gas-fired unit upon divestiture. Energy efficiency, demand response, and short-term purchases supply capacity that primarily contributes to peak load growth.

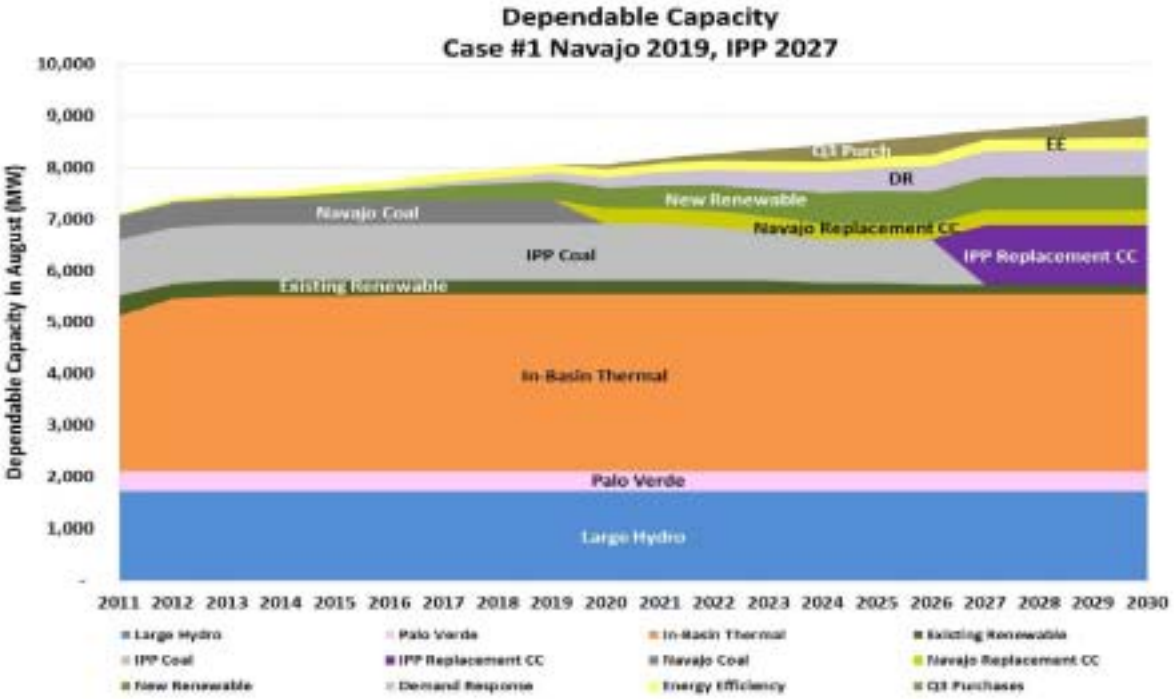
When IPP energy ceases in 2027 for Cases 1 and 2 and 2020 for Case 3, that production is replaced entirely with a 1,150 MW combined cycle natural gas unit. The larger combined cycle unit will be necessary to reduce short-term purchases and to provide for additional load growth. By 2020, most of the renewable portfolio will have already been built to replace Navajo with continued load growth being offset by renewables, energy efficiency, demand response, short-term purchases, and a portion of the 1,150 MW combined cycled gas-fired unit.

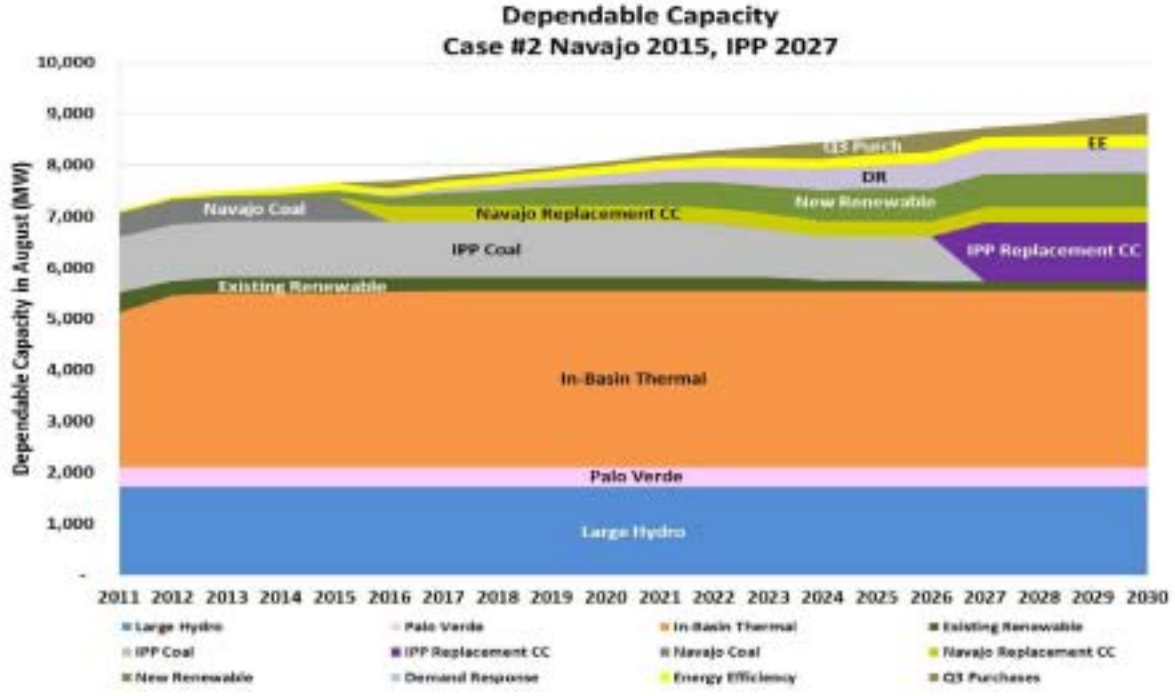
Short-term purchases are meant to satisfy peak load growth in the summer months where capacity is needed only over a short period of time. The planned addition of short-term purchases helps to limit the amount of capital intensive resources that would be necessary to supply peak load growth. Continual evaluation of future market conditions will be needed to insure that the market possesses adequate depth and reasonable pricing so that these purchases can be relied upon to fill system capacity needs.

In Cases 2 and 3 with Navajo divested in 2015, the 300 MW combined cycle gas-fired unit and demand response resources are fulfilling two purposes, (1) replacing capacity and energy that would have been provided by NGS and (2) providing dispatchable resources to enable

AR0071170

the integration of increasing amounts of intermittent renewable energy as these resources are ramped up from the current 20% RPS to 33% RPS in 2020.





AR0071171

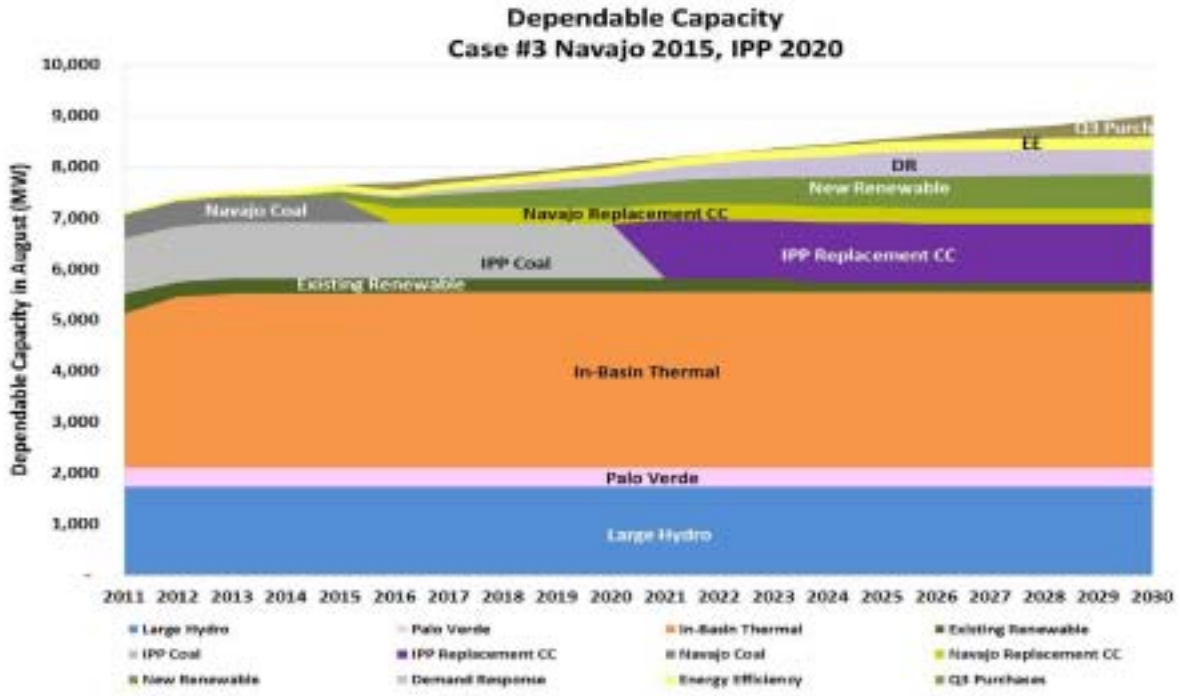


Figure 4-2. Dependable capacity mix by calendar year.

4.3.2 GHG Emissions Considerations

The primary objective of coal divestiture is to reduce overall GHG emissions. Energy produced from coal emits approximately twice the amount of GHG emissions on a lbs/mmbtu basis, when compared to energy produced from natural gas. The reductions of GHG emissions are reflected in the production cost model simulations. Figure 4-3 illustrates a comparison of the resulting GHG emission levels of the three cases. Divestiture of Navajo results in an average 1.86 Million Metric Tons (MMT) reduction in GHG each year while IPP results in an average 3.26 MMT reduction each year. GHG reductions are accelerated in Cases 2 and 3 with the divestiture of Navajo and IPP prior to the expiration of existing power contracts with these facilities. Case 1 represents the normal course of emissions reductions with no early divestiture. Reduction levels are eventually reached in all cases in 2019 and then again in 2027 when SB 1368 essentially prohibits the importation of energy produced from coal when the existing power contracts expire.

Current GHG emissions levels are approximately 14.1 MMT which is 21 percent below 1990 levels due to the elimination of Mojave and Colstrip Coal, completed repowering of units at Haynes and Valley generating stations with cleaner gas-fired replacements, and increased renewable generation from 3% in 2003 to 20% in 2010. Early divestiture of Navajo shown in Cases 2 and 3 results in approximately 7.5 MMT less GHG emissions between 2016 and 2019 and early divestiture of IPP shown in Case 3 results in a reduction of GHG emissions of 21.1 MMT between 2020 and 2027.

AR0071172

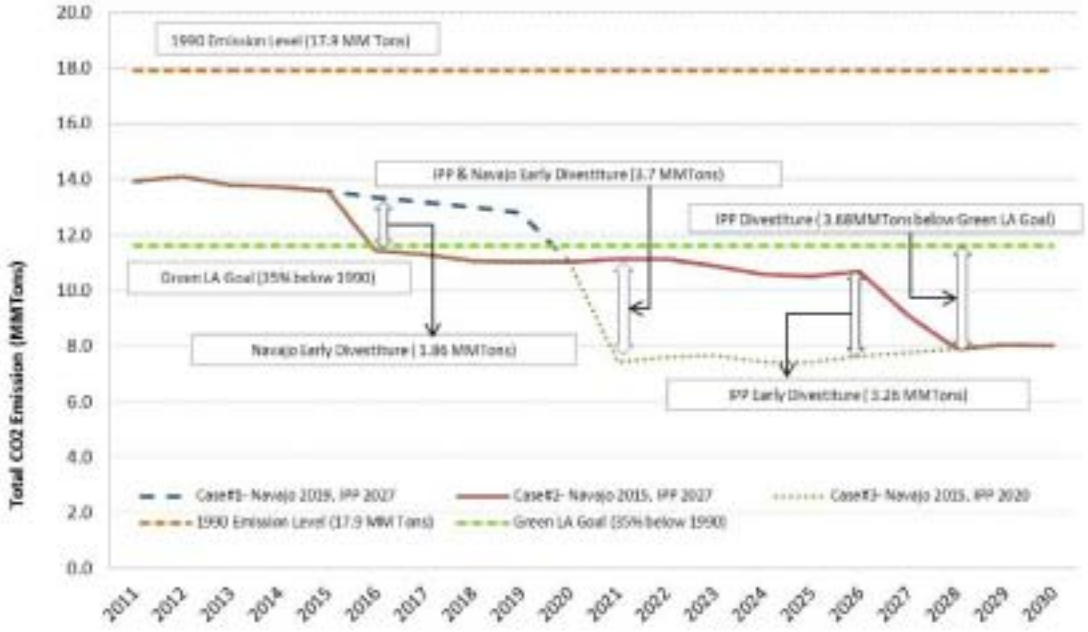

Figure 4-3. GHG emissions comparison by calendar year.

In addition to GHG, Oxides of Nitrogen (NO_X) were also measured within the production model. Figure 4-4 summarizes NO_X emissions for each of the three cases. With the installation of SCR equipment since 1989, NO_X emissions of in-basin generation has been reduced by 90 percent and represents approximately 0.5 percent of all LADWP NO_X emissions with the other 99.5 percent coming from out-of-basin coal-fired generation.

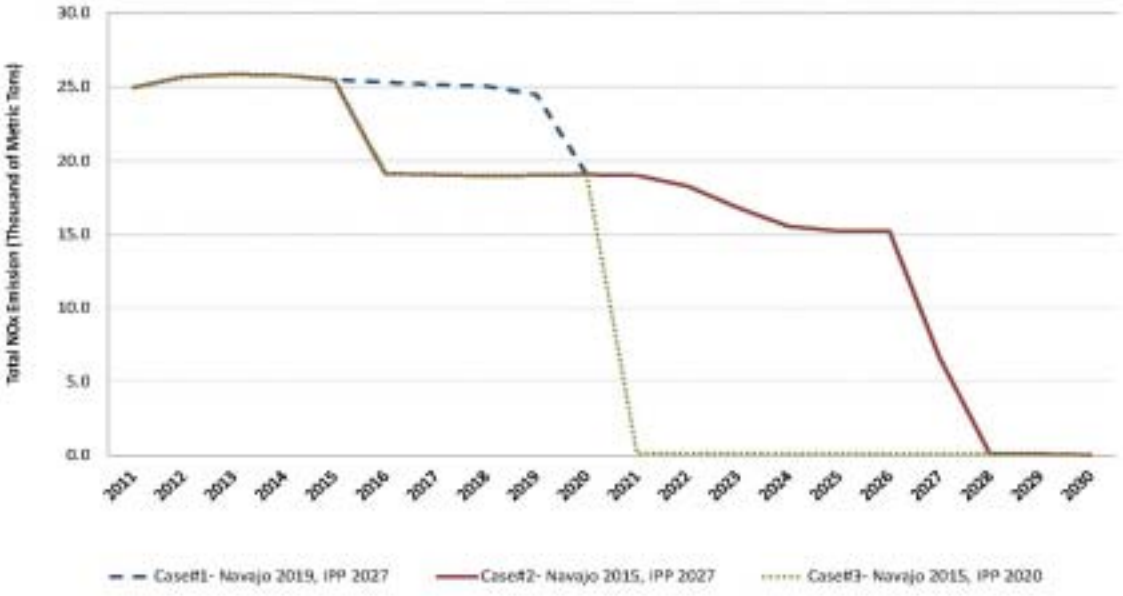

Figure 4-4. NO_X emissions comparison by calendar year

AR0071173

4.3.3 Economic Considerations

The economic considerations for the three cases included a comparison of fuel and variable costs, and a fuel price stress test to account for potential future price volatility which affects possible ranges of bulk power costs. Reliability and regulatory revenue requirements are also addressed to quantify the impact of these programs on future total power system costs.

4.3.3.1 Cost Comparison Between Cases

The total fuel and variable costs for the 3 coal divestiture cases are shown in Figure 4-5 below. The natural gas price used in the production model was the 20-yr long-term natural gas price forecast from Platts and is also considered as the expected natural gas price in the stress test study in Section 4.3.3.2.

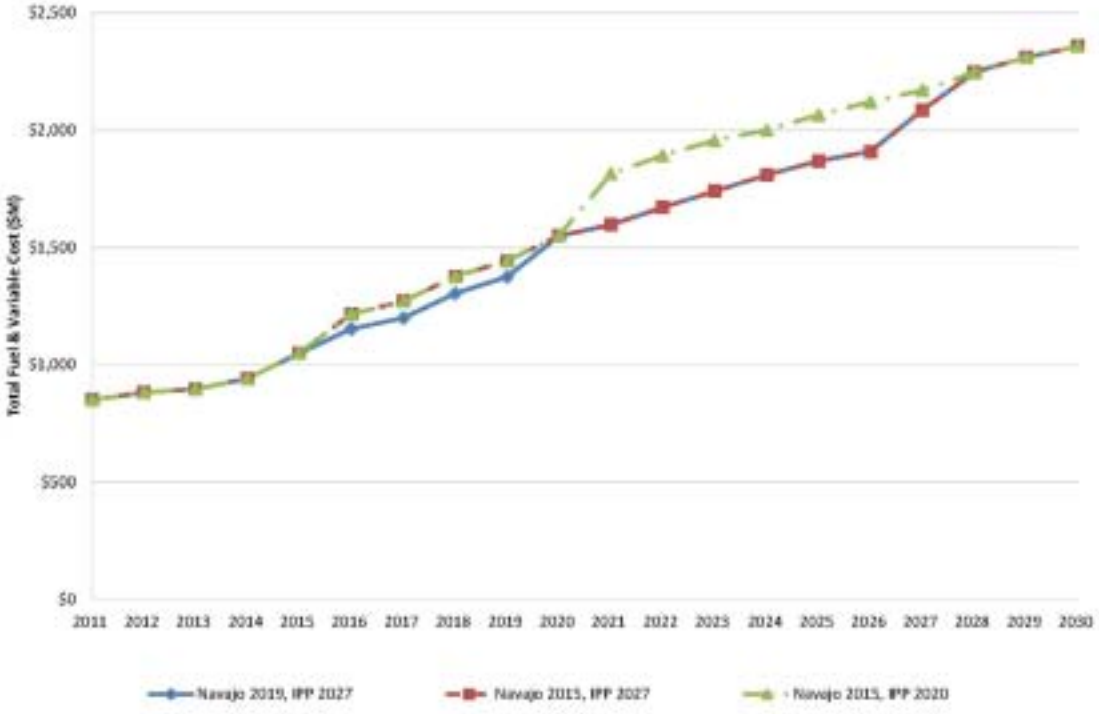

Figure 4-5. Total fuel and variable cost comparison by calendar year (Includes renewable project costs).

Divestiture of IPP and Navajo results in higher fuel and variable O&M costs, as less expensive coal is replaced with relatively higher cost gas-fired energy. The resulting increase in fuel costs from the Navajo divestiture is due to a blended increase of in-basin and out-of-basin gas fired generation. In reality, resources replacing Navajo consist of a blend of new replacement gas-fired combined cycle units and new renewable energy. The gas-fired

AR0071174

replacement resources for Navajo can be better seen in Table 4-4. Because all 3 cases analyzed have the same renewable portfolio, the cost differences between the cases can only be attributed to increased gas cost; therefore, the costs shown in Table 4-4 do not include any costs associated with new renewable resources.

Table 4-4. Increased capital, fuel, and variable O&M costs related to divestiture of Navajo and IPP by fiscal year

4.3.3.2 Fuel Price Stress Test

The importance of stress testing the model results of the 3 cases is to determine the range of exposure to economic risk due to fuel price volatility. Historically, natural gas prices have tended to be volatile and unpredictable and LADWP employs hedging techniques to constrain volatility within acceptable ranges. However, diversification of fuel resources is also an effective means to mitigate economic exposure to a single fuel source. For example, renewable energy supplies a necessary hedge against increased fuel price exposure and eliminates the fuel cost for 20 percent of our current fuel supply.

AR0071175

Coal purchased by LADWP over the last 30 years has traditionally been provided primarily through long term coal contracts where future costs are predictable. Additionally, a small portion of LADWP's coal supply is provided through short term coal purchases subject to market fluctuations. Therefore, natural gas prices become the primary concern when assessing future cost impacts. Replacing Navajo and IPP Generating Stations with gas fired generation would expose our ratepayers to fuel markets which may result in higher or lower fuel costs which are much less predictable.

Realizing the need for accurate fuel price forecasts, LADWP contracted with Wood Mackenzie Research and Consulting to provide natural gas price high and low forecasts to stress test future power production costs as shown in Figure 4-6. Also included in the high and low range forecasts were coal prices received from LADWP's External Generation Group. Based on the expertise and experience of the Coal Supply Group, a ±20 percent factor was applied to the expected coal fuel price to determine a high and low range for coal prices.

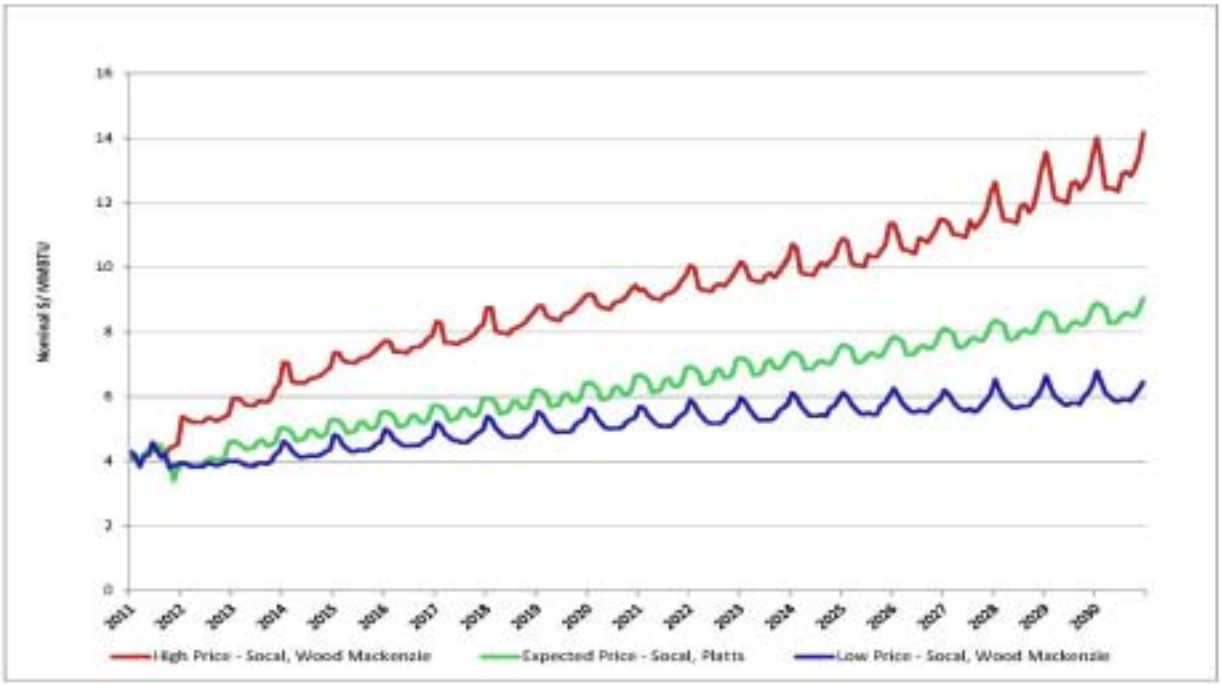

Figure 4-6. High, low, and expected natural gas price forecasts (So Cal Gas).

The natural gas price curves furnished by Wood Mackenzie Research and Consulting show a greater propensity towards higher than expected gas fuel prices, and less risk of lower than expected prices. This is wholly consistent with past historical gas prices which are shown in Figure 4-7 – the relative shape of the curve is asymmetrical with the forward tail (higher prices) extending further away from the mean of the curve.

AR0071176

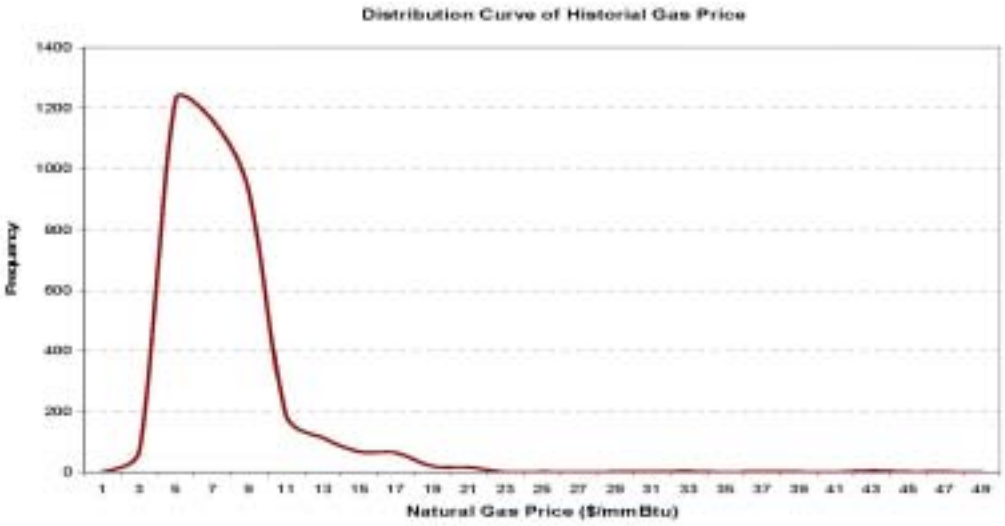

Figure 4-7. Historical distribution of natural gas prices (SoCal, 2005 through 2010).

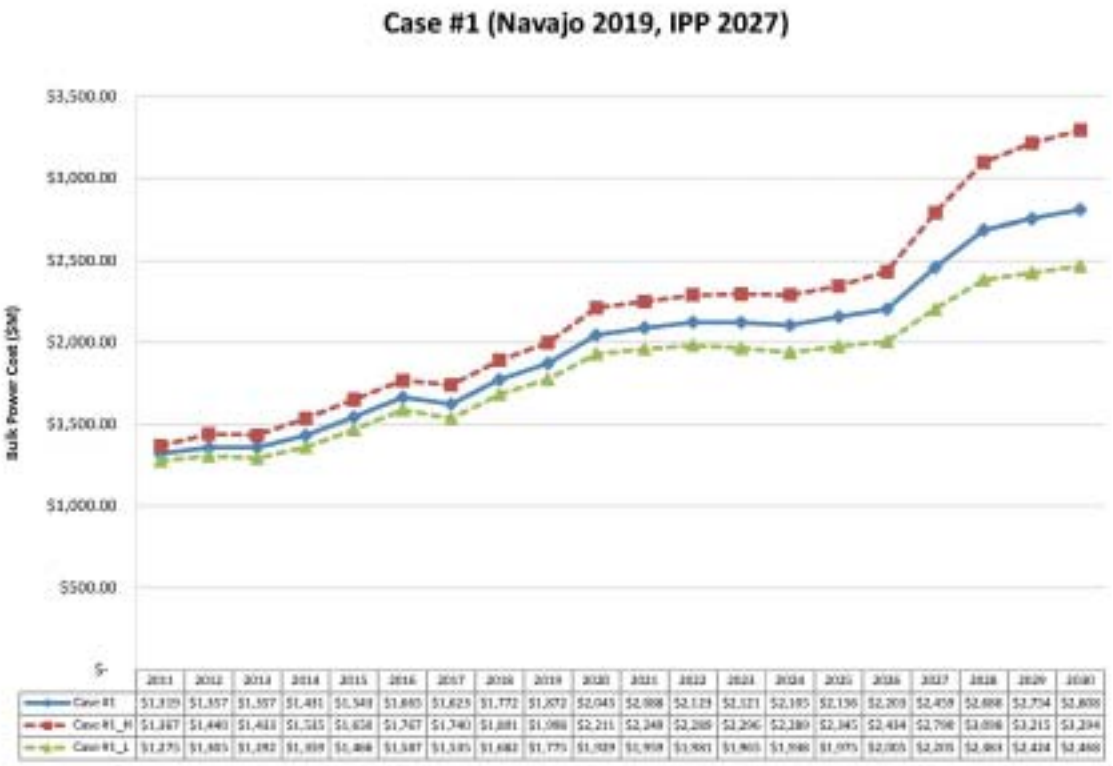
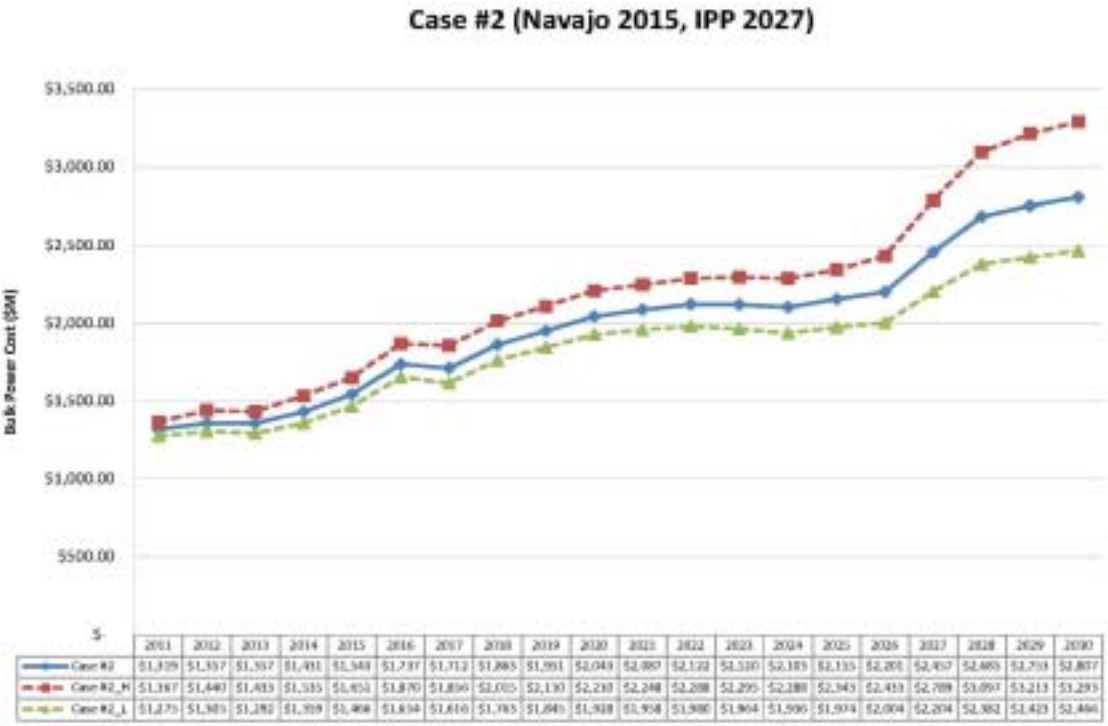
The high and low fuel price ranges were then incorporated into the three strategic case model runs. The three charts shown in Figure 4-8 display the results of bulk power costs for each of the 3 cases. The wider the range from the high fuel case to the medium fuel case indicates increased exposure to risk from the higher fuel costs.



AR0071177



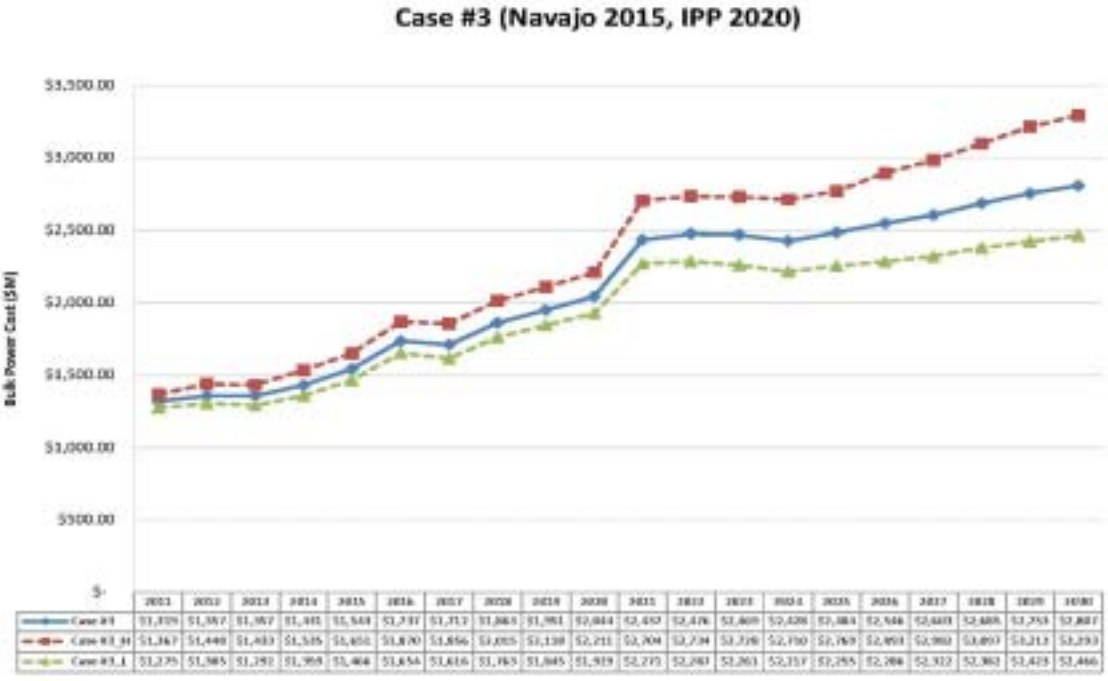


Figure 4-8. Bulk power cost comparison - high, low, and expected fuel prices.

AR0071178

To better compare the risk associated with higher natural gas prices between the 3 strategic cases, three years - 2016, 2019, and 2021 - are used for comparison as shown in Figure 4-9 below.

In the year 2016, both Cases 2 and 3 show divestiture of NGS with 300 MW of gas-fired CC replacement generation. These cases are facing higher fuel and variable spending risk exposure to natural gas price fluctuations.

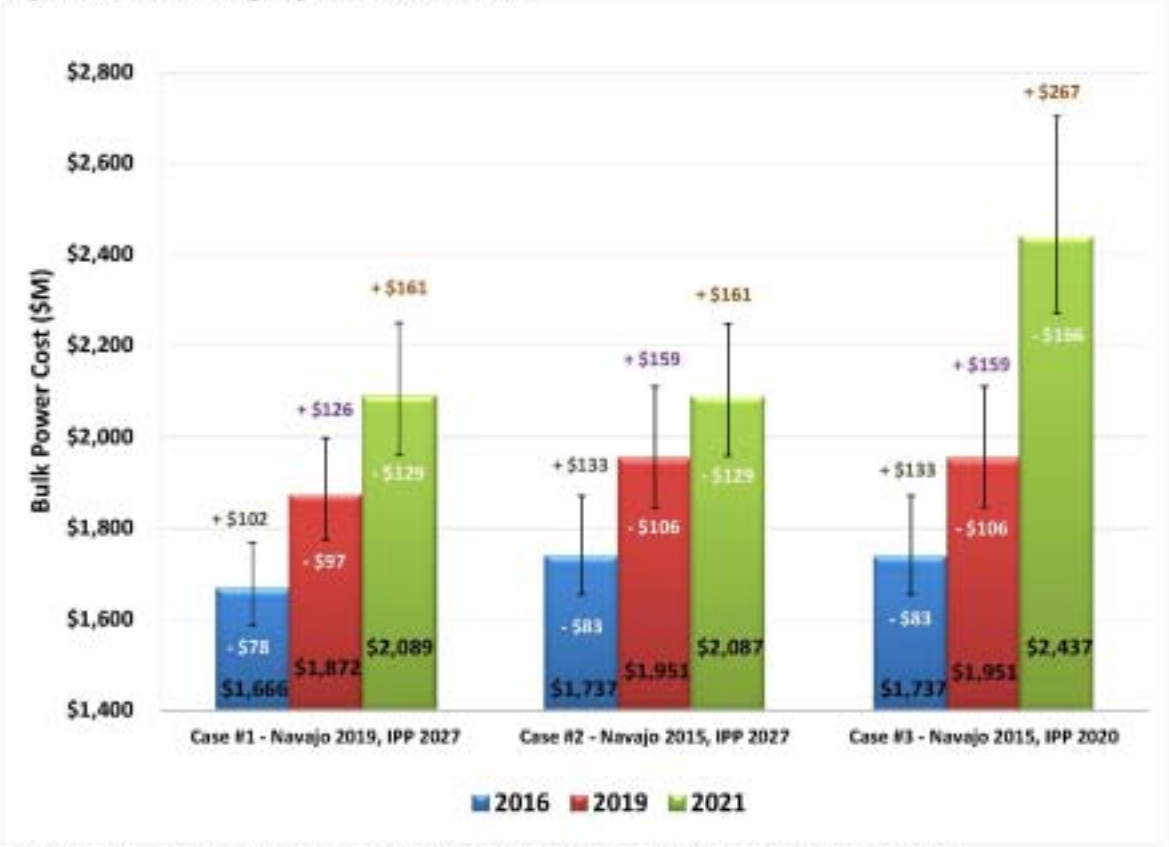

Figure 4-9. Bulk power cost with high and low comparison by calendar year.

By the year 2020 NGS will retire in all three cases, with Case 3 showing IPP also being replaced in 2020 with two 575 MW combined cycle units. With all coal generation being eliminated in 2021 for Case 3, the exposure risk of much higher spending on fuel and variable costs will be present.

Increased risk exposure from high fuel costs may translate into higher customer electric rates. Figure 4-10 shows the potential rates that could be experienced under the 3 cases given high, expected, and low fuel ranges.

AR0071179

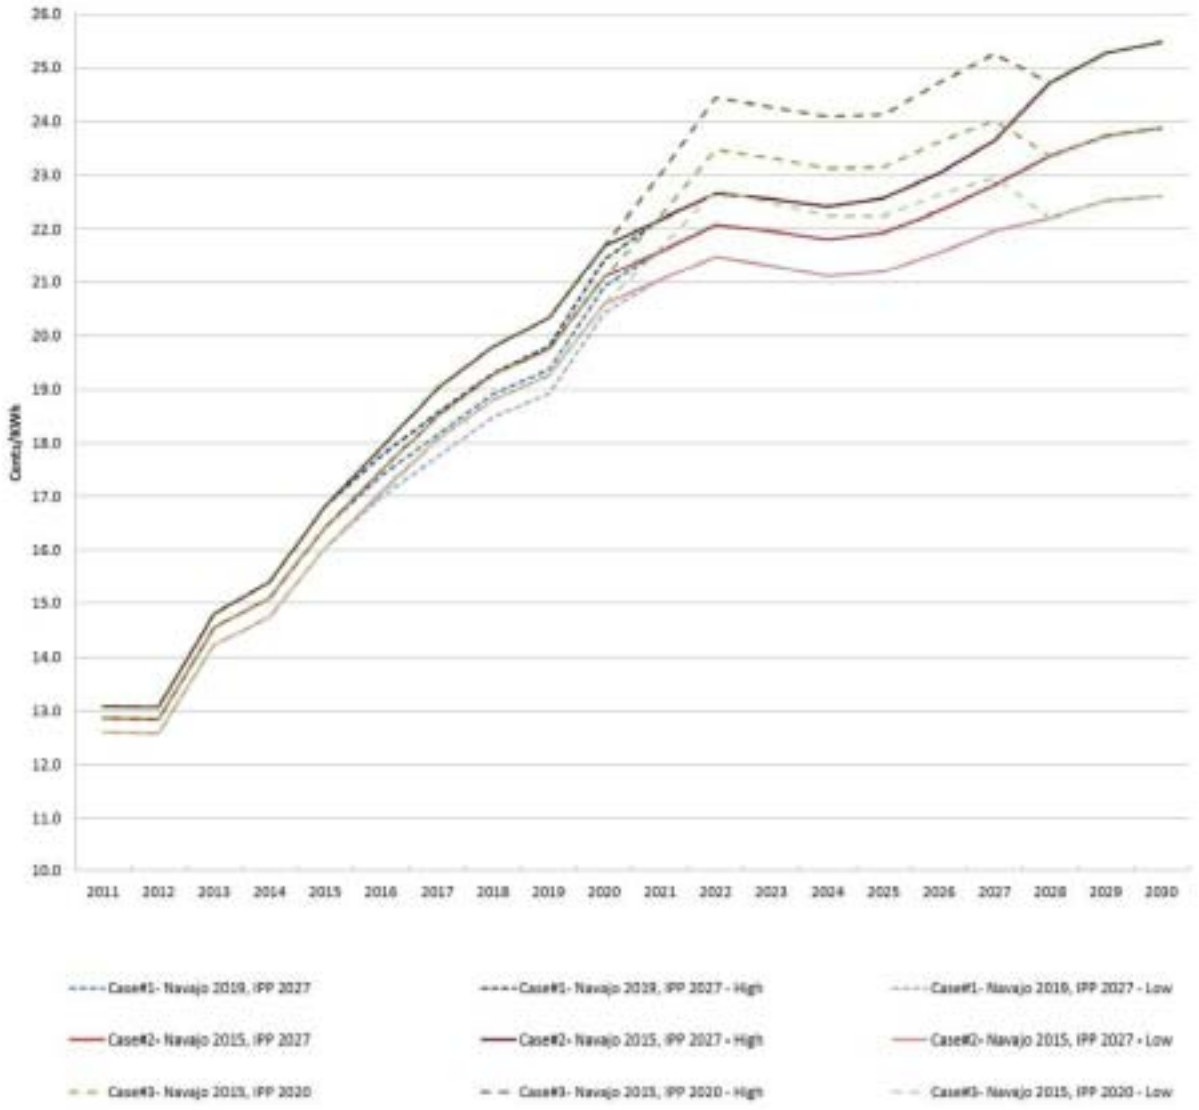

Figure 4-10. Estimated electric rate comparison over 20 years by fiscal year-ending.

4.3.3.3 Reliability and Regulatory Revenue Requirements

Bulk Power costs discussed previously make up less than half of the cost to operate the electric power system. Continued investments in transmission, distribution, and generation resources are required to maintain a reliable electric system. While specific regulatory and reliability programs such as RPS, OTC, and PRP attract the most attention, investments in these programs are a subset of the generation, transmission, and distribution system that comprises the power system. Besides fuel and inflation costs, these reliability and regulatory programs are the largest factors driving increases in power system costs.

AR0071180

The revenue requirements of these programs are further illustrated in Figure 4-11 and Table 4-5. Today, these reliability and regulatory programs comprise 32% of all power system costs and in 2020 these same programs will grow to approximately 47%.

Table 4-5 shows the breakdown of these reliability and regulatory costs with RPS and PRP programs clearly being the major drivers behind overall increases in power system costs. The importance of adequately funding of these programs through consistent revenue increases over time is essential to achieving the goals of reliability, environmental stewardship, and maintaining competitive rates.

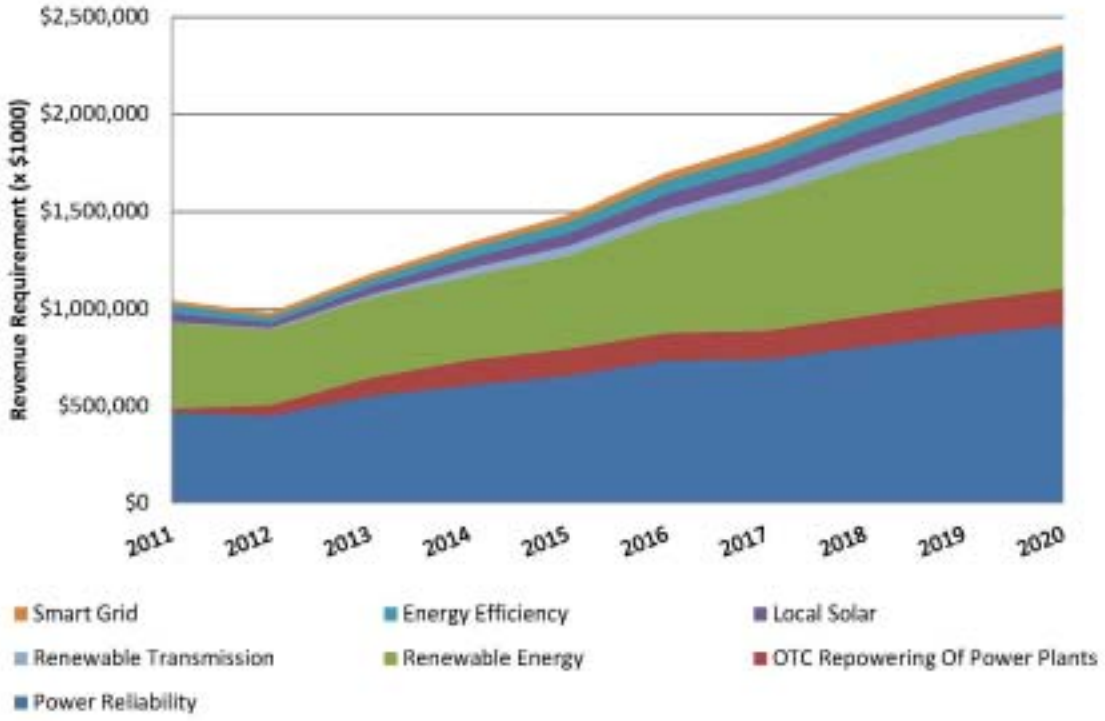

Figure 4-11. Annual revenue requirement for reliability and regulatory program for fiscal year ending 2011 through 2020.

4.3.3.4 Total Power System Cost Comparisons

The total power system cost for each case includes bulk power costs, depreciation costs related to transmission, distribution, and generation, bond debt-service, and city transfer costs. These costs assume full funding of the Power System programs including the Power Reliability Program and Energy Efficiency programs among others. Total annual Power

AR0071182

System costs are shown in Figure 4-12 and reflect short-term spending reductions through 2011-12 fiscal year with subsequent years reflecting a restoration of funding levels to insure that the longer term IRP recommendations can be realized. The costs shown do not attempt to represent a thorough analysis of Power System finances. The main goal of this section is to illustrate the general trend of Power System costs relative to the 3 cases analyzed.

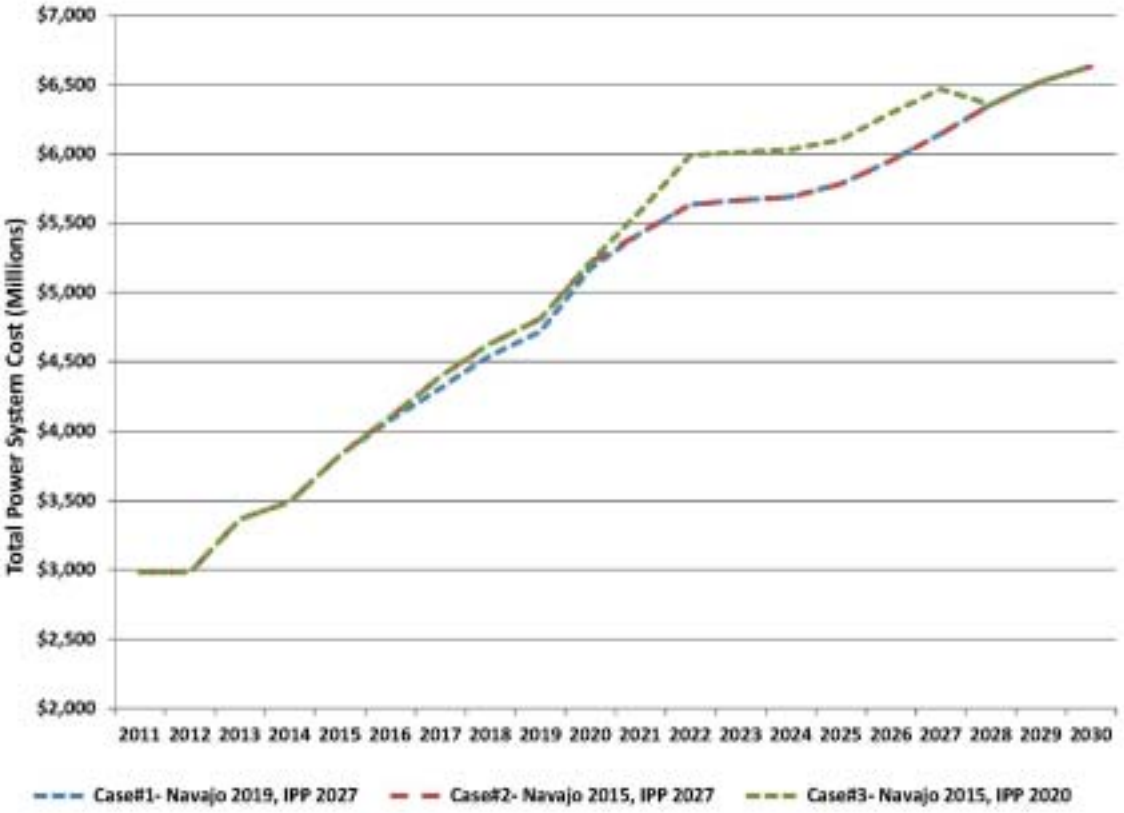

Figure 4-12. Comparison of annual power system costs over the next 20 fiscal years.

Figure 4-13 illustrates the net present value of the total power system costs for each of the strategic cases.

AR0071183

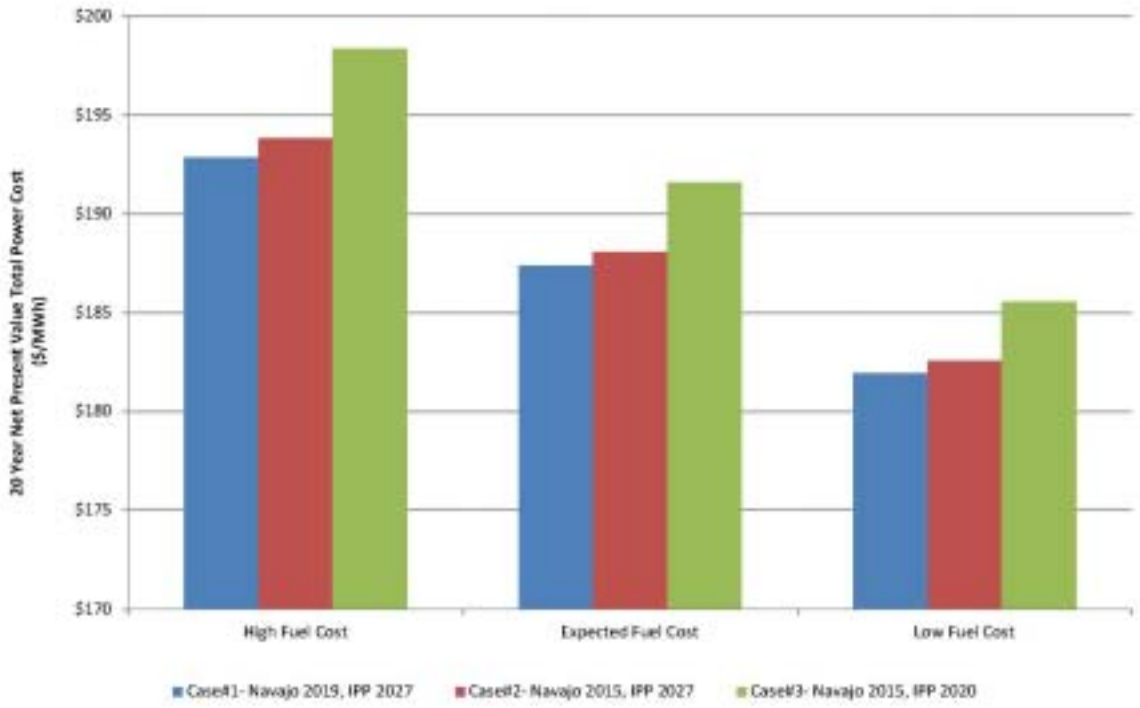

Figure 4-13. Total net present value comparison of power system costs.

4.4 Strategic Case Conclusions and Recommendations

4.4.1 Reliability

All three cases were designed to satisfy power system reliability requirements. Based on the loss of load probability and resource adequacy analysis discussed in Section 4.3.1, all three cases are considered equal in terms of meeting reliability. To insure that reliability is maintained during the divestiture of Navajo and IPP, specific replacement strategies should be employed to assure a smooth transition. Further analysis may be required to refine the appropriate blend of renewable, gas-fired, energy efficiency, and demand response resources to replace Navajo and IPP based on reliability considerations.

4.4.2 GHG Emissions Reduction

As expected, the sooner generation from coal is removed from LADWP's portfolio, the greater the reduction of GHG emissions is achieved. Case 2 removes NGS energy four years earlier than in Case 1 and results in 7.5 million metric tons less GHG emissions over the 20-year study period. In addition to early NGS divestiture, Case 3 accelerates the replacement of IPP seven years earlier than Case 2, results in a further reduction of 21.1 million metric tons over the 20-year period.

AR0071184

4.4.3 Economic

While the Base Case appears the least cost assuming moderate GHG emission costs, it fails to make significant progress toward the reduction of GHG emissions goals set forth by LADWP. The choice between coal divestiture options of either Case 2 and 3 depends on the level of rate increases ratepayers are willing to support while achieving the 33% required RPS by 2020, repowering of in-basin gas fired generation, funding and implementing Demand Response and Energy Efficiency programs, and providing additional external generation to supplement the lost generation resulting from coal divestiture.

With early divestiture of Navajo, additional rate increases of 0.36 cents per kwh or a one time 2.0% increase in the average customer bill would be necessary to achieve GHG reductions of 7.5 million metric tons between years 2016 and 2019. However, as previously discussed in Section 4.3.3.2, the early divestiture of Navajo will expose ratepayers to potentially higher natural gas fuel prices that may result in rate increases up to 1 cent per kwh or a one time increase of 5.7% in the average customer bill if gas prices were to remain at these higher levels.

Considering Case 3 with early divestiture of IPP and Navajo, rate increases of approximately 1.35 cents per kwh or a one time 6.1% average increase in the typical customer bill would be necessary to achieve additional GHG reductions of 21.2 million metric tons between the years 2021 and 2027 due to the divestiture of IPP. With potentially higher natural gas fuel prices, resulting rate increases could be as high as 2.4 cents per kwh or a one time increase of 11% in the average customer bill if gas prices were to remain at these higher levels.

4.4.4 Recommended Case

Decisions to fund coal divestiture strategies cannot take place independent of other power system programs. Maintaining reliability and meeting regulatory requirements are primary considerations before any coal divestiture cases can be considered. However, this IRP presupposes funding of these programs so that the recommended coal divestiture case can be implemented.

Achieving the goals of reliability and environmental stewardship, while maintaining competitive rates, requires that costs be closely managed. Considering these factors, Case 2 with early Navajo coal divestiture in 2015 becomes the recommended case for the 2011 IRP. Although Case 2 represents additional cost as compared to Case 1, the additional costs to rate payers appears to be reasonable in light of the environmental benefit of reducing GHG emissions by 7.5 MMT. Early divestiture of Navajo also provides additional time to insure a smooth transition in acquiring and implementing replacement resources. The 2010 IRP included the same recommendation to accelerate divestiture of Navajo and this IRP further clarifies and supports this prior recommendation. This recommended case presents a reasonable approach to achieving environmental goals without excessive costs to our ratepayers while limiting potential exposure to possible fuel price volatility to within manageable limits.

AR0071185

5.0 RECOMMENDATIONS

5.1 Overview

LADWP's recommended strategy set forth in this IRP for meeting its key objectives can be separated into two areas: (1) Regulatory and Reliability Initiatives, and (2) Strategic Initiatives. Regulatory and Reliability Initiatives are required actions to ensure system reliability and compliance with regulatory and legislative mandates. Strategic Initiatives are policy actions to achieve objectives established by the LADWP Board of Water and Power Commissioners and the Los Angeles City Council, and reflect their vision and leadership. These mandates include, for example, establishment of LADWP's RPS, early compliance with SB 1368, and investing in local solar.

The analysis performed in Section 4 to identify the 2011 IRP recommended case closely mirrors the same recommended strategy put forth in the 2010 IRP which incorporated feedback from LADWP's community outreach efforts which were conducted in 2010. The 2011 IRP recommended strategy differs slightly from the 2010 IRP in the timing of the Navajo coal divestiture which is now planned for 2015 instead of 2013. Another difference is in the renewable installed capacity by technology type (e.g. geothermal, wind, and solar). The reasons for these changes are further explained in Section 3.1.1.

Regulatory and Reliability Initiatives

- SB 2 (1X) - RPS Percentage

  LADWP must increase its percentage of renewable energy per recently enacted state law, from the current 20 percent at the end of 2010, to 33 percent by the end of 2020. SB 2 (1X) also establishes interim targets to ensure progress towards the 33 percent goal. Addressing this mandate requires the continued diligence LADWP has demonstrated in raising its renewable portfolio from 3 percent in 2003 to 20 percent in 2010.

- Power Reliability Program (PRP) and system infrastructure investment

  LADWP must re-establish sustained funding to invest in replacing aging transmission and distribution infrastructure to ensure system reliability, especially during significant weather events. Recent funding shortfalls have resulted in an increase in system outages. Section 1.6.4 of this IRP discusses the negative consequences that continued underfunding poses to the city.

- Re-powering for Reliability and to Address OTC

  LADWP will continue to re-power older, gas-fired generating units at its coastal generating station for the reasons discussed previously. The repowering program is a long term series of projects that will increase reliability and eliminate the need for once-through ocean cooling.

AR0071187

- AB 32 – GHG Cap and Trade

  LADWP will participate in the mandated green house cap-and-trade system which is scheduled to start January 1, 2013. During the next year, LADWP will participate in the regulatory process that will clarify some outstanding details of the proposed program.

- SB 1368 Compliance

  Navajo and IPP must be compliant with the mandates established in SB 1368 by 2019 and 2027, respectively. IRP modeling determined that these units will be replaced with a combination of renewable energy, demand response, i.e., short term market purchases, and conventional gas-fired generation.

- Energy Efficiency

  LADWP must procure sufficient resources to meet load growth and maintain system reliability and will continue to pursue and implement energy efficiency programs per AB 2021 standards and as recommended in its latest Market Potential Study. Along with augmenting its generation portfolio, LADWP will implement EE to reduce energy demand. EE programs are not only crucial for meeting customer load growth, they also represent a cost-effective strategy for reducing GHG emissions, since the cleanest kilowatt-hour any utility can produce is one that is never generated.

- Castaic FERC Re-licensing Program

  On January 31, 2033, the Federal Energy Regulatory Commission's (FERC) license to operate Castaic Pumped-storage Hydroelectric Plant will expire. The license is a co-license between LADWP and the Department of Water Resources (DWR) and includes a number of hydro power plants along the California Aqueduct. Both parties have initiated the joint re-licensing process that, on average, requires ten years to complete. Through 2015, LADWP expects to complete preliminary studies, contract negotiations, and prepare a filing strategy. In 2016, LADWP expects to file a notice-of-intent (NOI) and initiate the formal studies and applications. Based on reviews of re-licensing activity for similar projects, LADWP could expect cumulative expenditures of approximately $19 million prior to filing the NOI and approximately $80 million before the license expires.

- Transmission

  LADWP should implement those recommendations of the latest Ten-Year Transmission Assessment Plan, in order to maintain reliability in accordance with regulatory guidelines.

AR0071188

Strategic Initiatives

- Early Compliance with SB 1368

  Comments from the public workshops indicated the desire to comply with SB 1368 as early as possible. Navajo must be compliant with SB 1368 by 2020. LADWP recommends divestiture from Navajo by 2015. This will reduce LADWP's GHG emissions by 7.5 million metric tons and required additional revenue of about $343 million.

  LADWP recommends modeling and planning for IPP to be compliant with SB 1368 by 2027. However, LADWP will continue to evaluate options in future IRPs. LADWP will continue to work with the Intermountain Power Agency (IPA) Board and the other participants to secure IPP as a renewable energy hub and provide replacement generation compliant with SB 1368. LADWP recommends no change in IPP until 2027 at which time the site would be reconfigured, providing LADWP with firm transmission capacity for potential renewable projects.

- Local Solar

  Comments received at the public workshops indicate local solar development should be a priority in LADWP's renewables procurement strategy. LADWP is recommending a policy action to allow approximately 40-50 percent of its solar resources be sited locally through initiatives including the Solar Incentive Program, feed-in tariffs, and installation of solar on City-owned properties. Local solar costs an estimated additional $50/MWh over utility-scale solar located outside the Los Angeles Basin, estimated to cost $120/MWh, primarily due to economies of scale and about 30% better solar insolation, even when considering transmission and distribution costs.

- Public Benefits

  LADWP should continue to pursue public benefit initiatives, including low-income and lifeline programs, refrigerator exchange, conservation, public outreach and education.

- Advanced Reliability Improvements

  LADWP is looking ahead to technologies that will enhance the reliability of its system, including smart grid technologies, enhanced information systems, automation of system functions, and advanced methods of outage management. These advanced system enhancements are recommended from a planning perspective to not only increase reliability, but also to better integrate local generation such as solar into the distribution network, enable smart charging of electric vehicles, and advance demand side management technologies.

AR0071189

- System Losses

  To reduce system losses, LADWP should implement the recommendations of the recently completed Reactive Power Management Study, including the installation of shunt capacitors and shunt inductors at appropriate locations within the system grid.

- Demand Response

  LADWP should begin the development of a formal Demand Response program that will initially provide 5 MW of peak demand capacity beginning in 2013 and gradually build to 260 MW by 2020 and 500 MW by 2026. Ramping the program in this manner will provide the development of in-house expertise, and will also allow time to deploy the supporting information systems necessary to implement these systems successfully.

AR0071190

5.2 Incorporating Public Input

Through its public outreach efforts in 2010, LADWP received various suggestions from the community including increasing energy efficiency and conservation, eliminating coal from LADWP's resource mix, emphasizing local solar generation, maintaining competitive rates, and increasing transparency. This input played a key role in shaping the recommendations set forth in this IRP. A discussion of these themes is presented below.

- Theme: Emphasize a variety of energy resources

  Related IRP Recommendations

  - LADWP will procure 160 MW of generic renewable resources, potentially including biomass, ocean tidal power, and other emerging technologies.
  - LADWP will also continue to seek a diversified energy portfolio as well as continue to diversify its portfolio regionally to enhance system reliability.

  Discussion

  As LADWP continues to work towards attaining its state-mandated RPS requirement, it is also imperative that the renewable energy technologies support LADWP's objectives of providing reliable service at competitive rates while maintaining environmental stewardship. Of the aforementioned renewable technologies, those believed to be available in large quantities in the western US at competitive prices are geothermal, wind, biogas, and solar, which make up a bulk of LADWP's renewable portfolio. Recent advancements in these technologies have resulted in an increase in their capacity factors, therefore providing more energy at lower cost as well as benefiting from large economies of scale. Consumption of natural gas, which is already a major component of LADWP's generation resource portfolio, will increase to support increasing amounts of intermittent renewable resources and to help supply baseload power as LADWP transitions away from coal. Nuclear power, which makes up about nine percent of LADWP's energy mix, would likely remain at current levels in the next decade. In addition to "traditional" renewable resources such as wind and solar, LADWP will certainly consider up and coming technologies such as algae and wave power as these technologies become more mature and economically competitive.

- Theme: Maximize Energy Efficiency and Conservation to Meet Future Energy Needs

  Related IRP Recommendations

  - LADWP is recommending to increase energy efficiency to reduce at least seven percent of the total load by 2020 (three percent was achieved prior to

AR0071191

2016). LADWP will pursue the recommended programs contained in the recently completed market potential study.

- LADWP is recommending 300 MW of demand-side management/response programs to shift load away from peak hours or to control load during peak hours. Tactical plans will be developed that may utilize smart grid technology, incentives, and rate designs to meet this objective.

Discussion

LADWP's Demand Side Management program, which includes the Energy Efficiency, Demand Response, and Combined Heat and Power programs, plays an integral role in shaping power system planning. With the goals of lowering overall energy consumption and shifting peak demand loads to off peak periods, the need to build additional generation is reduced, resulting in capital and fuel cost savings as well as emissions reduction.

LADWP is exploring ways which would educate and empower ratepayers to reduce energy consumption, whether that is in the form of technology, incentives, and programs, or a combination of these. Future installation of two-way smart meters will facilitate real time pricing based on current supply and demand, and customers will be able to make smarter choices on energy use based on market driven Time of Use rates. LADWP is formulating strategies that will include new incentives and Time of Use tiered rate structures allowing ratepayers to fully participate on the demand side of the equation. To increase efficient buildings, LADWP offers an incentive program to building owners and developers for construction of new buildings to conform to high efficiency LEED standards, which are 25 percent to 35 percent more energy efficient than regular buildings.

As discussed in this 2011 IRP, LADWP has completed its Energy Efficiency Market Potential Study and is preparing its implementation plans that will support program execution. Like many other areas, however, adequate funding is essential if the city is to realize the benefits that efficiency provides.

- Theme: Eliminate Coal from LADWP's Energy Portfolio

Related IRP Recommendations

- LADWP is recommending a policy action to replace Navajo Generating Station by 2015, four years ahead of the SB 1368 requirement. The Intermountain Power Project is modeled in this IRP through 2027, but LADWP is open to a mutually agreeable early compliance plan between the project participants that preserves the site and transmission for compliant fossil and renewable generation.
  LADWP is currently 21 percent below 1990 levels of GHG emissions and is planning further emissions reductions.

AR0071192

Discussion

Recommendations set forth in this 2011 IRP include making the transition away from coal to other forms of generation earlier than the contract termination date, such as terminating the Navajo contract in 2015 instead of 2019. Depending on the outcome of legislation which may impose GHG emission taxes and cap and trade requirements, it may be prudent for LADWP to divest away from coal resources early and replace it with a combination of renewable technologies and combined cycle units. Securing renewable resources early may also substantially save LADWP and its ratepayers money, before demand for renewables increase as mandated levels of renewable energy increases over the next several years.

Since coal generation is a baseload resource, the optimal solution is to replace the coal generation with geothermal, a renewable baseload resource. However given the disparity between the amount of available geothermal resources and the amount of coal generation that needs to be replaced, the remainder would need to be made up of other renewable sources such as wind and solar with natural gas powered combined cycle plants to act as backup maintaining a constant level of generation when the wind is not blowing and when the sun is not shining. Combined cycle plants have operating characteristics which allow for a higher penetration of intermittent renewable resources than coal-fired generation. The characteristics assist in maintaining grid reliability with high levels of intermittent resources. Natural gas plants are also much more environmentally friendly than coal plants, emitting only half as much CO_2.

- Theme: Emphasize Local Solar Generation

Related IRP Recommendations

- LADWP is recommending a policy action to allow approximately 40-50 percent of its solar resources be sited locally through initiatives including the Solar Incentive Program, feed-in tariffs, and installation of solar on City-owned properties. LADWP recommends this as a balanced approach between the benefits of local solar and the benefits of large, controllable solar projects connected to LADWP's transmission lines. The actual percentage will vary based on the success of the local programs.

Discussion

As outlined in this 2011 IRP, LADWP has designated 40 percent of solar development to be in-basin, or approximately 325 MW, enough to power almost ninety thousand homes. In-basin solar eliminates transmission issues and losses, and improves local grid reliability. LADWP realizes that developing in-basin solar fosters local economic growth, and will utilize incentive programs, Feed-in-Tariff schemes, and other stimulus in order to promote development. In August 2011, LADWP resumed its solar incentive program

AR0071193

which was redesigned to better accommodate customer demand. LADWP also hopes to implement a feed-in tariff over the next year.

- Theme: Avoid Adverse Impacts to Vulnerable Communities

  Related IRP Recommendations:

  - LADWP will continue to implement a low-income electric rate program.
  - LADWP will develop plans that address energy efficiency deployment and other incentive programs that effectively reach out to low income communities and may help mitigate impacts of future rate increases.
  - Local geographic diversity is critical to maintain high reliability of the electric grid, and LADWP will continue this policy so that no single community will experience an inequitable share of impacts from energy facilities.

  Discussion:

  Even though acquiring more renewable resources may result in potential future rate increases, this may not necessarily translate into higher bills for all customers. Increased adoption of Demand Side Management techniques could offset a rate increase, and may even result in lower bills. LADWP strives to provide low-income ratepayers as much assistance as possible, and will continue to offer a lower rate to those that are economically disadvantaged. LADWP also proposes to conduct free residential energy audits to low income customers first, so that additional savings achieved by increased energy efficiency could be realized immediately. An example of this is that such audits may provide low income ratepayers free energy efficient refrigerators, funded by the LADWP Energy Efficiency Program.

  Having geographical diversity in generation is important at both the regional and local levels. At the regional level, having resources that are geographically dispersed provides LADWP additional reliability, and results in efficient resource utilization and lower cost. For example, LADWP's system interconnects to BPA's network in the Pacific Northwest, fostering a symbiotic relationship that allows abundant inexpensive hydroelectric power to be delivered to LADWP in the spring and summer, when BPA's demand is low and LADWP's demand is high, at the same time enabling LADWP to sell excess power to BPA in the winter when BPA's demand is high and LADWP's is low. At the local level, it would be technically advantageous to distribute solar installations evenly throughout the LA basin, so that circuits will not be overloaded. This would ensure that there will be no unequal impact to any one community, since an equal distribution of distributed generation sources is necessary to maintain reliability.

AR0071194

- Theme: Clarify Costs of IRP Implementation and Potential Impacts to Ratepayers

  Related IRP Recommendations

  - LADWP will incorporate a detailed financial analysis into the IRP development process to identify the costs of various planning alternatives and recommendations using computer modeling software

  Discussion

  Impacts of the Strategic Case Alternatives, including the recommended case, on electricity rates, as well as the strategic, regulatory and reliability investments recommended in this IRP are included in Sections 4.2. Included in the rate analysis is a sensitivity analysis that considers high and low forecasts for natural gas and coal fuel costs. Also presented is the annual revenue requirements of power system programs through 2020.

  While there are secondary costs associated with environmental and health impacts of fossil fuel plants, LADWP is not in a position to quantify these costs since there are governing bodies at the federal and state levels responsible for setting standards and legislation that would address these concerns. However, LADWP is working to make the transition from coal to renewables and clean natural gas earlier than originally scheduled so that GHG emissions can be curtailed sooner.

  As discussed previously, potential future increases may not necessarily translate into higher bills nor impact low-income communities. As for improved transparency and accountability, the Board of Water and Power Commissioners recently approved the establishment of an independent ratepayer advocate whose responsibility is to review, analyze, and provide expert independent advice to policy makers regarding utility rates and proposed rate changes, and to provide ongoing review and analysis regarding rate-related and budgetary issues.

- Theme: Reduce Environmental Impacts

  Related IRP Recommendations

  - To minimize environmental impacts, LADWP will maximize the use of existing transmission and facility infrastructure to generate and deliver energy. All projects will have the proper environmental review and impacts on the environment will be mitigated as necessary.

AR0071195

Discussion

Being a good environmental steward is one of LADWP's main objectives, and we strive to meet that standard with the construction and maintenance of each and every project. As we look to making the transition away from coal, one strategy that we have adopted is to procure and develop renewable resources in close proximity to the coal plant, so that we can take advantage of the existing transmission infrastructure. For solar, we would maximize the use of rooftops as installation sites. This principal of siting new generation facilities on existing brownfield sites and reusing existing structures not only minimizes environmental impact but is also very cost effective.

- Theme: Provide Proactive Leadership and Transparency

Related IRP Recommendations

- LADWP will develop plans to better educate ratepayers on progress related to this IRP (e.g. energy efficiency) and will continue the IRP process of biannual updates to provide transparency on its long-term goals.
- LADWP will improve its system operations and run its power grid as effectively as possible. LADWP has recently completed a study on how it can increase the efficiency of the power delivery grid through advanced reliability improvements.
- This 2011 IRP sets forth LADWP's long-term plans and objectives, clarifying implementation of various initiatives and their potential impacts on ratepayers. A discussion of rate impact is included in Section 4 of this IRP.

Discussion

LADWP will take steps to expand public outreach programs to better educate the public about the critical roles that energy efficiency and conservation have on the power system. LADWP is also instituting programs to improve operations and system reliability, performing system wide technical studies, as well as identifying ways to incorporate smart meters. As discussed previously, a ratepayers' advocate would help facilitate transparency and accountability in any new actions undertaken by LADWP. An IRP public outreach effort similar to the one held in 2010, is scheduled for next year's 2012 IRP process.

AR0071196

5.3 Recommended Strategic Case

Based on the results of LADWP's stakeholder meetings and public outreach effort, and rigorous cost-benefit analysis, LADWP has developed a Recommended Case for this 2011 IRP that includes the following:

- At least seven percent of Los Angeles' electric needs will be met through new customer energy efficiency measures by 2020.
- At least 500 MW of capacity reduction through Demand Response programs by 2026.
- Generate at least 33 percent of its electricity from renewable resources by 2020 and maintain that level through 2030. Although this IRP incorporates one combination set of renewable resources to achieve a 33% RPS, LADWP will not limit itself to only these types and amounts of resources to achieve its goals and needs flexibility in resource development for the best fit for the electrical system.
- Diversify LADWP's RPS through incorporating 162 MWs of generic renewable resources by 2030. These resources could be technologies such as biomass, ocean tidal power or other emerging technologies.
- Diversify LADWP's energy portfolio through a variety of fuels, technologies and power plant sites throughout the western United States to maintain a high level of reliability.
- Replace the Navajo Generating Station by 2015, 4 years ahead of the legally mandated date. IPP is recommended to be replaced in 2027 at the end of its contract, however LADWP is open to a mutually agreeable early compliance for GHG reduction between project participants that preserves the site and transmission for compliant fossil and renewable generation.
- Implement advanced reliability improvements.
- Emphasize local solar by proposing approximately 40 to 50 percent of solar capacity being proposed to be locally sited in Los Angeles. This will be accomplished through programs such as the Customer Solar Incentive Program, Feed-in tariffs, and Solar on Los Angeles properties under public/private partnership.

This recommended case is summarized in Table 5-1.

AR0071197

Table 5-1. 2011 IRP Recommended Case

	2020	SB 1368 Compliance Date		New Renewables Installed (MW) 2011-2020			New Renewables Installed (MW) 2011-2030			
Case ID	RPS Target	Navajo Replacement	IPP Replacement	Geo/ Biomass	Wind	Solar	Geo/ Biomass	Wind	Solar	Generic
Case 2	33%	12/31/2015	6/15/2027	243	492	726	308	492	917	162

Figure 5-1 illustrates the changing generation resource percentages for 2010, 2020, and 2030 based on the Recommended Case. Energy efficiency savings of 1,256 GWh or 5.5 percent of sales that was implemented between 2000 and 2010 is already factored into the load and is not included as part of the generation resource mix shown below.

AR0071198

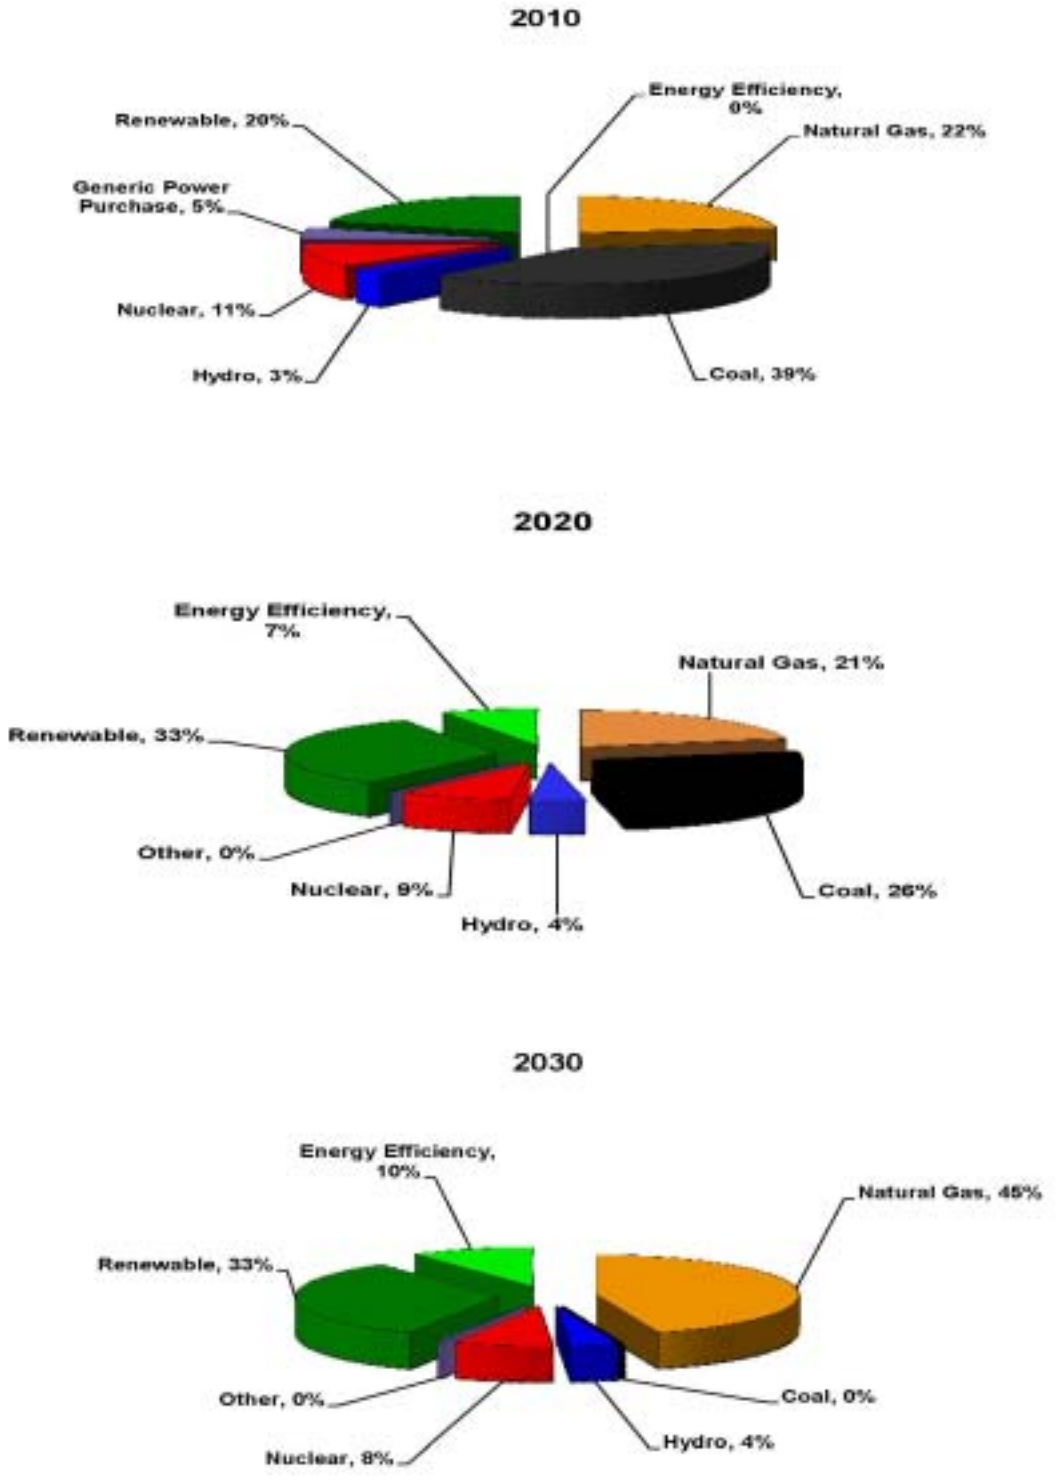

Figure 5-1. Generation resource percentages for 2010, 2020, and 2030.

AR0071199

Figure 5-2 shows the renewable energy resource mix of the Recommended Case. The major change from the 2010 IRP is that biogas fills a critical gap in meeting RPS targets by replacing primarily geothermal generation in the short term.

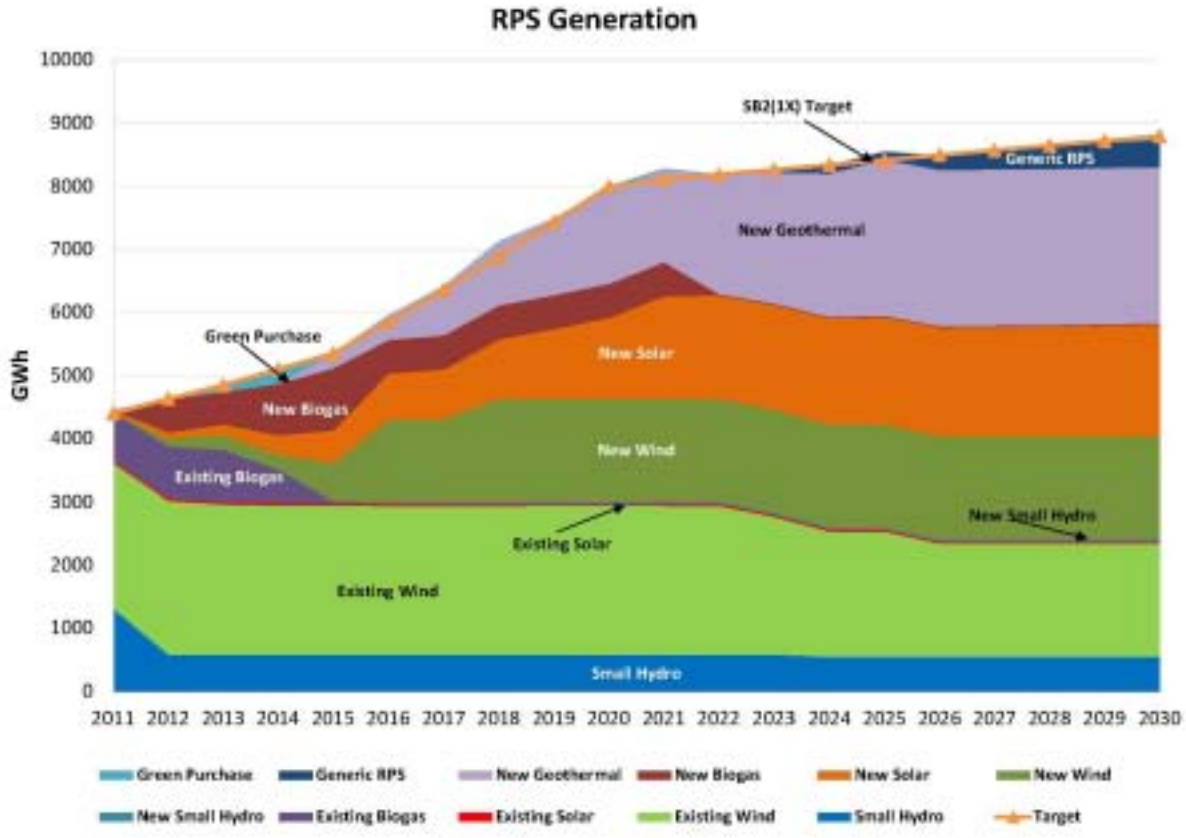

Figure 5-2. Recommended case renewable generation by technology.

With the early divestiture of Navajo in 2015 and the IPP coal contract ending in June, 2027, increased bulk power costs are expected to rise with the divestiture of each of these resources as shown on Figure 5-3. It is important to note that bulk power costs shown in Figure 5-3 include fuel, renewable and other purchase power costs in addition to coal divestiture related costs which are displayed in Table 4-4. Applying high and low fuel prices to these bulk power costs as discussed in Section 4.2.3.2, the divestiture of these resources could result in large cost increases should fuel prices remain at higher than expected levels. Conversely, lower than expected fuel prices could have the opposite effect on bulk power costs.

AR0071200

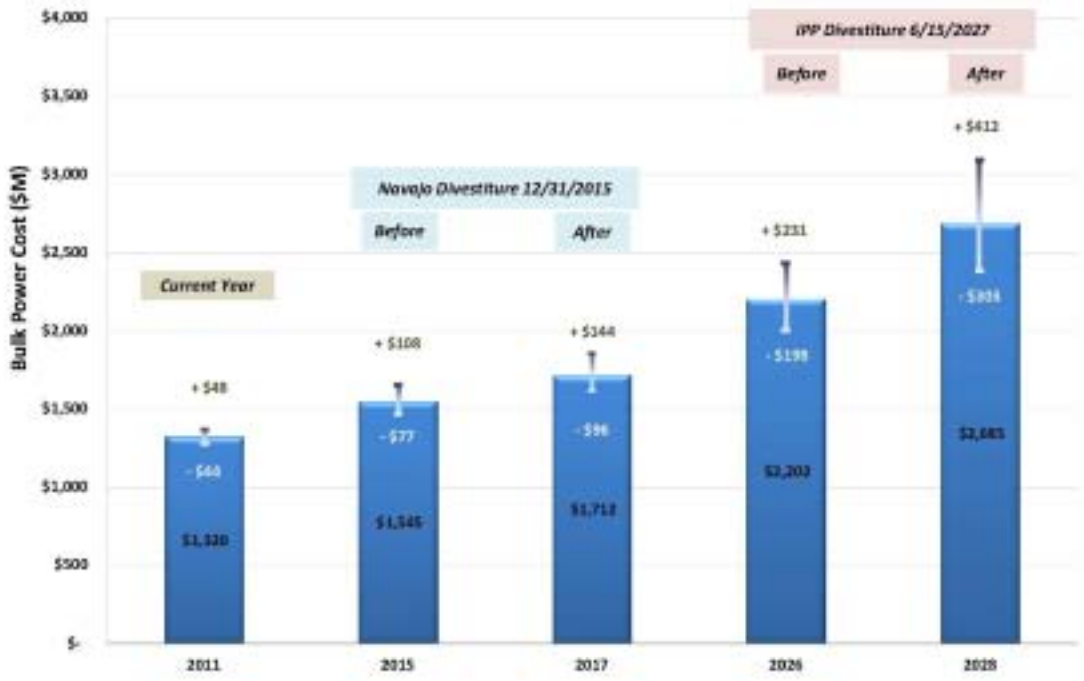

Figure 5-3. Recommended case - bulk power cost before and after coal divestitures with potential cost impacts from high and low fuel prices.

The Table 5-2 below illustrates the revenue requirements necessary to supply the recommended resources required to meet future load growth, reach and maintain the RPS requirement of 33% by 2020 and thereafter, and insure that the necessary replacement resources are in-service before divestiture of Navajo in 2015 and IPP in 2027 can occur.

AR0071201

Table 5-2. Revenue and resources recommended to replace coal and load growth ($ million)

FY	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029	2030

These projected costs are in addition to the total annual power operating revenue requirement today of about 2.95 billion. In addition to the revenue required to replace coal and meet future peak load growth, additional revenue is required to fund the Power Reliability Program, modernize gas-fired in-basin generation to eliminate once-through cooling, support investments in smart grid to support energy efficiency and demand response programs, and maintain the basic funding of the existing generation, transmission, and distribution infrastructure as shown in Table 5-3.

Table 5-3. Recommended revenue to fund program initiatives, 2011-2020

PROGRAM INITIATIVE	Revenue Requirement ($ Billion)
Power Reliability	$6.8
OTC Repowering of Power Plants	$1.2
Transition from Coal (Navajo GS)	$0.4
Increasing Renewable Energy	$6.0
Expand Renewable Transmission	$0.5
Expand Local Solar	$0.7
Increasing Energy Efficiency	$0.7
Smart Grid Investments	$0.3
SUBTOTAL	$16.6
Basic Generation, Transmission and Distribution	$23.4
TOTAL	$39.9

AR0071202

The Recommended Case will meet the LADWP combined objectives of maintaining a reliable power system, environmental stewardship, and minimizing ratepayer impacts. The Recommended Case provides a roadmap for the LADWP to achieve its long-term planning goals, while providing the required reliability and necessary flexibility to adapt to dynamic economic, environmental, and regulatory conditions. The Recommended Case will put upward pressure on retail rates, but will maintain adequate reliability and avoid fines and penalties that may otherwise result from violations in state and federal laws. The recommended case also successfully reduces the amount of GHG emissions released into the environment.

5.4 Revenue Requirements

A brief discussion, repeated from Section 1, is in order here regarding budget shortfalls over the past few years. These shortfalls have prevented LADWP from fully funding existing and new programs during that timeframe. The delays surrounding resolution of the Power System budget have the potential of impeding LADWP's ability to meet its long term plans and obligations.

Based on last year's 2010 IRP, a multi-year rate increase was recommended beginning fiscal year 2011-12. The rate increase would have supported elements of last year's IRP, all of which remain as the foundation for LADWP's short and long term plans. Because the rate increase was not realized in July 2011, many of the programs that required funding were scaled down, delayed or deferred.

A multi-year funding plan is necessary to provide consistent and sustainable project and program development. Funding that is based on annual budgets are subject year-to-year fluctuations which introduces uncertainty for our customers and the inefficient use of staff and financial resources that are necessary to meet LADWP's objectives and compliance requirements.

Properly funded programs will enable LADWP to achieve the following objectives:

- Modernize its coastal generation units to replace aging equipment and to satisfy once-through cooling regulatory requirements.
- Implement early coal divestiture.
- Secure the state-mandated amounts of renewable energy.
- Through the Power Reliability Program, reduce the number of distribution outages and improve system reliability.
- Implement necessary transmission improvements to maintain reliability.
- Achieve energy efficiency target levels.
- Implement Smart Grid initiatives.
- Comply with FERC-approved reliability standards.

A rate process that began earlier this year is addressing the revenue needs for LADWP. A proposed 3-year rate adjustment that would support the programs listed above is being considered. The expectation is that the rate process will conclude sometime in 2012. Securing adequate multi-year funding is crucial to ensure LADWP's ability to stay on track towards meeting its future long term goals and obligations.

5.5 Electric Rates

LADWP currently uses an Excel-based financial model that has been developed and used for over a decade. This financial model has been used to develop forward-looking Power System financials for the Board of Water and Power Commissioners' annual budget approval and for rating agency presentation for debt issuances during the similar period.

The model is modified to analyze the three cases with their respective fuel expense, purchased power expense, and additional capital and O&M expenses for any new LADWP-owned resource additions as well as off-balance sheet resource additions. The nine strategic cases are overlaid on existing capital and O&M expenses for the approved FY11-12 budget data, which contains forward-looking budget data up until FY20-21. For years beyond FY20-21, general capital and O&M expenses are escalated at 3 percent per annum.

LADWP retail revenue comes from three billing factors: (1) base rate (2) energy cost adjustment (ECA) and reliability cost adjustment (RCA) factors. The interplay of these three factors is described briefly below.

The ECA is used to cover fuel, purchased power, RPS and energy efficiency-related expenses. The ECA is adjusted quarterly and currently has an adjustment cap of 0.1 cts/kWh (i.e., increasing by no more than 0.1 cts per kWh).

The RCA is used to cover power reliability related expenses. The RCA is adjusted annually and has a maximum factor of 0.3 cts/kWh. This maximum has been reached in FY10-11 and cannot be adjusted any higher. Since reliability related expenses are not projected to go lower than FY10-11 spending levels, significant RCA under-collection may exist.
