systems eroded the upper Pleistocene sediments, forming Dominguez Gap. Streams draining the Santa Monica Mountains across the Sawtelle Plain and the Hollywood Piedmont Slope cut through the El Segundo Sand Hills and probably the Baldwin Hills to form Ballona Gap. At various times, the Los Angeles River and possibly the Rio Hondo-San Gabriel River system drained seaward through Ballona Gap. Since the last rise of sea level (post-Wisconsin or Recent time), the Los Angeles and San Gabriel River systems have reached the sea mainly through Dominguez and Alamitos Gaps, respectively.

Fluctuations of sea level associated with the last glacial stage have been rather complex in other portions of the world and available evidence indicates that such fluctuations were complex in this region as well. Because of these complexities it is almost impossible to tell at which period any given sand or gravel was deposited or when any given gap in the coastal plain was cut or backfilled.

Wind gaps in the Santa Monica Mountains, and the Elysian, Repetto, Merced, and Puente Hills indicate that streams other than those now existing have flowed from the San Fernando and San Gabriel Valleys across what are now the bordering highlands into the present coastal plain. Most of these streams probably were formed while the bordering highlands and mountains were being raised.

Recent History

Recent geologic time, as defined in this report, began with the melting of the last extensive world-wide glacial ice sheets. This event began about 15,000 years ago according to Shepard (1956) and Hopkins (1959), and evidently occurred rapidly, for the sea level rose at an accelerated rate. Coarse gravels were deposited or backfilled in the stream channels

AR0068866

throughout the coastal plain. In Ballona Gap such material is found up to 60 feet below the present sea level. This stream aggradation was accompanied by wave erosion of the marine terrace deposits on exposed beaches and by marine deposition offshore. About 9,000 years ago the rate of sea level rise began to decrease and, as stream gradients decreased, finer materials were deposited in Dominguez and Ballona Gaps. Baymouth bars cut off the mouths of streams at various times, forming lagoons and playa lakes. At the present time Dominguez, Ballona, and Alamitos Gaps all contain considerable lagoonal deposits at shallow depth. The sea level was stabilized near its present level about 4,000 years ago, though a slight sea level rise occurred about 1200 A. D. which may have led to deposition of the peat now found in some areas near the coast.

Events that have occurred during the period of recorded history may help to reveal what has happened during the geologic past. Prior to 1825 and again during the flood of 1867-68, the Los Angeles River flowed westerly from the Los Angeles Narrows through Ballona Gap instead of south through Dominguez Gap. It is reasonable to assume that if rapid changes in the drainage patterns can occur in such a short time they may have occurred many times in the geologic past. The Santa Ana River is shown on older United States Geological Survey topographic maps as flowing westerly from the mouth of Santa Ana Canyon across Orange County in the direction of the present Coyote Creek drainage. The sediments which fill the basin, creating the flat, tilted plain that now exists, probably were deposited by streams migrating back and forth across the coastal plain.

Earthquakes occurring during historic times indicate that the coastal plain and surrounding highlands are still actively being folded and faulted. Deposition of active dune sands along the coast bordering

AR0068867

Santa Monica Bay and erosion and deposition of sediments by streams and by the ocean, is continuing where not controlled by man.

AR0068868

CHAPTER III. PHYSIOGRAPHY

This chapter describes the land forms or physiographic features in and surrounding the Coastal Plain of Los Angeles County. Within the area of investigation portions of two geomorphic provinces are present. The coastal plain is in the northwest corner of the Peninsular Range geomorphic province, which extends southward into San Diego County and Baja California. The Peninsular Range province consists of essentially northerly and northwesterly trending mountain ranges and associated valleys. This province is bordered on the north by the Transverse Range province, an east-west trending series of mountains which include the Santa Monica and San Gabriel Mountains. The northern portion of the coastal plain is a part of the transition area between these two major geomorphic provinces and the physiographic features reflect the complexity of the underlying structure caused by the abruptness of this transition.

The major land forms of the coastal plain consist of bordering highlands and foothills, older plains and hills, and younger alluvial plains, the rivers which drain the area, and the offshore topography. Names of land forms utilized by Poland, et al., (1945, 1956) are used herein except where additional features have been named, and their locations are shown on Plate 2.

Bordering Highlands and Foothills

Highland areas adjacent to the coastal plain include the Santa Monica Mountains, the Palos Verdes Hills, and the Puente Hills. All of these features are geologically young in origin, moderate to bold in relief, and generally mature in form.

AR0068869

The highest elevations on these highlands within the area of investigation are: Santa Monica Mountains, 2,126 feet; Puente Hills, 1,387 feet; and the Palos Verdes Hills, 1,480 feet. The highland areas are more or less gullied and incised by streams, though extensive relatively smooth surfaces remain which have not been entirely removed. These smooth surfaces and their associated subdued hills and valleys are possibly remnants of an old erosion surface (Eldridge and Arnold, 1907), which has been deformed, uplifted, and removed in most areas by more recent erosion.

Thirteen wave-cut terraces on the Palos Verdes Hills, extending up to 1,300 feet above sea level, have been identified by Woodring, et al., (1946). Similar wave-cut terraces have been described in the Santa Monica Mountains and offshore islands (i.e., San Miguel, Santa Rosa, and Santa Cruz Islands) to the northwest and west of this area, but within the coastal plain only the equivalent of the lower terraces have been identified. As mentioned in the chapter on geologic history, these terraces indicate continued uplift of the highland areas in late Pleistocene time.

The highland areas generally consist of relatively impermeable rocks which yield little water to wells. Minor springs and seeps add to direct runoff from precipitation and are probably a negligible source of supply to adjacent water-bearing areas. Springs and seeps contribute to slope stability problems in certain areas.

The foothills are the Elysian, Repetto, and Merced Hills. These hills are mostly underlain by Tertiary rocks and may have been one continuous surface at some time in the past (Poland, et al., 1956). These features, like the highlands, are geologically young. The Elysian and Repetto Hills are now separated by the Los Angeles Narrows, and the Repetto and Merced

AR0068870

Hills are separated by an abandoned stream channel along Potrero Grande Drive. Whittier Narrows separates the Merced Hills from the Puente Hills.

Maximum elevations in the foothills are: Elysian Hills, 757 feet; Repetto Hills, 735 feet; and the Merced Hills, 550 feet. These features have moderate relief and have been considerably eroded. Probable wind gaps are present in the Elysian Hills along Los Feliz and Silverlake Boulevards. Wind gaps are also present in the Repetto Hills north of Boyle Heights, east of City Terrace, and along Eastern Avenue, Monterey Pass Road, Atlantic Boulevard and Potrero Grande Drive.

The Tertiary sediments in these foothills are essentially nonwater-bearing. Water-bearing materials are present only in small thin patches and supply little water to wells.

Older Plains and Hills

Many physiographic features in the coastal plain are characteristically covered with a reddish, or brown, deeply weathered soil formed prior to Recent time. In some areas this soil and the surface which it forms may be in its original position, but in many areas both it and the underlying sediments have been warped, folded, faulted and at least partially eroded away. In other areas this deeply weathered soil has been downwarped and covered with younger alluvial material.

Land forms characterized by the red weathered soil include older dissected alluvial aprons, the Coyote Hills, older marine plains, the El Segundo Sand Hills, and the Newport-Inglewood belt of hills. Most of these land forms were formed at essentially the same time and have been deformed and eroded to about the same degree. The Coyote Hills, near the eastern boundary of the county, and the Baldwin and Signal Hills, which are part of

AR0068871

the Newport-Inglewood belt of hills, have been uplifted and eroded to a greater degree than most of the other features included in this group. Available evidence suggests, however, that a deeply weathered soil was formed on these features before the latest erosional cycle began.

Older Dissected Alluvial Aprons

The older dissected alluvial aprons are located adjacent to the highlands and foothills previously described. In this category are the Santa Monica Plain, La Brea Plain, Montebello Plain, and the Santa Fe Springs Plain. Their locations are shown on Plate 2. Soils of deeply weathered, reddish material, 3 to 20 feet thick, have developed on the surface of these alluvial aprons. Within this soil profile, rock fragments, cobbles and boulders are commonly deeply weathered and soft. These soil features are easily recognized in most of the areas where they have been preserved from erosion. The older dissected alluvial aprons are generally underlain by water-bearing sediments of considerable thickness. Some parts of these areas are susceptible to recharge, and changes in ground water storage could occur in some underlying aquifers.

Santa Monica Plain. The Santa Monica Plain lies along the south flank of the Santa Monica Mountains and extends from the ocean inland to the Newport-Inglewood belt of hills. The plain has been dissected by streams draining the Santa Monica Mountains. Streams draining Sepulveda, Dry, Stone, and Brown Canyons have eroded and back-filled an area near Sawtelle, leaving a surface which slopes to the southeast and lies at a lower elevation than the Santa Monica Plain. This area, referred to as the Sawtelle Plain in this report, is

AR0068872

discussed under a subsequent subheading - Alluvial Aprons. The Santa Monica Plain was originally deposited, however, in the form of several large alluvial fans which overlapped onto the Ocean Park Plain and Beverly Hills. Remnants of the surface of these fans are found 175 feet to about 500 feet above sea level. Gradients from apexes to the lower end of the surfaces average about 150 feet per mile.

La Brea Plain. The La Brea Plain is located east of the Newport-Inglewood belt of hills and west of the Elysian Hills. A surface was originally cut by the sea during Pleistocene time on lower Pleistocene and older formations. On this eroded surface 90 to 200 feet of alluvial sediments have been deposited, the top of which now forms the La Brea Plain.

The La Brea Plain has apparently been warped into an east-west anticlinal structure extending westerly from the Elysian Hills. Because of this warping and partial uplifting, the plain is being dissected and removed by erosion. A younger series of alluvial fans forming the Hollywood piedmont slope have buried the La Brea Plain from the north. Poland, et al., (1956) described the La Brea Plain and the Santa Monica Plain as being of similar origin, and additional exposures and close study of the land forms indicate that both of these forms are related in age to the Ocean Park Plain and the Torrance Plain.

Montebello Plain. The Montebello Plain extends south of the Repetto and Merced Hills between the Los Angeles River and the Rio Hondo and has been folded by an east-west anticlinal flexure extending westerly from the Montebello oil field. South of this anticlinal area, the Montebello

AR0068873

Plain dips very gradually toward the Downey Plain and continues beneath a portion of it. In the area which has been affected or folded by the extension of the Montebello anticline, the Montebello Plain has been dissected by small streams draining southward from the Repetto Hills, forming deep gullies crossing the axis of the fold. Along the north side of the Montebello Plain near Boyle Heights, the physiographic relationships suggest that a marine-cut terrace was formed prior to deposition of the alluvial materials that now form the present surface of the Montebello Plain in that area. However, fossil evidence supporting this theory is absent.

Santa Fe Springs Plain. The Santa Fe Springs Plain is located south of Whittier and east of the San Gabriel River, in the area of the City of Santa Fe Springs, and is apparently a continuation of the Coyote Hills uplift to the southeast. The Santa Fe Springs Plain is only a low, slightly rolling topographic feature unlike the somewhat rugged Coyote Hills to the southeast. The Santa Fe Springs Plain has probably been warped by the Santa Fe Springs-Coyote Hills anticlinal system and dips gently both to the northeast toward Whittier and to the southeast toward the Downey Plain. The difference in elevation ranges from 100 to 175 feet above sea level.

Coyote Hills

The Coyote Hills, a youthful anticlinal feature, are most developed in Orange County. The feature continues northwesterly into Los Angeles County where it becomes a low hill dissected by streams and grades gradually into the Santa Fe Springs Plain.

AR0068874

Maximum elevation in the Coyote Hills is 600 feet above sea level and occurs in Orange County. The hills that lie to the west of La Habra Road and in the area of investigation have elevations of approximately 25 feet to 325 feet above sea level. The north slope is steeper than the south, which grades gradually into the Downey Plain.

Older Marine Plains

The Older marine plains include the Torrance, Long Beach, and Ocean Park Plains, all of which have similar histories and are closely related to the Newport-Inglewood belt of hills. All of these plains are underlain by water-bearing sediments.

During upper Pleistocene time, it is probable that the Ocean Park Plain continued undisturbed southward and was united with the El Segundo Sand Hills and Torrance Plain. The Torrance and Long Beach Plains, originally one, have been separated by downcutting of the Los Angeles-Rio Hondo-San Gabriel River systems. Landing Hill, part of the Newport-Inglewood belt of hills, and Long Beach Plain have been separated because of erosion by Coyote Creek and possibly the Rio Hondo and San Gabriel River.

Much attention has been given to the fact that marine fossils are commonly found from 10 to 30 feet below the surface of the Long Beach, Torrance, and Ocean Park Plains. Fresh water fossils have also been observed in shallow deposits in the Torrance Plain near Dominguez Creek. Many remains of extinct land mammals have been found in this same thickness of sediments in the Long Beach and Torrance Plains. These fossils suggest that there were periods of complete or nearly complete emergence of the land between periods of subsidence so that both land and sea animals could have access to the area.

AR0068875

Ocean Park Plain extends inland from the Pacific Ocean approximately three miles bordering on the north of Ballona Gap. Elevation on the plain ranges from sea level to 200 feet above sea level. Poland, et al., (1956) lists three physiographic areas within the plain: a bench on the eastern portion, a central unit with an undulating surface, and a ridge-and-trench area on the western portion. His ridge-and-trench area is equivalent to the El Segundo Sand Hills to the south. The Ocean Park Plain is slightly dissected by local streams.

The Torrance Plain parallels the Newport-Inglewood belt of hills from Ballona Gap southwest to Dominguez Gap. It is a broad featureless area only slightly dissected by local streams north of Centinela Creek and cut in the south by Dominguez Creek. The plain is immediately underlain by fine-grained materials of marine and nonmarine origin, and in small low lying areas the fine-grained materials are overlain by Recent alluvium.

The Long Beach Plain is located on the southwest side of the Newport-Inglewood belt of hills between Dominguez and Alamitos Gaps. This plain is underlain by the same kind of sediments as the Torrance Plain; however, no aquifers have been delineated in this area.

El Segundo Sand Hills

The El Segundo Sand Hills extend from Ballona Gap south to Torrance and the Palos Verdes Hills, and approximately three to four miles inland from the ocean. Remnants of similar hills are found on the western edge of Ocean Park Plain. The sand hills consist of a narrow strip of active or recent dunes along the coast and older stabilized sand dunes inland. The active dunes are up to one-half mile wide, with a maximum elevation of 185 feet above sea level. These active dunes have undergone

AR0068876

at least two stages of development, as shown by excavations for the Scattergood Steam Plant of the Los Angeles Department of Water and Power near El Segundo. A earlier phase of the recent unweathered sand dunes had a surface which was inhabited by man and subsequently covered with over 30 feet of sand to form the present dunes.

The active dunes are underlain by older sand dunes of probable late Pleistocene age. In several areas of the El Segundo Sand Hills, fossils and sedimentary features in excavations indicate that these older sand dunes were originally beach deposits which have been altered in form by wind action and deeply weathered. These beach deposits resemble in many respects the marine and underlying portions of the Torrance and Long Beach Plains and are probably contemporaneous with them. The form of the older beach sands was modified by the wind so that the surface now has closed depressions. The closed depressions have been formed by a combination action of removing and piling up of sand. One to three miles inland, the older sand dunes overlie silts and clays which apparently were deposited on the landward side of the beach sands and which now form a portion of the Torrance Plain. Weathering and associated stabilizing processes have removed all but the gross features of dune topography in the older sand dune area. Thin remnants of similar dune sands have been observed in excavations for the Harbor Freeway on the Rosecrans Hills.

Newport-Inglewood Belt of Hills

The area of deformation that extends from the foot of the Santa Monica Mountains near Beverly Hills southeasterly as far as Newport Beach in Orange County is named the Newport-Inglewood belt of hills and plains. As originally defined by Poland, et al., (1956), this belt of hills and

AR0068877

plains included the Torrance and Ocean Park Plains; however, in this report the term Newport-Inglewood belt of hills is used to delineate the area of deformation exclusive of the Torrance and Ocean Park Plains which have been described separately. The area of deformation varies in width from one to four miles and is underlain by a series of folds and faults which have given rise to most of the surface hills, plains, and mesas. For this reason, in discussions of structural geology this belt of hills is referred to as the Newport-Inglewood uplift. Poland's findings indicate that the many features of the Newport-Inglewood belt of hills and plains are of the same age as the Torrance and Ocean Park Plains. Observations during this investigation support this conclusion.

In the Newport-Inglewood belt of hills, the surface is frequently underlain by a highly weathered reddish colored soil which is itself underlain by sand and silt containing marine fossils. This sand and silt was deposited in a shallow sea or lagoonal environment. The original surface, after withdrawal of the sea, extended into Ocean Park Plain, Beverly Hills, and possibly the La Brea Plain. The marine-formed surface may have extended to the Montebello Plain, although fossil evidence has not been found to substantiate this theory. In general, the upper Pleistocene sediments have been strongly deformed in some areas along the uplift and completely removed by erosion in others.

The following paragraphs briefly describe the various features that comprise the Newport-Inglewood belt of hills, all of which are underlain by water-bearing sediments.

The Beverly Hills are the most northerly feature of the Newport-Inglewood belt of hills which have easily identifiable topographic characteristics. They range in elevation from 75 feet to 300 feet above sea level.

AR0068878

The area displays a rolling topography, as a result of warping and of erosion by local streams. The marine upper Pleistocene deposits capping Beverly Hills were probably continuous with the Ocean Park and Torrance Plains and with remnants of similar sediments which now cap Baldwin Hills. The Beverly Hills apparently have been warped and faulted. In a small area near Cheviot Hills, which is a portion of Beverly Hills, lower Pleistocene marine sediments are exposed (Rodda, 1957); elsewhere they are overlain by marine upper Pleistocene deposits.

The Baldwin Hills, south of Ballona Gap, are a prominent feature extending some 513 feet above sea level and more than 400 feet above the central lowlands to the east and northeast. Sediments of the Baldwin Hills have been considerably warped and faulted. The north flank of the Baldwin Hills has been deeply incised by erosion, whereas the south flank slopes gently to the Torrance Plain and Rosecrans Hills.

The Rosecrans Hills, beginning near Inglewood and extending southward to Dominguez Hill, comprise a low swell about three miles wide with its crest ranging from 100 to 240 feet above sea level. The surface of the Rosecrans Hills is underlain by upper Pleistocene sediments which dip southwesterly toward and merge with the Torrance Plain and northeasterly toward and probably beneath the Downey Plain.

Dominguez Hill, an anticlinal dome with a northwest-southeast trending axis, is located just northwest of Dominguez Gap. On the west and north, Dominguez Hill grades into the Torrance Plain and the Rosecrans Hills. Elevations range from 20 feet to 195 feet above sea level. Little erosion has occurred on the hill to modify the surface topography, with the exception of the east flank where a local stream has cut a deep gully, and on the southeast where the Los Angeles River has eroded into the hill.

AR0068879

Signal Hill, Bixby Ranch Hill and Bouton Plain were grouped by Poland, et al., (1956) as the Signal Hill uplift, but are considered to be separate though related features in this report. Signal Hill, southeast of Dominguez Gap, rises to an elevation of about 365 feet above sea level. Its southwesterly side is approximately bounded by a fault scarp. The north side of Signal Hill slopes gradually down to the Bouton Plain, which in turn slopes northerly toward the Downey Plain. On Signal Hill the upper Pleistocene sediments have been folded and eroded to such a degree that they have been removed, exposing the lower Pleistocene sediments in small areas. Southeast of Signal Hill is Bixby Ranch Hill, which is located to the northwest of Alamitos Gap. The south and north sides of Bixby Ranch Hill are apparently closely related to fault scarps.

Landing Hill, although just across Alamitos Gap in Orange County, is another feature of the Newport-Inglewood belt of hills. The surface slopes to the northeast beneath the Downey Plain and is capped with the same type of sediments as those on Signal Hill and the remainder of the Newport-Inglewood belt of hills.

Younger Alluvial Plains

Younger alluvial plains include those areas where alluvium has been deposited in Recent time. The alluvial material has buried parts of the older weathered surface. The younger alluvial plains have been grouped into alluvial aprons and the Downey Plain. All of these areas are underlain by water-bearing material.

Alluvial Aprons

The younger alluvial aprons consist essentially of coalescing alluvial fans or alluvial piedmont slopes which have overlapped in Recent

AR0068880

time some of the older Pleistocene plains previously mentioned. These younger alluvial aprons include the Sawtelle Plain, Hollywood piedmont slope and the La Habra piedmont slope.

The Sawtelle Plain is essentially a thin sheet of alluvium deposited on an eroded surface in the area surrounded by the Santa Monica and Ocean Park Plains and Beverly Hills. Alluvium in the Sawtelle Plain appears to be relatively thin, possibly no more than 30 or 40 feet deep. The surface slope averages between 60 and 80 feet per mile.

The Hollywood piedmont slope lies south of the Santa Monica Mountains, north of the La Brea Plain, and east of the Newport-Inglewood belt of hills. This area consists of several small alluvial fans deposited by streams draining from the Santa Monica Mountains. These fans form a relatively flat surface, with minor undulations, that slopes to the south and southwest with a gradient of about 90 feet per mile. The small coalescing fans are approximately 100 feet thick near the base of the Santa Monica Mountains, but to the south near Beverly Hills, excavations indicate that they decrease to a thickness of 10 to 30 feet. The Hollywood piedmont slope has been deposited partly on the La Brea Plain, Beverly Hills, and the Elysian Hills. Along the north side of Ballona Gap, sediments from the Hollywood piedmont slope and from Sawtelle Plain have been deposited as small alluvial fans. These small fans are moderately thick and have overlapped and become interbedded with sediments of Recent age deposited by the Los Angeles River which, as late as 1868, flowed through Ballona Gap into the ocean near Venice.

The La Habra piedmont slope extends southeasterly along the southwest foot of the Puente Hills from Whittier Narrows into Orange County.

AR0068881

This area consists of several small alluvial fans deposited by streams draining the Puente Hills. These fans coalesce forming an undulating surface that slopes to the south and southwest with a gradient of about 170 feet per mile. This area has been more extensively dissected than has the Hollywood piedmont slope. As a result of this dissection, the topographic expression of the La Habra piedmont slope is quite complex. Some of the exposed features are probably of the same age as the Santa Fe Springs Plain and the Montebello Plain, that is, of upper Pleistocene age. Many younger fans of shallow depth cover portions of the area.

Downey Plain and Related Features

The Downey Plain, the largest area of Recent alluvial deposition, is located south and southeast of the La Brea, Montebello, and Santa Fe Springs Plains, and of the Coyote Hills, and northeast of the Newport-Inglewood belt of hills (Poland, et al., 1956). It extends from Ballona Gap across the central lowland of the Coastal Plain of Los Angeles County into the Coastal Plain of Orange County nearly to Santa Ana. The Downey Plain ranges in elevation from 275 feet in the Los Angeles Narrows and 200 feet in the Whittier Narrows to sea level at the ocean near Dominguez Gap. The slope of the Downey Plain varies from 7 to 23 feet per mile, but is generally less than 18 feet per mile. It is essentially a depositional feature, although minor erosion has occurred. Alluvial fans formed by the Los Angeles and Rio Hondo-San Gabriel River systems have coalesced to form a very gentle plain. During past flood times these large rivers have swung over most of the area depositing their debris. Near the ocean some of the stream deposited sediments are interbedded with marine and tidal sands, gravels, and clays.

AR0068882

Ballona Gap, located between the Baldwin Hills and Beverly Hills and extending to the ocean, was initially formed by headward erosion from the ocean, capturing drainage from the Sawtelle Plain and the Hollywood piedmont slope. Although the Los Angeles River has flowed through the Gap, available evidence indicates that it has caused less erosion than the smaller streams.

Dominguez Gap includes the lower portion of the Los Angeles River area between Dominguez and Signal Hills. It is about two miles wide and slopes toward the ocean at a gradient of about four feet per mile.

Alamitos Gap, separating Long Beach Plain and Bixby Ranch Hill from Landing Hill, has been eroded by Coyote Creek and presumably other streams. The surface slopes oceanward at the same gradient as Dominguez Gap.

The Los Angeles Narrows, located between the Elysian and Repetto Hills, is an erosional feature cut through a relatively weak portion of the Santa Monica Mountains by the Los Angeles River. Terraces and complex subsurface alluvial deposits indicate that erosion and deposition has been complex in the Narrows.

The Whittier Narrows separates the Merced and Puente Hills and forms the avenue through which drainage from the San Gabriel Valley and surrounding highlands passes to the coastal plain. The two major streams passing through Whittier Narrows are the Rio Hondo and the San Gabriel River. The width of the Whittier Narrows varies from 1.6 miles to 2 miles. Although generally flat with steep sides, the surface configuration of the Narrows is further complicated by terraces, alluvial fans from local small canyons, and abandoned stream courses and meanders. This physiographic

AR0068883

feature appears to have been formed in late Pleistocene time, although Slosson (1958) suggests that the area was a submarine canyon in lower Pliocene time.

Drainage Systems

The Coastal Plain of Los Angeles County is drained primarily by the Los Angeles and Rio Hondo-San Gabriel River systems. Within historical times the Los Angeles River has flowed through Ballona Gap, and the Santa Ana River in Orange County has drained through Alamitos Gap. It is probable that all three river systems crossing the coastal plains of both counties have entered the ocean at various locations from Dominguez Gap on the north to Santa Ana Gap near Huntington Beach on the south.

Minor stream systems include Dominguez Creek on the Torrance Plain which drains to the ocean and Comptom Creek on the Downy Plain that enters the Los Angeles River northeast of Dominguez Hills. Coyote Creek, flowing through the Coyote Hills, now occupies a wide valley much larger than ncessary for its present flow. Physiographic evidence in the area north of Coyote Hills indicates that Brea Creek flowed down the present Coyote Creek channel in late geologic time, but has been diverted to its present channel southeast of Coyote Hills leaving the old channel to drain only its present small watershed.

Physiographic evidence is abundant that other streams have drained the San Gabriel Valley across the Repetto Hills to the coastal plain, and their courses have since been abandoned, forming wind gaps. What are probably wind gaps are also found in the Santa Monica Mountains; they may represent relatively old stream courses which drained the San Fernando Valley at the beginning of late Pleistocene time.

AR0068884

Offshore Physiography

Physiography of the offshore area of Southern California is well described by Emery (1954), Shepard (1948), Terry, et al., (1956), Stevenson, et al., (1958), and Gorsline and Emery (1959). This large offshore area is described briefly in this report because of the close stratigraphic and physiographic relationship it has with the onshore area covered by this investigation. The offshore features are shown on Plate 2.

The first submarine physiographic province encountered is the continental shelf. The western boundary of the continental shelf, roughly delineated by the 50 fathom contour (300 feet), parallels the coastline at distances from shore varying from a few hundred feet to 8 or 10 miles. The continental shelf slopes seaward at a gradient of about 25 feet per mile in Santa Monica and San Pedro Bays. The shelf is generally smooth, though such minor irregularities as longshore troughs, mounds, bars, and depressions occur in water less than 20 feet deep where they are constantly changing position. Such features are known as micro-relief. Along the break in slope at the outer margins of the continental shelf are terraces, steps, and notches. Submarine canyons interrupt the shelf and may represent lines of weakness or remnants of pre-existing drainage channels. A zone of bedrock mounds, more than 2,000 feet in diameter, many of which are connected by steep-sided ridges, occur approximately five to six miles offshore in Santa Monica Bay on the continental shelf.

The second major offshore physiographic province is the basin slope. This slope extends from one to ten miles seaward from the rim of the continental shelf at about 300 feet to 2400 feet below sea level with an average 450 feet per mile gradient except where it steepens near submarine canyons.

AR0068885

Beyond the basin slope for a distance of approximately 140 miles seaward lies a broad area of fault block structures, referred to by Shepard (1948) as the continental borderland. The downfaulted blocks are mostly closed basins separated by sills or upfaulted submarine ridges which rise about 2,000 feet above the floor of the basins. Included in the uplifted blocks are San Clemente, Santa Catalina, San Nicholas, San Miguel, Santa Rosa, and Santa Cruz Islands. Emery (1954) explains that this series of uplifted and downdropped structures may be due to faulting and/or folding.

The fourth of this series of physiographic provinces, the continental slope, begins at the edge of the continental borderland and plunges steeply to abyssal ocean depths of 12,000 feet or more.

Three subprovinces of the continental shelf named by Terry, et al., (1956) are the Santa Monica Shelf (Point Dume to Palos Verdes Point), the Palos Verdes Shelf (Palos Verdes Point to Point Fermin), and the San Pedro Shelf (Point Fermin to Corona Del Mar) are shown on Plate 2. The Santa Monica and San Pedro Shelves are significant in respect to the occurrence and movement of ground water.

The Santa Monica Shelf extends seaward about eight miles and is subdivided into three segments by two submarine canyons that cut transversely across it offshore from Santa Monica and Redondo Beaches.

The Palos Verdes Shelf is narrow and extends seaward about one mile from the coast of the Palos Verdes Hills. Because of the lack of water-bearing sediments in the southwestern Palos Verdes Hills and in the offshore area, the Palos Verdes Shelf is not significant for this study.

Located southeasterly from the Palos Verdes Hills is the San Pedro Shelf. This shelf extends seaward 2 miles from Point Fermin and

AR0068886

achieves a maximum extension of 12 miles at its central projection, before it diminishes again to 2 miles off Corona Del Mar. Moore (1951) gives an account of the physiography, structure, and sediments in this area; the formations were also described by Stevenson, Uchupi, and Gorsline (1958). This flat, featureless plain slopes southward and southeastward toward the basin slope, which has here been named the San Pedro Escarpment by Shepard and Emery (1941). Erosion followed by deposition of Recent sediments has reduced both positive and negative topographic features, obliterating the ancient stream channels of the Los Angeles and San Gabriel Rivers that once crossed it.

The Santa Monica and Redondo Submarine Canyons occur along the basin slope extending westward off the Santa Monica Shelf. The Santa Monica Canyon begins about four miles offshore at a depth of 180 feet and assumes a curved and sinuous course into the Santa Monica Submarine Basin, the nearest closed basin of the continental borderland. The canyon is relatively smooth with only small tributaries entering from the south wall. The Redondo Canyon begins a few hundred feet offshore from the City of Redondo Beach, follows a straight course across the Santa Monica Shelf, and empties into the Santa Monica Submarine Basin. A steep gradient of about 400 feet per mile at the canyon head gradually decreases to about 130 feet per mile at its fan-like terminal approximately 2,200 feet below sea level. Tributaries along the north side contribute to the variable topography of the canyon walls. Slumping occurs within the canyons and along the basin slope and carries recently deposited sediments to greater depths offshore.

Subsurface evidence provides at least a partial history of the development of the Redondo Canyon. During a part of late Pleistocene

AR0068887

time when the sea level was much lower, drainage from the San Gabriel River, and possibly the Los Angeles River, flowed across what is now the Downey Plain, Rosecrans Hills, Torrance Plain and El Segundo Sand Hills to the present head of Redondo Canyon and continued oceanward to the rim of the continental shelf. Downcutting probably occurred rapidly along the basin slope and further entrenched the stream channel landward. A rapid rise in sea level has since caused the backfilling of coarse debris in this entrenched channel.

The San Pedro Sea Valley, an east-west trending submarine canyon, begins on the San Pedro Shelf south of Point Fermin. A branch or tributary leads off from the northern side of the main valley and trends northeasterly toward the mouth of the San Gabriel River. Both the main valley and its tributary lose their identity above a depth of about 150 feet. At the eastern extremity of the San Pedro Shelf, about 10 miles south of Sunset Beach, two smaller valleys trend in a southerly direction from a depth of 150 feet. This valley system has been named the San Gabriel Canyon by Emery (1960).

AR0068888

CHAPTER IV STRATIGRAPHY

This chapter describes the stratigraphy, or the physical characteristics of the natural groupings of the rocks and sediments, in the Coastal Plain of Los Angeles County, including the age of rocks and sediments, their order in relationship to each other, and their position in the area. In order to simplify the discussion of stratigraphy, the rocks and sediments in the coastal plain are divided into water-bearing deposits and nonwater-bearing rocks.

The water-bearing deposits include the unconsolidated and semiconsolidated marine and nonmarine alluvial sediments of Recent, Pleistocene, and Pliocene age which form ground water basins. These materials absorb, transmit, and yield water readily to wells. Sizes of individual particles may grade from coarse gravel and boulders to clay. Coarse sands and gravels form the conduits for transmission of ground water and are called aquifers, while the finer sands, silts and clays, which also transmit ground water, but very slowly, are known as aquicludes.

The types of materials encountered by surface and subsurface geologic exploration and water well drilling, as reported by various individuals and agencies, are summarized on Table 1, which is bound at the end in this report. Based upon this information, the areal extent, thickness, and depths of the various aquifers and aquicludes underlying the coastal plain were estimated. The aquifers were named and their stratigraphic positions are illustrated schematically on Plate 5, entitled "Generalized Stratigraphic Column, Coastal Plain of Los Angeles County". Since the aquicludes which separate aquifers are generally of secondary interest, and because of additional complications of nomenclature, only the surface aquiclude is named. An attempt has been made to bring together and clarify the nomenclature

AR0068889

used by many individuals and agencies. Therefore Plate 5 also relates the nomenclature system utilized in this report with that employed by others in the past.

The term "nonwater-bearing rocks" used in this report should not be construed to mean rocks which contain no water, but rather materials from which wells produce relatively limited quantities of water. Nonwater-bearing rocks are the parent rocks from which alluvium is derived. These rocks flank, underlie, and sometimes form the limits of the ground water basins and provide watersheds for runoff or drainage to valley-fill areas. Nonwater-bearing rocks include granitic, metamorphic, volcanic, and consolidated sedimentary types. Locally, the sedimentary rocks may yield a small amount of brackish, saline, or other poor quality waters. Water which drains from these rocks may also affect the quality of water in the sediments of valley-fill areas. Even within the crystalline basement rocks, some extractable water is contained within the joints, fractures, and solution cavities. In the highland areas, wells in volcanic flows and breccias yield limited quantities of water. The yield of wells in the volcanics, however, is usually restricted either because there is a lack of connected interstices or because they are so situated topographically or structurally that cementation, folding and faulting interferes with the vertical and lateral flow of ground water.

The following sections describe the water-bearing deposits and nonwater-bearing rocks in detail beginning with the geologically most recent, and working backward in time to the oldest strata. The surface outcroppings of the various formations are delineated on Plate 3. The conclusions of this study relating to the depth and thickness of the various aquifers and aquicludes in the coastal plain are illustrated by a series of idealized

AR0068890

geologic sections cutting the area in east-west and north-south directions. These sections are shown on Plates 6A through 6G, entitled "Idealized Geologic Sections"; and the geographic locations of the sections are indicated on Plate 3, together with the locations of wells and test holes from which the geologic sections were derived. In addition to the wells and test holes shown on these plates, there were two to three times as many wells and test holes that were studied. These data were used to assist in delineating the boundaries of the aquifers and aquicludes.

In constructing the geologic sections, it was much easier to correlate aquifers from well log to well log in the marine sediments found southwest of the Newport-Inglewood uplift than it was in the area to the northeast. Consequently, the correlations in the continental sediments, especially those adjacent to the high lands are more definitive than are those in the marine sediments closer to the ocean. Also, the geologic sections in the West Coast Basin (this basin is described in Chapter 6) were mainly based on data taken from the Report of Referee (Calif. D.W.R. 1952a), modified slightly by unpublished data obtained from the Los Angeles County Flood Control District.

Subsurface structure and positions of aquifers in the area downstream from Whittier Narrows are illustrated by a series of cut-away diagrams shown on Plate 7, entitled "Cut-Away Diagrams of Aquifers in Vicinity of Whittier Narrows". These diagrams are of assistance in following the discussion of stratigraphic relationships but are discussed in detail in Chapter V. Detailed discussions of structural features referred to in the following sections are also contained in Chapter V.

AR0068891

Quaternary System

Sediments of Quaternary and late Pliocene age comprise the water-bearing formations in the coastal plain. The Quaternary deposits are divided into the Recent and Pleistocene series.

Alluvial materials and rocks of Recent and Pleistocene age usually are unconsolidated and have suffered deformation to a lesser degree than the older underlying rocks. These younger alluvial materials are generally more heterogeneous than the older sediments although this may be more apparent than real, since more detailed information is usually available for younger sediments than for those older in age. In the detailed studies of oil fields, by contrast, the heterogeneity of older sediments is apparent.

Ground water extracted from wells is obtained primarily from aquifers of Recent and Pleistocene age, with the exception of a few wells in the Lakewood and North Long Beach areas which are perforated in sediments of late Pliocene age.

Deposition of Quaternary sediments has been controlled by tectonic activity, geomorphic processes, changes in climate, and world-wide changes in sea level, as previously discussed. The physical characteristics of those water-bearing series that favor high production of ground water are: their unconsolidated and permeable nature, their relatively undeformed state, their low topographic position, which permits infiltration of drainage from higher surrounding areas, their freedom from obstructions to flow in most areas, the ease with which their materials may be dewatered, or drained, and the ease with which in certain areas they may be naturally or artificially recharged.

AR0068892

Recent Series

Reade (1872) first defined the Recent epoch as that time which has elapsed since the beginning of the last major rise in sea level, and this definition has been adopted for use in this report. An approximate age of 15,000 years has been assigned to the Recent epoch by Shepard (1956) and Hopkins (1959).

Recent materials were laid down upon the erosional surface that existed toward the end of the last glacial stage. In most of the Coastal Plain of Los Angeles County these sediments are stream deposits but near the ocean they include tidal, marine, and wind-deposited materials.

Recent deposits are recognizable by:their generally coarse, unconsolidated or uncemented nature (however, on Recent flood plains, alluvial fans, and certain marine deposits, fine-grained silts and clays are common), their unconformable relationship with the underlying late Pleistocene and older deposits, their relationship to the present drainage system including numerous gaps along the coast and other physiographic features, and the youthful or poorly developed soil normally found on the surface. Little deformation of the Recent sediments has occurred except where they cross tectonically active areas, as in Dominguez and Ballona Gaps. Two major members of the Recent series are shown in the areal geology presented on Plate 3 namely, alluvium, represented by the symbol Qal and active dune sand represented by Qsr.

Alluvium. Recent Alluvium is primarily stream deposited gravel, sand, silt and clay with some interbedded littoral and estuary or bay deposits near the ocean. Geologic members found within the alluvial deposits include the Semiperched aquifer, Bellflower aquiclude, Gaspur aquifer, and

AR0068893

Ballona aquifer. Portions of the Semiperched aquifer and Bellflower aquiclude are of late Pleistocene age, placing them in the Lakewood formation. They are described here, however, together with the deposits of Recent age.

Semiperched Aquifer. Coarse sands and gravels, called the Semiperched aquifer, are found on or near the surface of much of the Coastal Plain of Los Angeles County. These materials vary in thickness from 0 to 60 feet and may contain significant amounts of unconfined water where they are more than 20 feet thick. The most important areas where this aquifer appears are in the Los Angeles and Montebello Forebay Areas, and irregular patches occur throughout the rest of the coastal plain.

Where the underlying aquifers are confined, the Semiperched aquifer is generally separated from them by silts and clays or other material of relatively low permeability, called the Bellflower aquiclude. These materials inhibit the free percolation of water from the Semiperched aquifer to the underlying aquifers.

Permeable sediments of both Recent and late Pleistocene age are included within the Semiperched aquifer. Most of the sediments are probably remnants of abandoned stream channels, although marine deposits previously known as the Palos Verdes Sand are a part of the aquifer underlying portions of the Torrance Plain.

Little beneficial use is made of water in the Semiperched aquifer since wells perforated in it yield very small quantities of water. Furthermore, the poor quality of the water in some areas makes it undesirable for widespread use.

AR0068894

Bellflower Aquiclude. Lying directly beneath the Semiperched aquifer are sediments of lesser permeability which restrict vertical movement of ground water. These relatively impermeable materials, referred to in numerous reports in generalized terms, have been designated the Bellflower aquiclude. Physical features and dimensions of this aquiclude are delineated on Plate 8, entitled "Lines of Equal Elevation on the Base of the Bellflower Aquiclude", and on Plate 9, entitled "Lines of Equal Thickness of the Bellflower Aquiclude". The Bellflower aquiclude comprises all of the fine grained sediments that extend from the ground surface, or from the base of the Semiperched aquifer, down to the first aquifer below. Other names that have been used to refer to these materials are: "Upper Division of the Alluvial Deposits of Recent Age" (Poland, et al 1956); "Upper Fine Grained Phase" in California D.W.R. 1952b; and "clay cap" in California D.W.R., 1952c, 1957a, and 1958b. The flood plain deposits referred to by Poland, (1959b) which are found in many portions of the Downey Plain may be equivalent, at least in part, to the Bellflower aquiclude as here defined. Although other reports refer to these sediments as Recent in geologic age, the Bellflower aquiclude, as defined in this report, is composed of both Recent sediments in some areas, and late Pleistocene deposits in others.

The Bellflower aquiclude extends throughout most of the Coastal Plain of Los Angeles County, except for the Los Angeles and Montebello Forebay Areas. According to drillers logs and from visual observation of exposed formations in excavations, this aquiclude is a heterogeneous mixture of fine grained continental, marine, and wind-blown sediments. In about a third of the coastal plain, the aquiclude consists only of clays and silty clays, but extensive lenses and pockets of sandy or gravelly clays occur in the remainder of the area, as shown on Plate 9. These predominantly

AR0068895

sandy and gravelly clays may permit waters to percolate slowly to the underlying aquifer or aquifers, or ground water in these latter areas may move upward if pressure levels in the underlying aquifer are sufficiently high. Classification of materials from the descriptions usually found in well logs is difficult; however, in logs where descriptions of materials are more precise and presumably of greater reliability, the sand content is greater than has been generally assumed. Consequently, the aquiclude is believed to have a somewhat greater, though still restricted, permeability than has been supposed in the past.

That portion of the aquiclude of Recent age has not been appreciably faulted or folded; however, the portion of late Pleistocene age has been affected to some extent by tectonic movements.

The thickness of the Bellflower aquiclude, as shown on Plate 9, varies from zero to 200 feet. The areas of greatest thickness occur along the center and east flank of the Gardena Syncline in the West Coast Basin. Other areas of considerable thickness, ranging up to 140 feet, are generally aligned with the South Gate-Santa Ana Depression.

Gaspur Aquifer. The basal coarse phase of the Recent series has been referred to in previous reports as the Gaspur water-bearing zone. These sediments were described by Poland, et al (1956) and in California D.W.R. 1952a and 1952b. The term "aquifer" is used in this report rather than "water-bearing zone", the expression previously employed, as being more descriptive of the function of the deposits. According to Poland, et al (1956) the name of the aquifer is derived from the identification of a typical section in the log of a well near Gaspur Station at the coastal end of Dominguez Gap.

AR0068896

The extent of the Gaspur aquifer is shown on Plate 10, entitled "Lines of Equal Elevation on the Base of the Gaspur, Ballona, Artesia, and Exposition Aquifers". Its westerly arm, extending southerly from the Los Angeles Narrows, joins the easterly arm extending southwesterly from the Whittier Narrows near Downey and continues southwesterly through Dominguez Gap to the ocean. Throughout the 23 mile length of the aquifer the width varies from one to five and a half miles.

The type cobbles and pebbles in the Gaspur aquifer indicate that they are derived from the San Gabriel Mountains and other highland areas surrounding the San Gabriel and San Fernando Valleys.

The continental stream deposits found in the Gaspur aquifer range in size from boulder gravel to silt and clay. In vertical section, the upper part is medium to coarse-textured sand while the lower part consists of sand, gravel, and cobbles as large as four or five inches in diameter. There is also a lateral variation in lithology. Well logs north of Rosecrans Boulevard generally show 80 to 90 percent coarse sands and gravels with 10 to 20 percent finer-grained materials. South of Rosecrans Boulevard, about 40 to 50 percent of the sediments comprising the Gaspur aquifer are fine-grained. The fine-grained patches are discontinuous within the Whittier Narrows, and occur as stringers, or elongated lenses. Variations in the thickness and width of the Gaspur aquifer seem to indicate that the stream or streams responsible for original deposition were meandering, braiding, eroding and aggrading. The absence of fine deposits in the lower portion suggests that they were removed by erosion during flood stages. Thickness of the Gaspur aquifer ranging up to about 120 feet, is delineated on Plate 11 entitled, "Lines of Equal Thickness of the Gaspur, Ballona, Artesia, and Exposition Aquifers".

AR0068897

The Gaspur aquifer is merged with surface deposits in the Montebello Forebay between the Rio Hondo and San Gabriel River, extending as far south as Slauson Avenue. It also crops out in the Los Angeles Narrows in an area bounded by the Los Angeles River and the Harbor Freeway, and extends from the Narrows as far south as Firestone Boulevard. These two outcrops areas are shown on Plate 10A.

The gradient of the base of the westerly arm of the Gaspur aquifer is 44.5 feet per mile (a 300-foot drop in elevation in 6.75 miles). The gradient of the base of the Gaspur aquifer along the easterly arm is about 19 feet per mile (a drop of 200 feet in 10.5 miles). Between San Pedro Bay and the point where the two arms of the Gaspur aquifer join, the gradient is 10 feet per mile (a 60-foot drop in elevation in 6.0 miles). The steepness of the westerly arm may indicate uplift to the north and west, although greater rock hardness in Los Angeles Narrows and/or a difference in stream flow regimen caused by changing debris loads also may have caused this steep gradient. Minor warping of both the aquifer and overlying Recent deposits has probably occurred within the Whittier Narrows and Dominguez Gap. The Gaspur aquifer has apparently not been affected by faulting.

Water levels and well histories indicate that the Gaspur aquifer has been partially dewatered. The majority of new wells drilled in the area under which this aquifer lies do not depend solely on this aquifer but are usually drilled into and perforated in deeper aquifers as well. Many existing wells, however, depend only on this aquifer for their supply, and in these wells the yields are usually high. Permeabilities in this aquifer range up to 6000 gallons per day per square foot. (See Table D in Attachment 2 for general values of permeabilities used in the coastal plain).

AR0068898

The Gaspur aquifer is merged with the deeper aquifers in the area immediately south of Los Angeles Narrows, which at one time served as a recharge area. However, this area is now completely covered by buildings and paved streets. Little, if any, direct percolation of water is possible; even the channel of the Los Angeles River is now lined where it passes through this area.

In the vicinity of Whittier Narrows, the deeper aquifers are also merged with the Gaspur aquifer and receive their natural recharge waters through it. Because percolation in the Los Angeles Narrows has been rendered infeasible, the Whittier Narrows is the most suitable remaining location for artificial recharge of the underlying aquifers. Consequently, the principal recharge basins and projects for recharging local surface flood waters and imported waters are located in this area, from whence natural percolation processes carry this water into the deeper aquifers.

Ballona Aquifer. The other principal aquifer of Recent age is the Ballona aquifer, which has previously been termed the "50-foot gravel". Poland, et al (1959a) originally assigned the name "50-foot gravel" to the lower divisions of the Recent series in Ballona Gap, because these occurred at an average depth of 50 feet below the surface. Although this aquifer is included within the Recent series it is believed that at least part of it may be of late Pleistocene age.

The Ballona aquifer lies north of the Ballona escarpment and extends inland to a point east of the Overland Avenue fault. The extent of this aquifer is shown on Plate 10. It is composed of coarse sand, rounded to subrounded gravel, and cobbles up to five inches in diameter that are of both granitic and metamorphic origin. Slate pebbles in this aquifer suggest

AR0068899

that the Santa Monica Mountains were a possible source of material; on the other hand, granitic rocks and pebbles appear to come from the San Gabriel Mountains. The Los Angeles River has flowed north of the Baldwin Hills and along Ballona Creek channel in historic time, but no attempt has been made to determine the relative contribution to the Ballona aquifer from the two drainage systems.

The Ballona aquifer varies in thickness from less than 10 feet at the coast to 40 feet near Beverly Hills. Thickness of the Ballona aquifer is delineated on Plate 11.

The base of the Ballona aquifer drops from more than 100 feet above sea level beneath the Sawtelle Plain to 60 feet below sea level near the Ballona Escarpment, a gradient of about 40 feet per mile. There is a southward tilt to the base, which corresponds to the southerly dip into West Coast Basin of the San Pedro formation, and may be due to either erosion and depositional processes or to tilting, or possibly both.

Well yields from the Ballona aquifer are highly variable, ranging from 100 to 800 gpm (Poland, et al 1959a). This may be due to the irregularity and discontinuity of its composition and thickness.

Miscellaneous Alluvial Deposits. Other Recent alluvial deposits include beach deposits, playa lake deposits and lagoonal marshland deposits. These have been described more elaborately (Poland, et al 1959a), and are treated only briefly in this report.

Narrow strips of beach deposits, with materials ranging in size from fine sand to cobbles, are found adjacent to wave-cut cliffs along the coastline. They also exist as barrier beaches across the various gaps along the coast. The beach deposits act as a source for wind-blown material

AR0068900

for the coastal-dune belt and may also serve as a permeable conduit for sea-water intrusion into aquifers near the surface along the coast.

Playa lake deposits found near the intersection of the Coast Highway and Vermont Avenue, about one mile west of Wilmington, have been deposited in shallow closed depressions. Standing water accumulates in these closed drainage areas after heavy rains. These deposits are usually fine-grained sands, silts, and clays.

Lagoonal marshlands extend along the coastal reaches of the Los Angeles and San Gabriel Rivers and Ballona Creek for a distance of one-half to three miles inland. Deposits in these areas appear to be heterogeneous in nature, lenticular, and mostly fine-grained. These sediments may also include medium sand, silty sand, clay and peat deposits.

Active Dune Sand. Wind-blown sands occur in a narrow strip 0.2 to 0.5 miles inland and parallel to the coast and continue from Ballona Escarpment southward to Redondo Beach for a distance of about nine miles. These deposits are known as the Active Dune Sands. Plate 3B shows the extent of these deposits which are identified by the symbol Qsr. These eolian deposits are lenticular, and composed of fine to medium, white or grayish sand, usually well sorted. These sediments may also include medium sand, silty sand, clay and peat deposits. The Active Dune Sands range up to 70 feet in thickness. Being above the zone of saturation, the sands do not yield water to wells. However, they are relatively permeable and water held in closed depressions after heavy rains does percolate vertically downward and laterally. The dune sands may therefore serve as recharge media to any water bodies that underlie this area.

AR0068901

Pleistocene Series

The Pleistocene series is divided into upper Pleistocene and lower Pleistocene in most of coastal California, primarily because they are separated by an angular unconformity in many uplift areas. Fossils are used as an additional index to separation of the Pleistocene series. The boundary between deposits of Pliocene and Pleistocene age is difficult to determine and consequently is somewhat arbitrary in many areas.

In the coastal plain the upper Pleistocene is represented by the Older Dune Sands and the Lakewood formation, while the lower Pleistocene consists of the San Pedro formation (Poland, et al, 1956). Where they appear on the surface the Older Dune Sands, Lakewood formation, and the San Pedro formation are identified by the symbols Qso, Qlw, and Qsp, respectively. on Plate 3. A small zone of transitional material, cropping out between the San Pedro formation and the underlying Pico formation of Pliocene age is also shown on Plate 3 and identified by the symbol Qsp-Pp.

Older Dune Sand. Dune deposits occur in West Coast Basin which are older than those described under the Recent Series. These wind-blown materials are sufficiently significant in manner of deposition, lithology and topography, to be considered in this report as a separate unit. The term "Older Sand Dunes" has been previously used to designate these wind-blown deposits; however, in this report, the more descriptive term "Older Dune Sand" is used to identify these deposits.

The Older Dune Sand has been described by Poland, (1956, 1959b) and in Calif. D.W.R. 1952a and 1957c. Although these sediments have been previously classed as Recent materials, they are now considered to be of late Pleistocene age.

AR0068902

The Older Dune Sand covers an area three to four miles wide and about 13 miles long extending along the Santa Monica Bay Coast line south of Ballona Escarpment. Surface exposures and well logs indicate that the dune sediments cover the Ocean Park Plain as well as a portion of the West Coast Basin. In the Ballona Creek area the older dunes have been removed. In the West Coast Basin the Older Dune Sand together with the Active Dune Sand form the El Segundo Sand Hills.

The Older Dune Sand consists of fine to medium sand with minor sandy silt, clay, and gravel lenses. Within the weathered zone the materials are yellow to brown in color although the unweathered formation in place is white, gray and black in color. The Older Dune Sand generally consists of three divisions: a deeply weathered surface, an intermediate horizon of clean sands and basal beach sands and gravels, and a lowermost horizon which apparently includes a zone of transition to the underlying Bellflower aquiclude.

Cross-bedding, and fossils in exposures near the Hyperion Sewage Treatment Plant at El Segundo and elsewhere, indicate that the sands were originally beach deposits with associated coarse gravels. These beach deposits were exposed to the wind by lowering of the sea level, resulting in formation of the present Older Dune Sand. Deep weathering has oxidized the iron minerals which, through cementation and leaching processes, have partially filled the interstices between individual grains, thus reducing the permeability of the weathered Older Dune Sand to some extent. Uplifting may have gently tilted these dunes toward the southwest.

Deep percolation of surface water occurs in most of the Older Dune Sand area, especially where closed depressions occur. Directly beneath these older dunes in part of the El Segundo Sand Hills, the fine sediments

AR0068903

of the Bellflower aquiclude restrict downward movement of ground water. However, the aquiclude is missing along the ocean and ground water can move laterally into an area where downward percolation can again occur.

Lakewood formation. The Lakewood formation includes all upper Pleistocene deposits other than the Older Dune Sand. It includes what has previously been termed "terrace deposits", "Palos Verdes sand", and "unnamed upper Pleistocene deposits". Other names which have been used for upper Pleistocene deposits or parts of these deposits include the Sunny Hill formation (Hoskins, 1954,), and San Dimas formation (Eckis, 1928). These names, however, are awkward for use in the entire coastal plain since the named formations have been described as existing only in the limited associated area. The present designation was selected from a typical section indicated in the log of a well at Lakewood where this formation reaches a maximum thickness of approximately 400 feet.

In the upper part of the Lakewood formation lithologic changes are rapid, with discontinuous permeable zones and considerable variation in particle size. No shell zones have been found in the upper part of this formation. These features represent typical stream type alluviation with flood plain fine-grained sediments comprising from 40 to 80 percent of the total deposits. In the lower horizons the gravels and coarse sands are confined to a narrow belt extending over the Newport-Inglewood uplift. Gravels range from pea-size to cobbles, three to four inches in diameter. Over the balance of the coastal plain, coarse basal deposits of sand and gravel are fairly continuous with discontinuous lenses of sandy silt and clay. The basal part of the Lakewood formation in the Cheviot Hills area of Beverly Hills has been called the Medill sand by Rodda (1957)..

AR0068904

The Lakewood formation extends beneath most of the coastal plain. In portions of the Baldwin Hills, Signal Hill, Palos Verdes Hills, and Coyote Hills, it has been eroded, exposing the underlying San Pedro and older formations. In the La Brea, Santa Monica, and Montebello Plains, and on the flanks of the Palos Verdes Hills and Puente Hills, the Lakewood formation unconformably overlies the lower Pleistocene San Pedro formation, the Pliocene Pico and Repetto formations, and the Miocene Puente formation.

The Lakewood formation is divided into the Artesia-Exposition aquifers, the Gage-Gardena aquifers, and the unnamed aquicludes between the aquifers. In some areas, portions of the Semiperched aquifer and the Bellflower aquiclude, described under Recent alluvium, are included. The base of the Lakewood formation generally coincides with the base of the Gage and Gardena aquifers. The aquifers of the Lakewood formation are discussed in the following paragraphs.

Artesia-Exposition Aquifers. The Artesia and Exposition aquifers, although located in separate geographical areas, are similar in composition and mode of deposition; this leads to the conclusion that they are contemporaneous. They are, therefore, jointly discussed in this section. The Artesia aquifer appears to be related to the San Gabriel River, Coyote Creek, and Santa Ana River systems, and the Exposition aquifer is related to the Los Angeles River drainage system. As shown on geologic section C-C'-C", Plate 6B, these aquifers extend beneath the Gaspur aquifer at which point they merge with each other and with the overlying Gaspur aquifer. On Plates 10 and 11, the contours on the base of the Artesia-Exposition aquifers and lines of equal thickness are not extended beneath the Gaspur aquifer since it is difficult to distinguish the separate aquifers.

AR0068905

The Artesia aquifer extends from the middle of the Santa Fe Springs Plain southward, where it underlies the northern portions of the Bouton Plain, Signal Hill, and Bixby Ranch Hill. It follows the general trend of the present San Gabriel-Coyote Creek drainage as shown on Plate 10. The Artesia aquifer extends southeasterly from the Gaspur aquifer to and beyond the Los Angeles-Orange County line. However, since no study has been made of the extension of this or any other aquifer outside the area of investigation, it is terminated at the county line.

The Artesia aquifer is composed of coarse gravel, coarse to fine sand and interbedded silts and clays. In some areas, individual gravel members within the aquifer can be identified in drillers logs for considerable distances. The Artesia aquifer has a general southwesterly dip, and varies in thickness (Plate 11) and bottom configuration (Plate 10).

The ancestral San Gabriel and Santa Ana Rivers, and Coyote Creek, appear to have been the main source of the sediments comprising this aquifer. The Santa Ana River may have contributed sediments to the southern portion of the area since this river once flowed directly west and joined the San Gabriel River near its present confluence with Coyote Creek.

The geographical extent of the Exposition aquifer is shown on Plate 10. This aquifer consists of one to four discontinuous coarse members. Materials range in size from coarse gravels to clay, with the fine deposits separating the lenticular sandy and gravelly beds. Changes in lithology are frequent as evidenced by the many lenses of silt and clay encountered in the drillers logs.

Deposition of this material appears to have been controlled by the ancestral Los Angeles River, which may have flowed through the Silver Lake

AR0068906

area (Riveroll, 1957) in the geologic past, as well as by tributary streams from the Santa Monica Mountains, Elysian Hills, and Repetto Hills. The configuration of the base of the Exposition aquifer, as well as the Artesia aquifer, is highly irregular and it appears that both were deposited on an erosional surface. A study of well logs indicates that the upper coarse members of the Exposition aquifer were either eroded and backfilled by Gaspur deposits or that some of the upper members were deposited contemporaneously with the formation of the Gaspur aquifer. Highway excavations in the vicinity of Boyle Heights and other areas along the south slope of the Repetto Hills and along the east bank of the Los Angeles River have exposed clean sands and gravels which are apparently an upper member of the Exposition aquifer.

The maximum thickness of the Exposition aquifer is 100 feet. Lines of equal thickness of the aquifer, including interbedded fine materials as well as the permeable zones, are shown on Plate 11.

Stratigraphically, the Artesia and Exposition aquifers lie above the Gage aquifer, described subsequently, and are generally deeper than the Gaspur aquifer, although some of the upper coarse members abut directly into the Gaspur aquifer and may be of the same age. At Boyle Heights and other places, the Artesia and Exposition aquifer have been uplifted and are now higher in elevation than the adjacent Gaspur aquifer. Lower members of the Exposition continue beneath the Gaspur aquifer and merge laterally with the Artesia aquifer. The Exposition aquifer merges with the underlying Gage aquifer approximately three miles northwest of downtown Los Angeles and also in the triangular area between the easterly and westerly arms of the Gaspur aquifer on the Montebello Plain,as shown on Plate 12, "Lines of Equal Elevation on the Base of the Gage and Gardena Aquifers".

AR0068907

The Potrero fault is the only known structure that displaces the Exposition aquifer. However, both the Artesia and Exposition aquifers have been affected by folding and show slight warping near the Newport-Inglewood uplift and in the downwarped area of the Central Basin.

Gage Aquifer. The basal or lowest member of the Lakewood formation is termed the Gage aquifer. The name "200-foot sand" was applied to this aquifer by Poland, et al (1948 and 1959a), later by Richter (1950) and in the "Report of Referee", (Calif. D.W.R. 1952a). Originally the designation of the "200-foot sand" was used because the aquifer occurred about 200 feet below land surface in the syncline extending from Inglewood southeasterly through Gardena. In the Central Basin the base of the aquifer varies from 100 to over 350 feet below the surface; consequently the term "200-foot sand" is inapplicable. The lowest elevation this aquifer attains is in the vicinity of Lynwood, where an elevation of 350 feet below sea level occurs. The Gage aquifer extends over most of the Coastal Plain of Los Angeles County, although insufficient data is available to verify its extension beneath the Santa Monica Plain. Contours on the base of the aquifer are shown on Plate 12.

The composition of the Gage aquifer varies from a fine to medium sand with variable amounts of gravel, sandy silt, and clay in the West Cosst Basin, to a coarse yellow sand and minor gravel (two to four inches in diameter) in the center of the Central Basin, and to a fine yellow sand and gravel toward the Whittier Narrows region. The thickness varies from 10 feet to a maximum of 160 feet in the Torrance area. The thickness of the aquifer is shown on Plate 13, "Lines of Equal Thickness of the Gage and Gardena Aquifers".

AR0068908

Deposits that comprise this aquifer are of both marine and continental origin. Along the northerly boundary of the Central Basin, that is, along the base of the Santa Monica Mountains and the Elysian and Repetto Hills, the deposits appear to be continental in origin. In the southeastern half of the coastal plain the aquifer consists mainly of mixed continental and marine, or in some areas, solely marine sediments.

Subsurface structures which either cut the aquifer or against which the aquifer terminates are shown on Plate 12. Areas where the aquifer is merged with overlying aquifers are also shown on this plate.

While this aquifer generally consists of sand, wells have been perforated in it only in areas where coarser materials exist. Approximately 200 wells have been drilled into the Gage aquifer in the West Coast Basin in the vicinity of Gardena but it is unimportant as a producing aquifer in other areas.

Gardena Aquifer. In 1950 Richter described the coarse deposits comprising this aquifer within the West Coast Basin under the term "Gardena Water-bearing Zone". In "Report of Referee" (Calif. D.W.R. 1952a) the description of the Gardena Water-bearing Zone was further elaborated. In the present investigation the extent of the Gardena water-bearing zone in the Central Basin was determined and these deposits have been designated the "Gardena aquifer". This term now applies to all of the coarse deposits that are contemporaneous with the Gage aquifer (fine grained deposits) in both the Central and West Coast Basins.

The Gardena aquifer extends inland from Redondo Beach beneath the City of Gardena, across the Newport-Inglewood uplift and into the Central Basin, where it loses its identity near Lynwood. Further inland, identical

AR0068909

coarse deposits are again discernible underlying the Montebello Plain and within the Whittier Narrows. These two areas, however, are separated by the Gage aquifer which underlies that part of the Central Basin where the water-bearing deposits are deepest. In the western part of the coastal plain, the deposits form a strip one to four and one-half miles wide extending from Lynwood to the coast. Other coarse deposits, believed to be at the same stratigraphic horizon, extend southwesterly from the Whittier Narrows and then form two southeasterly trending lobes. One lobe reaches the area south of downtown Los Angeles and the Elysian Hills, and the other extends along the south side of the Santa Fe Springs Plain to the vicinity of Norwalk. The extent of these deposits is shown on Plate 12.

The lithology of the Gardena aquifer in the West Coast Basin is given by Richter (1950) as coarse sand and gravel with discontinuous lenses of sandy silt and yellow to blue clay, with the gravel sizes ranging from pea-size to cobbles three to four inches in diameter and the sand ranging from fine to coarse. Deposits in the Central Basin also contain coarse sands and gravels, with minor lenses of sand, silty clay, and clay. The deposits are similar in thickness and elevation to those of the Gage aquifer and are in direct continuity with the Gage materials. According to Richter (1950), the thickness within the West Coast Basin varies from 50 to 75 feet between the Avalon-Compton fault and the City of Gardena; from 75 to 100 feet west of Gardena, and is over 100 feet where it overlaps the merged Lynwood and Silverado aquifers near the coast. The present study indicates that the Gardena aquifer varies in thickness from 40 feet near Lynwood to 100 feet near Gardena and increases to 160 feet northwest of Torrance. Lines of equal thickness are shown on Plate 13.

AR0068910

As shown on Plate 12, the lowest elevation of the base of this aquifer is 350 feet below sea level in the Central Basin and 200 feet below sea level in the West Coast Basin. On the Newport-Inglewood uplift, as well as in the merged area near the coast, the elevation of the base is 100 feet below sea level.

Richter (1950) indicated that this aquifer was one of fluvial origin since the alignment over the Newport-Inglewood uplift was narrow and perpendicular to probable ancient shore lines; furthermore, these deposits are similar to other Recent alluvial deposits in Dominguez and other Gaps. However, Poland (1959a) suggested that this coarse deposit may have been laid down beyond a shore line fringing the Newport-Inglewood uplift. Work in conjunction with this investigation, however, leads to the same conclusion outlined by Richter.

Some ancestral river flowing southwesterly incised a channel across the Newport-Inglewood uplift and eroded away most of the sediments comprising the Gage aquifer ("200-foot sand"). In this channel coarse fluvial deposits were laid down during a subsequent rise of sea level. Coastward from the uplift some shells have been found in wells drilled in this aquifer suggesting that fluvial action may have been affected by shallow lagoons or estuaries. From further study conducted during this investigation, it appears that the Rio Hondo-San Gabriel River systems have been the principal transporting agencies for sediments comprising the Gardena aquifer. However, because the two inland lobes of the Gardena aquifer extend parallel to the inland foothills there is a possibility that the Los Angeles River may have deposited portions of it.

In the Whittier Narrows, the Gardena aquifer is cut by the Rio Hondo fault shown on Plate 7, and it has been folded up to 11 degrees along

AR0068911

the edge of the area near Boyle Heights. Recent uplift along the crest of the Rosecrans anticline has arched the Gardena aquifer, and this is shown on Plate 12 by contours plotted of the base of the aquifer.

The Gardena aquifer has yielded large quantities of water to wells. Because of its coarse texture and continuity, it is an important aquifer in the coastal plain. It is in hydraulic continuity with the Gage aquifer throughout most of its extent and for this reason the isopachs (lines of equal thickness) and elevation contours are plotted on the same maps as the Gage aquifer.

San Pedro Formation. The San Pedro formation has previously been defined to Poland, et al (1945, 1948, 1956, 1959a), as "that stratigraphic unit underlying the unnamed upper Pleistocene deposits and overlying the Pico formation of the late Pliocene age..... Essentially, the San Pedro formation embraces all strata of lower Pleistocene age." Richter (1950) defined the San Pedro formation as "all of the deposits of lower Pleistocene age which underlie West Basin." The original type section of the San Pedro formation contained San Pedro sand, Timms Point silt, and Lomita marl; however, Poland has stated that the San Pedro formation "includes some strata that are younger and may include some that are older than any exposed in the type section cited."

Eckis, (Calif. D.W.R., 1934) used the term "Fernando Group" for the lower Pleistocene and upper Pliocene strata that occurs along the inland foothills of the coastal plain. Since this term included the upper Pliocene deposits, not considered important fresh-water-bearing sediments, the designation "San Pedro formation" is used in this report for the heterogeneous materials comprising the lower Pleistocene horizons.

AR0068912

The San Pedro formation underlies most, if not all, of the Coastal Plain of Los Angeles County as well as portions of the Santa Monica and San Pedro shelves offshore. In the type section along the north flank of the Palos Verdes Hills the San Pedro formation is composed of stratified sand with some beds of fine gravel, silty sand, and silt. Crossbedding occurs frequently in the outcrop. Some pebbles of limestone, siliceous Miocene shales and schist are also found. Away from the Palos Verdes Hills the percentage of granitic fragments increase. In 1950, Richter described the lithology of the San Pedro formation as it occurs in West Coast Basin as "gray sand, which weathers brown or reddish brown on exposure, and interbeds of small gravel are characteristic. Sand and gravel fragments are mainly granitic, indicating a common source area, probably the San Gabriel Mountains". Fine-grained members are generally marine type, blue to black clays, sea muds, or quicksand with abundant shells. The Anchor silt found in the Cheviot Hills (Rodda, 1957) is one of these members. It is correlative with the Timms Point silt, of lower Pleistocene age, and to the lower part of the San Pedro formation. The Coyote silt found in the Coyote Hills (Hoskins, 1954) is also of lower Pleistocene age and resembles the Anchor silt.

The thickness of the San Pedro formation is about 1050 feet beneath the Downey Plain along the South Gate-Santa Ana Depression, and increases to a maximum of 1350 feet in the area about two miles east and southeast of Norwalk along the Norwalk synclinal axis. Where section C-C'-C" (Plate 6b) crosses the Rosecrans anticline, the thickness is 570 feet. Within the West Coast Basin the thickness is greatest along the Gardena syncline, varying from 400 feet about 1 1/2 miles west of Inglewood to 500 feet 1 mile north of Hawthorne, 700 feet at Gardena, and to as much as 1050 feet near the intersection of Carson and Alameda Streets.

AR0068913

The San Pedro formation crops out along the south side of the Repetto, Merced, and Puente Hills; on the Coyote Hills, Baldwin Hills, and Beverly Hills; along the north side of the Palos Verdes Hills; and on Signal Hill. Around the margins of the coastal plain, the San Pedro formation is upturned, and in some local areas is beveled and capped by younger strata.

Most of the structures encountered within the area of study affect at least part of the San Pedro formation. Elevation contour maps on the bases of the aquifers that comprise this formation indicate which fault or faults displace the aquifers. Much folding and warping, along with erosion, also has affected many of the aquifers. The structures affecting the San Pedro formation will be discussed in the descriptions of individual aquifers to follow.

On Plate 3 the San Pedro formation, where it appears at the ground surface, is represented by the symbol "Qsp". Although the formation is shown as one unit for convenience, it has been divided into various stratigraphic units or members. Only those members capable of storing or conveying ground water in suitable quantities have been named as aquifers, while the intervening finer-grained zones were not named. In downward succession, excluding the fine-grained interbedded layers, the aquifers are: The Hollydale aquifer, the Jefferson aquifer, the Lynwood aquifer ("400-foot gravel"), the Silverado aquifer, and the Sunnyside aquifer. Since most of the important aquifers used for production within the coastal plain are contained within the San Pedro formation, their complex water-bearing characteristics are discussed in Chapter VI rather than in the following description.

AR0068914

Hollydale Aquifer. The uppermost aquifer within the San Pedro formation is named the Hollydale aquifer. Although discontinuous in extent, it reaches from the Newport-Inglewood uplift north and northeastward to the south line of the Elysian, Repetto, Merced, and Puente Hills, and eastward and southeastward to and beyond the Los Angeles-Orange County line. Plate 14, entitled "Lines of Equal Elevation on the Base of the Hollydale Aquifer", shows the sinuous irregular courses of this aquifer.

The lithology of this aquifer is variable and consists of yellow sands and gravels (pea-size to two inches) in the northeastern portion of the area, while grey, blue, and black sands, with muds, clays, and marine shells become more predominant toward the Newport-Inglewood uplift. Well log reports are the only means of determining the lithology for this aquifer because it does not crop out on the surface. The well logs indicate that some of the marine sands are mushy, while others are cemented and hard.

The irregular, sinuous, and meander-like courses of the aquifer suggests a stream deposition, but the lithology of the aquifer over three-fourths of the area indicates shallow marine deposition. Because the two main lobes of the aquifer open toward the Los Angeles and Whittier Narrows, it is assumed that streams flowing through these two narrows have controlled the deposition of those parts, while a part of the sediments were laid down beneath shallow water in lagoons or estuaries.

Lines of equal thickness of this aquifer are shown on Plate 15, "Lines of Equal Thickness of the Hollydale Aquifer". The thickness varies from less than 10 feet to a maximum of 100 feet near Lakewood.

In stratigraphic position the Hollydale aquifer is the first important aquifer beneath the Gage-Gardena aquifers. The Hollydale aquifer is overlain and underlain, in most areas, by fine-grained members or aquicludes

AR0068915

of the San Pedro formation. Elevation contours on the base of the Hollydale aquifer and areas of mergence with overlying aquifers are shown on Plate 14. The aquifer attains its greatest depth at an elevation of 500 feet below sea level about two miles east of Compton. In the area between the towns of Norwalk and Bellflower, the depth is about 450 feet below sea level. The slope of the base of the Hollydale aquifer is generally toward these two areas of greatest depth.

Upfolding along the Newport-Inglewood uplift has apparently limited the depositional area of the Hollydale aquifer to the Central Basin. Within the Central Basin the aquifer does not exist in upfolded areas. Downfolding along the axis of the Paramount and Norwalk synclines has, however, placed the base of the aquifer at an elevation of 500 feet below sea level.

This aquifer apparently does not yield large quantities of water to wells, therefore few wells are perforated in this interval and even then only when producing horizons above and below are also perforated. Low productivity of the Hollydale aquifer may be due to the fineness of the materials of which it is composed and the lack of continuity in its extent.

Recharge of the Hollydale aquifer can be accomplished only where it merges with the overlying Gage or younger aquifers (Plate 14) because of the absence of outcrop areas.

Jefferson aquifer. Within the Central Basin, the second aquifer in downward succession within the San Pedro formation is designated the Jefferson aquifer. This aquifer extends over most of the Central Basin, although it is not known to reach the surface. Lobes of this aquifer extend into the Whittier Narrows, into the La Brea Plain, and south of the Coyote Hills through Buena Park into Orange County. Within the boundaries of

AR0068916

the aquifer, some irregular areas exist where the aquifer has not been identified, as indicated on Plate 16, "Lines of Equal Elevation on the Base of the Jefferson Aquifer". This aquifer has not been located in the West Coast Basin. The Jefferson aquifer occurs in sinous courses extending from both the Los Angeles and Whittier Narrows into Orange County.

The lithology of the Jefferson aquifer is known only from drillers logs of water wells. The sediments comprising this aquifer are, for the greater part, fine-grained. Gravels are most extensive in the Whittier Narrows but also occur in scattered patches through the rest of the Central Basin. The remainder of the aquifer consists primarily of sand with some gravelly and clayey lenses.

From the pattern of distribution of sediments comprising this aquifer, source areas are assumed to have been the San Fernando and San Gabriel Valleys and their surrounding highlands. The Los Angeles and San Gabriel Rivers appear to have transported the material through the Los Angeles and Whittier Narrows into or through three possible areas: the La Habra Piedmont slope, the Buena Park area, and southward toward Seal Beach. Extensions of these areas into Orange County have not been determined.

The thickness of the Jefferson aquifer is shown on Plate 17, "Lines of Equal Thickness of the Jefferson Aquifer", and varies from a few feet to a maximum of 140 feet along the Los Alamitos fault. At Norwalk the Jefferson aquifer is 120 feet thick. The Jefferson aquifer has been considerably folded and its base varies in elevation from 700 feet below sea level to 50 feet above sea level.

Structures that affect the Jefferson aquifer are the Los Alamitos, Rio Hondo, Pico, and Cherry Hill faults, and possibly the Seal Beach fault.

AR0068917

It is believed that the general upwarped area along the Newport-Inglewood uplift has controlled or confined to the Central Basin the deposition of sediments comprising this aquifer.

Although it does not crop out on the surface, the Jefferson aquifer does merge with the overlying Hollydale aquifer and also with the Gage aquifer along the Elysian Hills, Repetto Hills, and within the Whittier Narrows. These areas of mergence are shown on Plate 16.

Artificial recharge within the Whittier Narrows would have some effect on this aquifer. Since less than 10 percent of the wells in the Central Basin are perforated in this horizon, and then only in areas where coarse sandy and gravelly zones are found, it is not considered an important water producing aquifer.

Lynwood Aquifer. The Lynwood aquifer is the term used for the third aquifer in stratigraphic sequence within the San Pedro formation. The term "400-foot gravel" has been applied to this aquifer in the West Coast Basin. This latter term was first used by Poland (1948) and defined as "a distinct water-bearing zone in the upper part of the San Pedro formation .... its base is about 400 feet below land surface along the axis of the syncline" (southwest of the Newport-Inglewood uplift). Plate 18, "Lines of Equal Elevation on the Base of the Lynwood Aquifer", and Plate 19, "Lines of Equal Thickness of the Lynwood Aquifer" show the extent, elevation of the base, and thickness of this aquifer.

The Lynwood aquifer extends throughout the Central and West Coast Basins and its existence has been verified in the Hollywood Basin. There is no evidence to show that it exists in the Santa Monica Basin, nor has it been identified in the Baldwin Hills.

AR0068918

Materials of which the Lynwood aquifer is composed appear to be both continental and marine in origin. Continental deposits, of yellow, brown, and red coarse gravels, sands, silts, and clays, are found in the vicinity of the Montebello Forebay Area. A line bounding this area extends from the Whittier Narrows to Bellflower, thence to Compton, South Gate, Huntington Park, and back to the Whittier Narrows. One arm of continental sediments extends from the area just described toward Hawthorne. Sediments of the Lynwood aquifer surrounding the Montebello Forebay Area are mostly marine deposits and are characterized by sand and gravel and blue, grey, and black silts and clays. Some of the sands and gravels have been cemented. The several areas where the marine deposits consist predominantly of fine-grained materials vary from less than 100 acres to about six or seven square miles in extent, and are shown on Plate 19.

From the study of well logs and the materials from wells drilled into this aquifer, it appears that the Rio Hondo and San Gabriel River systems have been the major contributing source for the continental sediments. Marine-type deposits appear to have been laid down when the area was covered by shallow seas.

The Lynwood aquifer ranges from less than 50 feet to about 200 feet in thickness near Wilmington, as shown on Plate 19. Near Lakewood, Torrance, Inglewood, and Montebello it is about 150 feet in thickness. The base contours and lines of equal thickness are not shown west of the Gardena syncline because of mergence with the Silverado aquifer.

In stratigraphic sequence the Lynwood aquifer is overlain and underlain in most of the area by fine-grained materials such as clays, silts, and sandy and silty clays. It is beneath the Jefferson aquifer and above the Silverado aquifer. Known areas of mergence with the overlying aquifers

AR0068919

are shown on Plate 18, while the areas of mergence with the Silverado aquifer are shown on Plate 20, "Lines of Equal Elevation on the Base of the Silverado Aquifer".

Folding has been the primary structural factor affecting the Lynwood aquifer. Upfolding or upwarping has occurred along the coast in the West Coast Basin, over the Newport-Inglewood uplift, in the Artesia area over the Santa Fe Springs uplift, along the edge of the Elysian, Repetto, and Puente Hills, and within the Whittier Narrows. Downwarping has affected the aquifer in the Hawthorne-Long Beach depression extending to San Pedro, within the South Gate-Santa Ana depression (includes Paramount and Norwalk synclines), and within the La Habra syncline. Within the West Coast Basin the Charnock fault has offset the Lynwood aquifer. Along the Newport-Inglewood uplift, the Inglewood, Potrero, Avalon-Compton, Cherry Hill, Northeast Flank, and other associated transverse faults cut the aquifer. Within the Central Basin the Los Alamitos fault offsets the Lynwood aquifer as does the Rio Hondo and Pico faults within and south of Whittier Narrows.

The Lynwood aquifer is an important producer of ground water and is discussed in more detail in the descriptions of the ground water basins in Chapter VI. Most wells in the coastal plain drilled to or below this aquifer are perforated in it. Yields of wells perforated only in the Lynwood aquifer vary from 200 to 2100 gallons per minute.

Surface and subsurface flow of water through the Whittier Narrows moves downward through the shallow aquifers into the Lynwood aquifer. Water is also artificially spread in shallow pits below the Whittier Narrows where the Lynwood aquifer is in contact with the permeable materials extending upward into the pits, thus permitting this water to reach the Lynwood aquifer. This artificial method of recharging is not generally

AR0068920

applicable in other areas where the Lynwood aquifer is merged with the overlying aquifers because of the greater depth of those aquifers as well as the Lynwood aquifer below the surface, the lack of continuous permeable materials to conduct water vertically downward, and the lack of available space for large surface pits. In these areas, therefore, other methods of recharge would be necessary, such as injection wells drilled into and perforated in this aquifer.

Silverado Aquifer. The Silverado aquifer is the name applied in this report to those water-bearing materials which are stratigraphic equivalents of the "Silverado Water-Bearing Zone" in the West Coast Basin. Originally named by Poland, et al (1956), from its typical occurrence in a well in Silverado Park, Long Beach, the Silverado Water-Bearing Zone has been found throughout the rest of the Coastal Plain of Los Angeles County and extends across the Los Angeles County line into Orange County. For the purpose of this report the term, "Silverado aquifer", will apply to these materials throughout the Coastal Plain of Los Angeles County. Areas of Pleistocene deposits occurring in the Santa Monica and San Pedro shelves offshore may be continuations of the Silverado and underlying Sunnywide aquifers. Plate 20 shows the known extent and elevation contours of the base of the Silverado aquifer.

Sediments comprising the Silverado aquifer are both continental and marine. Where continental deposits predominate, yellow to brown, coarse to fine sands and gravels are interbedded with yellow to brown silts and clays. Marine deposits which comprise the Silverado aquifer over the remainder of the basin are primarily blue to grey sand, gravel, silt, and clay. Some black sands, quicksand, marine shells, peat, and wood fragments

AR0068921

are also shown on drillers logs of wells located in the area of marine sediments. In the West Coast Basin, Richter (1950) describes the lithology as fine to coarse, blue-black arkosic sand with the larger grains composed of granite, granodiorite, and diorite. Along the flanks of the Palos Verdes Hills, limestone and schist pebbles are abundant, while in the Ballona Gap area slate, schist, and volcanic pebbles are commonly found.

The ancestral Rio Hondo and San Gabriel River systems have been the major transporting agent for materials comprising the continental portion of the Silverado aquifer in Central Basin, although some contributions may have been added by the Santa Ana River flowing in one of its earlier courses. The regional evidence indicates that the Los Angeles River did not flow into the coastal plain during much of the lower Pleistocene time and probably did not contribute sediment to the Silverado aquifer. However, streams flowing from the Santa Monica Mountains, Elysian Hills, and Palos Verdes Hills have added debris from these areas. Much of this material was deposited beneath the shallow ocean that covered the coastal plain at this time. The continental deposits appear to have been laid down when the sea was retreating from the coastal plain.

The varying thickness of the Silverado aquifer is depicted on Plate 21, "Lines of Equal Thickness of the Silverado Aquifer". This aquifer reaches a maximum thickness of 500 feet between the Wilmington anticline and the Cherry Hill fault. One mile west of Lakewood, along Carson Street, the Silverado aquifer is 450 feet thick. Along the south side of the Santa Fe Springs Plain and also two miles southeast of Huntington Park it is 300 feet thick.

The maximum depth reached by the base of the Silverado aquifer, 1200 feet below sea level, is found southwest of the Cherry Hill fault

AR0068922

within Dominguez Gap, along the north side of the Los Alamitos fault, and about three miles southeast of Norwalk. A depth of 1100 feet below sea level occurs near Long Beach Harbor.

The Silverado aquifer crops out along the northeast flank of the Palos Verdes Hills, possibly on the continental shelf beneath Santa Monica Bay, along the southern margin of the Baldwin Hills, in the Repetto and Merced Hills, along the south slope of the Puente Hills, and possibly in the Coyote Hills. Outcrops in the areas named are shown as the San Pedro formation, Qsp on Plate 3, because insufficient data are available to definitely identify the aquifer involved.

Areas where the Silverado aquifer merges with overlying aquifers are shown on Plate 20. In the Montebello Forebay Area and Whittier Narrows the Silverado aquifer is directly overlain by and merges with aquifers younger than the Lynwood aquifer. Merged areas are irregular in extent but are generally found along the Newport-Inglewood uplift, in the area from Huntington Park to Santa Fe Springs, and also within the Whittier Narrows. In the West Coast Basin the Silverado is merged with the overlying Lynwood aquifer everywhere except beneath the Gardena syncline and the Wilmington anticline. Near Santa Monica Bay the Silverado aquifer is in hydraulic continuity with the Gardena and Gage, as well as the Lynwood aquifers. In the Montebello Forebay Area the Silverado aquifer merges with the overlying Lynwood, Jefferson, Hollydale and Gardena aquifers, as delineated on Plate 20A.

The Silverado aquifer has suffered a greater degree of folding than the overlying Lynwood aquifer. It has been deformed by all of the major anticlinal and synclinal folds. All the major faults shown on Plate 3 seem to have affected this aquifer. After faulting occurred, the aquifer

AR0068923

may be found at either different or the same elevation but separated by a region of altered permeability. Sufficient data is lacking to determine whether the geologic structure just south of Santa Fe Springs is a fault or downfold. On the basis of the data available it is believed that the postulation of a sharp downfold would explain the existing structure in a more adequate manner than the assumption of a fault.

This aquifer is one of the most important ground water producers in the coastal plain. Specific capacities of wells perforated in it range up to a maximum of 159 gallons per minute per foot of drawdown and yields range up to 4700 gallons per minute.

In the Whittier Narrows the Silverado aquifer is merged with many overlying aquifers and recharging the shallow aquifers in that area would cause additional water to reach the Silverado aquifer. Recharge from the surface in the Los Angeles Forebay Area may also reach the Silverado aquifer where it is truncated by the Gaspur. Other possible recharge areas for the Silverado aquifer are in the outcrop along the Coyote and Baldwin Hills, or in the Ballona Gap, where the Silverado aquifer is directly beneath the Ballona aquifer and close to the surface. Natural recharge takes place in those areas shown on Plate 3 where the San Pedro formation crops out on the surface.

Sunnyside Aquifer. The water-bearing materials occurring within the Central Basin beneath the Silverado aquifer but above the Pico formation have been termed the "Sunnyside aquifer" after a typical occurrence illustrated by the log of a well located in Sunnyside Cemetery in North Long Beach.

The Sunnywide aquifer extends throughout the Central Basin. Its extent and elevation of its base are shown on Plate 22, "Lines of Equal

AR0068924

Elevation on the Base of the Sunnyside Aquifer". Recent drilling along the coastal region from Palos Verdes Hills to Ballona Escarpment has revealed a zone of coarse deposits approximately 500 feet thick occurring beneath the Silverado aquifer, but separated from it by silts and clays. These coarse materials are similar to the Sunnyside aquifer in the Central Basin and may be the extension of the Sunnyside aquifer in the West Coast Basin.

The materials comprising this aquifer are coarse-grained sands and gravels sepsrated by fine-grained interbeds of sandy clay and clay. The lithology shown on a typical well log near the intersection of Del Amo and Cherry Streets is compacted blue sand, coarse blue gravel (up to four inches in diameter), hard blue sandy clay, and clay. Toward the Los Angeles-Orange County line, mushy blue sands and coarse gravels with greater amounts of blue clay are found. At Spring Street and Bloomfield Avenue, well logs indicated that instead of clay, fine blue sand with minor clay streaks was present. Along the center of the coastal plain, about one mile north of Manchester and near Alameda Avenue, fine to medium gravel (one quarter to one inch in diameter), and partly cemented blue clay, and grey to brown shale are typical materials. In Whittier Narrows hard grey sands and gravels, boulders, and blue sandy shale are present.

From drillers descriptions of materials, it is believed that the aquifer is of marine origin and has been affected very little by weathering. Many well logs show marine shells included with the sediments in addition to the interbedded marine-type clays and shales.

The Sunnyside aquifer attains its maximum known thickness of about 300 feet about one to one and a half miles southeast of Maywood in the vicinity of Slauson Avenue and the Long Beach Freeway. Plate 23, "Lines of Equal Thickness of the Sunnyside Aquifer", gives the thickness of the

AR0068925

Sunnyside aquifer. No data is available to determine thickness in the central downfolded area because none of the water wells have reached the aquifer in this area.

It is not definitely known whether the Sunnyside aquifer crops out in any particular location within the Central Basin; however, it is assumed that some of the outcrop areas shown as the San Pedro formation on Plate 3 include the Sunnyside aquifer also. The most likely areas for this to occur are along the south slope of the Repetto, Merced, and Puente Hills, and especially on the top of the Coyote Hills.

In stratigraphic position the Sunnyside aquifer is overlain by the fine-grained Timms Point silt and Lomita marl and underlain by the Pico formation. It may be correlated in age with the unit mapped by Hoskins (1954) as the Coyote silt, the Anchor silt of Rodda (1957), and the La Habra conglomerate of Eckis (Calif. D.W.R., 1934).

Structurally, the Sunnyside aquifer is offset by most, if not all, of the faults within the Central Basin. Some of the faults appear to act as boundaries for the aquifer. Northeast of the Los Alamitos fault the base of the Sunnyside aquifer occurs at a maximum depth of about 1500 feet below sea level.

The Sunnyside merges with the Silverado and other overlying aquifers in many areas delineated on Plate 22, "Lines of Equal Elevation on the Base of the Sunnyside Aquifer". In these merged areas hydraulic continuity is possible through a series of aquifers to the surface. The only known areas where this aquifer may be recharged are limited to outcrops of the San Pedro formation and merged areas where folds have lifted the Sunnyside aquifer near the surface of the ground.

AR0068926

Yields of wells perforated in this aquifer range up to 1500 gallons per minute. Specific capacities of known wells using only this aquifer for production are only fair, ranging from 6 to 25 gallons per minute per foot of drawdown.

Undifferentiated Plio-Pleistocene Sediments

An area of sediments of either Pliocene or Pleistocene age, or possibly both, is shown on Plate 3 in the Repetto Hills southeasterly of Monterey Park. In the geologic literature these sediments have been classified variously as both Pliocene and Pleistocene. Although various fossils are present, age designation based upon them is uncertain. While these sediments are somewhat permeable they have relatively little significance as far as ground water in the coastal plain is concerned; therefore, no attempt was made to determine their age.

These undifferentiated sediments consist of thin bedded to massive silts, sands, and gravels that are locally well indurated and contain limited marine fossil remains. The sediments have been folded and many minor faults and fractures are seen in outcrops.

Although these sediments are considered to be relatively unimportant as far as ground water is concerned, a drainage well constructed in 1959 reportedly yields fair quantities of good quality water. Firm conclusions, however, cannot be drawn from this limited experience.

Tertiary System

Aquifers have not been differentiated in sediments and rocks older than Pleistocene age because of limited well log data. Few wells extend into these materials and little ground water of suitable quality is extracted from them. Some fresh water is now being extracted from the upper member

AR0068927

of the Pico formation, discussed first in this section. For pre-Pleistocene materials in general, the sediments and rocks are described by formations or broad age classification.

Pliocene Series

The Pliocene series is divided into two formations, the Pico formation and the Repetto formation. In addition, the Pico formation is divided into upper, middle, and lower divisions.

Pico Formation. The Pico formation is shown, where it outcrops at the surface, on Plate 3 by the symbol "P_p". The upper division or upper member of the Pico formation is a potential source of ground water. It has not been exploited to date, though wells along Carson Street near Lakewood do obtain water from upper Pico aquifers. This member is thickest in the synclinal areas, and it outcrops on the hills surrounding the coastal plain.

The upper Pico formation is generally composed of sand, silt, and clay of marine origin interbedded with marine gravels. Beds of gravels and sands range in thickness from 20 to 100 feet and are separated by beds of micaceous siltstone and clays.

Unconformably beneath this upper member are the middle and lower members of the Pico formation, or in some areas, the Repetto formation. The middle and lower divisions of the Pico formation are differentiated from upper Pico sediments by the contained foraminiferal faunas. Lithologically, the middle and lower divisions are composed of greenish-grey micaceous siltstone and fine to coarse light grey feldspathic sandstone interbedded with claystone and shale. The thickness of these lower division materials ranges from 400 to more than 2,000 feet. Throughout most of the coastal plain these rocks are far below the depths reached by the deepest

AR0068928

water wells. Oil well data indicate that, although portions of these sediments may be sufficiently permeable to transmit water in usable quantities, the water is of poor quality and unsuitable for general use.

Repetto Formation. The Repetto formation, of early Pliocene age, is exposed in several areas adjacent to the coastal plain. The outcrops of this formation are identified by the symbol "Pr" on Plate 3. These deposits are composed mostly of siltstone with layers of sandstone and conglomerate, containing fragmental marine shells locally. The Repetto formation is about 5,000 feet in thickness. Wissler (1943) states that the maximum thickness occurs in the Montebello-Santa Fe Springs area. Conrey (1958) and Slosson (1958) confirm this and discuss the distribution and thickness of the Repetto rocks in some detail.

Miocene Series

Rocks of Miocene age are shown on Plate 3 by the symbols "Ms" for sedimentary rocks and "Mv" for volcanic rocks. Nomenclature of the sediments of Miocene age is somewhat complicated; however, the relationship between the various names and brief descriptions of the various formations are presented in Table 1.

Sedimentary Rocks. Sedimentary rocks of middle and late Miocene age have been called the Monterey formation in the Palos Verdes Hills, the Modelo formation in the Santa Monica Mountains, and the Puente formation beneath the coastal plain and in the Repetto and Puente Hills. These formations, up to 11,000 feet thick, consist predominantly of clay shales but siliceous shales, sandstones, and conglomerates are common.

AR0068929

The Topanga formation is of middle and possibly early Miocene age. It is interbedded with and lies below the Miocene volcanic rocks. The formation attains a thickness of 7,500 feet and consists of shale, sandstone, and conglomerate.

No wells are known to produce fresh water from these formations in the immediate area of the coastal plain. However, water wells in other parts of Southern California do obtain limited supplies from hard fractured shales and poorly consolidated sandstones and conglomerates of these formations.

Volcanic Rocks. Calcic andesite flows, tuffs, and breccias underlie at least parts of the coastal plain, and usually contain interbedded marine sand, conglomerate, and shale. Where these materials outcrop on the surface they are identified by the symbol "Mv" on Plate 3. Available data indicate that the fractured sills, dikes, and flows, along with interbedded sand and gravels, yield water to wells, while the conglomerates and agglomerates are relatively nonwater-bearing.

Older Tertiary Sedimentary Rocks

Rocks of Eocene and Oligocene age are missing beneath West Coast Basin, though they may underlie the Central Basin. Hoots (1931) gives some evidence for the presence of the Sespe and Vaqueros formations of Oligocene(?) or early Miocene age in the Santa Monica Mountains. Paleocene rocks crop out in the Santa Monica Mountains and may underlie a part of the coastal plain. Hoots (1931) termed these rocks the Martinez formation. Other exposures of Martinez sandstone and conglomerate were found in the Santa Monica Mountains by Durrell (1954) and others. Outcrops of Eocene and Oligocene rocks are shown on Plate 3 by the symbols "E" and "Ø", respectively, while outcrops of Paleocene rocks are marked by the symbol "E-K".

AR0068930

Cretaceous System

A sequence of Upper Cretaceous sediments within the Santa Monica Mountains are differentiated and have been called the Chico formation by Hoots (1931). Durrell (1954) however, appears to have divided the same sequence into the Chico and Trabuco formations. The symbol "K_s" represents the areas of outcrops of these rocks on Plate 3.

Quartz dioritic intrusive rocks, shown by the symbol "K_g" on Plate 3 have previously been assumed to be Jurassic by comparison with similar rocks in the Sierra Nevada (Durrell, 1954). On the basis of dating by lead-alpha activity ratios of intrusive rocks in Southern California, Larsen, et al (1958) suggests that these rocks are of an early Late Cretaceous age rather than Jurassic.

Jurassic System

Rocks, called the Catalina schist, crop out on the Palos Verdes Hills and are identified on Plate 3 by the symbol "J". These have been also referred to as the Western bedrock complex because they underlie Miocene rocks of the West Coast Basin. The age of these schistose rocks is questionable and, according to Woodford, et al (1954), may be either Mesozoic (when compared to the Jurassic Franciscan formation of the coast ranges) or Precambrian (when compared with the Pelona schist of the San Gabriel Mountains). In this report they are mapped as Jurassic.

Triassic System

Metamorphosed black shale and sandstone crops out in the Santa Monica Mountains and have been called the Santa Monica slate (Hoots, 1931) and the Santa Monica formation (Durrell, 1954). Intrusion of these rocks

AR0068931

by the quartz dioritic magma was responsible for changing these rocks into grey to black slates, mica schists, and spotted slates. These rocks are dated as Triassic by comparison with similar rocks of Triassic age in the Santa Ana Mountains. In the coastal plain, these are presumably the oldest rocks known, although the Cataline schist mentioned under the Jurassic System may possibly be older. These Triassic rocks are identified on Plate 3 by the symbol "T_R".

AR0068932

CHAPTER V. GEOLOGIC STRUCTURE

Geologic structural features within the Coastal Plain of Los Angeles County have a pronounced effect upon ground water movement and storage. Faulting offsets aquifers, creates zones of cementation and low permeability, and generally disrupts the flow of subsurface waters. Folding and faulting raise aquifers either to or near the land surface, thereby enhancing the possibility of recharge. In some instances, uplifted fault blocks and folds are deterrents to ground water movement where structural highs of bedrock disrupt or change the course of ground water movement. Locally, aquifers are partially or entirely eroded away across these features, or are being dewatered because of the lowering of ground water levels. Elsewhere, ground water reservoirs are formed in structural lows created by faulting and synclinal folding of aquifers.

The tectonic forces which produced the structural deformation within and adjacent to the coastal plain were continuous throughout Tertiary time and possibly Quaternary time. This deformation, however, was most severe during mid-Miocene, Pliocene, and Pleistocene time. Sediments of Recent age have not been seriously disturbed, even though earth movements have been recorded during historic time.

Descriptions of individual geologic structures presented in this chapter are of necessity brief. Emphasis is given to those structures which influence ground water movement. Heretofore unrecognized or unpublished subsurface structural features have been noted during the course of this investigation. Most of these features are not evident from surface topography even though some of them affect relatively shallow sediments.

AR0068933

The structural characteristics of Pleistocene and Recent aquifers were determined by constructing geologic cross sections and maps showing lines of equal elevation on the bases of aquifers. Available geologic maps and subsurface maps of oil field structures were used to help determine the structural patterns of the various aquifers and underlying Tertiary formations. The locations of faults and fold axes in these Tertiary formations, however, do not necessarily coincide with locations of similar structures in the Pleistocene sediments.

Those structures which have a surface expression or which affect water-bearing sediments are included in the areal geology shown on Plate 3.

Regional Features

Geologic structures within and bordering the coastal plain are generally aligned along regional uplifts and depressions. For descriptive purposes, these are herein grouped into the "Mountain and Foothill structures", "Transitional structures", the "South Gate-Santa Ana depression", the "Newport-Inglewood uplift", the "Hawthorne-Long Beach depression", and "Offshore structures". These structural systems are reasonably distinct, but where systems join, local structural features may be common to each of the systems.

The coastal plain is bordered to the north, northeast, and southwest by mountains and hills which have been uplifted by folding and faulting. The hills bordering the northeast margins of the coastal plain are flanked to the south by the Transitional structures consisting of partially buried anticlines and synclines. The Transitional structures do not constitute one structural system but are grouped together because of their

AR0068934

relative positions. The South Gate-Santa Ana depression, a general northwest trending synclinal depression, underlies the Downey Plain and extends from the La Brea Plain to beyond the investigational area into Orange County. The South Gate-Santa Ana depression is bordered on the northeast by transitional structures and on the southwest by the Newport-Inglewood uplift, a system of echelon faults and anticlinal folds. In Los Angeles County, the Newport-Inglewood uplift is bordered on the southwest by the Hawthorne-Long Beach depression, a synclinal depression, which underlies the Torrance Plain and extends northwest from the City of Long Beach toward the Santa Monica Mountains. On the west side of the Hawthorne-Long Beach depression, beneath the El Segundo Sand Hills, water-bearing sediments of Pleistocene age rise gently as a homocline toward Santa Monica Bay. The Offshore structures affect the water-bearing sediments extending beneath the Santa Monica and San Pedro Bays.

Mountain and Foothill Structures

The northern and eastern margins of the coastal plain are bordered by the Santa Monica Mountains and the Elysian, Repetto, Merced, and Puente Hills. The Palos Verdes Hills border the plain to the southwest. These highlands are almost entirely composed of rocks of pre-Tertiary and Tertiary age and are essentially nonwater-bearing. Therefore, only brief mention of the structural nature of each of these areas will be made. Detailed description of geologic structures within these highlands may be found in many of the references listed in the Bibliography. Between the Merced and Puente Hills is the Whittier Narrows, an erosional gap. Since it is closely associated with the highlands and is the location of the

AR0068935

major subsurface flow to the ground water basins of the Coastal Plain of Los Angeles County, the structures within it are described in detail in this section.

Santa Monica Mountains

The Santa Monica Mountains (Plate 2) are essentially a westerly plunging, asymetric anticline that has had a complex history of development. The anticline has been faulted, deformed by secondary folding, and further complicated by igneous intrusion. Important periods of deformation are recorded by several major unconformities between various formations of Cretaceous and Tertiary age. The Hollywood fault extends along the southern edge of the Santa Monica Mountains and at depth serves as the northerly edge of the Hollywood Basin, one of the ground water basins included in the coastal plain. The fault is buried by sediments of Pleistocene and Recent age.

Elysian Hills

Principal structures in the Elysian Hills include the Elysian Park anticline and secondary folding and faulting which deform its southern flank. The Elysian Park anticline extends southeast across the Los Angeles Narrows and through the Repetto Hills. In the Los Angeles Narrows, the structure has been cut by erosion and Miocene and Pliocene sediments are unconformably overlain by sediments of late Pleistocene and Recent age.

Repetto and Merced Hills

The Repetto and Merced Hills are essentially continuous but are structurally separated by a westerly trending syncline. In both uplift areas, angular unconformities locally exist between Tertiary sediments and the San Pedro formation, and between the San Pedro and Lakewood formations.

AR0068936

North of the San Bernardino Freeway, the Repetto Hills are formed into three nearly parallel fold systems which trend slightly north of west. These consist of a syncline which separates the Highland Park-South Pasadena anticlinal system on the north from the Elysian Park anticline on the south. The Elysian Park anticline is flanked on the south by another syncline and then the Boston Heights anticline.

South of the San Bernardino Freeway, the Repetto Hills are a westerly trending, southerly dipping homocline that is cut by the Coyote Pass fault west of Atlantic Boulevard. The Coyote Pass fault extends westerly along the south flank of the hills, and brings sediments of Pliocene age into fault contact with those of Pleistocene age.

The Merced Hills are a westerly trending, structural high developed by faulting and anticlinal folding. Major structures include the North Montebello thrust fault and the Montebello anticline. These structures are exposed at the surface and are developed in sediments of Pliocene and Pleistocene age. The anticlinal structures containing the East and West Montebello oil fields are developed at depth in sediments of Tertiary age, and are not reflected in water-bearing sediments of Pleistocene and Recent age.

Whittier Narrows Area

The Whittier Narrows area is not itself an uplift, but is a structurally controlled erosional gap located between and structurally related to the adjacent Merced and Puente Hills. Beneath the Whittier Narrows, the sediments of the San Pedro formation, and possibly the Pico formation, are folded into a northeast trending, synclinal depression. Southwest of the Whittier Narrows Dam, the subsurface structure is further

AR0068937

complicated by both block faulting and transverse folding. Sediments of the Lakewood formation unconformably overlie the syncline and are only slightly deformed (Section P-P', Plate 6G).

The synclinal structure underlying the Whittier Narrows separates the anticlinal form of the Merced Hills on the west from the essentially anticlinal structure of the Puente Hills on the east. These anticlinal structures have been cut through by erosion, and are locally interrupted by faulting. The Montebello anticline plunges east into the Whittier Narrows and is reflected in sediments of the San Pedro formation. The anticlinal structure of the Puente Hills, in its western extremity, is cut by the Cemetery fault, as hereafter presented.

The structure of that portion of Whittier Narrows lying directly southwest of the Whittier Narrows Dam is exceedingly complex, and the available data may be interpreted to derive two differing patterns of subsurface structure. One explanation of a portion of the data would picture sharp folding of the sediment parallel to the northeast-southwest trending synclinal axis, possibly coupled with the extension of the Whittier fault through Whittier Narrows perpendicular to the synclinal axis. After careful analysis, however, this theory was held to be inadequate in explaining all data.

This report therefore presents the subsurface structure of Whittier Narrows as being governed by three faults generally parallel to the axis of the syncline. The following discussion of the structural system in the Whittier Narrows is based on the presence of these assumed faults. These faults have been named, from east to west, the Cemetery, Pico, and Rio Hondo faults, and they divide the area into two fault blocks that are tilted to the west. (Plates 3, 6A, and 6G). The available evidence also

AR0068938

indicates that within the Whittier Narrows, water-bearing sediments of Pleistocene and Recent ages are not offset by the Whittier fault. Vertical offsetting along the three parallel faults occurs primarily in the uppermost Pico and San Pedro formations; local displacement of the Lakewood formation occurs along the southern extent of the Rio Hondo fault (Section A-A'-A", Plate 6A). Sediments of Recent age are not disturbed by these faults. Considerable merging of aquifers occurs throughout the narrows and is related to displacement along faults and to unconformities among aquifers of Pleistocene and Recent ages. The pattern of the aquifers and their relationship to the fault system in this area are shown pictorially in the cut-away diagram on Plate 7.

The Rio Hondo fault is about four miles long and generally follows the east side of the Rio Hondo. West of the fault, aquifers of the San Pedro formation are raised close to the surface and are unconformably overlain by the Gardena and Gaspur aquifers (Section A-A'-A", Plate 6A).

The Pico fault, which can be traced for about three miles, is located about one mile east of, and essentially parallel to, the Rio Hondo fault. The fault block west of the Pico fault has been raised relative to that of the east side. The vertical displacement of the San Pedro formation brings different aquifers into hydraulic continuity with each other across the structure, as illustrated on Section A-A'-A", Plate 6A.

The Cemetery fault extends for about two miles along the east margin of the Whittier Narrows, and apparently displaces the west extent of the Puente Hills. The fault block west of the fault is downthrown relative to the east side. Available evidence suggests that the Cemetery fault terminates at the Whittier fault, and is possibly related to this major shear zone.

AR0068939

Two complexly folded and tilted fault blocks are developed between the Rio Hondo, Pico and Cemetery faults. The western block is downthrown on the Rio Hondo fault, and upthrown on the Pico fault. Within this fault block, sediments of the upper Pico and San Pedro formations are folded into an anticline, which trends northeast and crests adjacent to the Pico fault. This high disrupts the synclinal depression in its southwest extremity, as shown by contours drawn on the base of the Sunnyside aquifer (Plate 22). The Gardena aquifer unconformably overlies the anticline and the truncated aquifers of the San Pedro formation. (Section P-P', Plate 6G).

The eastern fault block is downthrown between the Pico and Cemetery faults. Within this block, the San Pedro formation is gently folded as shown on Section N-N'-N", Plate 6F, and by contours drawn on the base of the Sunnyside, Silverado and Lynwood aquifers (Plates 22, 20, and 18). Sediments of the Lakewood formation unconformably overlie these gentle folds, and the Gardena Aquifer merges with the Jefferson aquifer locally across these flexures.

Puente Hills and Whittier Fault Zone

The Puente Hills are essentially a west trending anticline that is complicated by secondary folding and faulting. The predominant structural feature of the Puente Hills is the Whittier fault or fault zone. This major structure trends southeast along the south flanks of the Puente Hills and extends from the vicinity of the Whittier Narrows into Orange County. Northeast of the City of Whittier, the principal fault separates into a complex of smaller breaks and probably diminishes as it approaches the Whittier Narrows. Available oil well data indicate that it is a high angle reverse fault, with the north side rising over the south side at an angle of approximately 70 degrees. Offset drainage of La Mirada Creek and Turnbull and Brea Canyons

AR0068940

in Orange County suggest that right lateral displacement has occurred along the fault in relatively late geologic time, the southwest side having moved several thousand feet northwest relative to the northeast side.

The Puente Hills have been uplifted by vertical displacement along the Whittier fault and by normal faulting along the Workman Hill, Handorf and Rowland fault systems. The hills are further characterized structurally by minor faults, unconformities, and tight and overturned folds in sediments of Miocene, Pliocene and Pleistocene age. South of the Whittier fault zone, an angular unconformity exists between Pico and overlying San Pedro sediments, but both formations have a general southerly homoclinal dip into the La Habra syncline.

Palos Verdes Hills

The Palos Verdes Hills are an uplifted fault block composed of Catalina schist basement and marine sediments of Tertiary and Quaternary age that have been folded into a general anticlinal form. This general anticlinal high extends through the central portion of the hills and may extend beneath alluvial cover into the San Pedro area; it may also continue as a subsea structure beneath the San Pedro Shelf (Moore, 1951).

A fault which extends in a northwest direction along the northern boundary of the hills has been termed the "Palos Verdes Fault Zone" by Woodford, et al (1954). This break, although only partially reflected at the surface by minor faults and steep northeast dipping sediments of Miocene, Pliocene and Pleistocene age, offsets Catalina schist basement at depth. Test drilling by the Los Angeles County Flood Control District has verified the continuity of this fault zone out into the Pacific Ocean near Redondo Beach.

The Gaffey anticline and the Gaffey syncline extend northwest along the northeastern portion of the Palos Verdes Hills. These folds plunge

AR0068941

southeast and apparently extend beneath Recent alluvium east of the hills and into San Pedro Harbor where they may affect ground water movement.

Transitional Structures

Transitional structures are those structural features that lie along the generally south-dipping homoclinal flanks of those mountain and foothill structures to the north and east of the coastal plain. They are also north and northeast of the South Gate-Santa Ana depression. A few of these structures have topographic expression; the remainder are buried beneath upper Pleistocene and Recent sediments. These structures, like most on the coastal plain, are generally best developed in Miocene and Pliocene formations, and for the most part have been determined from subsurface oil exploration studies.

From northwest to southeast, the Transitional structures include the Hollywood syncline, La Brea high, Boyle Heights anticline, Bandini anticline, East Los Angeles anticline, the Santa Fe springs-Coyote Hills uplift, and La Habra syncline. Since the Bandini and East Los Angeles anticlines are developed at depth and do not appear to affect the overlying water-bearing sediments, they are not included in the following discussions of the other Transitional structures.

Hollywood Syncline

The Hollywood syncline is a downwarped area between the Santa Monica Mountains to the north and the La Brea Plain to the south. The syncline plunges to the southwest where it may be displaced by the Inglewood fault. Northeast of Western Avenue the flexure becomes ill defined and is apparently broken up by upfaulted blocks of Tertiary bedrock. The

AR0068942

location of the synclinal axis, as shown by the areal geology on Plate 3A is inferred from available subsurface data.

Ground water moves south and west from the syncline. The Santa Monica Mountains and the Hollywood fault, which truncate the syncline's northern flank, are complete barriers to ground water movement to the north and east. To the south and southeast, ground water movement is impeded by the La Brea high.

La Brea High

The La Brea Plain is closely underlain by a structural high developed in sediments of Tertiary age and unconformably overlain by 100 to 200 feet of the Lakewood formation. The structural nature of the high is known in part. The northwestern portion of the high, which contains the Salt Lake oil field, includes a northwest plunging anticline, a northwest plunging syncline, and a southwest plunging anticline, all in Miocene rocks. South of these folds the structural configuration of bedrock is largely unknown. The south dipping monocline of Tertiary sediments in the Los Angeles oil field may extend west beneath the southern portion of the La Brea Plain and could be the upper expression of the east-west trending Santa Monica fault system described by Barbat (1958).

The crest of the La Brea high is located about one mile south of, and generally parallel to, Santa Monica Boulevard from Western Avenue to near the Inglewood fault. This feature plunges steeply in its western extremity, and the San Pedro formation is continuous from the south into the Hollywood syncline around the warped slope thus formed. Across the crest of the high, sediments of the San Pedro formation have been removed by erosion. Ground water movement from the Hollywood syncline south across

AR0068943

the La Brea high is therefore limited to aquifers of the Lakewood formation, and to the San Pedro formation around the western nose of the La Brea high.

Boyle Heights Anticline

The Boyle Heights anticline contains the Boyle Heights oil field. This structure, developed in sediments of Miocene, Pliocene and Pleistocene age, is essentially a minor anticlinal flexure on the south dipping homoclinal flank of the western Repetto Hills. The anticlinal axis trends southeast: the crest approximately underlies the intersection of 4th and Soto Streets. The fold is asymetric with the north flank dipping more gently than the south flank. Well logs show that the San Pedro formation has been eroded from the crest of the anticline. The Lakewood formation, here approximately 250 feet thick, unconformably overlies the Repetto formation at the crest and the San Pedro formation along the southern flanks of the anticline. Ground water movement across the structure is restricted due to anticlinal folding, thinning of water-bearing section over the crest and the nonwater-bearing core of the Repetto formation.

Santa Fe Springs-Coyote Hills Uplift

The surface of the Santa Fe Springs Plain and the Coyote Hills reflects a structural high which trends northwest from the Coyote Hills in Orange County and is primarily developed in underlying formations of Miocene and Pliocene age. In these sediments, the uplift consists of anticlinal folds which contain the Santa Fe Springs, Leffingwell, and West Coyote oil fields. The San Pedro and Lakewood formations are similarly folded across the uplift, and the folds developed in these sediments generally correspond to the underlying structures.

AR0068944

Santa Fe Springs Anticline. The Santa Fe Springs oil field is contained in an elongated anticlinal dome which trends northwest and underlies the Santa Fe Springs Plain. The fold is symmetrical and has gently dipping flanks. The San Pedro and Lakewood formations are folded over the structure and have a minimum combined thickness of 700 feet above the dome. Contours depicting the base of Pleistocene aquifers show that in the San Pedro and Lakewood formations the fold crest is located slightly north of the axis as defined by the Pliocene beds of the oil reservoir. Contours depicting the base of fresh-water materials correspond to the structural high and indicate that in this area the uppermost Pico sediments contain fresh water.

While some of the shallow aquifers thin out in the area of the Santa Fe Springs anticline, it does not otherwise affect movement of ground water.

Leffingwell Anticline. The Leffingwell oil field is located approximately two miles east of the Santa Fe Springs oil field and is contained in a faulted, eastward plunging, anticlinal nose developed in sediments of Tertiary age. The anticline is offset in its central portion by two northern trending faults which are not definable above sediments of Miocene age. Contours of the base of the Silverado aquifer (Plate 20) reflect the underlying high, but no effect on the movement of ground water is known.

West Coyote Anticline. The West Coyote anticline, an elongated dome, contains the West Coyote oil field and is defined in the outcropping San Pedro formation within that portion of the Coyote Hills immediately east

AR0068945

of the Los Angeles-Orange County line. The anticline trends east-west and is complicated by faulting in the central and western portion and by secondary folding. Dips on the south flank are steeper than on the north flan. Contours of the base of lower Pleistocene aquifers show that the anticline plunges west into Los Angeles County. The coarse gravels exposed at the surface and across the crest are believed to be the Sunnyside aquifer. The uplifted, relatively impermeable upper Pico formation acts as a barrier to the movement of ground water across the anticline.

La Habra Syncline

This syncline is located between the Puente Hills on the north and Santa Fe Springs-Coyote Hills uplift on the south. The axis of the syncline trends slightly north of west and its location (Plate 3) is inferred from available subsurface data. Water-bearing materials extend up both limbs of the syncline and outcrop in the Puente Hills and the Coyote Hills. The syncline is closed at the eastern end by the northeast trending East Coyote anticline. Available data suggests that a saddle exists at the western end of the structure where it disappears into the Whittier Narrows area.

South Gate-Santa Ana Depression

The South Gate-Santa Ana depression is the generally downwarped area which underlies the Downey Plain. The depression trends northwest between the Baldwin Hills and the La Brea Plain and extends beyond the investigational area into Orange County. The Newport-Inglewood uplift borders the depression on the southwest in Los Angeles County. The La Brea Plain, Elysian Hills, Montebello Plain, Santa Fe Springs, Coyote Hills,

AR0068946

and Santa Ana Mountains border the depression to the northeast. Minor anticlinal folds or warps lie along the limbs of this synclinal depression.

As shown on the geologic cross sections, sediments of lower Pleistocene age have been folded to a greater extent than upper Pleistocene and Recent materials. The trough in older sediments lies in the central portion of the plain, about one mile southwest of Huntington Park. In upper Pleistocene sediments it lies west of the central portion of the Downey Plain in the vicinity of Carson Street and Palo Verde Avenue. Recent alluvium is generally flat lying, although slight local folding occurs in the Whittier Narrows. The major structural features in the South Gate-Santa Ana depression are the Paramount Syncline and Los Alamitos fault, and the Norwalk Syncline.

Paramount Syncline and Los Alamitos Fault

The principal axis of the depression, determined from aquifers of the San Pedro formation, is named the Paramount syncline. This structure underlies the City of Paramount and extends northwesterly to the Inglewood fault. South of Huntington Park the trend of the synclinal axis changes from northwest to slightly north of west, as shown on Plate 3.

Southeast of the City of Paramount an extension of the axis of the Paramount syncline coincides with the Los Alamitos fault. This fault trends southeasterly from one mile north of the City of Lakewood and extends about six and one-half miles to the southwest limits of the Los Alamitos Naval Reservation. Apparent movement along the fault appears to have been vertical with the aquifers to the east of the fault having moved down relative to those of the west. Aquifers of late Pleistocene and Recent age apparently

AR0068947

have not been displaced. Merging of differing aquifers occurs across the fault because of their vertical displacement. Water quality and water well logs on either side of the structure indicate that movement of ground water across the fault is only slightly affected.

The manner in which the Los Alamitos fault continues on as an apparent extension of the Paramount syncline suggests that the displacement of aquifers in this area might be a result of folding of the sediments rather than the postulated faulting. However, the available data are primarily derived from water well drillers logs and water quality data, indicate the presence of a fault, possibly the same fault believed by some petroleum geologists to exist in this area in the older sediment underlying the San Pedro formation. Subsequent drilling may resolve the question as to whether this feature is actually a fold or a fault.

Norwalk Syncline

The Norwalk syncline is located south of the Coyote Hills and extends southeast from the City of Norwalk into Orange County. As shown by contours depicting the base of the Silverado aquifer (Plate 20A), the syncline plunges northwesterly toward the City of Norwalk.

Newport-Inglewood Uplift

The Newport-Inglewood uplift is an important regional structure extending from Newport Mesa in Orange County northwesterly approximately 40 miles to its terminus in Beverly Hills. At depth, the uplift is considered a complex fault system that serves as the boundary between Catalina schist basement to the west and granitic basement to the east. At the surface it is characterized by a series of echelon faults and anticlinal folds and domes which underlie the Beverly, Baldwin, Rosecrans, Dominguez, Signal, Bixby Ranch and Landing Hills (Plate 2). Formations on both flanks of the uplift dip away from the axis. The anticlines are characteristically closed at

AR0068948

both ends and are separated by structural saddles. The structures forming the uplift are deformed by high-angle normal and reverse faults at the surface and, at depth, Tertiary sediments are offset by low angle reverse faults.

The faults of the Newport-Inglewood uplift in some cases exert considerable barrier influence upon the movement of subsurface water. In other places sediments offset by the faults have been scoured and backfilled by ancient rivers and streams so that in these areas the faults offer little or no restraint to the movement of ground water. Offsetting of sediments along these faults is usually greater in the deeper, older formations. Displacement is less in younger, stratigraphically higher formations. In the Pleistocene deposits and on the surface, actual displacement by faulting is minor and folding is predominant.

The folds and faults of the Newport-Inglewood uplift, from north to south, include the Beverly Hills dome, Inglewood fault, the Baldwin Hills uplift, Potrero fault and dome, the Rosecrans anticline, Avalon-Compton fault, Dominguez and Long Beach anticlines, Cherry Hill, Northeast Flank, Pickler, and Reservoir Hill faults, and the Seal Beach structure. The structural features of the Newport-Inglewood uplift are described in the following sections.

Beverly Hills Dome

The Beverly Hills dome, a small fold developed at depth in sediments of Tertiary age, is the northernmost anticlinal structure of the Newport-Inglewood uplift. The dome, which contains the Beverly Hills oil field, is apparently not reflected in overlying sediments of Pleistocene and Recent age. Pleistocene formations in the area have reportedly been penetrated by only a few water wells on which data are not available. Available oil well information, however, indicates that Pleistocene sediments dip northwesterly away from the Baldwin Hills and toward the Santa Monica Mountains.

AR0068949

Inglewood Fault

The Inglewood fault is approximately nine miles long, trends northwest-southeast, and extends from approximately one mile south of the City of Beverly Hills to nearly two miles southeast of the City of Inglewood. An eroded escarpment which is probably the surface expression of the Inglewood fault is present in the Cheviot Hills (Poland, et al 1949).

Beneath Ballona Gap, the fault offsets aquifers of Pleistocene age as shown on section A-A'-A", Plate 6A. In this area, the sediments east of the fault have dropped down relative to those on the west side and the fault forms a barrier to ground water movement. Between the Cheviot Hills and the Santa Monica Mountain front, the presence of the Inglewood fault and its probable effect on ground water is largely conjectural. Water level data for the vicinity of Beverly Hills, however, suggest that the fault does not affect water-bearing sediments in that area.

In the Baldwin Hills, the Inglewood fault is marked at the surface by an escarpment along which over 200 feet of vertical displacement has been measured (Driver, 1943). Available evidence indicates that displacement along the fault is both normal and right lateral, the latter being the principal movement. The fault dips steeply west and is offset by several cross faults which trend northeast. In the Baldwin Hills, the west block is dropped; between the Baldwin Hills and Ballona Gap, therefore, pivotal movement must have occurred as the west block is uplifted in Ballona Gap.

South of the Baldwin Hills, the Inglewood fault has also been called the Townsite fault (Willis and Ballantyne, 1943) and is offset by the Fairview Avenue and Centinela Creek faults which trend northeast. The

AR0068950

Inglewood fault offsets aquifers of the San Pedro formation as shown on section B-B'-B", Plate 6A, and forms a partial barrier to ground water movement in the vicinity of the City of Inglewood.

Baldwin Hills Uplift

The Baldwin Hills, containing the Inglewood oil field, are underlain by a faulted, northwest-trending anticline which is developed in sediments of Tertiary and Pleistocene age. Two principal northwesterly trending, nearly parallel faults offset the central portion of the hills, developing a downdropped block or graben across the crest of the anticline. The more easterly of the two structures is the Inglewood fault, described in preceding paragraphs; the other fault is unnamed. Both faults are offset by secondary cross faults which trend northeast. The block east of the Inglewood fault is composed of sediments of Pliocene age and older and is cut by several small unnamed faults. One such fault extends along the northeast border of the Baldwin Hills and may be related to the prominent excarpment in that area. The Slauson Avenue fault extends northeast beyond the Baldwin Hills and offsets aquifers of the San Pedro formation.

The Baldwin Hills form a complete barrier to ground water movement where the essentially nonwater-bearing Pico formation crops out (Plate 3A).

Potrero Structures

This term is assigned to those structures of the Newport-Inglewood uplift which are located between the Baldwin Hills to the northwest and the Rosecrans anticline to the southeast. Principal structures include the Inglewood and Potrero faults and the Potrero dome. The faults are continuous from the Baldwin Hills to the Rosecrans anticline, but the dome is an independent structural feature.

AR0068951

The Inglewood and Potrero faults extend southeast from the Baldwin Hills and border a linear, tilted block, approximately four miles long and several thousand feet wide, which is broken into smaller blocks by several nearly parallel, northeasterly trending cross faults (Plate 3A).

Potrero Fault. The Potrero fault is about four miles long and is expressed at the surface as an escarpment along the west flank of the Rosecrans Hills. It is essentially a fracture zone, 100 to 200 feet wide, that trends northwesterly and dips steeply to the west. Both normal and right lateral displacements have been observed, but the latter is more pronounced. In those areas where vertical displacement of aquifers exists, the fault acts as a barrier to subsurface flow, as was shown by a pumping test conducted in the Inglewood oil field.

A series of transverse faults cut both the Inglewood and Potrero faults and enclose a number of tilted, uplifted or downdropped blocks. From north to south these faults are: The Slauson Avenue fault, Fairview Avenue fault, Centinela Creek fault, Inglewood Park Cemetery fault, Manchester Avenue fault, and the Century Boulevard fault. These faults probably offset aquifers of Pleistocene age and are believed to act as partial barriers to ground water movement (Poland, et al 1959).

Potrero Dome. The Potrero dome, primarily developed at depth in sediments of Tertiary age, is located immediately east of the City of Inglewood and contains the Potrero oil field. The dome trends northwest and is offset by the Inglewood and Potrero faults. Dips along the flanks are gentle, becoming steepest to the north and east.

AR0068952

Rosecrans Anticline

Defined by aquifers of the San Pedro formation, the Rosecrans anticline trends northwest and extends for approximately five miles near the middle of the Newport-Inglewood uplift in Los Angeles County and lies beneath the Rosecrans Hills. The Howard Townsite, Rosecrans, and South Rosecrans oil fields underlie this Pleistocene structure, and are developed in sediments of Tertiary age. These oil structures are offset and complicated by several nearly parallel, westerly trending thrust faults which do not affect sediments of Pleistocene age. Thinning and pinching out of the aquifers across the anticline may be a deterrent to ground water movement between the Central Basin and the West Coast Basin.

Avalon-Compton Fault

The Avalon-Compton fault is about two and one-half miles long and trends northwesterly from the north flank of Dominguez Hill to the south end of Rosecrans anticline. The normal displacement along the fault increases with depth, and the southwest block is dropped. The fault offsets the Silverado, Lynwood, and Gardena aquifers, as shown on Section D-D'-D", Plate 6B. Water level differences on either side of the fault indicate that this structure is an effective ground water barrier (Poland, et al 1959a).

Dominguez Anticline

The structure underlying Dominguez Hill and containing the Dominguez oil field has been described by Grinsfelder (1943) as an elliptical, northwesterly trending anticline. Similar to most structures on the Newport-Inglewood uplift, the anticline, fully developed in the deeper

AR0068953

Tertiary formations, is also reflected in Pleistocene sediments at the surface. Dominguez Hill, rising about 150 feet above the surrounding land surface, is typical of this relationship. The anticline is offset by high angle normal faults and lower angle reverse faults at depth. This deformation does not appear to extend more than 4,000 feet below sea level. The base of Pleistocene sediments across the anticlinal crest is about 400 feet below sea level and it is believed that the aquifers are not affected by faulting across the anticline. The southwest flank of the anticline dips more steeply than the northeast flank. The extreme northwest flank of the structure is cut by the Avalon-Compton fault, described above.

Long Beach Anticline

The Long Beach anticline is a narrow, elongated, asymmetrical structure which trends northwest and is offset by several prominent faults. The structure extends approximately five miles through Signal Hill and Reservoir Hill and contains the Long Beach oil field. The plunge of the axis is less to the northwest than to the southeast. Dips on the southwest flanks are generally steeper away from the crest than dips on the northeast flanks. Three prominent faults, the Cherry Hill, Northeast Flank, and the Reservoir Hill faults, trend northwest along the crest of the anticline. A short, transverse fault, the Pickler fault. extends across the crest of the anticline from the northern expression of the Northeast Flank fault to the Cherry Hill fault. A surface scarp along the north side of the Bixby Ranch Hill may be a surface expression of a fault, but subsurface evidence available at this time does not clearly confirm this.

AR0068954

Available data in the Signal Hill and Reservoir Hill areas and in that portion of the City of Long Beach adjacent to and west of the Resevoir Hill fault are insufficient for definition of aquifers in these areas and for correlation of aquifers across the Pickler, Northeast Flank, and Reservoir Hill faults. According to Poland, the Signal Hill area is a complete barrier to movement of ground water between the Long Beach Plain and the Downey Plain. No new evidence was available to confirm or disprove this assertion. Even though data are sparse, however, it is apparent that the structural character of Signal Hill and Reservoir Hill is sufficient to restrict ground water movement.

Cherry Hill Fault. Stolz (1943a) designated the fault that extends along the southwest flank of the Long Beach anticline as the Cherry Hill fault. Movement along the fault is up on the northeast side and down on the southwest side. Vertical displacement of water-bearing sediments is considerable for several miles along this fault. Along the southwest side, the Silverado aquifer, for example, has been displaced against older rocks of low permeability. Northeast of the structure at Signal Hill, these rocks of low permeability rise above the zone of saturation.

The Cherry Hill fault extends across Dominguez Gap and disappears along the northeast flank of Dominguez Hill. Although the fault does not act as a barrier to movement of ground water in the Gaspur aquifer, it does have a barrier effect in the underlying formations in Dominguez Gap (Poland, et al 1946b).

AR0068955

Northeast Flank Fault. The Northeast Flank fault, also named by Stolz (1943), extends along the northeast flank of Signal Hill for about one mile. The northeast side of the fault is downdropped relative to Signal Hill, which is an uptilted block between this fault and the Cherry Hill fault. In this area, Pleistocene aquifers have apparently been entirely offset and ground water movement is impeded by the Northeast Flank fault.

Pickler Fault. The Pickler fault is a transverse fault which strikes southwest along the northwest margin of Signal Hill. Its existence was inferred largely from a difference in the productivity of oil wells on either side of the fault. The area northwest of the fault is downdropped relative to Signal Hill. The vertical displacement at the base of the San Pedro formation is believed to be about 150 feet. This displacement brings sediments of relatively low permeability in the block to the southeast into contact with the water-bearing sediments to the northwest.

Reservoir Hill Fault. The Reservoir Hill fault is a normal, steep, northeasterly dipping fault aligned with the northeast flank of Reservoir Hill. The fault trends southeast and is named the Seal Beach fault in Alamitos Gap and Landing Hill. It is in echelon with the Northeast Flank fault. The southwest side of the fault has moved up in relation to the northeast side. Vertical displacement along the fault, about opposite the crest of Reservoir Hill, is about 280 feet. Materials of the San Pedro and underlying Pico formation have been displaced by at least this amount; however, no displacement occurs within the uppermost alluvial deposits of Recent age. The fault is believed to restrict ground water movement in Alamitos Gap (Poland and Sinnott, 1959b).

AR0068956

Seal Beach Structure

The Seal Beach structure, containing the Seal Beach oil field, consists of two elongated domes separated by a saddle. The domes are developed in underlying sediments of Tertiary age, trend northwesterly, and are offset by the Seal Beach fault, the local name applied to the southern portion of the Reservoir Hill fault. The more northerly dome underlies Bixby Ranch Hill; the southerly dome has its apex in Alamitos Gap under the present channel of the San Gabriel River. Bowes (1943) stated that the San Gabriel River is antecedent to the later periods of folding and its position may have been controlled by the saddle that exists between these two domes.

Hawthorne-Long Beach Depression

The Hawthorne-Long Beach depression is the downfolded area that underlies the El Segundo Sand Hills, Torrance Plain, Dominguez Gap, Long Beach Plain, and most of the Santa Monica and Sawtelle Plains, but only portions of Beverly Hills and Ballona Gap. The depression trends northwesterly and extends from its northwestern terminus at the base of the Santa Monica Mountains to the City of Long Beach and continues offshore beneath San Pedro Bay. It is bounded on the west by the Pacific Ocean, on the southwest by the Palos Verdes Hills and on the northeast by the Newport-Inglewood uplift.

The following structures lie within the depression and are briefly discussed in the succeeding paragraphs: Overland Avenue and Charnock faults, the Gardena syncline, the Torrance and Wilmington anticlines, the Lomita syncline, and unnamed structures beneath the Santa Monica Plain.

AR0068957

Overland Avenue Fault

The Overland Avenue fault trends northwest and extends from Santa Monica Boulevard to the northwest flank of the Baldwin Hills. Displacement of the fault is believed to be vertical, with a magnitude of approximately thirty feet. The northeast side of the fault is raised relative to the southwest side. Over a 15-year period, water levels east of the fault have remained 60 to 100 feet higher than those west of the fault (Poland, et al 1959a), indicating its relative effectiveness as a barrier to the movement of ground water.

Charnock Fault

The Charnock fault extends southeast from near Venice Boulevard to the City of Gardena and runs parallel to the axis of the Gardena syncline for most of its length. The northeast side of the fault is downthrown relative to the southwest side. Because of the displacement of lower Pleistocene aquifers as shown on Section C-C'-C", Plate 6B, the fault acts as a partial barrier to ground water movement. This barrier effect increases as the fault approaches the Ballona Escarpment, and then apparently diminishes as it continues northwest beyond Ballona Gap into the Sawtelle Plain.

Gardena Syncline

The principal structure of the Hawthorne-Long Beach depression is the Gardena syncline, an elongated, northwesterly trending flexure extending from Culver City to the City of Long Beach. It parallels the Newport-Inglewood uplift which borders it on the northeast. Along the southwest border, beneath the El Segundo Sand Hills, Pleistocene sediments gently dip northeasterly into the syncline from beneath the Pacific Ocean. The syncline

AR0068958

is best developed in Tertiary and lower Pleistocene sediments and is moderately defined in upper Pleistocene sediments. Its deepest part, as shown on the contour map of the Silverado aquifer (Plate 20B), lies beneath the intersection of Alameda Street and Carson Street. From the northwest, the synclinal axis plunges gently into this low. The axial plunge from the southeast is relatively steeper.

Northwest of the City of Gardena, lower Pleistocene aquifers along the southwest flank of the syncline are offset by the Charnock fault (Section C-C'-C", Plate 6B), though the Gardena aquifer of late Pleistocene age is not displaced. Further north, beginning at the south margin of the Ballona Gap, the northeast flank of the syncline is displaced by the Overland fault. Beneath Ballona Gap and continuing northwest to approximately the Santa Monica Plain, the syncline becomes a downfaulted block lying between the Charnock and Overland Avenue faults.

Torrance Anticline

The Torrance anticline, located in the southerly part of the Hawthorne-Long Beach depression, is a gentle fold which trends southeast from Redondo Beach and contains the Torrance oil field. In sediments of Tertiary age, several echelon faults trend diagonally across the principal fold, dividing it into three elements. The water-bearing formations are affected by the broad, gentle folding, but available evidence indicates that they are not offset by faulting.

Wilmington Anticline

The Wilmington anticline is essentially continuous with the Torrance anticline but the two are separated by a structural saddle developed

AR0068959

in sediments of Tertiary age. The anticline plunges to the northwest and to the southeast and, according to Winterburn (1943), consists of five blocks developed by several faults. The San Pedro and Lakewood formations are not affected by these faults, and only the San Pedro formation is folded.

Lomita Syncline

The Lomita syncline is located between the Torrance-Wilmington anticlinal highs to the north, and the Palos Verdes fault zone and Gaffey anticline to the south. The syncline parallels the southeasterly trend of these bordering uplifts and extends southeast from the City of Redondo Beach. Similar to the Gardena syncline, it is best developed in San Pedro and older sediments.

Unnamed Structures

Hoots (1931) and Barbat (1958) indicate that there are structures under the alluvial cover of the Santa Monica Plain which trend east-west and parallel to the structural trend of the Santa Monica Mountains. Since there is little subsurface information available in this area, the geologic structure is inferred on Section G-G', Plate 6D. This section shows the San Pedro formation dipping gently to the south beneath Ballona Gap and the Torrance Plain.

Offshore Structures

Those structures that lie beneath Santa Monica and San Pedro Bays have a direct effect upon the water-bearing strata that extend into these areas. Much work remains to be done to determine the nature and extent of offshore folding and faulting and their effects on ground water. The

AR0068960

general structure of the offshore region is discussed by Emery (1954) as follows:

> "In general, the region consists of many blocks of roughly equal size that bear a close resemblance to the fault blocks of the Basin Range province in Nevada and eastern California. . .The slopes that bound the blocks are fairly straight and steep (5° to 10° average and more than 40° locally), and some terminate downward in linear depressions similar to sag ponds. Earthquake epicenters are more frequent on the basin side of these slopes, suggesting that the slopes reflect the presence of normal faults that separate horsts and grabens, though later work may show that some of them are due to folding rather than to simple block faulting."

The Santa Monica shelf as a whole is a seaward continuation of the coastal plain, and available information suggests that the San Pedro formation becomes thinner there. The pattern of sea-water intrusion indicates that aquifers are exposed to the ocean all along the Santa Monica Bay.

The San Pedro shelf is underlain by the seaward extension of the anticline that comprises the Palos Verdes Hills, by the Gaffey syncline and anticline, by the Lomita syncline, and the Wilmington anticline. Available subsea data suggest that the extension of the main Palos Verdes Hills anticline beneath San Pedro Bay has resulted in uplift of the Lakewood and San Pedro formations, and possibly exposed them to the ocean floor south of the breakwater (Stevenson, et al 1958, Crouch, 1954, and Moore, 1954). Water levels in the Silverado aquifer, however, indicate little or no hydraulic continuity with the ocean beneath San Pedro Bay. The significance of this data is not clear, since no subsurface information is available seaward of the Wilmington oil field. It is not known, therefore, whether aquifers deeper than the Gaspur and above the Silverado are in hydraulic continuity with the ocean in San Pedro Bay.

AR0068961

CHAPTER VI. DESCRIPTION OF GROUND WATER BASINS

This chapter describes the ground water basins in the Coastal Plain of Los Angeles County and discusses the occurrence and movement of ground water within each basin. Information regarding geologic features presented in earlier chapters is summarized here for each ground water basin to show what effect these features have on ground water flow into, through, and out of each basin. The relationships between the geologic features and the occurrence and movement of ground water as discussed in this chapter are intended to clarify the geologic setting of the area for future studies of hydrology, water quality, and problems involving the use of ground water.

Basin Boundaries

The ground water basin as herein used is defined as the area underlain by one or more permeable formations capable of furnishing a substantial water supply. It does not necessarily coincide with the surface drainage basins and is usually smaller in size because the essentially nonwater-bearing hills and mountains of the surface drainage basin (watershed) are excluded. Ground water basins are separated from adjacent basins by geologic features such as nonwater-bearing rock, faults, or other geologic structures which impede ground water movement, and by natural or artificial mounds or divides in the water table or piezometric surface. Geologic features generally establish well defined, fixed boundaries while ground water mounds are subject to change in time, particularly with changes in the development and use of ground water. However, both of these types of boundaries do define limits of ground water movement.

AR0068962

Ground water basins also have been arbitrarily separated along political boundaries or surface features such as along topographic divides and across narrow gaps through a range of mountains or series of hills. Such arbitrary divisions may be useful but they do not really define the limit of ground water basins nor its movement as do geologic features. In many cases, the use of surface features to delimit a ground water basin has simplified hydrologic analysis, but this is seldom the case when political boundaries have been used.

The Coastal Plain of Los Angeles County consists mainly of unconsolidated sediments or alluvium underlain by and bounded on the north and east by essentially bedrock. On the west and south it is bounded by the Pacific Ocean. Ground water is stored within the interstices of these unconsolidated sediments and in the cracks or fractures of the nonwater-bearing rocks which bound the area.

The coastal plain has been divided into four ground water basins by geological and surface features. Two of these four ground water basins are southwest and two are northeast of the series of low hills formed by the folds and faults of the Newport-Inglewood uplift. The Santa Monica Basin ("West Coast Plain - North", Calif. D. W. R. 1934) and the West Coast Basin occupy what Mendenhall (1905b) called the "Western Coastal Plain" west and southwest of the Newport-Inglewood uplift (Plate 2). East and northeast of the Newport-Inglewood uplift are the Hollywood and Central Basins (Plate 2), which Mendenhall (1905a) considered together as the "Central Coastal Plain of Southern California".

The Santa Monica Basin is the northernmost of the two basins southwest of the Newport-Inglewood uplift; it extends south from the Santa

AR0068963

Monica Mountains to the Ballona Escarpment between the uplift and the Pacific Ocean. The West Coast Basin extends southeast to the Palos Verdes Hills, San Pedro Bay, and Orange County. Although the Santa Monica and West Coast Basins have been divided at the Ballona Escarpment, the escarpment does not signify any geologic discontinuity in the water-bearing sediments. Rather, the separation was based on the existence of a ground water mound developed at this location as a result of ground water extractions. This ground water mound was carefully defined in the Report of Referee on the West Coast Basin (Calif. D. W. R. 1952a). The Newport-Inglewood uplift, which bounds these basins on the east, is a series of geologic features that exerts considerable influence on ground water movement along much of its length.

The Hollywood Basin is located south of the Santa Monica Mountains and east of the Newport-Inglewood uplift. It extends eastward to the Elysian Hills and south to the La Brea high, a complex subsurface structural feature. The Central Basin borders the Hollywood Basin on the south and occupies the rest of the Coastal Plain of Los Angeles County east of the Newport-Inglewood uplift. Historically, ground water moved from the Hollywood Basin across the La Brea high into the Central Basin. However, under present conditions, ground water levels are lower than the dome of this high so that it currently represents a barrier to ground water movement along the eastern section of the southern boundary. This feature plunges steeply at its western extremity, and the San Pedro formation is continuous from the Central Basin into the Hollywood Basin around the warped slope formed by the plunging anticline. A pumping depression or trough, developed in the vicinity of Culver City as the result of

AR0068964

ground water extractions, now intercepts all flow from the Hollywood Basin, and has resulted in a ground water divide in the northern part of the Central Basin.

The southeast boundary of the Central Basin coincides with the Los Angeles-Orange County line. This boundary was originally defined (Calif. D. W. R. 1934) on the basis of a ground water mound generally paralleling the county line. Four areas are identified for descriptive purposes within the Central Basin: the Los Angeles and Montebello Forebay Areas, the Whittier Area, and the Central Basin Pressure Area (Plate 2). The boundaries of these areas are as described in Bulletin No. 45 (Calif. D. W. R. 1934). The forebay areas extend south from the Los Angeles and Whittier Narrows, two breaks in the hills which form the northern boundary of the basin. The Whittier area (formerly part of the La Habra Basin) is located in the northeastern part of the Central Basin, east of the Montebello Forebay Area. The Central Basin Pressure Area includes the rest of the Central Basin to the west and south of the other three areas.

Another basin, the "Los Angeles Narrows Basin" (Calif. D. W. R. 1934), was formerly recognized as part of the Coastal Plain of Los Angeles County. It extended from the Central Basin north to the San Fernando Basin, with an arm extending eastward along the Arroyo Seco into the San Gabriel Valley. Recent investigations have shown that the Los Angeles Narrows Basin should be divided; one part should be included with the San Fernando Basin and the remainder with the Central Basin. This change has been followed in this report and the boundary of the coastal plain in the vicinity of the Los Angeles Narrows was placed just north of and parallel

AR0068965

to Figueroa Street across the narrowest portion of the alluvial fill. The area south of this new line and eastward along the Arroyo Seco is now included within the Central Basin.

Ground Water Occurrence

Poland (1948 and 1959a) divided the ground water contained in the alluvial sediments of the Coastal Plain of Los Angeles County into three categories, each of which may appear in any single ground water basin. In downward succession these are: (1) a body of shallow, unconfined, semiperched water which occurs in the upper part of the alluvial deposits in the Downey Plain and the Torrance Plain, (2) the principal body of fresh ground water, which occurs chiefly in deposits of Recent and Pleistocene age, and possibly in underlying Pliocene rocks, and (3) saline water underlying the principal fresh water body throughout the area.

The only use at the present time of the saline water underlying the coastal plain has been to repressurize areas where oil has been extracted. Since the primary interest is in the fresh ground water resources of the area, this chapter considers Poland's first and second categories of ground water, and omits further consideration of the saline waters.

Ground Water Movement

In all ground water basins, water moves from the point or points of recharge through the basin to the point or points of discharge. Ground water flow occurs because of differentials in pressure between the points of recharge and discharge, which establish a hydraulic gradient in the water surface. This flow will continue in one or more directions until

AR0068966

the flow path is blocked by some structural barrier (i.e., fault, fold, unconformity, or a physical characteristic of the aquifer) or until the gradient of the water surface is altered by withdrawals or artificial recharge. The basin will generally discharge into another basin, or into a river, lake, or the ocean.

The ground water basins in the coastal plain are recharged by surface and subsurface inflow from the hills and mountains bordering the areas and from the adjacent San Gabriel and San Fernando Valleys, by downward percolation of the waters from the major streams crossing the area, by direct percolation of precipitation and other applied water, and by artificial recharge of either local or imported water through both spreading the water in specially prepared basins where it is impounded and allowed to percolate and injecting the water into wells.

The extensive paving of streets and construction of urban communities has greatly reduced the areas open to direct percolation of precipitation and applied water. Extension of sewer systems discharging through ocean outfalls, improvement in surface drains, and the lining of river channels to facilitate the runoff of floodwaters have all resulted in less water percolating into the ground water basins. In recent years the expansion of artificial recharge programs has tended to offset these reductions in the natural recharge to the ground waters of the coastal plain.

Discharge from the coastal plain under natural conditions has been to the Pacific Ocean. However, the increased withdrawals of ground water from the area, combined with the lower rate of replenishment during recent years, have reversed normal gradients as evidenced by sea

AR0068967

water moving inland in the coastal portions of the aquifers and by the presence of "troughs" or pumping depressions in the ground water surface. At the present time, there is little subsurface outflow to the ocean.

Evapo-transpiration processes account for a minor amount of the ground water naturally discharged from the basins. The major discharge of ground water is presently by pumpage and eventual discharge to the ocean through sewers of the amount not consumptively used.

Rates of flow of ground water within the basins depend not only on the hydraulic gradient, but also on the cross-sectional area and permeability of the sediments. A very useful term in determining rates of flow is the coefficient of transmissibility, which is defined as coefficient of permeability multiplied by the saturated thickness, usually in gallons per day per foot of width or in cubic feet per second per foot of width. About 40 well tests have been conducted in the Coastal Plain of Los Angeles County to determine coefficients of transmissibility and storage. Selected references used in these computations are included on Page 1-10 of Attachment 1. Results of the tests are summarized in Table C in Attachment 2. In a few cases, it was possible to compute vertical permeability of the overlying aquiclude as indicated in this table.

Using results of the transmissibility tests, average values for permeability were computed and assigned to drillers logs. This procedure is discussed in Attachment 2 of this report and the values are shown in Table D. Using all well tests and several hundred well logs, transmissibility was then estimated for the major aquifers. Lines of equal transmissibility of the aquifers were generalized and drawn on Plates 26A

AR0068968

through 26H. The values for all aquifers were later combined as shown on Plate 26I which is very generalized but is convenient to use in many hydrologic and operational studies.

Ground Water Storage

When discharge or outflow from a basin exceeds recharge or inflow, ground water is removed from storage in the basin. The amount of water in storage depends on the volume of sediments and their specific yield. Specific yield is defined as the ratio between the volume of stored water which a saturated sample of material will yield by gravity and the volume of that sample; it is customarily expressed in percent.

Specific yield values for the sedimentary deposits of Los Angeles County are given in Attachment 2, Table A. These specific yield values were compiled from available data, including work done by the State Water Rights Board for the San Fernando Valley Reference, and from Bulletin 45 (Calif. D. W. R. 1934). They were also checked against figures obtained from well tests but no new determinations were made during this investigation. Specific yield values are multiplied by the thickness and areal extent of the water-bearing sediments to determine the total storage capacity of these sediments. The variation in specific yield value over the coastal plain by elevational increments that were used in computations of storage are tabulated in Table B, Attachment 2.

Changes in the amount of ground water in storage in the ground water basins in the Coastal Plain of Los Angeles County have occurred mainly in the forebay areas. However, changes in storage have also occurred in other free ground water areas and in the pressure areas where water levels have been drawn below the base of the upper confining

AR0068969

aquiclude. Additional limited changes of storage have occurred by dewatering of the confining aquicludes. The areas where changes in storage have occurred are discussed in the description of the individual basins; however, because of the general widespread nature, changes of storage in the Bellflower aquiclude are not delineated. Within the area as a whole, total storage to the base of the Sunnyside aquifer, or to the Silverado aquifer where the Sunnyside is missing, is approximately 22 million acre-feet. Ground water storage depletion since 1904 is about 1,200,000 acre-feet and the storage between historical high water levels which occurred in 1904 and sea level is about 1,600,000 acre-feet.

The discussion which follows treats the geology of each basin and its relation to ground water, the means by which the aquifers present are replenished, the areas of confined water, the barriers to ground water movement within or between basins, and the movement of water in each basin.

Santa Monica Basin

The Santa Monica Basin is bounded by the Santa Monica Mountains on the north and the Ballona Escarpment on the south. It extends eastward from the Pacific Ocean to the Inglewood fault (see Plate 2). This area was originally considered a part of the West Coast Basin, which now is limited to the area immediately south of the Santa Monica Basin. The Santa Monica Basin has also been referred to in prior publications as "West Basin Northern Area" (Calif. D. W. R. 1934); "West Coastal Plain - North" (Calif. D. W. R. 1947); and "West Coast Basin - North" (Calif. D. W. R. 1958a).

The majority of the water wells in the Santa Monica Basin lie south of Santa Monica Boulevard in an area covered by Recent alluvium

AR0068970

(Plate 3B). North and northwest of Santa Monica Boulevard, where the Lakewood formation is exposed on the surface, and in the area covered by Older Dune Sand of late Pleistocene age, comparatively few wells have been drilled and little data are available. The area north of the Baldwin Hills, between the Overland Avenue and Inglewood faults (shown on Plate 3B), is also deficient in water well log data; however, oil well and electric log data indicate that fresh water is present in the undifferentiated Lakewood, San Pedro, and Pliocene formations. While no aquifers or aquicludes have been defined in either the northwest or northeast parts of the Santa Monica Basin, they do exist there.

Geologic Features

The Santa Monica Basin is overlain by six different physiographic features: Santa Monica Plain, Ocean Park Plain, Sawtelle Plain, part of the Beverly Hills, Ballona Gap, and the northern tip of the Baldwin Hills. These features are shown on Plate 2 and discussed in detail in Chapter III.

Recent alluvium, the Lakewood and San Pedro formations, and some older sediments have been identified in the Santa Monica Basin (Plate 3B). The known aquicludes and aquifers, however, are restricted to the Recent alluvium and the San Pedro formation. The Recent alluvium covers the Sawtelle Plain and Ballona Gap where it attains a maximum thickness of about 90 feet. Included within these sediments is a portion of the Bellflower aquiclude and the Ballona aquifer.

The Bellflower aquiclude (Plate 9B) within the Recent alluvium consists of 20 to 40 feet of clay and sandy clay extending to a maximum depth of about 50 feet (40 feet below sea level) below the surface (Plate 8B). It is also quite probable that the Bellflower aquiclude is present

AR0068971

in the undifferentiated Lakewood formation in the Ocean Park Plain, the Santa Monica Plain, and the Beverly Hills area where it would partially restrict percolation of surface water.

The Ballona aquifer, called the "50-foot gravel" in a prior report (Calif. D. W. R. 1952a), consists of 30 to 50 feet of gravel and coarse sand (Plate 11B) and has a maximum depth of 70 feet (60 feet below sea level) below ground surface (Plate 10B).

The Lakewood formation and the Older Dune Sand of late Pleistocene age cover most of the northern half of the Santa Monica Basin. The Lakewood formation includes the weathered, reddish-brown continental deposits covering the Santa Monica Plain and the sands, clays and conglomerates of marine origin that form the Beverly Hills. The Older Dune Sand consists of sand and silt washed free of clay, which, according to Hoots (1931), "...probably represents sand bars and shore-line bluffs that were developed when the ocean stood at a higher level with relation to the land." These Older Dune Sands were later modified by wind action. The thickness of the Lakewood formation and the dune sand is uncertain in this basin, but it is known that the Lakewood formation thins out in the northern part of the basin where it overlies the older rocks of the Santa Monica Mountains.

The San Pedro formation is found beneath the Recent alluvium over the southern half of the Santa Monica Basin with no evidence of intervening Lakewood materials. In the northern part of the basin, the Lakewood formation is present and in the westerly portion appears to directly overlie Pliocene and older sediments with the San Pedro formation apparently missing. In the northeastern part of the basin, oil well and fossil

AR0068972

data indicate that the San Pedro formation is at least 500 feet thick. In the Ballona Gap area available data indicate that the San Pedro formation has a thickness of about 300 feet.

The Silverado aquifer is the only member of the San Pedro formation identified in the Santa Monica Basin. It is mainly sand and gravel, with a small amount of clay. It ranges from 100 to 280 feet in thickness, and extends downward to elevation minus 420 feet, 450 feet below the ground surface (Plate 6D, Section G-G').

The San Pedro formation is underlain by sediments of Pliocene age in the southern and northeastern parts of the Santa Monica Basin. Oil well electric logs indicate that fresh water extends down several hundred feet below the base of the San Pedro formation in the western part of the Ballona Gap Area. In the northeastern part of the basin available oil well electric logs indicate that the San Pedro formation is underlain by saline water-bearing Pliocene sediments. Current subsurface work by oil companies in the northwestern portion of the basin may reveal the nature of the fresh water-bearing sediments there. Available outcrops suggest that the geology of the San Pedro and older formations is complex in that area. Plate 24, "Lines of Equal Elevation on the Base of Fresh Water-Bearing Sediments", indicate the spotty nature of the data in this basin by the limited number of elevations shown for this basin.

The major structural features of the Santa Monica Basin are the unconformity in the northern part, which brings the thin Lakewood formation into contact with the underlying Pliocene and Miocene deposits, and a number of faults in the area. Three of these faults, the Inglewood, Overland Avenue and Charnock faults, (Plate 3B) have been described previously. Several other faults in the basin have been reported in previous

AR0068973

literature. Hoots (1931) shows a small fault extending into the basin near Potrero Canyon. In the "Guide to Geology and Oil Fields of the Los Angeles and Ventura Regions, Barbat (1958)", postulates an east-west fault system extending from north of Santa Monica to a point about four miles southeasterly of the Los Angeles civic center. Poland (1959a) also shows a small east-west fault located east of Santa Monica, which may possibly be related to Barbat's fault system. These faults described by Barbat and Poland are not shown on the geologic map in this report because there is no clear evidence that they affect water-bearing sediments.

The Inglewood fault, which forms the eastern boundary of the Santa Monica Basin, appears to be a barrier to the movement of ground water in the area between the Baldwin Hills and a point about one-half mile south of Santa Monica Boulevard. North of this point the presence of the fault is largely conjectural; electric logs of oil wells show a deep zone of fresh water west of where the Inglewood fault would be if it continued northward. Water level records in these sediments suggest that in this area the fault is either not present or does not act as a barrier.

The Overland Avenue fault in Ballona Gap also appears to act as a barrier to ground water movement since ground water levels on the east side of the fault are much higher than on the west side.

The Charnock fault, the westernmost of the three principal faults mentioned, appears to affect only slightly ground water movement in the Santa Monica Basin. It cuts the Silverado aquifer, which shows a displacement of about 180 feet (Plate 6A, Section A-A'), but leaves the water-bearing sediments still in juxtaposition. Ground water movement

AR0068974

across the fault is still possible, though ground water levels are higher on the west side of the fault.

Occurrence of Ground Water

Ground water occurs in all sediments of the Santa Monica Basin from Recent alluvium to deposits of Miocene age. Water well information is available only where aquifers have been identified in the Sawtelle Plain and Ballona Gap areas. In these two areas ground water is found in deposits of Recent and lower Pleistocene age. In the area north of the Baldwin Hills between the Overland Avenue and Inglewood faults (Plate 3B), oil well data and electric logs indicate the presence of water in the undifferentiated Pleistocene and older formations as well.

Water levels in the Recent alluvium in the Sawtelle Plain are much higher than water levels in wells that penetrate the older sediments, suggesting that a perched or semiperched aquifer exists in this area.

Replenishment of ground water in the Santa Monica Basin is mainly by percolation of precipitation through sandy phases of the Bellflower aquiclude, the Lakewood formation and the Older Dune Sand, and by percolation of surface runoff into the basin from the mountains to the north. The Inglewood fault appears to inhibit replenishment from the Central Basin to the east. It is possible, however, that ground water does move between the Santa Monica and Hollywood Basins around the north end of the Inglewood fault.

Ground water in the Santa Monica Basin moves mainly toward the south, in the direction of Ballona Gap (Los Angeles County Flood Control District, 1958). Partial degradation of the ground water underlying the western part of Ballona Gap has taken place over the years (Calif. D. W. R.

AR0068975

1958b) as evidenced by an increase in the chloride content. Part of the degradation may be due to sea-water intrusion into the aquifers because water levels have fallen below sea level. However, north of Ballona Creek in the City of Santa Monica, available data suggest that minor subsurface flow toward the ocean may occur.

Aquifers in Santa Monica Basin generally have transmissibility rates less than about 100,000 gallons per day per foot. In this basin, the Silverado aquifer has a maximum transmissibility rate of about 150,000 (see Plate 26G "Lines of Equal Transmissibility of the Silverado Aquifer"), and the Ballona aquifer has a maximum transmissibility rate of about 70,000 (see Plate 26A, "Lines of Equal Transmissibility of the Gaspur and Ballona Aquifers"). Because thickness of aquifers is poorly known in the north portion of the basin, transmissibility rates are not shown there, but they appear to be increasing in that direction. However, the rates would decrease as the Santa Monica Mountains are approached and the aquifers become thinner.

Changes in storage and free ground water conditions could possibly occur along the north edge of the Baldwin Hills and the south edge of the Santa Monica Mountains where the Lakewood and San Pedro formations crop out at the surface. Free ground water conditions also may exist near the coast in the Ballona Gap area where the Bellflower aquiclude is missing.

Total storage to the base of the Sunnyside aquifer, or Silverado aquifer where the Sunnyside is missing, amounts to about 1,100,000 acre-feet. Historically utilized storage is difficult to determine because of the paucity of information available. It probably has amounted to about 38,000 acre-feet since 1904, and occurs in both shallow and deep aquifers. Storage between historical high water levels which occurred in 1904 and sea level is about 36,000 acre-feet.

AR0068976

West Coast Basin

The West Coast Basin extends southwesterly from the Newport-Inglewood uplift to Santa Monica Bay, to the drainage divide on the Palos Verdes Hills, and to San Pedro Bay. It extends from the Ballona Escarpment and Baldwin Hills on the northwest to the Los Angeles-Orange County line on the southeast. The basin boundaries are defined in the Report of Referee (Calif. D.W.R. 1952a).

Mendenhall (1905b) referred to this area as the "Western Coastal Plain Region". In Bulletin No. 45 (Calif. D.W.R. 1934) Eckis used the term "West Basin - Southern Area" for the West Coast Basin, which was slightly modified to "West Coastal Plain - South" in Bulletin No. 53 (Calif. D.W.R. 1947). The term "West Coast Basin" was officially accepted in the Report of Referee (Calif. D.W.R. 1952a, and has remained in use from that time.

Plates 6A and 6G and plates showing lines of equal elevation and lines of equal thickness of those aquifers in the West Coast Basin were based mainly on data taken from the Report of Referee (Calif. DWR, 1952a). However, in some areas, particularly along the coast line, the subsurface geology was modified pursuant to unpublished information obtained from the Los Angeles County Flood Control District. This district has undertaken extensive subsurface geologic exploration in connection with their studies of sea water barrier construction along Santa Monica Bay that will provide valuable detailed information on the geology of these areas. In the Long Beach Plain data are seriously lacking because only a few wells have been drilled.

AR0068977

AR0068978

Geologic Features

Physiographic features of the West Coast Basin are the Torrance and Long Beach Plains, the El Segundo Sand Hills, the Dominguez and Alamitos Gaps, and portions of the Baldwin Hills, the Rosecrans Hills, Dominguez Hill, Signal Hill, and the Palos Verdes Hills (Plate 2). The continuity of the Newport-Inglewood belt of hills, which flanks the West Coast Basin on the northeast, is broken by Dominguez and Alamitos Gaps, which are stream-cut channels eroded and backfilled by ancestral rivers. Most of the basin consists of a gentle, poorly drained plain flanked by the partly eroded highland areas of the Newport-Inglewood belt of hills and the heavily eroded Palos Verdes Hills. Toward Santa Monica Bay, a wide belt of sand dunes, containing many closed depressions, form the El Segundo Sand Hills.

Sediments of the Recent Series and the Lakewood and San Pedro formations of the Pleistocene Series have been identified within the West Coast Basin. The principal aquifers in these series are discussed below.

The Recent Series has two main divisions - the Active Dune Sand and the Recent alluvium. The Active Dune Sand occurs along the coast bordering Santa Monica Bay and extends inland for a maximum distance of about one-half mile. Some of these dunes are 70 feet thick. The Recent alluvium occurs mainly in the Gardena area and within Dominguez Gap, with a lobe extending northwesterly from Dominguez Gap between Dominguez Channel and Dominguez Hill. Another small sinuous area of alluvium extends into Bixby Slough from San Pedro Harbor. Irregular patches also occur south of Torrance. Members of the Recent alluvium include the Semiperched aquifer, the Bellflower aquiclude, the Gaspur aquifer, and miscellaneous beach, playa lake, and lagoonal marshland deposits.

AR0068979

The Recent portion of the Semiperched aquifer occurs only in Dominguez and Alamitos Gaps. It consists of sand, silty sand, silt and clay. The Semiperched aquifer can be detected in well logs, but water level measurements have been obtained from only a few test holes. Available evidence indicates that water levels in the Semiperched aquifer are generally above water levels in the Gaspur aquifer. Water in the Semiperched aquifer is generally of poor quality.

The Recent part of the Bellflower aquiclude occurs in Dominguez Gap where it overlies the Gaspur aquifer, and ranges in thickness from 40 to 80 feet (Plate 9B). The upper part of the aquiclude is sandy silt or sandy clay.

The Gaspur aquifer, entirely of Recent age, occurs only in Dominguez Gap. It has been slightly deformed over the Cherry Hill fault in such a manner that its base rises to an elevation of 80 feet below sea level. It reaches a maximum known depth of about 140 feet below sea level near Terminal Island (Plate 10B). Through the gap it is 40 to 80 feet thick (see Plate 11B). These coarse sands and gravels are confined and produce large quantities of water. Extensive sea-water intrusion into this aquifer is evidence that it is exposed to the ocean. The connection with the ocean may occur some distance offshore or may be through permeable overlying materials closer to shore or possibly both.

Upper Pleistocene deposits include the Older Dune Sand and the Lakewood formation. The Older Dune Sand occurs in a band from about three to four miles wide inland from Santa Monica Bay, extending from the Ballona Escarpment to the Torrance area. It forms the major part of the El Segundo

AR0068980

Sand Hills. Since deposition, the Older Dune Sand has been tilted, weathered, eroded, and further altered by cementation and leaching processes. Surface water percolates into the dunes from closed depressions after heavy rains. Ground water is not, however, extracted from the Older Dune Sand although some perched water bodies may occur.

Divisions of the Lakewood formation in the West Coast Basin include the Semiperched aquifer, the Bellflower aquiclude, the Gardena aquifer, and the Gage aquifer. Those deposits previously known as Terrace Cover and the Palos Verdes sand constitute that part of the Semiperched aquifer that is of late Pleistocene age. These sediments may have been deposited at the same time as the Artesia-Exposition aquifers in the Central Basin.

Underlying both the Older Dune Sand and the Semiperched aquifer is that part of the Bellflower aquiclude which is of late Pleistocene age; it has been previously called the fine-grained phase of the Unnamed Upper Pleistocene Deposits. In the West Coast Basin, the Bellflower aquiclude overlies most of the Newport-Ingleood uplift and Torrance Plain though it is missing over the Baldwin Hills. It reaches a maximum depth of 140 feet below sea level (Plate 8B) and ranges up to 200 feet in thickness (Plate 9B). This heterogeneous mixture of continental, marine, and wind-blown sediments is generally fine-grained, consisting of silty clays and clays. It also contains lenses of sandy or gravelly clays which may be permeable enough to permit water to move vertically downward from the overlying Semi-perched aquifer to the underlying aquifers. It is not significant as a source of ground water. The Gardens and Gage aquifers are constituted of part of those sediments previously referred to as Unnamed Upper Pleistocene Deposits.

AR0068981

The Gardena aquifer extends westward from Lynwood over the Newport-Inglewood uplift to Redondo Beach. It was deposited by an ancestral stream during a rise in sea level and has since been folded over the uplift. The aquifer is composed of sand and gravel with a few discontinuous lenses of sandy silt. It reaches a maximum depth of 200 feet below sea level (Plate 12B) and is as much as 160 feet in thickness (Plate 13B). Permeability is high in the Gardena aquifer, as evidenced by the many wells which tap this aquifer near the City of Gardena. Yields are high and range from 100 to 1,300 gallons per minute. Recharge to the aquifer occurs primarily in the Downey Plain and water is transmitted through the aquifer into the West Coast Basin. Some additional recharge is received by the Gardena aquifer from the overlying Semiperched aquifer and Active Dune Sand, and from the Gage aquifer, with which it is in hydraulic continuity.

The Gage aquifer (previously known as the "200-foot sand") extends over most of the West Coast Basin except for the Long Beach Plain. It is merged with the underlying aquifers near Torrance and south of the Ballona Escarpment along Santa Monica Bay. Except for local areas the Gage aquifer is confined by the Bellflower aquiclude. In the vicinity of Torrance, the Gage aquifer reaches a depth of 250 feet below sea level (Plate 12B) and attains a thickness of 160 feet (Plate 13B). It is composed chiefly of sand with minor amounts of gravel and thin beds of silt and clay. The aquifer exhibits moderate to low permeability and therefore is of secondary importance as a ground water producer in the West Coast Basin. The few wells extracting from this aquifer supply water for domestic and irrigation purposes.

Lower Pleistocene deposits are represented in the West Coast Basin by the San Pedro formation, which is of marine origin. The San Pedro

AR0068982

formation includes two main aquifers, the Lynwood and the Silverado. Outcrops of the San Pedro formation occur on the Baldwin Hills, along the northeastern margin of the Palos Verdes Hills, and on Signal Hill. Portions of the Santa Monica and San Pedro shelves in the ocean are underlain by it. The San Pedro formation thickens along the Gardena syncline from 400 feet near Ballona Gap to more than a thousand feet in Dominguez Gap. It has been offset by the Charnock, Inglewood, Potrero, Avalon-Compton, Cherry Hill and Northeast Flank faults.

The uppermost aquifer of the San Pedro formation in West Coast Basin, the Lynwood aquifer (previously known as the "400-foot gravel"), is composed, in the northern and central parts of the basin, of sand and gravel with lesser amounts of sandy silt, silt, and clay. South of Gardena the gravel is missing and the aquifer consists mainly of sand and sandy silt. The Lynwood aquifer attains its maximum thickness of 200 feet one mile west of the intersection of Alameda Street and Sepulveda Boulevard (Plate 19B). Just one mile northwest of Gardena it reaches its greatest depth, 550 feet below sea level (Plate 18B). The Lynwood aquifer is confined throughout the West Coast Basin except in those areas where it merges with the overlying Gage aquifer (Plate 18B). It also merges with the underlying Silverado aquifer along Santa Monica Bay and along the Newport-Inglewood uplift.

About ten percent of the wells in West Coast Basin are perforated in the Lynwood aquifer. These wells are located primarily in the Torrance, Compton, and Inglewood areas. Few of them draw water solely from the Lynwood aquifer because they are usually perforated in other aquifers as well. Yields of 500 and 600 gallons per minute have been reported.

AR0068983

Deposits of the Silverado aquifer, the lower defined aquifer of the San Pedro Formation in the West Coast Basin, consist of fine to coarse-grained, blue-grey sands and gravels that are continuous over most of the area but are interbedded in some places with discontinuous layers of relatively impermeable sandy silt, silt, and clay. These highly permeable marine deposits reach a maximum thickness of 500 feet (Plate 21B) between the Wilmington anticline and the Cherry Hill fault. The Silverado aquifer reaches its maximum depth at elevation 1,200 feet below sea level (Plate 20B), in Dominguez Gap. It also is most permeable in this area. The Silverado aquifer is merged with the overlying Lynwood aquifer along the coast from Ballona Gap to Redondo Beach, along the north flank of the Palos Verdes Hills, beneath the central and southern part of the Rosecrans Hills and the northern part of Dominguez Hill (Plate 20B). Near Redondo Beach and Hermosa Beach, the merged Lynwood-Silverado aquifers are in hydraulic continuity with the overlying Gardena aquifer; from Hermosa Beach to Ballona Gap, and along the north flank of the Palos Verdes Hills they are in continuity with the Gage aquifer.

Beneath the Silverado aquifer in some parts of the West Coast Basin are 500 to 700 feet of fresh water-bearing materials of the San Pedro and probable Pico formations which have not been identified as an aquifer or aquifers. The approximate elevation of these fresh water-bearing materials is shown on Plate 24B. Along the coast from Redondo Beach to the Ballona Escarpment these deposits are coarse sands and gravels which correspond in age and thickness to the Sunnyside aquifer in the Central Basin. Over the rest of the basin these deposits are fine-grained and act as an aquiclude. The upper division of the Pico formation consists of relatively impermeable

AR0068984

micaceous silt and clay members interbedded with fresh water sands and lenses of gravel. Water contained in deeper Pliocene sediments is mostly saline.

As previously stated, the Newport-Inglewood uplift exerts a partial barrier effect on ground water movement from the Central Basin into the West Coast Basin, especially in the Pleistocene aquifers, by offsetting, elevating, or thinning of the aquifers which pass over it. Lithologic changes and thinning across the uplift have been due primarily to movement during deposition of aquifers and the faulting and elevation which followed. Because of its elevation this area apparently has acted as a boundary for the Artesia-Exposition, Hollydale, and Jefferson aquifers during their deposition by controlling alluviation and restricting the aquifers to the Central Basin.

Pleistocene and older formations that continue across the Newport-Inglewood uplift into West Coast Basin are sharply downwarped into a complex regional basin structure, the Hawthorne-Long Beach depression immediately to the west of the uplift. Many secondary structures interrupt the regularity of this regional downwarp. One of these secondary structures is the Gardena syncline, which parallels the Newport-Inglewood uplift. It plunges toward the southeast and is faulted in the northern part of the West Coast Basin by the Charnock fault. West of the Charnock fault, the water-bearing deposits rise toward the ocean with a gentle slope, while in the southern portion of the West Coast Basin they are deformed over the Torrance, Wilmington, and Gaffey anticlines and downwarped by the Gaffey syncline. Farther to the southwest the water-bearing materials lap onto the northeast slope of the Palos Verdes Hills, a structural highland composed of Miocene and older rocks.

AR0068985

Occurrence of Ground Water

Ground water occurs in Recent and Pleistocene aquifers throughout the West Coast Basin, and some fresh water occurs in the underlying Pliocene sediments. The Semiperched aquifer of both Recent and late Pleistocene age is unconfined. The water in underlying aquifers is confined throughout most of the basin, though the Gage and Gardena aquifers are unconfined where water levels have dropped below the Bellflower aquiclude on the Newport-Inglewood belt of hills and in the northwest corner of the basin.

The major fresh water replenishment to the basin occurs by subsurface flow across the Newport-Inglewood uplift, also subsurface flows which have become increasingly saline occur from the seaward extensions of the aquifers under the influence of a landward hydraulic gradient. The merged Silverado-Lynwood-Gardena-Gage aquifers are in hydraulic continuity with Santa Monica Bay, while only the Gaspur aquifer appears to be in hydraulic continuity with San Pedro Bay. Subsurface flow occurs between the Santa Monica and West Coast Basins, with the direction of flow depending on the direction of the hydraulic gradient.

Subsurface flow across the Newport-Inglewood uplift is controlled by the difference in water levels between the Central Basin and West Coast Basin (which is itself influenced by the withdrawals, outflow, and replenishment measures taken in either basin), by the dewatering of the aquifers along the crest of the uplift, and by the degree to which the faults and folds act as barriers to ground water flow. The barrier effect may depend on cementation along fault zones, lithologic changes which in turn affect permeability, and the varying thicknesses of aquifers over the uplift.

AR0068986

Subsurface inflow across the Newport-Inglewood uplift occurs in the Gaspur aquifer of Recent age and through the Gage, Gardena, Lynwood, and Silverado aquifers of late and early Pleistocene age.

The Baldwin Hills are an effective barrier to ground water movement. South of the Baldwin Hills, the Inglewood fault, in conjunction with the Potrero fault and other transverse faults associated with it, acts as a barrier, which, although relatively impervious, is not completely water tight. The Lynwood aquifer has not been delineated in this fault zone because of insufficient data. The Silverado aquifer continues through the most southerly block of this fault zone.

From the physical characteristics of the aquifers extending across the Rosecrans anticline, a barrier effect would not be expected; however, a differential in water levels does exist across the anticline indicating at least a partial structural barrier effect.

South of the Rosecrans anticline the Avalon-Compton fault acts as a barrier to ground water movement only in the deeper lower Pleistocene deposits. The younger, overlying Lynwood aquifer and aquifers of the Lakewood formation extend across this barrier without offset.

Both the Lakewood and San Pedro formations continue without interruption over the Dominguez anticline, though wells producing from the San Pedro formation show a discontinuity in water levels. Within Dominguez Gap, no barrier effects are found in the Gaspur and Semiperched aquifers. The Lakewood formation also appears to be continuous, although warped, across the Cherry Hill fault. The San Pedro formation is in partial continuity across the fault but wells utilizing the Silverado aquifer show a barrier effect.

AR0068987

The Cherry Hill fault, along the west side of Signal Hill, has offset all aquifers. However, ground water movement across the fault is maintained and hydraulic continuity preserved by entirely different aquifers abutting against each other on opposite sides of the fault. Southeast of Signal Hill, the Cherry Hill and Reservoir Hill faults act as barriers to ground water movement in all aquifers. Poland (1959a), states that the barrier effect on Signal Hill may be interrupted by a gap 1,000 feet wide between the Northeast Flank and Reservoir Hill faults, an area in which sea-water intrusion may occur.

Within Alamitos Gap, the Seal Beach fault does not sever hydraulic communication within the Recent deposits, which extend to a depth of about 100 feet. Below this depth, the fault forms a substantial barrier to ground water movement through the aquifers of the Lakewood and San Pedro formations, which rise unconformably toward the fault on the inland side. Seaward from the Seal Beach fault, the Lakewood formation is absent, and aquifers of the San Pedro formation directly underlie Recent deposits.

Minor replenishment to the West Coast Basin occurs in the form of surface inflow from both the Los Angeles and San Gabriel Rivers which cross the Newport-Inglewood uplift through Dominguez and Alamitos Gaps, respectively. However, lining of the Los Angeles River in the West Coast Basin north of Willow Street (Sepulveda Boulevard) was completed in 1956, thereby eliminating recharge to the Basin in this area. Between Willow Street and Terminal Island, the bed of Los Angeles River is not lined and has a sandy bottom with riprap sides. Because the channel section and the wetted perimeter have been reduced, infiltration through the river sands has decreased.

AR0068988

The San Gabriel River has not been lined although a program of such lining has been proposed. In Alamitos Gap, therefore, some infiltration of stream flow still may occur into the Recent alluvial deposits. However, because the reach between the Seal Beach fault and the Pacific Ocean is only one and one-quarter miles in length, the quantity of infiltration involved is probably minor.

Changes in ground water levels in the West Coast Basin do not generally reflect seasonal variations of precipitation. Therefore it is believed that the annual quantity of recharge effected by percolation of precipitation is small.

Other sources of recharge by infiltration from the surface include return irrigation water from fields and lawns, industrial waters, oil field brines, and other applied surface waters. Poor surface drainage in the past resulted in large expanses of swamp and slough, but these conditions have been improved by the channelization of Dominguez Creek and improved street drainage. At the present time, some surface drainage still collects in the low areas until it disappears by slow infiltration or evapo-transpiration processes.

Near surface replenishment is from infiltration of cesspool effluent and leakage from water distribution systems. These surface and near surface waters are somewhat restricted from moving downward by the Bellflower aquiclude and therefore may remain within the Semiperched aquifer. Some of this water also moves downward through permeable sections of abandoned wells which may serve as conduits between aquifers. Improper abandonment of such wells needs to be restricted to prevent poor quality surface water from gaining access to the deeper horizons.

AR0068989

In the following discussion, the ground water movement throughout the West Coast Basin was derived from the most readily available ground water level contours which are reproduced in Appendix B, "Safe Yield Determinations", to Bulletin No. 104. Although "troughs" or "lows", which develop in both piezometric and free ground water areas, may migrate slightly from spring to fall in a given year, or from year to year, historical data from 1932 to the present show that the general pattern has not particularly changed.

In the spring of 1956, water levels of wells perforated in the Gaspur aquifer indicated ground water movement toward two pumping depressions in Dominguez Gap, one midway between the Cherry Hill fault and Long Beach Harbor and the other near Long Beach Harbor itself.

In 1959 subsurface inflow in the deeper aquifers occurred across the Ballona Escarpment from the Santa Monica Basin and moved southeasterly between the Charnock fault and the structures of the Newport-Inglewood uplift toward a pumping depression near Hawthorne. A general low or trough is aligned along the Gardena syncline and extends from Gardena southeastward toward Dominguez Gap. Piezometric levels reach a low elevation in the vicinity of Carson Street and Wilmington Avenue. Into this trough moves westerly flowing water which crosses the uplift between the Rosecrans anticline and the Avalon-Compton fault, and easterly flowing water from Redondo Beach and Hermosa Beach. A third major trough or pumping depression is centered just east of El Segundo. Water flows into it from that part of the coast between Manhattan Beach and the Ballona Escarpment.

Discharge of ground water from the basin under present conditions occurs primarily by pumping extractions. Some subsurface outflow has

AR0068990

occurred historically to the north into the Santa Monica Basin and to the west and south to the ocean; however, with the prevailing below-sea-level water levels, the subsurface flow is into the basin and sea water has intruded along the coastline. Should the water levels be raised above sea level, subsurface outflow could once again occur.

Aquifers in West Coast Basin have extremely variable rates of transmissibility. The Silverado aquifer (Plate 26G) has the highest transmissibility rate, averaging about 150,000 gallons per day per foot of width with a maximum of about 400,000 gallons per day per foot near Torrance and near the intersection of Alameda and Sepulveda Boulevards. The other aquifers generally have lower transmissibility rates since they are thinner and have smaller grain sizes. The Gaspur (Plate 26A),Gage, and Gardena aquifers (Plate 26C) "Lines of Equal Transmissibility of the Gage and Gardena Aquifers", Lynwood aquifer (Plate 26F), "Lines of Equal Transmissibility of the Lynwood Aquifer" have transmissibility rates of about 50,000 to 100,000 gallons per day per foot, in West Coast Basin. In general, transmissibility rates near the ocean are lower than they are in the center of the basin. Although the combined transmissibility rates of all aquifers are low along some parts of the Newport-Inglewood uplift, they are relatively high in other portions, particularly in the Dominguez Gap north of Long Beach. This is shown on Plate 26I, "Generalized Lines of Equal Transmissibility of the Combined Aquifers."

Change in ground water storage occurs within the merged areas along the Newport-Inglewood uplift, near the Palos Verdes Hills, along the northwest corner of Torrance Plain, and to a minor extent within Alamitos and Dominguez Gaps. Change in ground water storage has also occurred in

AR0068991

parts of the Semiperched aquifer and also the Bellflower aquiclude where piezometric levels have been lowered below its surface. Total storage to the base of the Silverado aquifer, the deepest aquifer delineated in the West Coast Basin, is about 6,500,000 acre-feet. Historically utilized storage since 1904 amounts to about 300,000 acre-feet. Most of this change in storage occurred in the Gage-Gardena aquifer, which is classified as a shallow aquifer. Small additional changes in storage have occurred in the deeper aquifers where they crop out along the northeastern side of the Palos Verdes Hills and along the southern slope of the Baldwin Hills. The storage capacity between the historical high water levels which occurred in 1904 and sea level is about 120,000 acre-feet.

Hollywood Basin

The Hollywood Basin extends from the Santa Monica Mountains southward to an arbitrary line which roughly parallels the crest of the La Brea high, a subsurface structural feature beneath the La Brea Plain. Its western and eastern boundaries are the Inglewood fault and the Elysian Hills, respectively (Plate 2). In Bulletin No. 45 (Calif. D.W.R. 1934) the name "Hollywood Basin" was first used for the area just described, although in more recent hydrologic studies, such as the State Water Resources Board Bulletin No. 8, "Central Basin Investigation", 1952, the basin was considered a part of the Central Basin.

Many water wells were present in the Hollywood Basin around the turn of the century, and ground water was the chief source of supply for irrigation and domestic use (Mendenhall, 1905b). Most of these wells have been since destroyed as land use changed from agricultural to urban. Most of the available water well data in the Hollywood Basin are restricted to

AR0068992

the deep portion of the Hollywood syncline near the southern edge of the Santa Monica Mountains next to the Inglewood fault. Comparatively few wells have been drilled in other parts of the basin.

Geologic Features

The Hollywood Basin is overlain by the Hollywood Piedmont Slope and part of the La Brea Plain (Plate 2). The sediments containing known aquifers extend to a maximum depth of 650 feet (410 feet below sea level) and include Recent alluvium and the Lakewood and San Pedro formations of Pleistocene age.

The Recent alluvium covers about one-half of the basin; it ranges in thickness from about 5 to 35 feet (Plate 6G, section H-H'). Near the Santa Monica Mountains and in the western end of the basin, available well logs and excavations indicate that the alluvium consists of relatively coarse sand and gravel. Some Semiperched water may be present although aquifers have not been differentiated. Since the alluvium is thin over much of the area, it is improbable that any appreciable quantity of water could be withdrawn from it.

The Lakewood formation of late Pleistocene age extends over the whole of the Hollywood Basin and crops out at the surface in the southern half of the area. It includes the Bellflower aquiclude and the Exposition and Gage aquifers. The Bellflower aquiclude consists of silty clay and clay ranging from 5 to 35 feet in thickness (Plate 6G, Section H-H'). It extends upward from the top of the Exposition aquifer to the base of the Recent alluvium or to the surface in areas where no Recent sediments are present.

AR0068993

The Exposition aquifer consists of 20 to 60 feet (Plate 11A) of sand and gravel with some interbedded clay, and attains a maximum depth of 150 feet (elevation 20 feet, Plate 10A).

The Gage aquifer is the major water-bearing member of the Lakewood formation in the Hollywood Basin; it consists of 20 to 80 feet (Plate 13A) of sand and gravel with interbedded clay, and attains a maximum depth of 260 feet (100 feet below sea level) in some areas (Plate 12A). The Gage aquifer is merged with the overlying Exposition aquifer over a large area in the northern and eastern part of the basin (Plate 12A).

The San Pedro formation of early Pleistocene age contains the Jefferson, Lynwood, Silverado, and Sunnyside aquifers in the Hollywood Basin. These aquifers have been identified only in the extreme western portion of the basin, south of the City of Beverly Hills. If additional well log information were available, some, if not all, of these aquifers probably could be defined in the northern portion of the basin along the axis of the Hollywood syncline.

The Jefferson aquifer consists of 20 to 40 feet (Plate 17) of gravel with some clay and attains a maximum depth of 380 feet (150 feet below sea level, Plate 16).

The Lynwood aquifer consists of about 50 feet (Plate 19A) of gravel with a small amount of interbedded clay, and reaches a depth of about 400 feet (200 feet below sea level, Plate 18A). It is merged with the overlying Jefferson aquifer in a small area in the southwestern part of the basin east of Beverly Hills (Plate 18A).

The Silverado aquifer consists of about 50 feet (Plate 21A) of sand and gravel with a small amount of clay, and reaches a maximum depth of about 500 feet (300 feet below sea level, Plate 20A).

AR0068994

The Sunnyside aquifer consists of 40 to 50 feet (Plate 23) of sand and gravel with a small amount of clay, and attains a maximum depth of 660 feet (400 feet below sea level, Plate 22 and section H-H', Plate 6G).

The aquifers of the Lakewood formation are underlain by deposits of Miocene age in the eastern and southern part of the Hollywood Basin. In the extreme southwestern portion of the basin, the San Pedro formation has been identified beneath the Lakewood formation. Along the axis of the Hollywood syncline (Plate 3A), sediments of Pliocene age may underlie the San Pedro formation. These Pliocene and Miocene sediments also contain some fresh water, but no aquifers have been differentiated. They are relatively impervious and contain saline water at depth.

The major structural features of the Hollywood Basin are the Hollywood and Inglewood faults, the Hollywood syncline, and the La Brea high (Plate 3A). The Hollywood fault along the northern boundary of the basin brings Pleistocene deposits into contact with the Jurassic and younger rocks of the Santa Monica Mountains. The Inglewood fault, which forms the western boundary of the Hollywood Basin, appears to impede ground water movement between it and Santa Monica Basin. Available water level data suggest that the Hollywood Basin may be in hydraulic continuity with the Santa Monica Basin to the west along the northwestern part of the basin boundary where the presence of the Inglewood fault is largely conjectural.

The Hollywood syncline in the northern portion of the basin contains sediments of Recent, Pleistocene, and probably Pliocene age underlain by Miocene deposits. The southern flank of the syncline forms the

AR0068995

La Brea high, a subsurface structural high extending from the Elysian Hills almost to the Inglewood fault where it plunges steeply westward and forms an anticlinal nose in the San Pedro formation. It acts as a partial barrier to ground water movement southward into the Central Basin. The San Pedro formation was originally folded up over the La Brea high and eroded off, and the Lakewood formation has been deposited unconformably on sediments of Miocene age and on what remains of the San Pedro formation.

Occurrence of Ground Water

Ground water in the Hollywood Basin occurs mainly in sediments of Recent and Pleistocene age. Some fresh ground water is present in the Pliocene deposits which underlie the San Pedro formation near the Inglewood fault. Mendenhall (1905b) reported flowing wells in what are now known to be Miocene sediments in the eastern part of the Hollywood Basin. Recently drilled oil wells also encounter fresh water at shallow depth in these rocks in the Elysian Hills.

Unconfined ground water conditions exist in the northern and eastern portions of the basin in the shallow aquifers. In the deeper aquifers and in the remainder of the basin ground water is confined, and clay members separate the aquifers over considerable areas.

Ground water in the Hollywood Basin is replenished by percolation of precipitation and stream flow from the higher areas to the north into Recent alluvial sands and gravels. Paving of streets and lining of drainage channels have decreased greatly the surface area open to direct percolation. Subsurface inflow may take place to a limited extent from the Santa Monica Mountains where the older crystalline rocks are sufficiently fractured to allow storage and passage of water.

AR0068996

Ground water in the deeper aquifers of the Hollywood Basin can move to the southwest around the La Brea high, provided the ground water gradient is in that direction. Some ground water in the Lakewood formation probably moves south across the La Brea high. However, a pumping depression in the area southeast of Beverly Hills just east of the Inglewood fault causes water in the Hollywood Basin and water from the Central Basin to flow toward its center.

Aquifers in Hollywood Basin have relatively low transmissibility rates, generally being less than 40,000 gallons per day per foot of width. The Lynwood aquifer (Plate 26F) has the highest transmissibility rate (60,000 gallons per day per foot of width) in this basin. Because of the erosion of the aquifers in the San Pedro formation over the La Brea high, the overall transmissibility rate is quite low there. The area of highest combined transmissibility rate is near Beverly Hills because of the greater thickness of coarser materials (Plate 26I).

Changes in ground water storage occur in the areas of free ground water, which are primarily along the north and east portions of the basin. Total storage to the base of the Sunnyside aquifer is about 200,000 acre-feet. Historically utilized storage since 1904 amounts to about 30,000 acre-feet. The storage capacity between the historical high water level which occurred in 1904 and sea level is about 80,000 acre-feet.

AR0068997

Central Basin

The Central Basin extends over most of the Coastal Plain of Los Angeles County east and northeast of the Newport-Inglewood uplift (Plate 2). It is bounded on the north by the Hollywood Basin and a series of low hills extending from the Elysian Hills on the northwest to the Puente Hills on the southeast. Where the Los Angeles and Whittier Narrows break the otherwise continuous line of hills, the Central Basin is separated from the ground water basins to its north by arbitrary lines. The Central Basin is bounded on the west and south by the Newport-Inglewood uplift and on the southeast by the Los Angeles-Orange County line. All of these boundaries do not coincide with the ones defined in earlier reports. In Bulletin No. 8 (Calif. D.W.R. 1952c) the Central Basin included the area referred to in this report as the Hollywood Basin. The present Central Basin includes part of the area formerly known as the Los Angeles Narrows Basin, and the Whittier Area which was formerly the western part of the La Habra Basin.

The Central Basin was historically divided internally into three areas (Calif. D.W.R. 1934): the Los Angeles and Montebello Forebay Areas and the Central Basin Pressure Area. This division is shown on Plate 2. The forebay areas have been described as intake areas (areas of free or unconfined ground water) where substantial infiltration of surface water could occur. In the pressure area, the aquifers were pictured as being confined between relatively impervious layers of considerable lateral extent that restricted percolation of water from the ground surface downward to the underlying aquifers. This investigation has shown that such a simplified division is not possible because aquicludes were found to extend into the so-called forebay areas and the pressure area aquicludes were found locally

AR0068998

to contain large amounts of sandy and gravelly clay and silts where considerable deep percolation could occur. The area of essentially unrestricted percolation of surface waters to the underlying ground water is limited to small areas in the vicinity of the Los Angeles and Whittier Narrows (Plate 9A). These areas are considerably smaller in extent than the historically defined Los Angeles and Montebello Forebay Areas. However, in large portions of the remainder of the basin, including the pressure area, the upper aquiclude is only partly effective in restricting downward percolation. Because of the heterogeneous pattern of these relatively permeable areas in and around the more impermeable aquicludes and the general gradation from one to the other, an attempt to divide the basin into pressure and forebay areas along a definite line for purposes of hydrologic analysis would not only be difficult but would have to be completely arbitrary. Nevertheless, the old delineation of forebay and pressure areas are used in the discussion of the geology of the Central Basin to follow because of their historical significance and descriptive usefulness.

The Central Basin is divided into four parts for descriptive purposes: the Los Angeles Forebay Area, the Montebello Forebay Area, the Whittier Area, and the Central Basin Pressure Area. The Los Angeles and Montebello Forebay Areas are located in the northern part of the Central Basin immediately south of the two breaks in the line of low hills bordering the basin. Through these breaks the Los Angeles River and the Rio Hondo-San Gabriel River systems flow from the valleys to the north into the coastal plain (Plate 2). These forebay areas spread southward from the two narrows in irregular semicircles. The southern boundary of the two forebay areas roughly coincides with the northernmost limit of the line of flowing

AR0068999

artesian wells delineated by Mendenhall in 1903. As explained above, these forebay areas are not true forebays in the academic sense of the word but are used herein for descriptive purposes.

The Whittier Area is located in the northeastern part of the Central Basin east of the Montebello Forebay Area, south of the Puente Hills and west of the Orange County line. The Whittier Area was described as part of the La Habra Basin in Bulletin 45 (Calif. D. W. R. 1934). However, since the aquifers present in this area, especially the deeper ones, are interconnected to varying degrees with the aquifers in the Central Basin, the area was renamed and treated as part of the Central Basin.

The Central Basin Pressure Area is the largest of the four divisions of the Central Basin. It encompasses all of the area east and northeast of the Newport-Inglewood uplift and northwest of the Orange County line that is not included in the other three areas. It is called a "pressure area" because the aquifers within it are confined by aquicludes or relatively impermeable layers of clay and silt over most of the area. One of the most important aquicludes is at or near the surface. As noted previously, this near surface aquiclude is missing in local areas and contains zones of relatively more permeable material in many places where water could move into or out of the underlying aquifer. Accordingly, completely confined conditions do not exist in the pressure area.

It should also be noted in this discussion of basin divisions that the pressure area could be further divided on the basis of a ground water mound which has existed in the northwestern portion of the basin since the early 1930's. This mound effectively divides the ground water movement in that portion of the basin into two parts; that which moves northward

AR0069000

toward the Hollywood Basin and that which moves southeasterly toward the center of the old pressure area and the Los Angeles Forebay Area. This ground water mound was used in the formulation of a portion of the northern boundary of the Central and West Basin Water Replenishment District organized in 1959 (Calif. D.W.R. 1959).

In the sections which follow, the geologic features of the Los Angeles Forebay Area, the Montebello Forebay Area, the Whittier Area and finally the Central Basin Pressure Area are summarized. For each area these summaries include information about the aquifers present, the areas where these aquifers merge, and barriers to ground water movement. The flow of water into and out of the Central Basin as a whole, replenishment of the aquifers, and areas of free ground water and storage change are described in a separate section under the heading of "Occurrence of Ground Water in the Central Basin".

Geologic Features of the Los Angeles Forebay Area

The Los Angeles Forebay Area, located in the northern part of the Central Basin, is shown on Plate 2. In general it is a free ground water area; however, in the course of this investigation it became evident that the Bellflower aquiclude extends into the southerly portion of the forebay area. The aquiclude in this area contains a high percentage of sand, and vertical percolation of water is apparently more rapid here than in other portions of the basin covered by it. Where the Bellflower aquiclude is missing within the forebay area (see Plate 8A), the aquifers are in direct hydraulic continuity with the surface.

The Los Angeles Forebay Area is overlain by parts of the La Brea, Downey, and Montebello Plains. The known water-bearing sediments extend to

AR0069001

a depth of 1600 feet (1440 feet below sea level) and include Recent alluvium, the Lakewood formation, and the San Pedro formation. Some fresh water also may be present in the Pliocene and Miocene rocks underlying these formations in this area.

Recent alluvium in the Los Angeles Forebay Area is found on the Downey Plain and in the Los Angeles Narrows. It attains a maximum thickness of 160 feet, and includes the western arm of the Gaspur aquifer and the parts of the Semiperched aquifer and Bellflower aquiclude lying west and south of the Los Angeles River.

The Semiperched aquifer is defined as the area where sand and gravel overlying the Bellflower aquiclude is more than 20 feet in thickness. This Semiperched aquifer is also present in the Lakewood formation just south of the Repetto Hills. Although the aquifer can be defined on well logs, water levels in wells indicate that it contains little or no water.

The Bellflower aquiclude consists of clay and sandy clay, ranging from 0 to 90 feet in thickness (Plate 9A) and attains a maximum depth of 100 feet (elevation 40 feet) in the southern part of the forebay area (Plate 8A). It is also present in the Lakewood formation in which it underlies the Semiperched aquifer east and north of the Los Angeles River and extends south into the Central Basin Pressure Area. In the Lakewood formation it varies from less than 40 feet to 50 feet or more in thickness, consists of clay and sandy clay, and attains a maximum depth of 80 feet (elevation 20 feet, Plate 9A). The lack of water in the Semiperched aquifer overlying the Bellflower aquiclude suggests that the Bellflower aquiclude is reasonably permeable in the forebay area.

AR0069002

The Gaspur aquifer consists mainly of sand and gravel with a very small percentage of clay. It ranges from 10 to more than 80 feet in thickness (Plate 11A) and extends down to a depth of 160 feet (60 feet below sea level, Plate 10A). The Gaspur aquifer is overlain by the Bellflower aquiclude over part of the forebay area. However, in the smaller area open to direct percolation shown on Plate 10A, the Gaspur aquifer is either exposed at the surface or overlain by a thin layer of fine sand or soil.

The Lakewood formation is exposed on the surface of the La Brea and Montebello Plains and extends underneath the Recent alluvium on the Downey Plain. It is present in the Los Angeles Narrows, but aquifers have not been defined there. The Lakewood formation includes the portions of the Bellflower aquiclude and the overlying Semiperched aquifer east and north of the Los Angeles River and the Exposition, Gardena, and Gage aquifers. It ranges from 0 to more than 220 feet thick in the southern part of the area.

The Exposition aquifer has been delineated in that portion of the Los Angeles Forebay Area that is beyond the boundaries or limits of the Gaspur aquifer. The Expositon aquifer consists of as many as three sand and gravel members separated in some areas by discontinuous clay and silt lenses. It attains a maximum thickness of 80 feet (Plate 11) and varies in depth from 100 to 160 feet (elevation 200 to 20, Plate 10). Although the Exposition aquifer is known to extend beneath the Gaspur aquifer, it was not differentiated from the Gaspur aquifer, because the contact between the two is indistinct.

The Gardena aquifer is present over much of the Los Angeles Forebay Area. It consists mainly of sand and gravel with a little clay, and

AR0069003

ranges from 0 feet to 60 feet thick (Plate 13A). The maximum depth is 290 feet (100 feet below sea level, Plate 12A).

The Gage aquifer is also present in the forebay area, but over a large part of the area it has been eroded away and subsequently replaced by the Gardena aquifer. The Gage aquifer consists of sand and sandy clay with some gravel. It ranges from 5 feet to 100 feet in thickness (Plate 13A) and extends to a depth of 375 feet (250 feet below sea level, Plate 12A). The Gage aquifer is the basal member of the Lakewood formation. It rests unconformably on the underlying San Pedro formation, except in the extreme northern part of the area, where the San Pedro is missing (Plate 6E, section K-K'-K").

The San Pedro formation is the lowest, stratigraphically, of the formations in the Los Angeles Forebay Area that contain known aquifers. It crops out along the southern edge of the Repetto Hills and extends over the whole of the forebay area except in the Los Angeles Narrows. The San Pedro formation is about 1,050 feet thick in the Los Angeles Forebay Area and includes the Hollydale, Jefferson, Lynwood, Silverado and Sunnyside aquifers.

The Hollydale aquifer is missing in the west end of the forebay. In the rest of the area, it consists of sand and sandy clay with some gravel. It ranges from 0 feet to 60 feet in thickness (Plate 15) and extends 475 feet (350 feet below sea level, Plate 14).

The Jefferson aquifer is missing in the extreme southern part of the forebay area. In the Central and northern portions of the area, it consists of sand with some gravel and clay. It ranges from 0 to 70 feet in thickness (Plate 17) and extends 640 feet down (450 feet below sea level, Plate 16).

AR0069004

The Lynwood aquifer is present over all of the Los Angeles Forebay Area where the San Pedro formation occurs. It consists maily of sand and gravel with a little clay, ranges from 20 feet to 130 feet in thickness, (Plate 19A) and extends down to 720 feet (600 feet below sea level, Plate 18A).

The Silverado aquifer is found throughout most of the Los Angeles Forebay Area and consists of gravelly sand with some interbedded clay. It ranges from 20 feet to 150 feet in thickness (Plate 21A) and extends 1,070 feet down (880 feet below sea level, Plate 20A).

The Sunnyside aquifer also is found over most of the forebay area and consists mainly of sand with interbedded clays. It ranges from 50 to 430 feet in thickness (Plate 23) and extends down to 1,600 feet (1,440 feet below sea level, Plate 22).

The San Pedro formation is unconformably underlain by sediments of Pliocene age which probably contain fresh water in their upper portions.

Within the Los Angeles Forebay Area, the Miocene and Pliocene rocks and the San Pedro formation in the north limb of the Paramount syncline dip to the south. There is a sharp angular unconformity between the steeply dipping, truncated San Pedro formation, and the overlying gently dipping Lakewood formation. This unconformity permits water moving through the Recent and Lakewood formations to percolate downward into the aquifers of the San Pedro formation. (See sections J-J'-J", Plate 6D and K-K'-K", Plate 6E). To the north, in the narrows itself, the Recent alluvium rests directly upon Miocene rocks. Erosion has removed all of the San Pedro formation here, as well as parts of the Lakewood formation which occurs only as terrace remnants along the sides of the narrows.

AR0069005

Movement and occurrence of ground water in the Los Angeles Forebay Area and the other areas in the Central Basin will be discussed later.

Geologic Features of the Montebello Forebay Area

The Montebello Forebay Area extends southward from the Whittier Narrows and presently is the most important area of recharge in the Central Basin. The boundary, shown on Plate 2, is the same as the Montebello Forebay Area boundary described in Bulletin No. 45 (Calif. D.W.R. 1934).

The Montebello Forebay Area is overlain by parts of the Montebello, Downey, and Santa Fe Springs Plains. The water-bearing sediments vary in age from Recent to early Pleistocene and extend to a maximum depth of about 1,050 feet (900 feet below sea level).

The Recent alluvium contains parts of the Semiperched aquifer and the Bellflower aquiclude, and the eastern arm of the Gaspur aquifer. The Semiperched aquifer consists of 20 to 60 feet of sand and gravel overlying the Bellflower aquiclude. The Semiperched aquifer is of Recent age over most of the area but in the northwest corner of the area it is part of the Lakewood formation of late Pleistocene age. The Bellflower aquiclude (Plates 8A and 9A) also is found both in Recent alluvium and the Lakewood formation in the Montebello Forebay Area. It consists of clay and sandy clay ranging in thickness from a few feet at its edge to about 60 feet northeast of Downey. Well logs and other data collected for this report show that where the Bellflower aquiclude extends into the forebay area, it contains a high percentage of sand and gravel. These data suggest that the permeability is sufficiently high to allow percolation through the aquiclude in portions of this area, and therefore it is not an aquiclude in fact in those areas. The areas where the Bellflower aquiclude is not present are shown on Plates 8A and 9A.

AR0069006

The eastern arm of the Gaspur aquifer extends northeasterly through the Montebello Forebay Area and into the Whittier Narrows. It consists of coarse sand and gravel ranging from 40 to 100 feet in thickness (Plate 11A). The maximum thickness is found in the vicinity of the Whittier Narrows Dam, and the maximum depth of 125 feet (20 feet below sea level) occurs in the vicinity of Downey (Plate 10A). The Gaspur aquifer is exposed at the ground surface from Whittier Narrows south to Imperial Highway (Plate 10A). South of this point it is overlain by the Bellflower aquiclude.

The Lakewood formation in the Montebello Forebay Area contains parts of the Semiperched aquifer and the Bellflower aquiclude mentioned earlier, and the Artesia, Exposition, Gage, and Gardena aquifers.

The Artesia and Exposition aquifers, present over a limited area in the Montebello Forebay (Plates 10A and 11A), appear to be contemporaneous in age and mode of deposition. The name "Artesia aquifer" has been given to water-bearing sediments immediately underlying the Bellflower aquiclude east and south of the Gaspur aquifer. The Exposition aquifer consists of similar deposits extending west and north of the eastern arm of the Gaspur aquifer. The Artesia and Exposition aquifers consist of from 10 to 90 feet of sand and gravel with some clay. The sediments comprising these aquifers underlying the Gaspur aquifer had been mostly eroded away prior to deposition of the Gaspur aquifer, and no effort has been made to identify those portions of the aquifers that may remain beneath the Gaspur. The composite name, Artesia-Exposition aquifer, is used for these water-bearing deposits which underlie and are in hydraulic continuity with the Gaspur aquifer.

The Gage aquifer (Plates 12A and 13A) is composed mainly of sand ranging from 20 to 80 feet in thickness, and extends over approximately

AR0069007

one-third of the forebay. The maximum thickness is found in the vicinity of Montebello. The maximum depth of 260 feet (150 feet below sea level) is southeast of Downey.

The Gardena aquifer (Plates 12A and 13A) is present over about two-thirds of the Montebello Forebay. This aquifer, deposited in channels incised into the Gage aquifer, is coarse sand and gravel and ranges from 20 to 140 feet in thickness. The maximum thickness is found just north of the Whittier Narrows Dam. The sediments extend down to a maximum depth of 265 feet (150 feet below sea level) north of Norwalk.

The San Pedro formation has been identified throughout the Montebello Forebay Area beneath the Lakewood formation. It also crops out on the south side of the Repetto Hills west of the Rio Hondo. All of the aquifers of the San Pedro formation are present in the Montebello Forebay Area. The Hollydale aquifer (Plates 14 and 15) is present over about one-half of the area and is compsed of about 20 to 60 feet of sand and gravel with a small amount of interbedded sandy clay and clay. The maximum depth of 260 feet (250 feet below sea level) occurs about one mile north of Norwalk. The Jefferson aquifer (Plates 16 and 17) has been identified over about three-quarters of the Montebello Forebay Area. It ranges in thickness from 20 to 60 feet and consists of sand and sandy clay. The maximum depth of 505 feet (300 feet below sea level) occurs about a mile north of Norwalk.

The Lynwood aquifer (Plates 18A and 19A) is found throughout the Montebello Forebay Area. It is mainly coarse sand and gravel ranging from 50 to 150 feet in thickness. The maximum depth of 705 feet (450 feet below sea level) occurs about one mile north of Norwalk. This aquifer yields water to many wells in the Montebello Forebay Area. The Silverado aquifer (Plates

AR0069008

20A and 21A), identified throughout the Montebello Forebay Area, ranges from 50 to 200 feet in thickness, and is about half sandy gravel and half interbedded clay. The maximum depth of about 1,000 feet (900 feet below sea level) is also just north of Norwalk.

The Sunnyside aquifer (Plates 22 and 23) is the basal member of the San Pedro formation and is the deepest aquifer identified in the Montebello Forebay Area. It is generally sand with local areas of coarse gravel and ranges in thickness from 100 to 350 feet. The maximum depth of about 1,400 feet (1,300 feet below sea level) occurs north of Norwalk.

The San Pedro formation is underlain by Pliocene deposits which are water bearing in some areas. Electric logs of oil wells show that fresh water is present below the San Pedro formation in the Montebello Forebay Area but no aquifers have been delineated in these older sediments.

The major structural features of the Montebello Forebay Area are the unconformity between the Lakewood and San Pedro formation and the faulting and folding in the Whittier Narrows. Geologic sections A-A'-A", Plate 6A, M-M', and N-N', Plate 6F and P-P', Plate 6G, show the gently dipping formations in the Whittier Narrows, and Plate 7 shows cutaway views of the aquifers therein. The Rio Hondo, Pico, and Cemetery faults, all trending approximately northeast, have been postulated in the Whittier Narrows where they evidently bound two distinct, folded blocks (see section on Whittier Narrows Area in Chapter V).

The Rio Hondo fault follows approximately along the southwest side of the Rio Hondo. It displaces the Gardena, Lynwood, and Sunnyside aquifers. The Recent alluvium continues unaffected across the fault. On the northwest side of the Rio Hondo fault, the Sunnyside aquifer has been downdropped as

AR0069009

much as 600 feet with respect to the aquifer on the southeast side. Northwest of the Rio Hondo fault near Whittier Narrows Dam, erosion has removed all aquifers between the Sunnyside and Gardena aquifers (geologic section P-P', Plate 6G).

The Pico fault extends parallel to the Rio Hondo fault and lies about one mile southeast of it. Only the aquifers of the San Pedro formation are cut by this fault, with the southeast side having been downdropped. The amount of offset varies along the fault and, for the Sunnyside aquifer, the maximum vertical offset is about 400 feet. This places the Sunnyside aquifer on the northwest side of the fault opposite the Lynwood and Jefferson aquifers on the southeast side, thus retaining some hydraulic continuity across the fault.

The Cemetery fault is located along the east side of Whittier Narrows and trends slightly east of north. No cross sections in this report cross through this fault. Because the fault coincides with the contact between the Recent alluvium of the Narrows and Pliocene formations of the Puente Hills and since data are not available to differentiate aquifers east of the fault in the Pliocene sediments, any displacement and the effect of the fault upon ground water movement cannot be ascertained.

Some idea of the complexity of the folding in the Whittier Narrows can be seen on geologic sections A-A'-A", M-M', N-N' and P-P' of Plates 6A, 6F, and 6G. Cutaway diagrams of aquifers in the vicinity of Whittier Narrows are shown on Plate 7, with the Gaspur, Gardena, and Silverado aquifers stripped off in succession. The fault displacement and folding can be understood particularly well with the use of this plate.

Ground water movement within the Whittier Narrows in a northwest-southeast direction would probably be impeded by these faults. Fortunately,

AR0069010

the faults trend is essentially parallel to the main subsurface inflow to the Central Basin through the Whittier Narrows and apparently do not affect this ground water movement.

Geologic Features of the Whittier Area

The Whittier Area of the Central Basin extends from the Puente Hills south and southwest to the axis of the Santa Fe Springs-Coyote Hills uplift. The western boundary is an arbitrary line separating the Whittier Area from the Montebello Forebay Area; the eastern boundary is the Orange County line (see Plate 2). The name "Whittier Area" is used for the first time in this report. In prior publications this area was considered to be part of the La Habra Basin (Calif. D.W.R. 1934 and 1947), the southern boundary of which coincided with the southern edge of the Coyote Hills. The southern boundary of the Whittier Area used in this report was chosen because it is a drainage divide and water applied on the south flank of the Coyote Hills would drain into the Central Basin Pressure Area.

Water well data are almost entirely lacking for the sediments found in the east end of the Whittier Area and around the City of Whittier. However, it is reasonably certain that ground water is present in these areas. In the portion of the Whittier Area where aquifers have been defined, many of the old wells have been destroyed and water level data are no longer available. Consequently, the descriptions of the aquifers and aquicludes present in the Whittier Area are not complete.

The Whittier Area is overlain by the La Habra Piedmont Slope and part of the Santa Fe Springs Plain and the Coyote Hills (Plate 2). The known water-bearing sediments, extending to a depth of about 1,000 feet (800 feet below sea level), include Recent alluvium and the Lakewood and San

AR0069011

Pedro formations. A part of the underlying Pliocene and older deposits may also contain water of good quality. Electric logs of oil wells in the Whittier Area indicate fresh water at greater depths than have been penetrated by water wells.

Recent alluvium in the Whittier Area consists of a thin finger of sand, gravel, and clay, which extends into the western portion of the area from the Montebello Forebay Area (Plate 3A). The sediments are 80 feet thick near the western boundary of the area, and thin out to the east. The Recent alluvium contains a portion of the Bellflower aquiclude and the Gaspur aquifer.

The Bellflower aquiclude in the Recent alluvium consists of clay and sandy clay ranging from 10 to over 40 feet in thickness (Plate 9A). It overlies the Gaspur aquifer in the extreme western part of the area. In much of the Whittier Area, the Bellflower aquiclude is part of the undifferentiated Lakewood formation. Lack of data in many parts of the area where the Lakewood formation is exposed at the surface makes it difficult to define the thickness, extent, and composition of this aquiclude. Where data are available, the Bellflower aquiclude is clay and sandy clay averaging 20 feet in thickness and extending down to a depth of about 70 feet below the ground surface (elevation 120 feet, Plate 8A). The degree to which the ground water can be transmitted through the Bellflower aquiclude depends on the thickness and composition of the aquiclude. While the aquiclude appears to be continuous over most of the Whittier Area, it may be either absent in some areas or so thin and discontinuous that ground water can be transmitted through it at an appreciable rate.

AR0069012

The Gaspur aquifer is mainly sand and gravel with a small amount of interbedded clay. It ranges from 30 to 60 feet in thickness (Plate 11A) and attains a depth of 145 feet below the surface (elevation 60 feet, Plate 10A).

The Lakewood formation crops out over most of the Whittier Area (Plate 3A). It consists of continental deposits of late Pleistocene age and attains a maximum thickness of 70 feet. The Lakewood formation contains the Artesia and Gage aquifers and that part of the Bellflower aquiclude described above.

The Artesia aquifer extends a short distance into the southwest corner of the Whittier Area in the vicinity of Santa Fe Springs. It is mostly sand with some interbedded clay and has an average thickness of about 40 feet (Plate 11A) and a maximum depth of about 50 feet (elevation 60 feet, Plate 10A). This aquifer is near the surface and has been exposed in excavations on the Santa Fe Springs Plain.

The Gage aquifer is the major water-bearing member of the Lakewood formation in the Whittier Area. It has been delineated only in the southern portion of the area and near the Los Angeles-Orange County line, where it consists of about 30 feet (Plate 13A) of sand with some interbedded clay, and has a maximum depth of about 150 feet (elevation 50 feet, Plates 12A and 6A, section B-B'-B").

The San Pedro formation underlies the entire Whittier Area, where it attains a maximum thickness of about 850 feet and extends down to a depth of about 920 feet (850 feet below sea level). The formation is composed of sand and gravel with interbedded clay, all probably of marine origin. Clay members separate the sands and gravels comprising the aquifers over most of

AR0069013

the basin. The San Pedro formation contains the Hollydale, Jefferson, Lynwood, Silverado, and Sunnyside aquifers. An extensive unconformity brings the aquifers of the San Pedro formation into contact with those of the Lakewood formation along the northern boundary of the area and along the edge of the Coyote Hills. Cross sections B-B'-B" and Q-Q' on Plates 6A and 6G show this relationship.

The Hollydale aquifer has been identified only in the western part of the Whittier Area. It may be present over the rest of the area, but data are lacking. It ranges in thickness from 10 to 25 feet (Plate 15) and consists of sand and gravel with a small amount of interbedded clay. It appears to reach a maximum depth of about 100 feet (elevation 50 feet, Plate 14). It is merged with the overlying Gage aquifer in the vicinity of South Whittier.

The Jefferson aquifer ranges in thickness from 20 feet to 40 feet (Plate 17) and consists of sand and gravel with a little interbedded clay. It extends over most of the Whittier Area and reaches a maximum depth of about 350 feet (100 feet below sea level, Plate 16). In the western part of the area, near the boundary with the Montebello Forebay, the Jefferson aquifer merges with the overlying Hollydale aquifer.

The Lynwood aquifer is present throughout the Whittier Area. It ranges in thickness from 50 to 100 feet (Plate 19A) and consists of sand and gravel with some interbedded clay. It extends to a maximum depth of about 460 feet (300 feet below sea level, Plate 18A).

The Silverado aquifer has been identified over all of the Whittier Area. It consists of 110 to 300 feet of sand and gravel with finer grained phases in some areas (Plate 21A). It extends to a depth of about 750 feet (600 feet below sea level, Plate 20A).

AR0069014

The Sunnyside aquifer also has been identified throughout the Whittier Area. It consists of 200 to 300 feet of sand and gravel with some interbedded clay (Plate 23). It is the lowest of the aquifers identified, reaching a maximum depth of about 1,000 feet (700 feet below sea level, Plate 22). The gravels exposed in the Coyote Hills and along the north side of the area are believed to be surface outcrops of the Sunnyside aquifer.

The Pliocene and Miocene sediments below the San Pedro formation generally contain saline water in this area, but may locally contain fresh water. Plate 24A shows the approximate elevation of the base of fresh water-bearing sediments.

The available data suggest that some of the water-bearing sediments in the Whittier Area may have been faulted. However, the location of such faulting and its effect on ground water has not been determined.

The water-bearing sediments of the Whittier Area comprise part of the generally east-west trending La Habra syncline. The Recent deposits are essentially undisturbed. The Lakewood formation underlying the Recent alluvium is also generally flat-lying, though in some areas it is slightly tilted. The San Pedro formation, however, which unconformably underlies the Lakewood formation, has been folded sharply and its flanks are exposed in the Coyote Hills and on the south side of the Puente Hills. The effects of this unconformity and the outcrops of the moderately dipping San Pedro formation upon the occurrence and movement of ground water will be discussed later.

Geologic Features of the Central Basin Pressure Area

The Central Basin Pressure Area, previously known as the Central Coastal Plain Pressure Area, is overlain by the Downey Plain and parts of

AR0069015

the Santa Fe Springs, Montebello, La Brea, and Bouton Plains. The area is generally flat and slopes gently to the south. Water-bearing sediments in the Central Basin Pressure Area range in age from Recent to Pliocene and extend to a probable maximum depth of 2,200 feet northeast of the City of Lakewood. Aquifers have been defined in the Recent alluvium and the Lakewood and San Pedro formations.

In this pressure area the aquifers are confined by many aquicludes, only one of which has been named. This is the near surface Bellflower aquiclude which restricts vertical percolation into the Gaspur and other underlying aquifers. Water levels in the confined area form a piezometric or pressure surface rather than a free ground water surface. As pressures change from aquifer to aquifer, the corresponding piezometric water levels in wells tend to vary according to which aquifer or aquifers are used for production. Also, as the aquicludes vary in extent, configuration, permeability, and thickness, their effectiveness as confining members also changes from place to place and with this change an exchange of water between aquifers may take place, depending on the direction of the pressure gradient.

The Recent alluvium covers most of the Central Basin Pressure Area, and attains a probable maximum depth of 200 feet near the City of Bellflower. It contains the Semiperched aquifer, the Bellflower aquiclude, and the Gaspur aquifer. The Semiperched aquifer consists of sands and gravels 20 to 60 feet thick overlying the Bellflower aquiclude.

The Bellflower aquiclude is found throughout the pressure area and is composed mainly of clay and silt; however, there are numerous areas where it consists mainly of clayey sands and gravels and where its effectiveness as an aquiclude is limited. It ranges from a few feet to 160 feet in

AR0069016

thickness (Plate 9A). It extends downward to about 200 feet (140 feet below sea level) southwest of the City of Bellflower (Plate 8A). The Bellflower aquiclude is also present in the Lakewood formation but no effort has been made to define separately the areas where the aquiclude is identified with each age. The Gaspur aquifer extends south from the forebay areas in two separate arms which merge in the vicinity of the City of Lynwood and then extend south along the course of the Los Angeles River to the ocean. The Gaspur aquifer consists of coarse sand and gravel and ranges in thickness from 40 to 100 feet (Plate 11A). The maximum depth of about 190 feet (170 feet below sea level) occurs in the vicinity of Terminal Island in San Pedro Bay (Plate 10B).

The Lakewood formation, of late Pleistocene age, extends over all of the Central Basin Pressure Area. It contains part of the Bellflower aquiclude and the Artesia, Exposition, Gage, and Gardena aquifers. The water-bearing materials immediately underlying the Bellflower aquiclude west of the easterly arm of the Gaspur aquifer are called the Exposition aquifer. The water-bearing materials immediately underlying the Bellflower aquiclude east of this arm of the Gaspur aquifer are called the Artesia aquifer and are believed to be contemporary both in age and mode of deposition with the materials in the Exposition aquifer. The boundary between the Artesia and Exposition aquifers is somewhere in the center of the basin under the Gaspur aquifer. All three aquifers are in hydraulic continuity. Both the Artesia and Exposition aquifers consist of sand and gravel with local areas of interbedded clay. The Exposition aquifer ranges from 20 to over 100 feet in thickness (Plate 11A) and reaches a maximum depth of about 230 feet (120 feet below sea level) southeast of Huntington Park (Plate 10A).

AR0069017

The Artesia aquifer consists of 10 to 140 feet of sand and gravel with some interbedded clays (Plate 11A). It extends down to a maximum depth of 230 feet (220 feet below sea level) southeast of the City of Lakewood (Plate 10A).

The Gage and Gardena aquifers of the Lakewood formation are also considered to be the same age. Their relationship was discussed in this chapter in the section on the West Coast Basin. The Gage aquifer consists of fine-grained sand and silty sand ranging from 5 to 120 feet in thickness (Plate 13A). The maximum depth attained is 380 feet (350 feet below sea level) west of the City of Lakewood (Plate 12A). The Gardena aquifer consists of coarse-grained sand and gravel from 10 to 60 feet in thickness. It extends down to a depth of about 390 feet (350 feet below sea level) near the City of Lynwood. The Gage and Gardena aquifers mark the base of the Lakewood formation and along this base they abut the underlying San Pedro formation unconformably.

The San Pedro formation, present throughout the Central Basin Pressure Area, contains some of the most important aquifers in the area. In all, five aquifers, the Hollydale, Jefferson, Lynwood, Silverado, and Sunnyside, have been delineated.

Two relatively minor aquifers, the Hollydale and Jefferson aquifers, are present in the upper part of the San Pedro formation in the Central Basin Pressure Area. The Hollydale aquifer, uppermost of the two, (Plates 14 and 15) extends over approximately 60 percent of the area. It is mostly sand and silty sand with interbedded clays, though some gravel is found locally. It ranges from approximately 10 to 100 feet in thickness, and the maximum depth of about 570 feet (500 feet below sea level) is reached a few miles east of the City of Compton. The Jefferson aquifer (Plates 16 and 17)

AR0069018

is present over only 40 to 50 percent of the pressure area. It is mostly fine-grained sand with scattered lenses of gravel, and ranges in thickness from about 10 feet to over 140 feet. The maximum depth of approximately 720 feet (650 feet below sea level) is found near the Orange County line southeast of the City of Norwalk. Although these two aquifers are not continuous over the entire Central Basin Pressure Area, they are important sources of water in some localities.

Both the Lynwood and Silverado aquifers yield considerable water to wells in the Central Basin Pressure Area. The Lynwood aquifer (Plates 18A and 19A) is composed mainly of coarse-grained sands and gravels, ranging in thickness from less than 50 feet to over 150 feet. The maximum depth of about 1,030 feet (950 feet below sea level) occurs southeast of the City of Norwalk. The Silverado aquifer (Plates 20A and 21A) is composed largely of sands and gravels, ranging in thickness from about fifty feet to over 450 feet. The greatest depth is found north of the City of Lakewood, where its base is about 1,240 feet below the ground surface (1,200 feet below sea level). The base of the Silverado aquifer was thought to correspond to the base of the Pleistocene deposits and of fresh water in the West Coast Basin, where it was first named. In the Central Basin, however, the Sunnyside aquifer has been differentiated below the Silverado aquifer.

The Sunnyside aquifer (Plates 22 and 23) marks the base of the San Pedro formation in most parts of the Central Basin Pressure Area. It varies from about 70 feet to over 500 feet in thickness and consists of sand, and sand and gravel. The maximum depth of about 1,700 feet (1,660 feet below sea level) occurs east of the City of Lakewood.

AR0069019

Below the Sunnyside aquifer is a thick section of Pliocene deposits, the coarse zones of which contain fresh water, as indicated by electric logs of oil wells. Around the margins of the Central Basin Pressure Area, where many oil fields exist and more data are available, it is apparent that the fresh water was introduced into the Pliocene sediments by flushing the saline water toward the ocean. Much of the pressure area is in the South Gate-Santa Ana depression where only widely scattered exploratory type oil well data are available. No contours depicting the base of fresh water could be drawn through this area; however, the replacement of saline waters with fresh water appears to have occurred here as well.

The structural features which control or influence the occurrence and movement of ground water in the Central Basin Pressure Area are the South Gate-Santa Ana depression and the Newport-Inglewood uplift. The South Gate-Santa Ana depression extends from south of Beverly Hills into Orange County. It is bounded by transitional structures adjacent to the Puente and Repetto Hills on the northeast and the Newport-Inglewood uplift on the southwest. The Recent sediments in this depression are generally flat-lying as are the underlying deposits of the Lakewood formation. The San Pedro formation, however, is moderately folded and unconformably underlies the younger formations in most of the Central Basin.

The major structural features in the South Gate-Santa Ana depression are the Paramount syncline and Los Alamitos fault, and the Norwalk syncline. These structures appear to be developed only in the San Pedro formation, and they do not affect the overlying younger sediments. The Paramount syncline underlies the City of Paramount and extends northwesterly to the Inglewood fault north of the Baldwin Hills. The Los Alamitos fault

AR0069020

appears as an extension of the axis of the Paramount syncline southeast of the City of Paramount. The Norwalk syncline extends from the City of Norwalk southeasterly to the Orange County line. It is separated from the Los Alamitos fault by an unnamed anticlinal fold which extends into Orange County. None of these structural features appear to materially affect ground water movement in the Central Basin Pressure Area.

The faults and anticlinal folds of the Newport-Inglewood uplift mark the west and southwest boundary of the Central Basin Pressure Area and are partial barriers to movement of ground water from the Central Basin to the West Coast Basin, as has been previously discussed.

AR0069021

Occurrence of Ground Water in the Central Basin

In all four areas of the Central Basin ground water is found in the Recent alluvium, the Lakewood and San Pedro formations, and sometimes in the older sediments. The aquifers in these formations have been discussed above under separate headings for each area of the Central Basin. The paragraphs that follow will take up the movement of ground water into and through the Central Basin as a whole, rather than by separate areas.

Ground water enters the Central Basin through surface and subsurface flow and by direct percolation of precipitation, stream flow, and applied water. The main surface and subsurface flow into the basin is through the Los Angeles and Whittier Narrows from the ground water basins in the interior valleys. However, minor subsurface flow probably enters the area from the bordering relatively impermeable formations, and some subsurface flow can take place from the other surrounding ground water basins.

Replenishment of the aquifers by percolation of precipitation, stream flow, and applied water occurs in the forebay areas where permeable sediments are exposed at ground surface. In addition, some water also moves into the aquifers where they crop out on the surface against the surrounding highlands and in those portions of the pressure area where the Bellflower aquiclude is missing or contains considerable sand and gravel.

In the Los Angeles and Montebello Forebay Areas the aquifers are in hydraulic continuity in varying degrees, with each other and with the ground surface. In some instances this hydraulic continuity results from the aquifers being superposed one on another with no intervening clay members. Areas where each aquifer is merged with the overlying one are shown on the plates depicting lines of equal elevation on the base of each aquifer

AR0069022

(Plates 10A, 12A, 14, 16, 18A, 20A, and 22). In other portions of the forebay areas aquicludes present between the aquifers restrict direct movement of ground water between aquifers. However, these aquicludes are not continuous over the entire area; consequently, the hydraulic gradient controls the lateral movement of ground water to points where the aquifers are merged.

The areas of contact between aquifers and areas of contact with the ground surface are important because it is only through these areas that surface water can be introduced by spreading into the aquifers in major quantity. The most important area in this regard in the Coastal Plain of Los Angeles County is in the vicinity of the Whittier Narrows in the Montebello Forebay Area because of the interconnection of the deeper aquifers through the shallower ones to the ground surface. This condition also exists in the vicinity of the Los Angeles Narrows in the Los Angeles Forebay Area, but the paving of this area has essentially eliminated surface recharge to the aquifers below.

Plate 25, entitled "Areas Where Aquifers are Merged with Permeable Surface Deposits or Overlying Aquifers in Vicinity of Whittier Narrows" shows the generalized interconnections in and near the Whittier Narrows in the Montebello Forebay Area and the areas of essentially direct connection between the aquifers and the ground surface. This plate was derived from the detailed delineation of the areas of mergence shown on the plates depicting lines of equal elevation on the base of each aquifer.

Water applied on the surface can move directly into the Gaspur aquifer within the area shown on Plate 25. The Gage and Gardena aquifers immediately underlie the Gaspur aquifer and they are in hydraulic continuity. Below the Gage and Gardena aquifers are the Hollydale and Jefferson

AR0069023

aquifers which are generally merged with the Gage and Gardena aquifers. This relationship is shown on Plates 12A, 14, 16, and Plate 25. These interconnections provide essentially complete continuity with the surface through the Gaspur aquifer. The areas of mergence of the deeper aquifers with the overlying ones are much more restricted and these limited areas are shown on Plate 25 as well as on Plates 18A, 20A, and 22. It will be noted from Plate 25 that the area of direct vertical recharge from the ground surface to the Lynwood aquifer is about one-third of the area of the Gaspur in contact with the ground surface. The area of direct vertical recharge to the Silverado and Sunnyside aquifers is even more restricted and is limited to a very small area in the immediate vicinity of Whittier Narrows Dam. These limited areas of interconnection severely restrict the amount of recharge that can directly reach the deeper aquifers from the ground surface. Fortunately, the areas of mergence through which water can reach the lower aquifers by devious paths is considerably larger than shown on Plate 25 (see Plates 12A, 14, 16, 18A, 20A, and 22). Therefore, even though the direct downward infiltration may be restricted or entirely impeded by an intervening aquiclude, water can move laterally in one aquifer to a point where the aquifer is merged with a lower one, permitting water applied at the surface to reach and replenish the deeper aquifers.

The areas of mergence between aquifers in the Los Angeles Forebay also are shown on the plates depicting lines of equal elevation on the base of each aquifer. It is evident that considerable opportunity existed for infiltration of water from the ground surface into the Gaspur aquifer and on into the deeper aquifers of the basin. However, as noted before, this area now is essentially covered with impervious material and the opportunity for surface recharge of the aquifers is practically nonexistent.

AR0069024

This is unfortunate from the standpoint of ground water basin utilization since the available storage capacity in the Los Angeles Forebay is large.

Under present conditions, ground water in the Montebello Forebay Area moves into the Los Angeles Forebay Area, the Whittier Area, and the Central Basin Pressure Area. Ground water from the Los Angeles Forebay Area also moves into the Central Basin Pressure Area. In the northern portion of the pressure area a ground water mound exists which separates ground water movement into two parts. North of this mound ground water moves northward into the Hollywood Basin while south of this mound ground water moves southwesterly toward the West Coast Basin.

Ground water movement in the Whittier Area in July 1958 was to the west and southwest in both the deep and shallow aquifers. The Santa Fe Springs-Coyote Hills uplift, the axis of which serves as the southern boundary of the Whittier Area, appears to restrict ground water movement to the south into the Central Basin Pressure Area in the aquifers of the Lakewood formation. The aquifers of the San Pedro formation are continuous across the uplift and it is reasonable to assume that ground water movement to the south could take place if the hydraulic gradient sloped in that direction.

Historically, subsurface flow took place from the Central Basin across the Newport-Inglewood uplift into the West Coast Basin. However, pumping has lowered the water level in the Central Basin and at present water levels in some aquifers are about equal on both sides of the Newport-Inglewood uplift. Further lowering of water levels on either side of the uplift could result in a hydraulic gradient being established which would slope toward the point of the lower water level with a consequent flow of water in that direction. A relatively small amount of subsurface flow occurs out of the Central Basin Pressure Area because most of the ground

AR0069025

water moves to a series of pumping holes developed along the Newport-Inglewood uplift north of Dominguez Hill, along the Cherry Hill fault, north of Signal Hill and in the Lakewood area. From these areas the water is removed by pumping for industrial, irrigation, and domestic uses.

The movement of ground water across the Los Angeles-Orange County line, which forms the eastern boundary of the Central Basin, is entirely dependent on the hydraulic gradient in that area, as no physical barrier to ground water movement exists except for the Coyote Hills.

Transmissibility rates of aquifers in Central Basin as shown on Plates 26A through 26I are extremely variable, ranging up to 400,000 gallons per day per foot of width, although most of the aquifers have transmissibility rates of less than 100,000.

The Gaspur aquifer (Plate 26A) generally has a transmissibility rate of less than 200,000 gallons per day per foot, but has a maximum of 400,000 in a small area in Whittier Narrows. Transmissibility rates in the Artesia-Exposition aquifer average about 30,000 with a maximum transmissibility rate of about 70,000 in several small areas (see Plate 26B, "Lines of Equal Transmissibility of the Artesia-Exposition Aquifers"). The Gage and Gardena aquifers (Plate 26C) also have average rates of about 30,000 but reach a maximum value of about 100,000 near Long Beach and in the Whittier Narrows. The transmissibility rates of the Hollydale and Jefferson aquifers, shown on Plates 26D and 26E entitled, "Lines of Equal Transmissibility of the Hollydale Aquifer" and "Lines of Equal Transmissibility of the Jefferson Aquifer", respectively, have average values of about 20,000 gallons per day per foot of width. The Lynwood aquifer rates (Plate 26F) average about 40,000 but attain a maximum transmissibility rate of about 100,000 gallons per day per foot of width in several areas.

AR0069026

The Silverado aquifer (Plate 26G) averages about 60,000 but reaches a maximum of 400,000 near the intersection of Carson and Atlantic Boulevards. Data on the Sunnyside aquifer in the middle, deeper portion of Central Basin is not very complete, but it appears to have an average transmissibility rate of about 100,000 with a maximum of 300,000 in several areas as shown on Plate 26H, "Lines of Equal Transmissibility of the Sunnyside Aquifer".

The overall transmissibility of all aquifers in the Central Basin is of considerable importance. It may be noted on Plate 26I that high transmissibility rates exist from Whittier Narrows toward Long Beach and Compton, but that an area of low transmissibility separates the Montebello and Los Angeles Forebays. This low transmissibility partly explains the existence of the large pumping depression around Huntington Park and Vernon, where pumping rates are generally not much higher than in the Downey area but there no pumping depression exists.

While the Central Basin Pressure Area is, as its name signifies, essentially an area of confined aquifers, free ground water conditions exist in the Semiperched aquifer overlying the Bellflower aquiclude, and probably in the vicinity of Baldwin Hills where the San Pedro formation is exposed at the surface. In addition, changes in ground water storage have occurred immediately south of the two forebay areas in the upper aquifers directly underlying the Bellflower aquiclude.

In past ground water studies of the Central Basin, it was believed that the clay layer or cap covered all of the basin south of the forebay areas and effectively prevented any percolation of surface water into the aquifers below. Plate 9 shows places where this clay cap, the Bellflower aquiclude, contains considerable amounts of sand and gravel. In

AR0069027

these areas, water applied on the surface could percolate down into the underlying aquifers and it is possible that free ground water conditions may exist from the surface down through one or more of the upper aquifers. These areas increase the total area of the Central Basin where changes in ground water storage can occur with changing water levels and where replenishment by deep percolation can occur. In addition, changes in storage in the Bellflower aquiclude itself is believed to occur as water levels are lowered. These changes in storage are relatively small however, because of the relatively low specific yield assigned to much of these sediments.

Total capacity to store ground water in the Central Basin above the base of the Sunnyside aquifer, or the Silverado aquifer where the Sunnyside is missing, is about 13,800,000 acre-feet. Historically utilized storage since 1904 amounts to about 780,000 acre-feet. As noted before, this change in storage has occurred primarily in the Montebello and Los Angeles Forebay Areas; however, some of the change in storage occurred in the pressure area immediately south of these areas where water levels were lowered below the base of the Bellflower aquiclude and near the Repetto and Whittier Hills where the San Pedro formation crops out at the surface. The storage capacity between high water levels, which occurred in 1904, and sea level amounts to about 1,340,000 acre-feet.

The storage and storage change for the Central Basin listed above may be broken down between the generalized areas delineated on Plate 2 as follows:

	Total storage to base of deepest aquifer	Storage between high water and sea level	Historically utilized storage
Los Angeles Forebay Area	1,800,000	430,000	190,000
Montebello Forebay Area	1,800,000	410,000	230,000
Whittier Area	600,000	60,000	20,000
Central Basin Pressure Area	9,600,000	440,000	340,000
Total	13,800,000	1,340,000	780,000

AR0069028

CHAPTER VII. CONCLUDING REMARKS

This report has been compiled primarily for use in studies of ground water hydrology, quality, and basin operation. While it is true that considerable detail is shown on the plates and discussed in the text, the emphasis has been on general relationships between the aquifers, geologic structures, and ground water. Detailed investigations of small areas may indicate that there are, in reality, many more aquifers, and that their relationships are more complex than outlined here. It is to be expected that many of the details presented in this report will eventually be revised. However, it is believed that this report provides a foundation for further refinement and revision of the geology of the fresh water-bearing sediments.

Before additional refinements and revisions can be made it will be necessary to accumulate more basic data. Accordingly the following observations and recommendations are proffered:

1) This study has shown the value of the continuous collection of geologic and hydrologic data in order to better understand the physical limits of ground water basins, their aquifers and structures, and the movement and occurrence of their contained ground water. Where detailed information was available, the geologic interpretation was easier and certain, but not necessarily final. Areas that were deficient in data required an extension of basic concepts from known areas into unknown areas. It was here that the experience gained from similar studies in Southern California proved of value.

Development of highland areas is expanding and more wells are being drilled in volcanic rocks, older sediments, and the alluvium of

AR0069029

mountain valleys. Although these areas are not in the principal ground water basins, the increased requests by the public for information on the ground water resources in the highlands have shown a need for more study of these upland areas.

It is therefore recommended that the data collection program be continued for areas both in the principal ground water basins as well as the lesser basins and highland areas. With more detailed information, the complex problems which will arise as ground water usage increases will be easier to analyze and perhaps solve. A continuous program of limited data collecting will also be necessary for a re-evaluation of areas already studied.

2) Similar studies of adjacent areas should clarify marginal basin features in the Coastal Plain of Los Angeles County. The regional interpretation sometimes sheds light on the local conditions. Conversely, information gained in this investigation will facilitate studies in these adjacent areas.

3) There is a need for more exploratory wells in areas where data is now deficient, in areas of sea-water intrusion, and in areas of complex geologic structures. These wells should be carefully logged by geologists, soil samples taken and examined for fossil or microfossil content, and water samples analyzed for water quality changes both in the vertical sequence of aquifers and laterally. Upon completion of the wells they should be pumped for transmissibility tests and to verify barrier effects, if any, of geologic structures.

4) There is a need for more control over the abandonment of water wells, such as the control that now exists in the oil well program,

AR0069030

to protect the aquifers containing good quality water from degradation or contamination from the surface or from other aquifers of poorer quality water.

5) As more information becomes available for the deeper Pliocene water-bearing materials, aquifers should be delineated and identified.

6) The present communication and cooperation between agencies conducting geologic and ground water investigations in Southern California should be continued and improved. This reduces the cost of future studies and eliminates duplication of effort.

TABLE A

SPECIFIC YIELD VALUES
Used in Coastal Plain of Los Angeles County

(After State Water Rights Board Revised Values of
Specific Yield as used for San Fernando Valley Reference,
7/9/59, which is based on values used in Bulletin 45,
Geology and Ground Water Storage Capacity of Valley Fill)
*Specific yield values above base of Bellflower aquiclude = 00

*00 Percent - Bellflower Aquiclude

03 Percent - Clay and Shale

Adobe
Boulders in clay
Cemented clay
Clay
Clayey loam
Decomposed shale
Granite clay
Hard clay
Hard pan
Hard sandy shale
Hard shell
Muck
Shale
Shaley clay
Shell rock
Silty clay loam
Soapstone

05 Percent - Clayey Sand and Silt

Chalk rock
Clay and gravel
Clayey sand
Clayey silt
Conglomerate
Decomposed granite
Gravelly clay
Loam
Rotten conglomerate
Rotten granite
Sand and clay
Sand and silt
Sand rock
Sandstone
Sandy clay
Sandy silt
Sediment
Shaley gravel
Silt
Silty clay
Silty loam
Silty sand
Soil

10 Percent - Cemented or Tight Sand or Gravel

Caliche
Cemented boulders
Cemented gravel
Cemented sand
Cemented sand and gravel
Dead gravel
Dead sand
Dirty pack sand
Hard gravel
Hard sand
Heavy rocks
Soft sandstone
Tight boulders
Tight coarse gravel

14 Percent - Gravel and Boulders

Cobbles and gravel
Coarse gravel
Boulders
Broken rocks
Gravel and boulders
Heaving gravel
Heavy gravel
Large gravel
Rocks
Sand and gravel, silty
Silty sand
Tight fine gravel
Tight medium gravel
Muddy sand

AR0069256

SPECIFIC YIELD VALUES
(continued)

16 Percent - Fine Sand

Fine sand	Quicksand	Sand, gravel and boulders
Heaving sand	Sand and boulders	Tight sand

21 - 23 Percent - Sand and Gravel

Dry gravel	Gravelly sand	Sand
Loose gravel	Medium gravel	Water gravel

26 Percent - Coarse Sand and Fine Gravel

Coarse sand	Fine gravel	Medium sand

Value of one added to given value where streaks of sand or gravel occur in clay or clayey material.

Footnotes:

1. Where no value is shown specific yield was assumed to be zero or the elevational increment was above the ground surface or below the base of the deepest aquifer. For this tabulation all the deposits above the base of the Bellflower Aquiclude were considered to have zero specific yield. Also the tabulation was limited to the elevations between + 320 and -200 feet because it is within this range that change in ground water storage occurs.
2. Location is referenced to the U. S. Public Land Survey as projected into the Coastal Plain of Los Angeles County. 1/14 - 30 refers to Township 1 South, Range 14W, Section 30, San Bernardino Base and Meridian. The estimated average specific yield values given refer to the section or portion of a section lying within the boundary of the specified ground water basin.

AR0069276

TRANSMISSIBILITY TEST PROCEDURES

The transmissibility rates of aquifers penetrated by wells in the Coastal Plain of Los Angeles County were determined by the use of drawdown and recovery tests, in addition to other available data. A drawdown test is one in which measurements of the ground water levels are taken starting the moment the well is turned on and continued as long as possible or until the water level stabilizes or draws down very slowly. The measurements are usually taken in an observation well perforated in the same aquifer as the pumping well, but the measurements may be taken in the pumping well. The quantity of ground water pumped is also measured.

A recovery test is essentially the reverse of a drawdown test. A well is pumped for a known amount of time and the discharge measured. Starting at the time the pump is shut off, ground water levels are measured at frequent intervals. The measurements are continued until the static level is approximately reached (the static water level is where the water level in the well would stand if not affected by pumping in the well or in nearby wells). The water level measurements are made in the pumping well, or in a nearby observation well perforated in the same aquifer as the pumping well.

In both tests, the change in water level can be plotted against the time required for the change. Using formulas previously determined, the transmissibility, horizontal permeability, storage coefficient, and vertical permeability can be computed when a pumping and observation well are used together. When a test is run in the pumping well, generally only transmissibility and horizontal permeability can be determined.

AR0069277

The transmissibility rate, or the coefficient of transmissibility, is the flow of water, in gallons per day at the prevailing water temperature, through a vertical strip of the aquifer one foot wide having a height equal to the thickness of the aquifer and under a unit hydraulic gradient. It has also been described at "the field coefficient of permeability" multiplied by the thickness, in feet, of the saturated part of the aquifer.

The permeability of a material is its capacity for transmitting a fluid. The coefficient of permeability is the rate of flow of water in gallons a day through a cross section of one square foot under a unit hydraulic gradient. The standard coefficient is defined for water at a temperature of 60°F. The field coefficient requires no temperature adjustment and the units are stated in terms of the prevailing water temperature.

The horizontal permeability refers to the flow of water into a pumping well from an aquifer penetrated by the well.

Vertical permeability as used in this attachment refers to the movement of water through a confining bed into the underlying aquifer.

The leakage coefficient is used to describe the numerical quantity derived by dividing the vertical permeability of a confining bed by the thickness in feet through which this leakage occurs.

Storage coefficient, or the coefficient of storage, is the volume of water in cubic feet released from storage in each vertical column of water having a base one foot square when the water table or piezometric surface declines one foot. It is expressed as a decimal figure with no units.

AR0069278

An aquifer is a geologic formation, group of formations, or part of a formation that transmits water in sufficient quantity to supply pumping wells or springs.

AR0069279

Assignment of Transmissibility Rates to Aquifer

The transmissibility rates for each aquifer and overall transmissibility rates for the coastal plain that were presented in this report were computed in the following manner:

1. All well logs used in the investigation were classified as to the aquifers intercepted and to the thickness of each aquifer at that well.

2. Permeability values of sediments were obtained from the transmissibility tests previously discussed. The results of these tests, summarized on Table C, were used as a basis for assigning representative values to the various materials encountered in the sediments. This simplification was necessary to reduce the amount of time that would otherwise have been necessary to evaluate each well log separately. The representative values of permeability used in the study are tabulated in Table D, following.

3. Using the values in Table D, a tabulation for each well log was completed that listed the materials encountered, the thickness of the material, and the permeability values used. By multiplying the thickness of each material by its permeability value, and adding together these products for the various materials found in each aquifer, the transmissibility rates of individual aquifers were computed for each well location.

4. The transmissibility values for each aquifer were plotted on maps of the coastal plain that also delineated lines of equal thickness of the particular aquifer in order to correlate the two. Contour lines of equal transmissibility rates were then drawn and interpolated and extrapolated into areas with only sparse data control. These contour lines are shown on Plates 26A to 26H for each aquifer.

5. Transmissibility rates at the northeast corner of each section for each aquifer were taken off the maps and tabulated. The values for each aquifer at each section corner were totaled, obtaining an overall transmissibility rate for that location. These overall rates were also plotted on a map and contours drawn representing lines of equal total transmissibility rates. This map of generalized lines of total transmissibility is presented as Plate 26I.

AR0069283

TABLE D

PERMEABILITY VALUES

ASSIGNED TO DRILLERS LOGS

Sandy Clay (includes gravelly clay, clay and sand, clayey sand, etc.)	50gpd/ft^2
Sand	500gpd/ft^2
Gravel (includes sand and gravel)	
Gaspur Aquifer	4000gpd/ft^2
Ballona Aquifer	2000gpd/ft^2
Marine Gravels (Silverado, Sunnyside, and portion of Lynwood aquifers)	1500gpd/ft^2
Nonmarine Gravels (Gardena, Artesia, Exposition, Jefferson, Hollydale, and portion of Lynwood Aquifer)	1000gpd/ft^2
Gravel with Clay Streaks	one-half of above values for gravel
Clay	0

AR0069287

Well Numbering System

The well numbering system employed herein is that utilized by the United States Geological Survey, according to the township, range, and section subdivision of the Federal Land Survey. It conforms to that used in all ground water investigations by the U. S. Geological Survey in California and has been adopted by the Department of Water Resources.

Under the system, each section is divided into sixteen 40-acre plots, which are lettered as follows:

Wells are numbered within each of these 40-acre plots according to the order in which they are located. For example, a well having the number 2S/11W-26B8 would be in Township 2 South, Range 11 West, Section 26, and would be further identified as the 8th well located in the 40-acre plot lettered B. Each well must be referenced to a particular Base and Meridian line, such as S. B. B. & M. for San Bernardino Base and Meridian (Southern California) or M. D. B. & M. for Mount Diablo Base and Meridian (Central California) and H. B. & M. for Humbolt Base and Meridian (Northern California).

Definitions

Anticline - Term applied to strata which dip in opposite directions from a common ridge or axis, like the roof of a house, and from what is

AR0069288

termed an "anticline" or "saddleback" (Page D, Handbook of Geological Terms, London, 1859).

Aquiclude - A formation which, although porous and capable of absorbing water slowly, will not transmit it fast enough to furnish an appreciable supply for a well or spring. (Tolman, 1937, p. 557).

Aquifer - A geologic formation, group of formations, or part of a formation that transmits water in sufficient quantity to supply pumping wells or springs.

Confined Ground Water - A body of ground water overlain by material sufficiently impervious to sever free hydraulic connection with overlying ground water except at the intake. Confined water moves in conduits under pressure due to the difference in head between the intake and discharge areas of the confined water body. (Tolman, 1937, p. 558).

Connate Water - Water entrapped in the interstices of a sedimentary rock at the time it was deposited. (Tolman, 1937, p. 558). These waters may be fresh, brackish, or saline in character. Because of the dynamic geologic and hydrologic conditions in California this definition has been altered in practice to apply to water in older formations, even though in these the water may have been altered in quality since the rock was originally deposited.

Free Ground Water - Water in interconnected interstices in the zone of saturation down to the first impervious barrier, moving under the control of the water-table slope. (Tolman, 1937, p. 559).

Graben - Fault block bounded on both sides by gravity faults, generally long compared to its width, that has been lowered relative to the blocks on either side. (Billings, 1954, p. 203).

AR0069289

Horst - A block of the earth's crust, generally long compared to its width, bounded on both sides by gravity faults, that has been uplifted relative to the blocks on either side. (Billings, 1954, p. 203).

Impermeable - Impervious. Having a texture that does not permit water to move through it perceptibly under the head differences ordinarily found in subsurface water. (Meinzer, 1923, p. 20).

Isopach or Isopachous line - A line drawn on a map through points of equal thickness of a designated unit. (Glossary of Geology and Related Sciences, 1957).

Orogeny - The process of mountain building (Fay, 1920).

Perched Ground Water - Ground water occurring in a saturated zone separated from the main body of ground water by unsaturated rock (Tolman, 1937, p. 562).

Permeability - The permeability (or perviousness) of rock is its capacity for transmitting a fluid. Degree of permeability depends upon the size and shape of the pores, the size and shape of their interconnections, and the extent of the latter. (Glossary of Geology and Related Sciences, 1957, p. 217).

Permeability, field coefficient of - The amount of water moving through a unit area of aquifer per unit time under unit hydraulic gradient at the natural temperature. Ordinarily in gallons per day per square foot.

Permeability, coefficient of - Same as above, except that a reference temperature of 60 degrees Fahrenheit is defined. Other units are also used such as cubic feet per second per square foot, acre-feet per year per square foot, etc.

AR0069290

Permeable - Pervious. Having a texture that permits water to move through it perceptibly under the head differences ordinarily found in subsurface water. (Meinzer, 1923, p. 29).

Piedmont Slope - "When two or more streams flow out from a highland and closely adjacent to one another they may build a sloping plain, which is relatively high near the highland and lower further out, and which is composed of a series of fans in whose growth there has been mutual interference. This process produces a piedmont slope or series of coalescing fans." (Bryan, Kirk, U.S.G.S.W.S.P., p. 28, 1923).

Piezometric Surface - The piezometric surface of an aquifer is an imaginary surface that everywhere coincides with the head of water in the aquifer. (Meinzer, 1942).

Specific Yield - The ratio of the water a saturated sediment will yield by gravity drainage to the total volume of the sediment and water prior to draining, customarily expressed in percent.

Storage Coefficient - Volume of water released from storage in each verticle column of aquifer having a base one foot square when the water level declines one foot. In an unconfined aquifer it approximates specific yield. In a confined aquifer it is related to elasticity of the aquifer and is usually very small.

Syncline - A fold in rocks in which the strata dip inward from both sides toward the axis. (Glossary of Geology and Related Sciences, 1957).

Transmissibility, coefficient of - The rate of flow of water, in gallons a day, at the prevailing water temperature through each vertical strip, one foot wide, having a height equal to the thickness of the aquifer and under a unit hydraulic gradient. (Glossary of Geology and Related Sciences, 1957).

AR0069291

Unconformity - A surface of erosion or nondeposition, usually the former, that separates younger strata from older rocks. (Glossary of Geology and Related Sciences, 1957).

Re: 110/10 Fwy Ramp Data Request

Hi Steven - If you recall, you helped me gather some traffic data in July (see below.) I have a new (and smaller) request. I was able to find all the ADT volumes, but not the peak hours for the ramps. Do you think you could fill in the blanks below? I would greatly appreciate your help!

101 Freeway, LA County

1. 101 South Off-Ramp to Vine Street
   Postmile 7.368
   AADT: 14,200
   Peak Hour: ____

2. 101 South Off-Ramp to Gower Street
   Postmile: 7.059
   AADT: 6,700
   Peak Hour: ____

3. 101 South On Ramp From Argyle Ave
   Postmile 6.969
   AADT: 3,100
   Peak Hour: ____

Traffic and Vehicle Data Systems Unit

To My Local Government Colleagues....

I am pleased to introduce this informational guide to air quality and land use issues focused on community health. As a former county supervisor, I know from experience the complexity of local land use decisions. There are multiple factors to consider and balance. This document provides important public health information that we hope will be considered along with housing needs, economic development priorities, and other quality of life issues.

An important focus of this document is prevention. We hope the air quality information provided will help inform decision-makers about the benefits of avoiding certain siting situations. The overarching goal is to avoid placing people in harm's way. Recent studies have shown that public exposure to air pollution can be substantially elevated near freeways and certain other facilities. What is encouraging is that the health risk is greatly reduced with distance. For that reason, we have provided some general recommendations aimed at keeping appropriate distances between sources of air pollution and land uses such as residences.

Land use decisions are a local government responsibility. The Air Resources Board's role is advisory and these recommendations do not establish regulatory standards of any kind. However, we hope that the information in this document will be seriously considered by local elected officials and land use agencies. We also hope that this document will promote enhanced communication between land use agencies and local air pollution control agencies. We developed this document in close coordination with the California Air Pollution Control Officers Association with that goal in mind.

I hope you find this document both informative and useful.

Barbara Riordan

Mrs. Barbara Riordian
Interim Chairman
California Air Resources Board

Acknowledgments

The ARB staff would like to acknowledge the exceptional contributions made to this document by members of the ARB Environmental Justice Stakeholders Group. Since 2001, ARB staff has consistently relied on this group to provide critical and constructive input on implementing the specifics of ARB's environmental justice policies and actions. The Stakeholders Group is convened by the ARB, and comprised of representatives from local land use and air agencies, community interest groups, environmental justice organizations, academia, and business. Their assistance and suggestions throughout the development of this Handbook have been invaluable.

Executive Summary

The Air Resources Board s (ARB) primary goal in developing this document is to provide information that will help keep California's children and other vulnerable populations out of harm s way with respect to nearby sources of air pollution. Recent air pollution studies have shown an association between respiratory and other non-cancer health effects and proximity to high traffic roadways. Other studies have shown that diesel exhaust and other cancer-causing chemicals emitted from cars and trucks are responsible for much of the overall cancer risk from airborne toxics in California. Also, ARB community health risk assessments and regulatory programs have produced important air quality information about certain types of facilities that should be considered when siting new residences, schools, day care centers, playgrounds, and medical facilities (i.e., sensitive land uses). Sensitive land uses deserve special attention because children, pregnant women, the elderly, and those with existing health problems are especially vulnerable to the non-cancer effects of air pollution. There is also substantial evidence that children are more sensitive to cancer-causing chemicals.

Focusing attention on these siting situations is an important preventative action. ARB and local air districts have comprehensive efforts underway to address new and existing air pollution sources under their respective jurisdictions. The issue of siting is a local government function. As more data on the connection between proximity and health risk from air pollution become available, it is essential that air agencies share what we know with land use agencies. We hope this document will serve that purpose.

The first section provides ARB recommendations regarding the siting of new sensitive land uses near freeways, distribution centers, rail yards, ports, refineries, chrome plating facilities, dry cleaners, and gasoline dispensing facilities. This list consists of the air pollution sources that we have evaluated from the standpoint of the proximity issue. It is based on available information and reflects ARB's primary areas of jurisdiction – mobile sources and toxic air contaminants. A key air pollutant common to many of these sources is particulate matter from diesel engines. Diesel particulate matter (diesel PM) is a carcinogen identified by ARB as a toxic air contaminant and contributes to particulate pollution statewide.

Reducing diesel particulate emissions is one of ARB's highest public health priorities and the focus of a comprehensive statewide control program that is reducing diesel PM emissions each year. ARB's long-term goal is to reduce diesel PM emissions 85% by 2020. However, cleaning up diesel engines will take time as new engine standards phase in and programs to accelerate fleet turnover or retrofit existing engines are implemented. Also, these efforts are reducing diesel particulate emissions on a statewide basis, but do not yet capture every site where diesel vehicles and engines may congregate. Because living or going to school too close to such air pollution sources may increase both cancer and non-cancer health risks, we are recommending that proximity be considered in the siting of new sensitive land uses.

AR0069311

There are also other key toxic air contaminants associated with specific types of facilities. Most of these are subject to stringent state and local air district regulations. However, what we know today indicates that keeping new homes and other sensitive land uses from siting too close to such facilities would provide additional health protection. Chrome platers are a prime example of facilities that should not be located near vulnerable communities because of the cancer health risks from exposure to the toxic material used during their operations.

In addition to source specific recommendations, we also encourage land use agencies to use their planning processes to ensure the appropriate separation of industrial facilities and sensitive land uses. While we provide some suggestions how to best achieve that goal is a local issue. In the development of these guidelines, we received valuable input from local government about the spectrum of issues that must be considered in the land use planning process. This includes addressing housing and transportation needs, the benefits of urban infill, community economic development priorities, and other quality of life issues. All of these factors are important considerations. The recommendations in the Handbook need to be balanced with other State and local policies.

Our purpose with this document is to highlight the potential health impacts associated with proximity to air pollution sources so planners explicitly consider this issue in planning processes. We believe that with careful evaluation, infill development, mixed use, higher density, transit-oriented development, and other concepts that benefit regional air quality can be compatible with protecting the health of individuals at the neighborhood level. One suggestion for achieving this goal is more communication between air agencies and land use planners. Local air districts are an important resource that should be consulted regarding sources of air pollution in their jurisdictions. ARB staff will also continue to provide updated technical information as it becomes available.

Our recommendations are as specific as possible given the nature of the available data. In some cases, like refineries, we suggest that the siting of new sensitive land uses should be avoided immediately downwind. However, we leave definition of the size of this area to local agencies based on facility specific considerations. Also, project design that would reduce air pollution exposure may be part of the picture and we encourage consultation with air agencies on this subject.

In developing the recommendations, our first consideration was the adequacy of the data available for an air pollution source category. Using that data, we assessed whether we could reasonably characterize the relative exposure and health risk from a proximity standpoint. That screening provided the list of air pollution sources that we were able to address with specific recommendations. We also considered the practical implications of making hard and fast recommendations where the potential impact area is large, emissions will be reduced with time, and air agencies are in the process of looking at options for additional emission control. In the end, we tailored our recommendations to minimize the highest exposures for each source category independently. Due to the large variability in relative risk in the source categories, we chose not to apply

AR0069312

a uniform quantified risk threshold as is typically done in air quality permitting programs. Instead, because these guidelines are not regulatory or binding on local agencies, we took a more qualitative approach in developing the distance-based recommendations.

Where possible, we recommend a minimum separation between a new sensitive land use and known air pollution risks. In other cases, we acknowledge that the existing health risk is too high in a relatively large area, that air agencies are working to reduce that risk, and that in the meantime, we recommend keeping new sensitive land uses out of the highest exposure areas. However, it is critical to note that our implied identification of the high exposure areas for these sources does not mean that the risk in the remaining impact area is insignificant. Rather, we hope this document will bring further attention to the potential air health risk throughout the impact area and help garner support for our ongoing efforts to reduce health risk associated with air pollution sources. Areas downwind of major ports, rail yards, and other inter-modal transportation facilities are prime examples.

We developed these recommendations as a means to share important public health information. The underlying data are publicly available and referenced in this document. We also describe our rationale and the factors considered in developing each recommendation, including data limitations and uncertainties. These recommendations are advisory and should not be interpreted as defined "buffer zones." We recognize the opportunity for more detailed site-specific analyses always exists, and that there is no "one size fits all" solution to land use planning.

As California continues to grow, we collectively have the opportunity to use all the information at hand to avoid siting scenarios that may pose a health risk. As part of ARB's focus on communities and children's health, we encourage land use agencies to apply these recommendations and work more closely with air agencies. We also hope that this document will help educate a wider audience about the value of preventative action to reduce environmental exposures to air pollution.

AR0069313

1. ARB Recommendations on Siting New Sensitive Land Uses

Protecting California's communities and our children from the health effects of air pollution is one of the most fundamental goals of state and local air pollution control programs. Our focus on children reflects their special vulnerability to the health impacts of air pollution. Other vulnerable populations include the elderly, pregnant women, and those with serious health problems affected by air pollution. With this document, we hope to more effectively engage local land use agencies as partners in our efforts to reduce health risk from air pollution in all California communities.

Later sections emphasize the need to strengthen the connection between air quality and land use in both planning and permitting processes. Because the siting process for many, but not all, air pollution sources involves permitting by local air districts, there is an opportunity for interagency coordination where the proposed location might pose a problem. To enhance the evaluation process from a land use perspective, section 4 includes recommended project related questions to help screen for potential proximity related issues.

Unlike industrial and other stationary sources of air pollution, the siting of new homes or day care centers does not require an air quality permit. Because these situations fall outside the air quality permitting process, it is especially important that land use agencies be aware of potential air pollution impacts.

The following recommendations address the issue of siting "sensitive land uses" near specific sources of air pollution, namely:

- High traffic freeways and roads
- Distribution centers
- Rail yards
- Ports
- Refineries
- Chrome plating facilities
- Dry cleaners
- Large gas dispensing facilities

The recommendations for each category include a summary of key information and guidance on what to avoid from a public health perspective.

AR0069315

Sensitive individuals refer to those segments of the population most susceptible to poor air quality (i.e., children, the elderly, and those with pre-existing serious health problems affected by air quality). Land uses where sensitive individuals are most likely to spend time include schools and schoolyards, parks and playgrounds, daycare centers, nursing homes, hospitals and residential communities (sensitive sites or sensitive land uses).

We are characterizing sensitive land uses as simply as we can by using the examples of residences, schools, day care centers, playgrounds, and medical facilities. However, a variety of facilities are encompassed. For example, residences can include houses, apartments, and senior living complexes. Medical facilities can include hospitals, convalescent homes, and health clinics. Playgrounds could be play areas associated with parks or community centers.

In developing these recommendations, ARB first considered the adequacy of the data available for each air pollution source category. We assessed whether we could generally characterize the relative exposure and health risk from a proximity standpoint. The documented non-cancer health risks include triggering of asthma attacks, heart attacks, and increases in daily mortality and hospitalization for heart and respiratory diseases. These health impacts are well documented in epidemiological studies, but less easy to quantify from a particular air pollution source. Therefore, the cancer health impacts are used in this document to provide a picture of relative risk. This screening process provided the list of source categories we were able to address with specific recommendations. In evaluating the available information, we also considered the practical implications of making hard and fast recommendations where the potential impact area is large, emissions will be reduced with time, and air agencies are in the process of looking at options for additional emission control. Due to the large variability in relative risk between the source categories, we chose not to apply a uniform, quantified risk threshold as is typically done in regulatory programs. Therefore, in the end, we tailored our recommendations to minimize the highest exposures for each source category independently. Additionally, because this guidance is not regulatory or binding on local agencies, we took a more qualitative approach to developing distance based recommendations.

Where possible, we recommend a minimum separation between new sensitive land uses and existing sources. However, this is not always possible, particularly where there is an elevated health risk over large geographical areas. Areas downwind of ports and rail yards are prime examples. In such cases, we recommend doing everything possible to avoid locating sensitive receptors within the highest risk zones. Concurrently, air agencies and others will be working to reduce the overall risk through controls and measures within their scope of authority.

AR0069316

The recommendations were developed from the standpoint of siting new sensitive land uses. Project-specific data for new and existing air pollution sources are available as part of the air quality permitting process. Where such information is available, it should be used. Our recommendations are designed to fill a gap where information about existing facilities may not be readily available. These recommendations are only guidelines and are not designed to substitute for more specific information if it exists.

A summary of our recommendations is shown in Table 1-1. The basis and references[1] supporting each of these recommendations, including health studies, air quality modeling and monitoring studies is discussed below beginning with freeways and summarized in Table 1-2. As new information becomes available, it will be included on ARB's community health web page.

[1]Detailed information on these references are available on ARB's website at: http://www.ARB.ca.gov/ch/landuse.htm.

AR0069317

Table 1-1

Recommendations on Siting New Sensitive Land Uses Such As Residences, Schools, Daycare Centers, Playgrounds, or Medical Facilities*

Source Category	Advisory Recommendations
Freeways and High-Traffic Roads	• Avoid siting new sensitive land uses within 500 feet of a freeway, urban roads with 100,000 vehicles/day, or rural roads with 50,000 vehicles/day
Distribution Centers	• Avoid siting new sensitive land uses within 1,000 feet of a distribution center (that accommodates more than 100 trucks per day, more than 40 trucks with operating transport refrigeration units (TRUs) per day, or where TRU unit operations exceed 300 hours per week). • Take into account the configuration of existing distribution centers and avoid locating residences and other new sensitive land uses near entry and exit points
Rail Yards	• Avoid siting new sensitive land uses within 1,000 feet of a major service and maintenance rail yard. • Within one mile of a rail yard, consider possible siting limitations and mitigation approaches.
Ports	• Avoid siting of new sensitive land uses immediately downwind of ports in the most heavily-impacted zones. Consult local air districts or the ARB on the status of pending analyses of health risks.
Refineries	• Avoid siting new sensitive land uses immediately downwind of petroleum refineries. Consult with local air districts and other local agencies to determine an appropriate separation.
Chrome Platers	• Avoid siting new sensitive land uses within 1,000 feet of a chrome plater.
Dry Cleaners Using Perchloro-ethylene	• Avoid siting new sensitive land uses within 300 feet of any dry cleaning operation. For operations with two or more machines, provide 500 feet. For operations with 3 or more machines, consult with the local air district. • Do not site new sensitive land uses in the same building with perc dry cleaning operations.
Gasoline Dispensing Facilities	• Avoid siting new sensitive land uses within 300 feet of a large gas station (defined as a facility with a throughput of 3.6 million gallons per year or greater). A 50 foot separation is recommended for typical gas dispensing facilities.

*Notes

- These recommendations are advisory. Land use agencies have to balance other considerations, including housing and transportation needs, economic development priorities, and other quality of life issues.

AR0069318

- Recommendations are based primarily on data showing that the air pollution exposures addressed here (i.e., localized) can be reduced as much as 80% with the recommended separation
- The relative risk for these categories varies greatly (see Table 1-2). To determine the actual risk near a particular facility, a site-specific analysis would be required. Risk from diesel PM will decrease over time as cleaner technology phases in
- These recommendations are designed to fill a gap where information about existing facilities may not be readily available and are not designed to substitute for more specific information if it exists. The recommended distances take into account other factors in addition to available health risk data (see individual category descriptions)
- Site-specific project design improvements may help reduce air pollution exposures and should also be considered when siting new sensitive land uses
- This table does not imply that mixed residential and commercial development in general is incompatible. Rather it focuses on known problems like dry cleaners using perchloroethylene that can be addressed with reasonable preventative actions
- A summary of the basis for the distance recommendations can be found in Table 1-2

AR0069319

Table 1-2

Summary of Basis for Advisory Recommendations

Source Category	Range of Relative Cancer Risk[1,2]	Summary of Basis for Advisory Recommendations
Freeways and High-Traffic Roads	300 – 1,700	• In traffic-related studies, the additional non-cancer health risk attributable to proximity was seen within 1,000 feet and was strongest within 300 feet. California freeway studies show about a 70% drop off in particulate pollution levels at 500 feet.
Distribution Centers[3]	Up to 500	• Because ARB regulations will restrict truck idling at distribution centers, transport refrigeration unit (TRU) operations are the largest onsite diesel PM emission source followed by truck travel in and out of distribution centers. • Based on ARB and South Coast District emissions and modeling analyses, we estimate an 80 percent drop-off in pollutant concentrations at approximately 1,000 feet from a distribution center.
Rail Yards	Up to 500	• The air quality modeling conducted for the Roseville Rail Yard Study predicted the highest impact is within 1,000 feet of the Yard, and is associated with service and maintenance activities. The next highest impact is between a half to one mile of the Yard depending on wind direction and intensity.
Ports	Studies underway	• ARB will evaluate the impacts of ports and develop a new comprehensive plan that will describe the steps needed to reduce public health impacts from port and rail activities in California. In the interim, a general advisory is appropriate based on the magnitude of diesel PM emissions associated with ports.
Refineries	Under 10	• Risk assessments conducted at California refineries show risks from air toxics to be under 10 chances of cancer per million.[4] • Distance recommendations were based on the amount and potentially hazardous nature of many of the pollutants released as part of the refinery process, particularly during non-routine emissions releases.
Chrome Platers	10-1,100	• ARB modeling and monitoring studies show localized risk of hexavalent chromium diminishing significantly at 300 feet. There are data limitations in both the modeling and monitoring studies. These include variability of plating activities and uncertainty of emissions such as fugitive dust. Hexavalent chromium is one of the most potent toxic air contaminants. Considering these factors, a distance of 1,000 feet was used as a precautionary measure.
Dry Cleaners Using Perchloro-ethylene (perc)	15-1,150	• Local air district studies indicate that individual cancer risk can be reduced by as much as 75 percent by establishing a 300 foot separation between a sensitive land use and a one-machine perc dry cleaning operation. For larger operations (2 machines or more), a separation of 500 feet can reduce risk by over 85 percent.

AR0069320

Source Category	Range of Relative Cancer Risk[1,2]	Summary of Basis for Advisory Recommendations
Gasoline Dispensing Facilities (GDF)[3]	Typical GDF: Less than 10 Large GDF: Between less than 10 and 120	• Based on the CAPCOA Gasoline Service Station Industry-wide Risk Assessment Guidelines, most typical GDFs (less than 3.6 million gallons per year) have a risk of less than 10 at 50 feet under urban air dispersion conditions. Over the last few years, there has been a growing number of extremely large GDFs with sales over 3.6 and as high as 19 million gallons per year. Under rural air dispersion conditions, these large GDFs can pose a larger risk at a greater distance.

[1] For cancer health effects, risk is expressed as an estimate of the increased chances of getting cancer due to facility emissions over a 70-year lifetime. This increase in risk is expressed as chances in a million (e.g., 10 chances in a million).

[2] The estimated cancer risks are a function of the proximity to the specific category and were calculated independent of the regional health risk from air pollution. For example, the estimated regional cancer risk from air toxics in the Los Angeles region (South Coast Air Basin) is approximately 1,000 in a million.

[3] Analysis based on refrigerator trucks.

[4] Although risk assessments performed by refineries indicate they represent a low cancer risk, there is limited data on non-cancer effects of pollutants that are emitted from these facilities. Refineries are also a source of non-routine emissions and odors.

[5] A typical GDF in California dispenses under 3.6 million gallons of gasoline per year. The cancer risk for this size facility is likely to be less than 10 in a million at the fenceline under urban air dispersion conditions.

[6] A large GDF has fuel throughouts that can range from 3.6 to 19 million gallons of gasoline per year. The upper end of the risk range (i.e., 120 in a million) represents a hypothetical worst case scenario for an extremely large GDF under rural air dispersion conditions.

AR0069321

Freeways and High Traffic Roads

Air pollution studies indicate that living close to high traffic and the associated emissions may lead to adverse health effects beyond those associated with regional air pollution in urban areas. Many of these epidemiological studies have focused on children. A number of studies identify an association between adverse non-cancer health effects and living or attending school near heavily traveled roadways (see findings below). These studies have reported associations between residential proximity to high traffic roadways and a variety of respiratory symptoms, asthma exacerbations, and decreases in lung function in children.

One such study that found an association between traffic and respiratory symptoms in children was conducted in the San Francisco Bay Area. Measurements of traffic-related pollutants showed concentrations within 300 meters (approximately 1,000 feet) downwind of freeways were higher than regional values. Most other studies have assessed exposure based on proximity factors such as distance to freeways or traffic density.

These studies linking traffic emissions with health impacts build on a wealth of data on the adverse health effects of ambient air pollution. The data on the effects of proximity to traffic related emissions provides additional information that can be used in land use siting and regulatory actions by air agencies. The key observation in these studies is that close proximity increases both exposure and the potential for adverse health effects. Other effects associated with traffic emissions include premature death in elderly individuals with heart disease.

Key Health Findings

- Reduced lung function in children was associated with traffic density, especially trucks, within 1,000 feet and the association was strongest within 300 feet. (Brunekreef, 1997)
- Increased asthma hospitalizations were associated with living within 650 feet of heavy traffic and heavy truck volume. (Lin, 2002)
- Asthma symptoms increased with proximity to roadways and the risk was greatest within 300 feet. (Venn, 2001)
- Asthma and bronchitis symptoms in children were associated with proximity to high traffic in a San Francisco Bay Area community with good overall regional air quality. (Kim, 2004)
- A San Diego study found increased medical visits in children living within 550 feet of heavy traffic. (English, 1999)

In these and other proximity studies, the distance from the roadway and truck traffic densities were key factors affecting the strength of the association with adverse health effects. In the above health studies, the association of traffic-related emissions with adverse health effects was seen within 1,000 feet and was

AR0069322

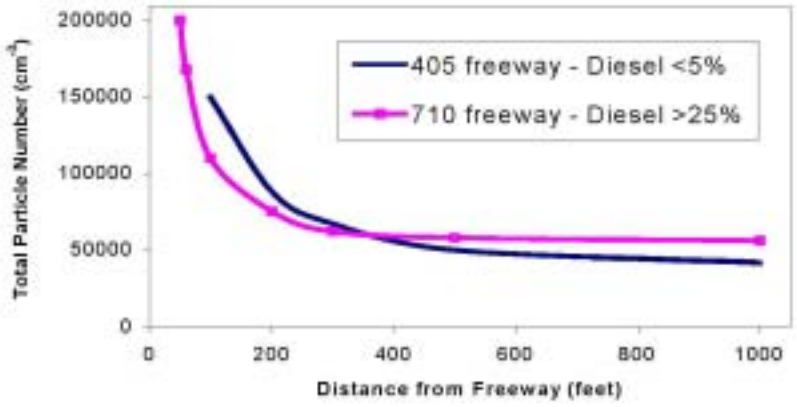
strongest within 300 feet. This demonstrates that the adverse effects diminished with distance.

In addition to the respiratory health effects in children, proximity to freeways increases potential cancer risk and contributes to total particulate matter exposure. There are three carcinogenic toxic air contaminants that constitute the majority of the known health risk from motor vehicle traffic – diesel particulate matter (diesel PM) from trucks, and benzene and 1,3-butadiene from passenger vehicles. On a typical urban freeway (truck traffic of 10,000-20,000/day), diesel PM represents about 70 percent of the potential cancer risk from the vehicle traffic. Diesel particulate emissions are also of special concern because health studies show an association between particulate matter and premature mortality in those with existing cardiovascular disease.

Distance Related Findings

A southern California study (Zhu, 2002) showed measured concentrations of vehicle-related pollutants, including ultra-fine particles, decreased dramatically within approximately 300 feet of the 710 and 405 freeways. Another study looked at the validity of using distance from a roadway as a measure of exposure

Figure 1-1
Decrease In Concentration of Freeway Diesel PM Emissions With Distance



to traffic related air pollution (Knape, 1999). This study showed that concentrations of traffic related pollutants declined with distance from the road, primarily in the first 500 feet.

These findings are consistent with air quality modeling and risk analyses done by ARB staff that show an estimated range of potential cancer risk that decreases with distance from freeways. The estimated risk varies with the local meteorology, including wind pattern. As an example, at 300 feet downwind from a freeway (Interstate 80) with truck traffic of 10,000 trucks per day, the potential cancer risk was as high as 100 in one million (ARB Roseville Rail Yard Study). The cancer health risk at 300 feet on the upwind side of the freeway was much

ess. The risk at that distance for other freeways will vary based on local conditions – it may be higher or lower. However, in all these analyses the relative exposure and health risk dropped substantially within the first 300 feet. This phenomenon is illustrated in Figure 1-1.

State law restricts the siting of new schools within 500 feet of a freeway, urban roadways with 100,000 vehicles/day, or rural roadways with 50,000 vehicles with some exceptions.[2] However, no such requirements apply to the siting of residences, day care centers, playgrounds, or medical facilities. The available data show that exposure is greatly reduced at approximately 300 feet. In the traffic-related studies the additional health risk attributable to the proximity effect was strongest within 1,000 feet.

The combination of the children's health studies and the distance related findings suggests that it is important to avoid exposing children to elevated air pollution levels immediately downwind of freeways and high traffic roadways. These studies suggest a substantial benefit to a 500-foot separation.

The impact of traffic emissions is on a gradient that at some point becomes indistinguishable from the regional air pollution problem. As air agencies work to reduce the underlying regional health risk from diesel PM and other pollutants, the impact of proximity will also be reduced. In the meantime, as a preventative measure, we hope to avoid exposing more children and other vulnerable individuals to the highest concentrations of traffic-related emissions.

Recommendation

- Avoid siting new sensitive land uses within 500 feet of a freeway, urban roads with 100,000 vehicles/day, or rural roads with 50,000 vehicles/day.

Distribution Centers

Distribution centers or warehouses are facilities that serve as a distribution point for the transfer of goods. Such facilities include cold storage warehouses, goods transfer facilities, and inter-modal facilities such as ports. These operations involve trucks, trailers, shipping containers, and other equipment with diesel engines. A distribution center can be comprised of multiple centers or warehouses within an area. The size can range from several to hundreds of acres, involving a number of different transfer operations and long waiting periods. A distribution center can accommodate hundreds of diesel trucks a day that deliver, load, and/or unload goods up to seven days a week. To the extent that these trucks are transporting perishable goods, they are equipped with diesel-powered transport refrigeration units (TRUs) or TRU generator sets.

The activities associated with delivering, storing, and loading freight produces diesel PM emissions. Although TRUs have relatively small diesel-powered engines, in the normal course of business, their emissions can pose a significant health risk to those nearby. In addition to onsite emissions, truck travel in and out of distribution centers contributes to the local pollution impact.

ARB is working to reduce diesel PM emissions through regulations, financial incentives, and enforcement programs. In 2004, ARB adopted two airborne toxic control measures that will reduce diesel PM emissions associated with distribution centers. The first will limit nonessential (or unnecessary) idling of diesel-fueled commercial vehicles, including those entering from other states or countries. This statewide measure, effective in 2005, prohibits idling of a vehicle more than five minutes at any one location.[3] The elimination of unnecessary idling will reduce the localized impacts caused by diesel PM and other air toxics

[3] For further information on the Anti-Idling ATCM, please click on: http://www.arb.ca.gov/toxics/idling/outreach/factsheet.pdf

in diesel vehicle exhaust. This should be a very effective new strategy for reducing diesel PM emissions at distribution centers as well as other locations.

The second measure requires that TRUs operating in California become cleaner over time. The measure establishes in-use performance standards for existing TRU engines that operate in California, including out-of-state TRUs. The requirements are phased-in beginning in 2008, and extend to 2019.[4]

ARB also operates a smoke inspection program for heavy-duty diesel trucks that focuses on reducing truck emissions in California communities. Areas with large numbers of distribution centers are a high priority.

Key Health Findings

Diesel PM has been identified by ARB as a toxic air contaminant and represents 70 percent of the known potential cancer risk from air toxics in California. Diesel PM is an important contributor to particulate matter air pollution. Particulate matter exposure is associated with premature mortality and health effects such as asthma exacerbation and hospitalization due to aggravating heart and lung disease.

Distance Related Findings

Although distribution centers are located throughout the state, they are usually clustered near transportation corridors, and are often located in or near population centers. Diesel PM emissions from associated delivery truck traffic and TRUs at these facilities may result in elevated diesel PM concentrations in neighborhoods surrounding those sites. Because ARB regulations will restrict truck idling at distribution centers, the largest continuing onsite diesel PM emission source is the operation of TRUs. Truck travel in and out of distribution centers also contributes to localized exposures, but specific travel patterns and truck volumes would be needed to identify the exact locations of the highest concentrations.

As part of the development of ARB's regulation for TRUs, ARB staff performed air quality modeling to estimate exposure and the associated potential cancer risk of onsite TRUs for a typical distribution center. For an individual person, cancer risk estimates for air pollution are commonly expressed as a probability of developing cancer from a lifetime (i.e., 70 years) of exposure. These risks were calculated independent of regional risk. For example, the estimated regional cancer risk from air toxics in the Los Angeles region (South Coast Air Basin) is approximately 1,000 additional cancer cases per one million population.

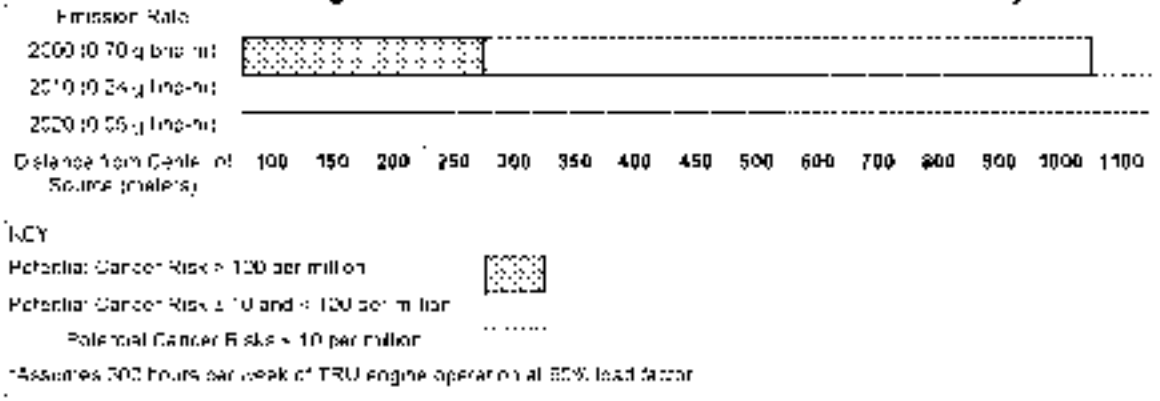
[4] For further information on the Transport Refrigeration Unit ATCM, please click on: http://www.arb.ca.gov/diesel/documents/trufaq.pdf

The diesel PM emissions from a facility are dependent on the size (horsepower), age, and number of engines, emission rates, the number of hours the truck engines and/or TRUs operate, distance, and meteorological conditions at the site. This assessment assumes a total on-site operating time for all TRUs of 300 hours per week. This would be the equivalent of 40 TRU-equipped trucks a day, each loading or unloading on-site for one hour, 12 hours a day and seven days a week.

As shown in Figure 1-2 below, at this estimated level of activity and assuming a current fleet diesel PM emission rate, the potential cancer risk would be over 100 in a million at 800 feet from the center of the TRU activity. The estimated potential cancer risk would be in the 10 to 100 per million range between 800 to 3,300 feet and fall off to less than 10 per million at approximately 3,600 feet. However, with the implementation of ARB's regulation on TRUs, the risk will be significantly reduced.[5] We have not conducted a risk assessment for distribution centers based on truck traffic alone, but on an emissions basis, we would expect similar risks for a facility with truck volumes in the range of 100 per day.

Figure 1-2

Estimated Risk Range versus Distance from Center of TRU Activity Area*



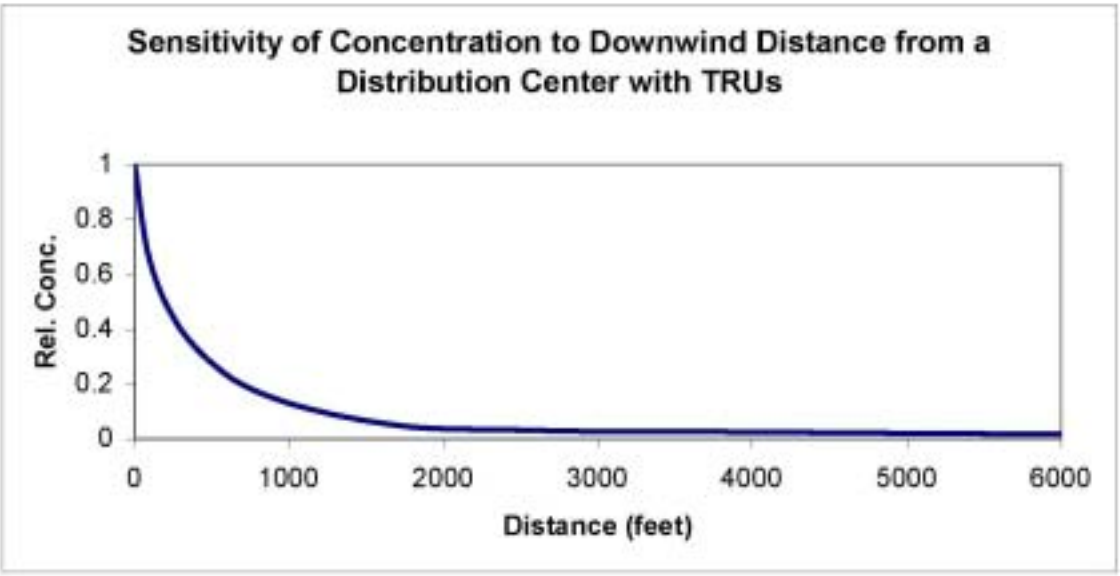
The estimated potential cancer risk level in Figure 1-2 is based on a number of assumptions that may not reflect actual conditions for a specific site. For example, increasing or decreasing the hours of diesel engine operations would change the potential risk levels. Meteorological and other facility specific parameters can also impact the results. Therefore, the results presented here are not directly applicable to any particular facility or operation. Rather, this information is intended to provide an indication as to the potential relative levels of risk that may be observed from operations at distribution centers. As shown in Figure 1-2, the estimated risk levels will decrease over time as lower-emitting diesel engines are used.

* These risk values assume an exposure duration of 70 years for a nearby resident and uses the methodology specified in the 2003 OEHHA health risk assessment guidelines.

AR0069327

Another air modeling analysis, performed by the South Coast Air Quality Management District (South Coast AQMD), evaluated the impact of diesel PM emissions from distribution center operations in the community of Mira Loma in southern California. Based on dispersion of diesel PM emissions from a large distribution center, Figure 1-3 shows the relative pollution concentrations at varying distances downwind. As Figure 1-3 shows, there is about an 80 percent drop off in concentration at approximately 1,000 feet.

Figure 1-3
Decrease In Relative Concentration of Risk
With Distance



Both the ARB and the South Coast AQMD analyses indicate that providing a separation of 1,000 feet would substantially reduce diesel PM concentrations and public exposure downwind of a distribution center. While these analyses do not provide specific risk estimates for distribution centers, they provide an indication of the range of risk and the benefits of providing a separation. ARB recommends a separation of 1,000 feet based on the combination of risk analysis done for TRUs and the decrease in exposure predicted with the South Coast AQMD modeling. However, ARB staff plans to provide further information on distribution centers as we collect more data and implement the TRU control measure.

Taking into account the configuration of distribution centers can also reduce population exposure and risk. For example, locating new sensitive land uses away from the main entry and exit points helps to reduce cancer risk and other health impacts.

Recommendations

- Avoid siting new sensitive land uses within 1,000 feet of a distribution center (that accommodates more than 100 trucks per day, more than 40 trucks with operating TRUs per day, or where TRU unit operations exceed 300 hours per week).

- Take into account the configuration of existing distribution centers and avoid locating residences and other new sensitive land uses near entry and exit points.

Rail Yards

Rail yards are a major source of diesel particulate air pollution. They are usually located near inter-modal facilities, which attract heavy truck traffic, and are often sited in mixed industrial and residential areas. ARB, working with the Placer County air district and Union Pacific Railroad, recently completed a study[6] of the Roseville Rail Yard (Yard) in northern California that focused on the health risk from diesel particulate. A comprehensive emissions analysis and air quality modeling were conducted to characterize the estimated potential cancer risk associated with the facility.

[6] To review the study, please click on: http://www.arb.ca.gov/diesel/documents/rrstudy.htm

The Yard encompasses about 950 acres on a one-quarter mile wide by four-mile long strip of land that parallels Interstate 80. It is surrounded by commercial, industrial, and residential properties. The Yard is one of the largest service and maintenance rail yards in the West with over 30,000 locomotives visiting annually.

Using data provided by Union Pacific Railroad, the ARB determined the number and type of locomotives visiting the Yard annually and what those locomotives were doing - moving, idling, or undergoing maintenance testing. Union Pacific provided the annual, monthly, daily, and hourly locomotive activity in the yard including locomotive movements, routes for arrival, departure, and through trains, and locomotive service and testing. This information was used to estimate the emissions of particulate matter from the locomotives, which was then used to model the potential impacts on the surrounding community.

The key findings of the study are:

- Diesel PM emissions in 2000 from locomotive operations at the Roseville Yard were estimated at about 25 tons per year.

- Of the total diesel PM in the Yard, moving locomotives accounted for about 50 percent, idling locomotives about 45 percent, and locomotive testing about five percent.

- Air quality modeling predicts potential cancer risks greater than 500 in a million (based on 70 years of exposure) in a 30-40 acre area immediately adjacent to the Yard's maintenance operations.

- The risk assessment also showed elevated cancer risk impacting a larger area covering about a 10 by 10 mile area around the Yard.

The elevated concentrations of diesel PM found in the study contribute to an increased risk of cancer and premature death due to cardiovascular disease, and non-cancer health effects such as asthma and other respiratory illnesses. The magnitude of the risk, the general location, and the size of the impacted area depended on the meteorological data used to characterize conditions at the Yard, the dispersion characteristics, and exposure assumptions. In addition to these variables, the nature of locomotive activity will influence a risk characterization at a particular rail yard. For these reasons, the quantified risk estimates in the Roseville Rail Yard Study cannot be directly applied to other rail yards. However, the study does indicate the health risk due to diesel PM from rail yards needs to be addressed. ARB, in conjunction with the U.S. Environmental Protection Agency (U.S. EPA), and local air districts, is working with the rail industry to identify and implement short-term, mid-term and long-term mitigation strategies. ARB also intends to conduct a second rail study in southern California to increase its understanding of rail yard operations and the associated public health impacts.

AR0069330

Key Health Findings

Diesel PM has been identified by ARB as a toxic air contaminant and represents 70 percent of the known potential cancer risk from air toxics in California. Diesel PM is an important contributor to particulate matter air pollution. Particulate matter exposure is associated with premature mortality and health effects such as asthma exacerbation and hospitalization due to aggravating heart and lung disease.

Distance Related Findings

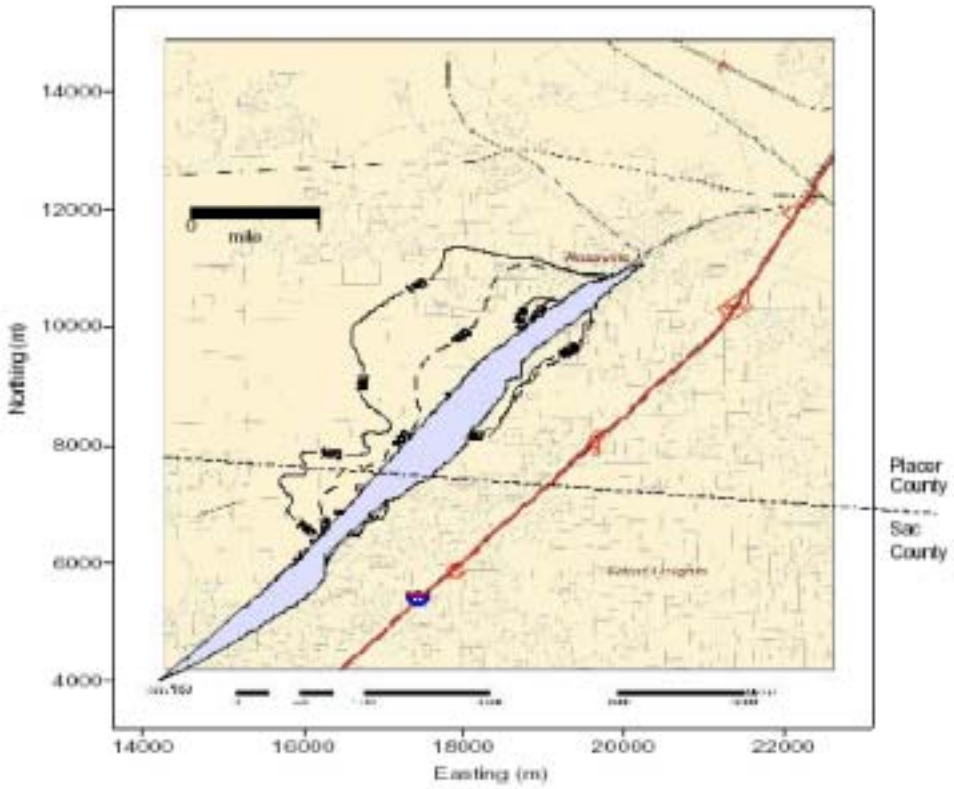
Two sets of meteorological data were used in the Roseville study because of technical limitations in the data. The size of the impact area was highly dependent on the meteorological data set used. The predicted highest impact area ranged from 10 - 40 acres with the two different meteorological data sets. This area, with risks estimated above 500 in a million, is adjacent to an area that includes a maintenance shop (see Figure 1-4). The high concentration of diesel PM emissions is due to the number of locomotives and nature of activities in this area, particularly idling locomotives.

The area of highest impact is within 1,000 feet of the Yard. The next highest impact zone as defined in the report had a predicted risk between 500 and 100 in one million and extends out between a half to one mile in some spots, depending on which meteorological conditions were assumed. The impact areas are irregular in shape making it difficult to generalize about the impact of distance at a particular location. However, the Roseville Rail Yard Study clearly indicates that the localized health risk is high, the impact area is large, and mitigation of the locomotive diesel PM emissions is needed.

For facilities like rail yards and ports, the potential impact area is so large that the real solution is to substantially reduce facility emissions. However, land use planners can avoid encroaching upon existing rail facilities and those scheduled for expansion. We also recommend that while air agencies tackle this problem, land use planners try not to add new sensitive individuals into the highest exposure areas. Finally, we recommend that land use agencies consider the potential health impacts of rail yards in their planning and permitting processes. Additional limitations and mitigation may be feasible to further reduce exposure on a site-specific basis.

Figure 1-4

Estimated Cancer Risk from the Yard
(100 and 500 in a million risk isopleths)



Notes: 100/Million Contours: Solid Line – Roseville Met Data; Dashed Line-McClellan Met Data, Urban Dispersion Coefficients, 80th Percentile Breathing Rate, All Locomotives' Activities (23 TPY), 70-Year Exposure

Recommendation

- Avoid siting new sensitive land uses within 1,000 feet of a major service and maintenance rail yard[7].
- Within one mile of a rail yard, consider possible siting limitations and mitigation approaches.

References

- *Roseville Rail Yard Study*. ARB (2004)

[7] The rail yard risk analysis was conducted for the Union Pacific rail yard in Roseville, California. This rail yard is one of the largest in the state. There are other rail yards in California with comparable levels of activity that should be considered "major" for purposes of this Handbook.

AR0069332

Ports

Air pollution from maritime port activities is a growing concern for regional air quality as well as air quality in nearby communities. The primary air pollutant associated with port operations is directly emitted diesel particulate. Port-related activities also result in emissions that form ozone and secondary particulate in the atmosphere. The emission sources associated with ports include diesel engine-powered ocean-going ships, harbor craft, cargo handling equipment, trucks, and locomotives. The size and concentration of these diesel engines makes ports one of the biggest sources of diesel PM in the state. For that reason, ARB has made it a top priority to reduce diesel PM emissions at the ports, in surrounding communities, and throughout California.

International, national, state, and local government collaboration is critical to reducing port emissions based on both legal and practical considerations. For example, the International Maritime Organization (IMO) and the U.S. EPA establish emission standards for ocean-going vessels and U.S.-flagged harbor craft, respectively. ARB is pursuing further federal actions to tighten these standards. In addition, ARB and local air districts are reducing emissions from ports through a variety of approaches. These include: incentive programs to fund cleaner engines, enhanced enforcement of smoke emissions from ships and trucks, use of dockside electricity instead of diesel engines, cleaner fuels for ships, harbor craft, locomotives, and reduced engine idling. The two ATCMs that limit truck idling and reduce emissions from TRUs (discussed under "Distribution Centers") also apply to ports.

ARB is also developing several other regulations that will reduce port-related emissions. One rule would require ocean-going ships to use a cleaner marine diesel fuel to power auxiliary engines while in California coastal waters and at dock. Ships that frequently visit California ports would also be required to further reduce their emissions. ARB has adopted a rule that would require harbor craft to use the same cleaner diesel fuel used by on-road trucks in California. In 2005, ARB will consider a rule that would require additional controls for in-use harbor craft, such as the use of add-on emission controls and accelerated turnover of older engines.

Key Health Findings

Port activities are a major source of diesel PM. Diesel PM has been identified by ARB as a toxic air contaminant and represents 70 percent of the known potential cancer risk from air toxics in California. Diesel PM is an important contributor to particulate matter air pollution. Particulate matter exposure is associated with premature mortality and health effects such as asthma exacerbation and hospitalization due to aggravating heart and lung disease.

AR0069333

Distance Related Findings

The Ports of Los Angeles and Long Beach provide an example of the emissions impact of port operations. A comprehensive emissions inventory was completed in June 2004. These ports combined are one of the world's largest and busiest seaports. Located in San Pedro Bay, about 20 miles south of downtown Los Angeles, the port complex occupies approximately 16 square miles of land and water. Port activities include five source categories that produce diesel emissions. These are ocean-going vessels, harbor craft, cargo handling equipment, railroad locomotives, and heavy duty trucks.

The baseline emission inventory provides emission estimates for all major air pollutants. This analysis focuses on diesel PM from in-port activity because these emissions have the most potential health impact on the areas adjacent to the port. Ocean vessels are the largest overall source of diesel PM related to the ports, but these emissions occur primarily outside of the port in coastal waters, making the impact more regional in nature.

The overall in-port emission inventory for diesel particulate for the ports of Los Angeles and Long Beach is estimated to be 550 tons per year. The emissions fall in the following major categories: ocean-going vessels (17%), harbor craft (25%), cargo handling (47%), railroad locomotive (3%), and heavy duty vehicles (8%). In addition to in-port emissions, ship, rail and trucking activities also contribute to regional emissions and increase emissions in nearby neighborhoods. Off-port emissions associated with related ship, rail and trucking activities contribute an additional 660 tons per year of diesel particulate at the Port of Los Angeles alone.

To put this in perspective, the diesel PM emissions estimated for the Roseville Yard in ARB's 2004 study are 25 tons per year. The potential cancer risk associated with these emissions is 100 in one million at a distance of one mile, or one half mile, depending on the data set used. This rail yard covers one and a half square miles. The Los Angeles and Long Beach ports have combined diesel PM emissions of 550 tons per year emitted from a facility that covers a much larger area - 16 miles. The ports have about twice the emission density of the rail yard - 34 tons per year per square mile compared to 16 tons per year per square mile. However, while this general comparison is illustrative of the overall size of the complex, a detailed air quality modeling analysis would be needed to assess the potential health impact on specific downwind areas near the ports.

ARB is in the process of evaluating the various port-related emission sources from the standpoint of existing emissions, growth forecasts, new control options, regional air quality impacts, and localized health risk. A number of public processes - both state and local - are underway to address various aspects of these issues. Until more of these analyses are complete, there is little basis for recommending a specific separation between new sensitive land uses and ports.

AR0069334

For example, the type of data we have showing the relationship between air pollutant concentrations and distance from freeways is not yet available.

Also, the complexity of the port facilities makes a site-specific analysis critical. Ports are a concentration of multiple emission sources with differing dispersion and other characteristics. In the case of the Roseville rail yard, we found a high, very localized impact associated with a particular activity: service and maintenance. By contrast, the location, size, and nature of impact areas can be expected to vary substantially for different port activities. For instance, ground level emissions from dockside activities would behave differently from ship stack level emissions.

Nonetheless, on an emissions basis alone, we expect locations downwind of ports to be substantially impacted. For that reason, we recommend that land use agencies track the current assessment efforts, and consider limitations on the siting of new sensitive land uses in areas immediately downwind of ports.

Recommendations

Avoid siting new sensitive land uses immediately downwind of ports in the most heavily impacted zones. Consult local air districts or the ARB on the status of pending analyses of health risks.

Petroleum Refineries

A petroleum refinery is a complex facility where crude oil is converted into petroleum products (primarily gasoline, diesel fuel, and jet fuel) which are then transported through a system of pipelines and storage tanks for final distribution by delivery truck to fueling facilities throughout the state. In California, most crude oil is delivered either by ship from Alaska or foreign sources, or is delivered via pipeline from oil production fields within the state. The crude oil then undergoes many complex chemical and physical reactions, which include distillation, catalytic cracking, reforming, and finishing. These refining processes have the potential to emit air contaminants and are subject to extensive emission controls by district regulations.

As a result of these regulations covering the production, marketing, and use of gasoline and other oil by products, California has seen significant regional air quality benefits both in terms of cleaner fuels and cleaner operating facilities. In

AR0069335

the 1990s California refineries underwent significant modifications and modernization to produce cleaner fuels in response to changes in state law Nevertheless, while residual emissions are small when compared to the total emissions controlled from these major sources, refineries are so large that even small amounts of fugitive, uncontrollable emissions and associated odors from the operations, can be significant This is particularly the case for communities that may be directly downwind of the refinery. Odors can cause health symptoms such as nausea and headache Also, because of the size, complexity and vast numbers of refinery processes onsite, the occasional refinery upset or malfunction can potentially result in acute or short term health effects to exposed individuals

Key Health Findings

Petroleum refineries are large single sources of emissions. For volatile organic compounds (VOCs), eight of the ten largest stationary sources in California are petroleum refineries. For oxides of nitrogen (NOx), four of the ten largest stationary sources in California are petroleum refineries Both of these compounds react in the presence of sunlight to form ozone. Ozone impacts lung function by irritating and damaging the respiratory system. Petroleum refineries are also large stationary sources of both particulate matter under 10 microns in size (PM_{10}) and particulate matter under 2.5 microns in size ($PM_{2.5}$). Exposure to particulate matter aggravates a number of respiratory illnesses including asthma and is associated with premature mortality in people with existing cardiac and respiratory disease Both long-term and short-term exposure can have adverse health impacts Finer particles pose an increased health risk because they can deposit deep in the lung and contain substances that are particularly harmful to human health NOx are also significant contributors to the secondary formation of $PM_{2.5}$.

Petroleum refineries also emit a variety of toxic air pollutants These air toxics vary by facility and process operation but may include: acetaldehyde, arsenic antimony benzene, beryllium, 1,3-butadiene, cadmium compounds, carbonyl sulfide, carbon disulfide, chlorine, dibenzofurans, diesel particulate matter formaldehyde, hexane hydrogen chloride, lead compounds, mercury compounds nickel compounds phenol, 2,3,7,8-tetrachlorodibenzo-p-dioxin, toluene and xylenes (mixed) among others. The potential health effects associated with these air toxics can include cancer respiratory irritation, and damage to the central nervous system, depending on exposure levels

Distance Related Findings

Health risk assessments for petroleum refineries have shown risks from toxic air pollutants that have quantifiable health risk values to be around 10 potential cancer cases per million Routine air monitoring and several air monitoring studies conducted in the San Francisco Bay Area (Crockett) and the South Coast Air Basin (Wilmington) have not identified significant health risks specifically

associated with refineries. However, these studies did not measure diesel PM as no accepted method currently exists, and there are many toxic air pollutants that do not have quantifiable health risk values.

In 2002, ARB published a report on the results of the state and local air district air monitoring done near oil refineries. The purpose of this evaluation was to try to determine how refinery-related emissions might impact nearby communities. This inventory of air monitoring activities included 10 ambient air monitoring stations located near refineries in Crockett and four stations near refineries in Wilmington. These monitoring results did not identify significant increased health risks associated with the petroleum refineries. In 2002-2003, ARB conducted additional monitoring studies in communities downwind of refineries in Crockett and Wilmington. These monitoring results also did not indicate significant increased health risks from the petroleum refineries.

Consequently, there are no air quality modeling or air monitoring data that provides a quantifiable basis for recommending a specific separation between refineries and new sensitive land uses. However, in view of the amount and potentially hazardous nature of many of the pollutants released as part of the refinery process, we believe the siting of new sensitive land uses immediately downwind should be avoided. Land use agencies should consult with the local air district when considering how to define an appropriate separation for refineries within their jurisdiction.

Recommendations

- Avoid siting new sensitive land uses immediately downwind of petroleum refineries. Consult with local air districts and other local agencies to determine an appropriate separation.

Chrome Plating Operations

Chrome plating operations rely on the use of the toxic metal hexavalent chromium, and have been subject to ARB and local air district control programs for many years. Regulation of chrome plating operations has reduced statewide emissions substantially. However, due to the nature of chrome plating

operations and the highly toxic nature of hexavalent chromium, the remaining health risk to nearby residents is a continuing concern.

Chrome plating operations convert hexavalent chromium in solution to a chromium metal layer by electroplating, and are categorized based upon the thickness of the chromium metal layer applied. In "decorative plating", a layer of nickel is first plated over a metal substrate. Following this step, a thin layer of chromium is deposited over the nickel layer to provide a decorative and protective finish, for example, on faucets and automotive wheels. "Hard chrome plating" is a process in which a thicker layer of chromium metal is deposited directly on metal substrates such as engine parts, industrial machinery, and tools to provide greater protection against corrosion and wear.

Hexavalent chromium is emitted into the air when an electric current is applied to the plating bath. Emissions are dependent upon the amount of electroplating done per year and the control requirements. A unit of production referred to as an ampere-hour represents the amount of electroplating produced. Small facilities have an annual production rate of 100,000 – 500,000 ampere-hours, while medium-size facilities may have a production rate of 500,000 to about 3 million ampere-hours. The remaining larger facilities have a range of production rates that can be as high as 80 million ampere-hours.

The control requirements, which reduce emissions from the plating tanks, vary according to the size and type of the operation. Facilities either install add-on pollution control equipment, such as filters and scrubbers, or in-tank controls, such as fume suppressants and polyballs. With this combination of controls, the overall hexavalent chromium emissions have been reduced by over 90 percent. Larger facilities typically have better controls that can achieve efficiencies greater than 99 percent. However, even with stringent controls, the lack of maintenance and good housekeeping practices can lead to problems. And, since the material itself is inherently dangerous, any lapse in compliance poses a significant risk to nearby residents.

A 2002 ARB study in the San Diego community of Barrio Logan measured unexpectedly high concentrations of hexavalent chromium near chrome platers. The facilities were located in a mixed-use area with residences nearby. The study found that fugitive dust laden with hexavalent chromium was an important source of emissions that likely contributed to the elevated cancer risk. Largely as a result of this study, ARB is in the process of updating the current requirements to further reduce the emissions from these facilities.

In December 2004, the ARB adopted an ATCM to reduce emissions of hexavalent chromium and nickel from thermal spraying operations through the installation of best available control technology. The ATCM requires all existing facilities to comply with its requirements by January 1, 2006. New and modified thermal spraying operations must comply upon initial startup. An existing thermal spraying facility may be exempt from the minimum control efficiency

AR0069338

requirements of the ATCM if it is located at least 1,640 feet from the nearest sensitive receptor and emits no more than 0.5 pound per year of hexavalent chromium.[8]

Key Health Findings

Hexavalent chromium is one of the most toxic air pollutants regulated by the State of California. Hexavalent chromium is a carcinogen and has been identified in worker health studies as causing lung cancer. Exposure to even very low levels of hexavalent chromium should be avoided.

The California Office of Environmental Health Hazard Assessment has found that: 1) many epidemiological studies show a strong association between hexavalent chromium exposure in the work place and respiratory cancer; and 2) all short-term assays reported show that hexavalent chromium compounds can cause damage to human DNA.

Hexavalent chromium when inhaled over a period of many years can cause a variety of non-cancer health effects. These health effects include damage to the nose, blood disorders, lung disease, and kidney damage. The non-cancer health impacts occur with exposures considerably higher than exposures causing significant cancer risks. It is less likely that the public would be exposed to hexavalent chromium at levels high enough to cause these non-cancer health effects. Non-cancer health effects, unlike cancer health effects, have a threshold or exposure level below which non-cancer health effects would not be expected.

Distance Related Findings

ARB's 2002 Barrio Logan Study measured concentrations of hexavalent chromium in the air near two chrome plating facilities. The study was conducted from December 2001 to May 2002. There were two chrome platers on the street - one decorative and one hard plater. The purpose of the study was to better understand the near source impact of hexavalent chromium emissions. Air monitors were placed at residences next to the platers and at varying distances down the street. The monitors were moved periodically to look at the spatial distribution of the impact. Source testing and facility inspections identified one of the facilities as the likely source.

The first two weeks of monitoring results showed unexpectedly high levels of hexavalent chromium at a number of the monitoring sites. The high concentrations were intermittent. The concentrations ranged from 1 to 22 ng/m3 compared to the statewide average of 0.1 ng/m3. If these levels were to continue for 70 years, the potential cancer risk would be 150 in one million. The highest value was found at an air monitor behind a house adjacent to one of the

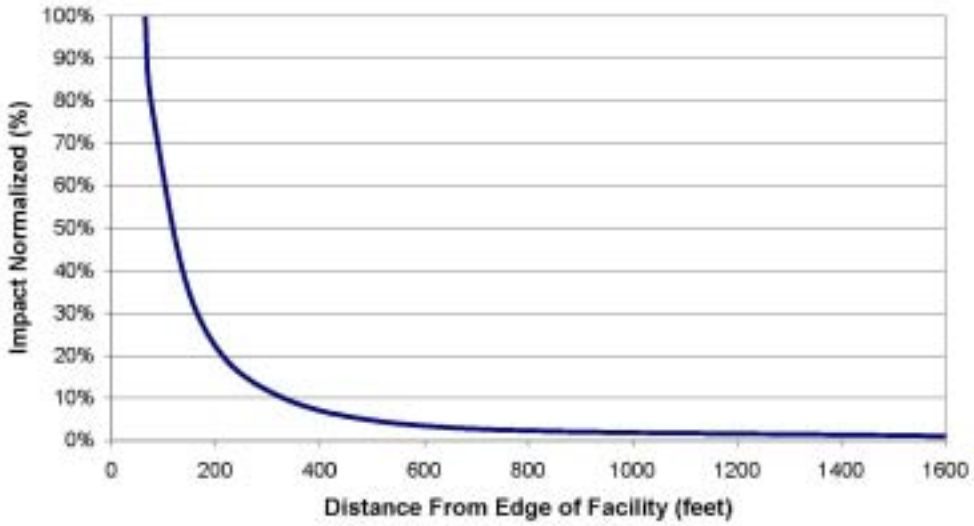
[8] For further information on the ATCM, please refer to: http://www.arb.ca.gov/regact/thermspr/thermalspr.htm

plating facilities–approximately 30 feet from the back entrance. Lower, but significant concentrations were found at an ambient air monitor 250 feet away.

The monitoring covered a period when the facility was not operating its plating tank. During this period, one of the highest concentrations was measured at an adjacent house. It appears that chromium-laden dust was responsible for high concentrations at this location since there was no plating activity at the time. Dust samples from the facility were tested and found to contain high levels of hexavalent chromium. On the day the highest concentration was measured at the house next door, a monitor 350 feet away from the plater's entrance showed very little impact. Similar proximity effects are shown in ARB modeling studies.

Figure 1-5 shows how the relative health risk varies as a function of distance from a chrome plater. This analysis is based on a medium-sized chrome plater with an annual production rate of 3 million ampere-hours. As shown in Figure 1- 5, the potential health risk drops off rapidly, with over 90 percent reduction in risk within 300 feet. This modeling was done in 2003 as part of a review of ARB's current air toxic control measure for chrome platers and is based on data from a recent ARB survey of chrome platers in California. The emission

Figure 1-5
Risk vs. Distance From Chrome Plater
(Based on plating tank emissions)



rates are only for plating operations. Because there are insufficient data available to directly quantify the impacts, the analysis does not include fugitive emissions, which the Barrio Logan analysis indicated could be significant.

Both the ARB Barrio Logan monitoring results and ARB's 2003 modeling analysis suggests that the localized emissions impact of a chrome plater diminishes significantly at 300 feet. However, in developing our recommendation, we also considered the following factors:

- some chrome platers will have higher volumes of plating activity
- potential dust impacts were not modeled
- we have only one monitoring study looking at the impact of distance and
- hexavalent chromium is one of the most potent toxic air contaminants ARB has identified

Given these limitations in the analysis, we recommend a separation of 1,000 feet as a precautionary measure. For large chrome platers, site specific information should be obtained from the local air district.

Recommendation

- Avoid siting new sensitive land uses within 1,000 feet of a chrome plater

Dry Cleaners Using Perchloroethylene (Perc Dry Cleaners)

Perchloroethylene (perc) is the solvent most commonly used by the dry cleaning industry to clean clothes or other materials. The ARB and other public health agencies have identified perc as a potential cancer-causing compound. Perc persists in the atmosphere long enough to contribute to both regional air pollution and localized exposures. Perc dry cleaners are the major source of perc emissions in California.

Since 1990, the statewide concentrations and health risk from exposure to perc has dropped over 70 percent. This is due to a number of regulatory requirements on perc dry cleaners and other sources, including degreasing operations, brake cleaners, and adhesives. ARB adopted an Airborne Toxic Control Measure (ATCM) for Perc Emissions from Dry Cleaning Operations in 1993. ARB has also prohibited the use of perc in aerosol adhesives and automotive brake cleaners.

AR0069341

Perc dry cleaners statewide are required to comply with ARB and local air district regulations to reduce emissions. However, even with these controls, some emissions continue to occur. Air quality studies indicate that there is still the potential for significant risks even near well-controlled dry cleaners. The South Coast AQMD has adopted a rule requiring that all new dry cleaners use alternatives to perc and that existing dry cleaners phase out the use of perc by December 2020. Over time, transition to non-toxic alternatives should occur. However, while perc continues to be used, a preventative approach should be taken to siting of new sensitive land uses.

Key Health Findings

Inhalation of perc may result in both cancer and non-cancer health effects. An assessment by California's Office of Environmental Health Hazard Assessment (OEHHA) concluded that perc is a potential human carcinogen and can cause non-cancer health effects. In addition to the potential cancer risk, the effects of long-term exposure include dizziness, impaired judgment and perception, and damage to the liver and kidneys. Workers have shown signs of liver toxicity following chronic exposure to perc, as well as kidney dysfunction and neurological effects. Non-cancer health effects occur with higher exposure levels than those associated with significant cancer risks. The public is more likely to be exposed to perchloroethylene at levels causing significant cancer risks than to levels causing non-cancer health effects. Non-cancer health effects, unlike cancer health effects, have a threshold or exposure level below which non-cancer health effects would not be expected. The ARB formally identified perc as a toxic air contaminant in October 1991.

One study has determined that inhalation of perc is the predominant route of exposure to infants living in apartments co-located in the same building with a business operating perc dry cleaning equipment. Results of air sampling within co-residential buildings indicate that dry cleaners can cause a wide range of exposures depending on the type and maintenance of the equipment. For example, a well-maintained state-of-the-art system may have risks in the range of 10 in one million, whereas a badly maintained machine with major leaks can have potential cancer risks of thousands in one million.

The California Air Pollution Control Officers Association (CAPCOA) is developing Industry-wide Risk Assessment Guidelines for Perchloroethylene Dry Cleaners which, when published, will provide detailed information on public health risk from exposure to emissions from this source.

Distance Related Findings

Risk created by perc dry cleaning is dependent on the amount of perc emissions, the type of dry cleaning equipment, proximity to the source, and how the emissions are released and dispersed (e.g., type of ventilation system, stack parameters, and local meteorology). Dry cleaners are often located near

residential areas and near shopping centers, schools, day-care centers, and restaurants.

The vast majority of dry cleaners in California have one dry cleaning machine per facility. The South Coast AQMD estimates that an average well-controlled dry cleaner uses about 30 to 160 gallons of cleaning solvent per year, with an average of about 100 gallons. Based on these estimates, the South Coast AQMD estimates a potential cancer risk between 25 to 140 in one million at residential locations 75 feet or less from the dry cleaner, with an average of about 80 in one million. The estimate could be as high as 270 in one million for older machines.

CAPCOA's draft industry-wide risk assessment of perc dry cleaning operations indicates that the potential cancer risk for many dry cleaners may be in excess of potential cancer risk levels adopted by the local air districts. The draft document also indicates that, in general, the public's exposure can be reduced by at least 75 percent by providing a separation distance of about 300 feet from the operation. This assessment is based on a single machine with perc use of about 100 gallons per year. At these distances, the potential cancer risk would be less than 10 potential cases per million for most scenarios.

The risk would be proportionately higher for large, industrial size, dry cleaners. These facilities typically have two or more machines and use 200 gallons or more per year of perc. Therefore, separation distances need to be greater for large dry cleaners. At a distance of 500 feet, the remaining risk for a large plant can be reduced by over 85 percent.

In California, a small number of dry cleaners that are co-located (sharing a common wall, floor, or ceiling) with a residence have the potential to expose the inhabitants of the residence to high levels of perc. However, while special requirements have been imposed on these existing facilities, the potential for exposure still exists. Avoiding these siting situations in the future is an important preventative measure.

Local air districts are a source of information regarding specific dry cleaning operations—particularly for large industrial operations with multiple machines. The 300 foot separation recommended below reflects the most common situation – a dry cleaner with only one machine. While we recommend 500 feet when there are two or more machines, site specific information should be obtained from the local air district for some very large industrial operations. Factors that can impact the risk include the number and type of machines, controls used, source configuration, building dimensions, terrain, and meteorological data.

AR0069343

Recommendation

- Avoid siting new sensitive land uses within 300 feet of any dry cleaning operation. For operations with two or more machines provide 500 feet. For operations with 3 or more machines, consult with the local air district.

- Do not site new sensitive land uses in the same building with perc dry cleaning operations.

Gasoline Dispensing Facilities

Refueling at gasoline dispensing facilities releases benzene into the air. Benzene is a potent carcinogen and is one of the highest risk air pollutants regulated by ARB. Motor vehicles and motor vehicle-related activity account for over 90 percent of benzene emissions in California. While gasoline-dispensing facilities account for a small part of total benzene emissions, near source exposures for large facilities can be significant.

Since 1990, benzene in the air has been reduced by over 75 percent statewide, primarily due to the implementation of emissions controls on motor vehicle vapor recovery equipment at gas stations, and a reduction in benzene levels in gasoline. However, benzene levels are still significant. In urban areas, average benzene exposure is equivalent to about 50 in one million.

Gasoline dispensing facilities tend to be located in areas close to residential and shopping areas. Benzene emissions from the largest gas stations may result in near source health risk beyond the regional background and district health risk thresholds. The emergence of very high gasoline throughput at large retail or

wholesale outlets makes this a concern as these types of outlets are projected to account for an increasing market share in the next few years.

Key Health Findings

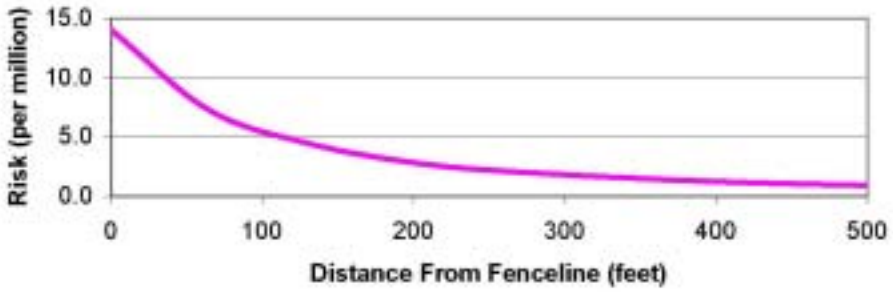
Benzene is a human carcinogen identified by ARB as a toxic air contaminant. Benzene also can cause non-cancer health effects above a certain level of exposure. Brief inhalation exposure to high concentrations can cause central nervous system depression. Acute effects include central nervous system symptoms of nausea, tremors, drowsiness, dizziness, headache, intoxication, and unconsciousness. It is unlikely that the public would be exposed to levels of benzene from gasoline dispensing facilities high enough to cause these non-cancer health effects.

Distance Related Findings

A well-maintained vapor recovery system can decrease emissions of benzene by more than 90% compared with an uncontrolled facility. Almost all facilities have emission control systems. Air quality modeling of the health risks from gasoline dispensing facilities indicate that the impact from the facilities decreases rapidly as the distance from the facility increases.

Statistics reported in the ARB's staff reports on Enhanced Vapor Recovery released in 2000 and 2002, indicated that almost 96 percent of the gasoline dispensing facilities had a throughput less than 2.4 million gallons per year. The remaining four percent, or approximately 450 facilities, had throughputs exceeding 2.4 million gallons per year. For these stations, the average gasoline throughput was 3.6 million gallons per year.

Figure 1-6
Gasoline Dispensing Facility Health Risk
for 3,600,000 gal/yr throughput



As shown in Figure 1-6, the risk levels for a gasoline dispensing facility with a throughput of 3.6 million gallons per year is about 10 in one million at a distance of 50 feet from the fenceline. However, as the throughput increases, the potential risk increases.

AR0069345

As mentioned above, air pollution levels in the immediate vicinity of large gasoline dispensing facilities may be higher than the surrounding area (although tailpipe emissions from motor vehicles dominates the health impacts). Very large gasoline dispensing facilities located at large wholesale and discount centers may dispense nine million gallons of gasoline per year or more. At nine million gallons, the potential risk could be around 25 in one million at 50 feet, dropping to about five in one million at 300 feet. Some facilities have throughputs as high as 19 million gallons.

Recommendation

- Avoid siting new sensitive land uses within 300 feet of a large gasoline dispensing facility (defined as a facility with a throughput of 3.6 million gallons per year or greater). A 50 foot separation is recommended for typical gas dispensing facilities.

Other Facility Types that Emit Air Pollutants of Concern

In addition to source specific recommendations, Table 1-3 includes a list of other industrial sources that could pose a significant health risk to nearby sensitive individuals depending on a number of factors. These factors include the amount of pollutant emitted and its toxicity, the distance to nearby individuals, and the type of emission controls in place. Since these types of facilities are subject to air permits from local air districts, facility specific information should be obtained where there are questions about siting a sensitive land use close to an industrial facility.

Potential Sources of Odor and Dust Complaints

Odors and dust from commercial activities are the most common sources of air pollution complaints and concerns from the public. Land use planning and permitting processes should consider the potential impacts of odor and dust on surrounding land uses, and provide for adequate separation between odor and dust sources. As with other types of air pollution, a number of factors need to be considered when determining an adequate distance or mitigation to avoid odor or

AR0069346

Table 1-3 – Examples of Other Facility Types That Emit[1] Air Pollutants of Concern

Categories	Facility Type	Air Pollutants of Concern
Commercial		
	Autobody Shops	Metals, Solvents
	Furniture Repair	Solvents[2], Methylene Chloride
	Film Processing Services	Solvents, Perchloroethylene
	Distribution Centers	Diesel Particulate Matter
	Printing Shops	Solvents
	Diesel Engines	Diesel Particulate Matter
Industrial		
	Construction	Particulate Matter, Asbestos
	Manufacturers	Solvents, Metals

	Chemical Producers	Solvents, Metals
	Furniture Manufacturers	Solvents
	Shipbuilding and Repair	Hexavalent chromium and other metals, Solvents
	Rock Quarries and Cement Manufacturers	Particulate Matter, Asbestos
	Hazardous Waste Incinerators	Dioxin, Solvents, Metals
	Power Plants	Benzene, Formaldehyde, Particulate Matter
	Research and Development Facilities	Solvents, Metals, etc.
Public		
	Landfills	Benzene, Vinyl Chloride, Diesel Particulate Matter
	Waste Water Treatment Plants	Hydrogen Sulfide
	Medical Waste Incinerators	Dioxin, Benzene, PAH, PCBs 1,3-Butadiene
	Recycling, Garbage Transfer Stations	Diesel Particulate Matter
	Municipal Incinerators	Dioxin, Benzene, PAH, PCBs 1,3-Butadiene
Transportation		
	Truck Stops	Diesel Particulate Matter
Agricultural Operations		
	Farming Operations	Diesel Particulate Matter, VOCs, NOx, PM10, CO, SOx, Pesticides
	Livestock and Dairy Operations	Ammonia, VOCs, PM10

[1] Note: for these air pollutants of concern due to process changes or chemical substitution. Consult the local air district regarding specific facilities.
[2] Some solvents may emit toxic air pollutants, but not all solvents are toxic air contaminants.

AR0069347

dust complaints in a specific situation. Local air districts should be consulted for advice when these siting situations arise.

Table 1-4 lists some of the most common sources of odor complaints received by local air districts. Complaints about odors are the responsibility of local air districts and are covered under state law. The types of facilities that can cause odor complaints are varied and can range from small commercial facilities to large industrial facilities and may include waste disposal and recycling operations. Odors can cause health symptoms such as nausea and headache. Facilities with odors may also be sources of toxic air pollutants (See Table 1-3). Some common sources of odors emitted by facilities are sulfur compounds, organic solvents, and the decomposition/digestion of biological materials. Because of the subjective nature of an individual's sensitivity to a particular type of odor, there is no specific rule for assigning appropriate separations from odor sources. Under the right meteorological conditions, some odors may still be offensive several miles from the source.

Table 1-4
Sources of Odor Complaints

- Sewage Treatment Plants
- Landfills
- Recycling Facilities
- Waste Transfer Stations
- Petroleum Refineries
- Biomass Operations
- Autobody Shops
- Coating Operations
- Fiberglass Manufacturing
- Foundries
- Rendering Plants
- Livestock Operations

Sources of dust are also common sources of air pollution-related complaints. Operations that can result in dust problems are rock crushing, gravel production, stone quarrying, and mining operations. A common source of complaints is the dust and noise associated with blasting that may be part of these operations. Besides the health impacts of dust as particulate matter, thick dust also impairs visibility, aesthetic values, and can soil homes and automobiles. Local air districts typically have rules for regulating dust sources in their jurisdictions, but dust sources can still be a concern. Therefore, separation of these facilities from residential and other new sensitive land uses should be considered.

In some areas of California, asbestos occurs naturally in stone deposits. Asbestos is a potent carcinogenic substance when inhaled. Asbestos-containing dust may be a public health concern in areas where asbestos-containing rock is mined, crushed, processed, or used. Situations where asbestos-containing gravel has been used in road paving materials are also a source of asbestos exposure to the general public. Planners are advised to consult with local air pollution agencies in areas where asbestos-containing gravel or stone products are produced or used.

AR0069348

2. Handbook Development

ARB and local air districts share responsibility for improving statewide air quality. As a result of California's air pollution control programs, air quality has improved and health risk has been reduced statewide. However, state and federal air quality standards are still exceeded in many areas of California and the statewide health risk posed by toxic air contaminants (air toxics) remains too high. Also, some communities experience higher pollution exposures than others - making localized impacts, as well regional or statewide impacts, an important consideration. It is for this reason that this Handbook has been produced – to promote better, more informed decision-making by local land use agencies that will improve air quality and public health in their communities.

Land use policies and practices, including planning, zoning, and siting activities, can play a critical role in air quality and public health at the local level. For instance, even with the best available control technology, some projects that are sited very close to homes, schools, and other public places can result in elevated air pollution exposures. The reverse is also true – siting a new school or home too close to an existing source of air pollution can pose a public health risk. The ARB recommendations in section 7 address this issue.

This Handbook is an informational document that we hope will strengthen the relationship between air quality and land use agencies. It highlights the need for land use agencies to address the potential for new projects to result in localized health risk or contribute to cumulative impacts where air pollution sources are concentrated.

Avoiding these incompatible land uses is a key to reducing localized air pollution exposures that can result in adverse health impacts, especially to sensitive individuals.

Individual siting decisions that result in incompatible land uses are often the result of locating "sensitive" land uses next to polluting sources. These decisions can be of even greater concern when existing air pollution exposures in a community are considered. In general terms, this is often referred to as the issue of "cumulative impacts." ARB is working with local air districts to better define these situations and to make information about existing air pollution levels (e.g. from local businesses, motor vehicles, and other areawide sources) more readily available to land use agencies.

In December 2001, the ARB adopted "Policies and Actions for Environmental Justice" (Policies). These Policies were developed in coordination with a group of stakeholders representing local government agencies, community interest

AR0069349

groups, environmental justice organizations, academia, and business (Environmental Justice Stakeholders Group).

The Policies included a commitment to work with land use planners, transportation agencies, and local air districts to develop ways to identify, consider, and reduce cumulative air pollution emissions, exposure, and health risks associated with land use planning and decision-making. Developed under the auspices of the ARB's Environmental Justice Stakeholders Group, this Handbook is a first step in meeting that commitment.

ARB has produced this Handbook to help achieve several objectives:

- Provide recommendations on situations to avoid when siting new residences, schools, day care centers, playgrounds, and medical-related facilities (sensitive sites or sensitive land uses);

- Identify approaches that land use agencies can use to prevent or reduce potential air pollution impacts associated with general plan policies, new land use development, siting, and permitting decisions;

- Improve and facilitate access to air quality data and evaluation tools for use in the land use decision-making process;

- Encourage stronger collaboration between land use agencies and local air districts to reduce community exposure to source-specific and cumulative air pollution impacts; and

- Emphasize community outreach approaches that promote active public involvement in the air quality/land use decision-making process.

This Handbook builds upon California's 2003 General Plan Guidelines. These Guidelines, developed by the Governor's Office of Planning and Research (OPR), explain the land use planning process and applicable legal requirements. This Handbook also builds upon a 1997 ARB report, "The Land Use-Air Quality Linkage" ("Linkage Report").[9] The Linkage Report was an outgrowth of the California Clean Air Act which, among other things, called upon local air districts to focus particular attention on reducing emissions from sources that indirectly cause air pollution by attracting vehicle trips. Such indirect sources include, but are not limited to, shopping centers, schools and universities, employment centers, warehousing, airport hubs, medical offices, and sports arenas. The Linkage Report summarizes data as of 1997 on the relationships between land use, transportation, and air quality, and highlights strategies that can help to reduce the use of single occupancy automobile use. Such strategies

[9] To access this report, please refer to ARB's website or click on: http://www.arb.ca.gov/ch/programs/link97.pdf

complement ARB regulatory programs that continue to reduce motor vehicle emissions.

In this Handbook, we identify types of air quality-related information that we recommend land use agencies consider in the land use decision-making processes such as the development of regional, general, and community plans, zoning ordinances, environmental reviews, project siting, and permit issuance. The Handbook provides recommendations on the siting of new sensitive land uses based on current analyses. It also contains information on approaches and methodologies for evaluating new projects from an air pollution perspective.

The Handbook looks at air quality issues associated with emissions from industrial, commercial, and mobile sources of air pollution. Mobile sources continue to be the largest overall contributors to the state's air pollution problems, representing the greatest air pollution health risk to most Californians. Based on current health risk information for air toxics, the most serious pollutants on a statewide basis are diesel PM, benzene, and 1,3-butadiene, all of which are primarily emitted by motor vehicles. From a state perspective, ARB continues to pursue new strategies to further reduce motor vehicle-related emissions in order to meet air quality standards and reduce air toxics risk.

While mobile sources are the largest overall contributors to the state's air pollution problems, industrial and commercial sources can also pose a health risk, particularly to people near the source. For this reason, the issue of incompatible land uses is an important focus of this document.

Handbook Audience

Even though the primary users of the Handbook will likely be agencies responsible for air quality and land use planning, we hope the ideas and technical issues presented in this Handbook will also be useful for:

- public and community organizations and community residents,
- federal, state and regional agencies that fund, review, regulate, oversee, or otherwise influence environmental policies and programs affected by land use policies, and
- private developers.

AR0069351

3. Key Community Focused Issues Land Use Agencies Should Consider

Two key air quality issues that land use agencies should consider in their planning, zoning, and permitting processes are:

1) **Incompatible Land Uses.** Localized air pollution impacts from incompatible land use can occur when polluting sources, such as a heavily trafficked roadway, warehousing facilities, or industrial or commercial facilities, are located near a land use where sensitive individuals are found such as a school, hospital, or homes.

2) **Cumulative Impacts.** Cumulative air pollution impacts can occur from a concentration of multiple sources that individually comply with air pollution control requirements or fall below risk thresholds, but in the aggregate may pose a public health risk to exposed individuals. These sources can be heavy or light-industrial operations, commercial facilities such as autobody shops, large gas dispensing facilities, dry cleaners, and chrome platers, and freeways or other nearby busy transportation corridors.

Incompatible Land Uses

Land use policies and practices can worsen air pollution exposure and adversely affect public health by mixing incompatible land uses. Examples include locating new sensitive land uses, such as housing or schools, next to small metal plating facilities that use a highly toxic form of chromium, or very near large industrial facilities or freeways. Based on recent monitoring and health-based studies, we now know that air quality impacts from incompatible land uses can contribute to increased risk of illness, missed work and school, a lower quality of life, and higher costs for public health and pollution control.[10]

Avoiding incompatible land uses can be a challenge in the context of mixed-use industrial and residential zoning. For a variety of reasons, government agencies and housing advocates have encouraged the proximity of affordable housing to employment centers, shopping areas, and transportation corridors, partially as a means to reduce vehicle trips and their associated emissions. Generally speaking, typical distances in mixed-use communities between businesses and industries and other land uses such as homes and schools, should be adequate to avoid health risks. However, generalizations do not always hold as we addressed in section 1 of this Handbook.

In terms of siting air pollution sources, the proposed location of a project is a major factor in determining whether it will result in localized air quality impacts. Often, the problem can be avoided by providing an adequate distance or setback

[10] For more information, the reader should refer to ARB's website on community health: http://www.arb.ca.gov/ch/ch.htm

between a source of emissions and nearby sensitive land uses. Sometimes, suggesting project design changes or mitigation measures in the project review phase can also reduce or avoid potential impacts. This underscores the importance of addressing potential incompatible land uses as early as possible in the project review process, ideally in the general plan itself.

Cumulative Air Pollution Impacts

The broad concept of cumulative air pollution impacts reflects the combination of regional air pollution levels and any localized impacts. Many factors contribute to air pollution levels experienced in any location. These include urban background air pollution, historic land use patterns, the prevalence of freeways and other transportation corridors, the concentration of industrial and commercial businesses, and local meteorology and terrain.

When considering the potential air quality impacts of polluting sources on individuals, project location and the concentration of emissions from air pollution sources need to be considered in the land use decision-making process. In section 4, the Handbook offers a series of questions that helps land use agencies determine if a project should undergo a more careful analysis. This holds true regardless of whether the project being sited is a polluting source or a sensitive land use project.

Large industrial areas are not the only land uses that may result in public health concerns in mixed-use communities. Cumulative air pollution impacts can also occur if land uses do not adequately provide setbacks or otherwise protect sensitive individuals from potential air pollution impacts associated with nearby light industrial sources. This can occur with activities such as truck idling and traffic congestion, or from indirect sources such as warehousing facilities that are located in a community or neighborhood.

In October 2004, Cal/EPA published its Environmental Justice Action Plan. In February 2005, the Cal/EPA Interagency Working Group approved a working definition of "cumulative impacts" for purposes of initially guiding the pilot projects that are being conducted pursuant to that plan. Cal/EPA is now in the process of developing a Cumulative Impacts Assessment Guidance document. Cal/EPA will revisit the working definition of "cumulative impacts" as the Agency develops that guidance. The following is the working definition:

> *"Cumulative impacts means exposures, public health or environmental effects from the combined emissions and discharges, in a geographic area, including environmental pollution from all sources, whether single or multi-media, routinely, accidentally, or otherwise released. Impacts will take into account sensitive populations and socio-economic factors, where applicable, and to the extent data are available."*

AR0069353

4. Mechanisms for Integrating Localized Air Quality Concerns Into Land Use Processes

Land use agencies should use each of their existing planning, zoning, and permitting authorities to address the potential health risk associated with new projects. Land use-specific mechanisms can go a long way toward addressing both localized and cumulative impacts from new air pollution sources that are not otherwise addressed by environmental regulations. Likewise, close collaboration and communication between land use agencies and local air districts in both the planning and project approval stages can further reduce these impacts. Local agency partnerships can also result in early identification of potential impacts from proposed activities that might otherwise escape environmental review. When this happens, pollution problems can be prevented or reduced before projects are approved, when it is less complex and expensive to mitigate.

The land use entitlement process requires a series of planning decisions. At the highest level, the General Plan sets the policies and direction for the jurisdiction, and includes a number of mandatory elements dealing with issues such as housing, circulation, and health hazards. Zoning is the primary tool for implementing land use policies. Specific or community plans created in conjunction with a specific project also perform many of the same functions as a zoning ordinance. Zoning can be modified by means of variances and conditional use permits. The latter are frequently used to insure compatibility between otherwise conflicting land uses. Finally, new development usually requires the approval of a parcel or tract map before grading and building permits can be issued. These parcel or tract maps must be consistent with the applicable General Plan, zoning and other standards.

Land use agencies can use their planning authority to separate industrial and residential land uses, or to require mitigation where separation is not feasible. By separating incompatible land uses, land use agencies can prevent or reduce both localized and cumulative air pollution impacts without denying what might otherwise be a desirable project.[1] For instance:

- a dry cleaner could open a storefront operation in a community with actual cleaning operations performed at a remote location away from residential areas;
- gas dispensing facilities with lower fuel throughput could be sited in mixed-use areas;
- enhanced building ventilation or filtering systems in schools or senior care centers can reduce ambient air from nearby busy arterials; or
- landscaping and regular watering can be used to reduce fugitive dust at a building construction site near a school yard.

[1] It should be noted that such actions should also be considered as part of the General Plan or Plan element process.

AR0069354

The following general and specific land use approaches can help to reduce potential adverse air pollution impacts that projects may have on public health.

General Plans

The primary purpose of planning, and the source of government authority to engage in planning, is to protect public health, safety, and welfare. In its most basic sense, a local government General Plan expresses the community's development goals and embodies public policy relative to the distribution of future land uses, forming the basis for most land use decisions. Therefore, the most effective mechanism for dealing with the central land use concept of compatibility and its relationship to cumulative air pollution impacts is the General Plan. Well before projects are proposed within a jurisdiction, the General Plan sets the stage for where projects can be sited, and their compatibility with comprehensive community goals, objectives, and policies.

In 2003, OPR revised its General Plan Guidelines, highlighting the importance of incorporating sustainable development and environmental justice policies in the planning process. The OPR General Plan Guidelines provides an effective and long-term approach to reduce cumulative air pollution impacts at the earliest planning stages. In light of these important additions to the Guidelines, land use agencies should consider updating their General Plans or Plan elements to address these revisions.

The General Plan and related Plan elements can be used to avoid incompatible land uses by incorporating air quality considerations into these documents. For instance, a General Plan safety element with an air quality component could be used to incorporate policies or objectives that are intended to protect the public from the potential for facility breakdowns that may result in a dangerous release of air toxics. Likewise, an air quality component to the transportation circulation element of the General Plan could include policies or standards to prevent or reduce local exposure to diesel exhaust from trucks and other vehicles. For instance, the transportation circulation element could encourage the construction of alternative routes away from residential areas for heavy-duty diesel trucks. By considering the relationship between air quality and transportation, the circulation element could also include air quality policies to prevent or reduce trips and travel, and thus vehicle emissions. Policies in the land use element of the General Plan could identify areas appropriate for future industrial, commercial, and residential uses. Such policies could also introduce design and distance parameters that reduce emissions, exposure, and risk from industrial and some commercial land uses (e.g., dry cleaners) that are in close proximity to residential areas or schools.

Land use agencies should also consider updating or creating an air quality element in the jurisdiction's General Plan. In the air quality element, local decision-makers could develop long-term, effective plans and policies to address

AR0069355

air quality issues including cumulative impacts. The air quality element can also provide a general reference guide that informs local land use planners about regional and community level air quality, regulatory air pollution control requirements and guidelines, and references emissions and pollution source data bases and assessment and modeling tools. As is further described in Appendix C of the Handbook, new assessment tools that ARB is developing can be included into the air quality element by reference. For instance, ARB's statewide risk maps could be referenced in the air quality element as a resource that could be consulted by developers or land use agencies.

Zoning

The purpose of "zoning" is to separate different land uses. Zoning ordinances establish development controls to ensure that private development takes place within a given area in a manner in which:

- All uses are compatible (e.g., an industrial plant is not permitted in a residential area)
- Common development standards are used (e.g., all homes in a given area are set back the same minimum distance from the street); and
- Each development does not unreasonably impose a burden upon its neighbors (e.g., parking is required on site so as not to create neighborhood parking problems).

To do this, use districts called "zones" are established and standards are developed for these zones. The four basic zones are residential, commercial, industrial and institutional.

Land use agencies may wish to consider how zoning ordinances, particularly those for mixed-use areas, can be used to avoid exacerbating poor land use practices of the past or contributing to localized and cumulative air pollution impacts in the community.

Sometimes, especially in mixed use zones, there is a potential for certain categories of existing businesses or industrial operations to result in cumulative air pollution impacts to new development projects. For example:

- An assisted living project is proposed for a mixed-use zone adjacent to an existing chrome plating facility, or several dry cleaners.
- Multiple industrial sources regulated by a local air district are located directly upwind of a new apartment complex.
- A new housing development is sited in a mixed-use zone that is downwind or adjacent to a distribution center that attracts diesel-fueled delivery trucks and TRUs; or
- A new housing development or sensitive land use is sited without adequate setbacks from an existing major transportation corridor or rail yard.

AR0069356

As part of the public process for making zoning changes, local land use agencies could work with community planning groups, local businesses, and community residents to determine how best to address existing incompatible land uses.

Land Use Permitting Processes

- **Questions to Consider When Reviewing New Projects**

Very often, just knowing what questions to ask can yield critical information about the potential air pollution impacts of proposed projects – both from the perspective of a specific project as well as in the nature of existing air pollution sources in the same impact area. Available land use information can reveal the proximity of air pollution sources to sensitive individuals, the potential for incompatible land uses, and the location and nature of nearby air pollution sources. Air quality data, available from the ARB and local air districts, can provide information about the types and amounts of air pollution emitted in an area, regional air quality concentrations, and health risk estimates for specific sources.

General Plans and zoning maps are an excellent starting point in reviewing project proposals for their potential air pollution impacts. These documents contain information about existing or proposed land uses for a specific location as well as the surrounding area. Often, just looking at a map of the proposed location for a facility and its surrounding area will help to identify a potential adjacent incompatible land use.

The following pages are a "pull-out" list of questions to consider along with cross-references to pertinent information in the Handbook. These questions are intended to assist land use agencies in evaluating potential air quality-related concerns associated with new project proposals.

The first group of questions contains project-related queries designed to help identify the potential for localized project impacts, particularly associated with incompatible land uses. The second group of questions focuses on the issue of potential cumulative impacts by including questions about existing emissions and air quality in the community, and community feedback. Depending on the answers to these questions, a land use agency may decide a more detailed review of the proposal is warranted.

The California Department of Education has already developed a detailed process for school siting which is outlined in Appendix E. However, school districts may also find this section helpful when evaluating the most appropriate site for new schools in their area. At a minimum, using these questions may encourage school districts to engage throughout their siting process with land use agencies and local air districts. The combined expertise of these entities can be useful in devising relevant design standards and mitigation measures that can

AR0069357

reduce exposure to cumulative em ssions, exposure, and health risk to students and school workers

As indicated throughout the Handbook, we strongly encourage land use agencies to consult early and often with local air districts. Local air districts have the expertise many of the analytical tools, and a working know edge of the sources they regulate. It is also critical to fully involve the public and businesses that could be affected by the siting decision The questions provided in the chart below do not imply any particular action should be taken by land use agencies. Rather the questions are intended to improve the assessmen: process and facilitate informed decision-making

- **Project-Related Questions**

This section includes project-related questions that, in conjunction with the questions in the next section, can be used to tailor the project evaluation. These questions are designed to help identify the potential for incompatible land uses from localized project impacts.

Questions to Consider When Reviewing New Projects

Project-Related Questions	Cross-Reference to Relevant Handbook Sections
1. Is the proposed project: ▲ A business or commercial license renewal ▲ A new or modified commercial project ▲ A new or modified industrial project ▲ A new or modified public facility project ▲ A new or modified transportation project ▲ A housing or other development in which sensitive individuals may live or play	See Appendix A for typical land use classifications and associated project categories that could emit air pollutants
2. Does the proposed project: ▲ Conform to the zoning designation? ▲ Require a variance to the zoning designation? ▲ Include plans to expand operations over the life of the business such that additional emissions may increase the pollution burden in the community (e.g., from additional truck operations, new industrial operations or process lines, increased hours of operation, build-out to the property line, etc.)?	See Appendix F for a general explanation of land use processes. In addition, Section 3 contains a discussion of how land use planning, zoning, and permitting practices can result in incompatible land uses or cumulative air pollution impacts.
3. Has the local air district provided comments or information to assist in the analysis?	See Section 5 and Appendix C for a description of air quality-related tools that the ARB and local air districts use to provide information on potential air pollution impacts.
4. Have public meetings been scheduled with the affected community to solicit their involvement in the decision-making process for the proposed project?	See Section 7 for a discussion of public participation, information and outreach tools.
5. If the proposed project will be subject to local air district regulations: ▲ Has the project received a permit from the local air district? ▲ Would it comply with applicable local air district requirements? ▲ Is the local air district contemplating new regulations that would reduce emissions from the source over time? ▲ Will potential emissions from the project	See Appendix C for a description of local air district programs

AR0069359

Project-Related Questions	Cross-Reference to Relevant Handbook Sections
trigger the local air district's new source review for criteria pollutants or air toxics emissions? ▲ Is the local air district expected to ask the proposed project to perform a risk assessment? ▲ Is there sufficient new information or public concern to call for a more thorough environmental analysis of the proposed project? ▲ Are there plans to expand operations over time? ▲ Are there land-use based air quality significance thresholds or design standards that could be applied to this project in addition to applicable air district requirements?	
6. If the proposed project will release air pollution emissions, either directly or indirectly, but is not regulated by the local air district ▲ Is the local air district informed of the project? ▲ Does the local air district believe that there could be potential air pollution impacts associated with this project category because of the proximity of the project to sensitive individuals? ▲ If the project is one in which individuals live or play (e.g., a home, playground convalescent home, etc.) does the local air district believe that the project's proximity to nearby sources could pose potential air pollution impacts? ▲ Are there indirect emissions that could be associated with the project (e.g., truck traffic or idling, transport refrigeration unit operations, stationary diesel engine operations, etc.) that will be in close proximity to sensitive individuals? ▲ Will the proposed project increase or serve as a magnet for diesel traffic? ▲ Are there land-use based air quality significance thresholds or design standards that could be applied to this project in addition to applicable air district requirements? ▲ Is there sufficient new information or public concern to call for a more thorough environmental analysis of the proposed project? ▲ Should the site approval process include identification and mitigation of potential	See Section 1 for recommendations on situations to avoid when siting projects where sensitive individuals would be located (sensitive sites)

AR0069360

Project-Related Questions	Cross-Reference to Relevant Handbook Sections
direct or indirect emissions associated with the potential project?	
7. Does the local air district or land use agency have pertinent information on the source, such as: ▲ Available permit and enforcement data including for the owner or operator of the proposed source that may have other sources in the State. ▲ Proximity of the proposed project to sensitive individuals. ▲ Number of potentially exposed individuals from the proposed project. ▲ Potential for the proposed project to expose sensitive individuals to odor or other air pollution nuisances. ▲ Meteorology or the prevailing wind patterns between the proposed project and the nearest receptor, or between the proposed sensitive receptor project and sources that could pose a localized or cumulative air pollution impact	See Appendix C for a description of local air district programs See Appendix B for a listing of useful information that land use agencies should have on hand or have accessible when reviewing proposed projects for potential air pollution impacts Also, do not hesitate to contact your local air district regarding answers to any of these questions that might not be available at the land use agency. See Section 1 for recommendations on situations to avoid when siting projects where sensitive individuals would be located (sensitive sites)
8. Based upon the project application, its location, and the nature of the source, could the proposed project: ▲ Be a polluting source that is located in proximity to, or otherwise upwind of, a location where sensitive individuals live or play? ▲ Attract sensitive individuals and be located in proximity to or otherwise downwind of a source or multiple sources of pollution including polluting facilities or transportation-related sources that contribute emissions either directly or indirectly? ▲ Result in health risk to the surrounding community?	See Section 3 for a discussion of what is an incompatible land use and the potential cumulative air pollution impacts See Section 1 for recommendations on situations to avoid when siting projects where sensitive individuals would be located (sensitive sites)
9. If a CEQA categorical exemption is proposed, were the following questions considered: ▲ Is the project site environmentally sensitive as defined by the project's location? (A project that is ordinarily insignificant in its impact on the environment may in a particularly sensitive environment be significant.) ▲ Would the project and successive future projects of the same type in the approximate location potentially result in cumulative impacts? ▲ Are there "unusual circumstances" creating the possibility of significant effects?	See CEQA Guidelines section 15300.2 and Public Resources Code section 21084 See Section 1 for recommendations on situations to avoid when siting projects where sensitive individuals would be located (sensitive sites) See also Section 5 and Appendix C for a description of air quality-related tools that the ARB and local air districts use to provide information on potential air pollution impacts.

AR0069361

- **Questions Related to Cumulative Impact Assessment**

The following questions can be used to provide the decision-maker with a better understanding of the potential for cumulative air pollution impacts to an affected community. Answers to these questions will help to determine if new projects or activities warrant a more detailed review. It may also help to see potential environmental concerns from the perspective of the affected community. Additionally, responses can provide local decision-makers with information with which to assess the best policy options for addressing neighborhood-scale air pollution concerns.

The questions below can be used to identify whether existing tools and procedures are adequate to address land use-related air pollution issues. This process can also be used to pinpoint project characteristics that may have the greatest impact on community-level emissions, exposure, and risk. Such elements can include: the compliance record of existing sources including those owned or operated by the project proponent; the concentration of emissions from polluting sources within the approximate area of sensitive sites; transportation circulation in proximity to the proposed project; compatibility with the General Plan and General Plan elements; etc.

The local air district can provide useful assistance in the collection and evaluation of air quality-related information for some of the questions and should be consulted early in the process.

Questions Related to Cumulative Impact Assessment

	Technical Questions	Cross-Reference to Relevant Handbook Sections
1	Is the community home to industrial facilities?	See Appendix A for typical land use classifications and associated project categories that could emit air pollutants.
2	Do one or more major freeways or high-traffic volume surface streets cut through the community?	See transportation circulation element of your general plan. See also Appendix B for useful information that land use agencies should have on hand or have accessible when reviewing proposed projects for potential air pollution impacts. See Section 1 for recommendations on situations to avoid when siting projects where sensitive individuals would be located (sensitive sites).
3	Is the area classified for mixed-use zoning?	See your general plan and zoning ordinances.
4	Is there an available list of air pollution sources in the community?	Contact your local air district.
5	Has a walk-through of the community been conducted to gather the following information:	See Appendix B for a listing of useful information that land use agencies

AR0069362

Technical Questions	Cross-Reference to Relevant Handbook Sections
▲ Corroborate available information on land use activities in the area (e.g., businesses, housing developments, sensitive individuals, etc.)? ▲ Determine the proximity of existing and anticipated future projects to residential areas or sensitive individuals? ▲ Determine the concentration of emission sources (including anticipated future projects) to residential areas or sensitive individuals?	should have on hand or have accessible when reviewing proposed projects for potential air pollution impacts. Also contact your local air district.
6. Has the local air district been contacted to obtain information on sources in the community?	See Section 7 for a discussion of public participation, information and outreach tools.
7. What categories of commercial establishments are currently located in the area and does the local air district have these sources on file as being regulated or permitted?	See Appendix A for typical land use classifications and associated project categories that could emit air pollutants. Also contact your local air district.
8. What categories of indirect sources such as distribution centers or warehouses are currently located in the area?	See Appendix A for typical land use classifications and associated project categories that emit air pollutants.
9. What air quality monitoring data are available?	Contact your local air district.
10. Have any risk assessments been performed on emission sources in the area?	Contact your local air district.
11. Does the land use agency have the capability of applying a G.I.S. spatial mapping tool that can overlay zoning, sub-development information, and other neighborhood characteristics, with air pollution and transportation data?	See Appendix B for a listing of useful information that land use agencies should have on hand or have accessible when reviewing proposed projects for potential air pollution impacts. Also contact your local air district for tools that can be used to supplement available land use agency tools.
12. Based on available information, is it possible to determine if the affected community or neighborhood experiences elevated health risk due to a concentration of air pollution sources in close proximity, and if not, can the necessary information be obtained?	Contact your local air district. Also see Section 1 for recommendations on situations to avoid when siting projects where sensitive individuals would be located (sensitive sites).
13. Does the community have a history of chronic complaints about air quality?	See Section 7 for a discussion of public participation, information and outreach tools. Also contact your local air district.
14. Is the affected community included in the public participation process for the agency's decision?	See Section 7 for a discussion of public participation, information and outreach tools.
15. Have community leaders or groups been contacted about any pre-existing or chronic community air quality concerns?	See Section 7 for a discussion of public participation, information and outreach tools. Also contact your local air district.

AR0069363

- **Mitigation Approaches**

In addition to considering the suitability of the project location, opportunities for mitigation of air pollution impacts should be considered. Sometimes a land use agency may find that selection of a different project location to avoid a health risk is not feasible. When that happens, land use agencies should consider design improvements or other strategies that would reduce the risk. Such strategies could include performance or design standards, consultation with local air districts and other agencies on appropriate actions that these agencies should, or plan to, undertake, and consultation and outreach in the affected community. Potential mitigation measures should be feasible, cost-effective solutions within the available resources and authority of implementing agencies to enforce.[17]

- **Conditional Use Permits and Performance Standards**

Some types of land uses are only allowed upon approval of a conditional use permit (also called a CUP or special use permit). A conditional use permit does not re-zone the land but specifies conditions under which a particular land use will be permitted. Such land uses could be those with potentially significant environmental impacts. Local zoning ordinances specify the uses for which a conditional use permit is required, the zones they may be allowed in, and public hearing procedures. The conditional use permit imposes special requirements to ensure that the use will not be detrimental to its surroundings.

In the context of land use planning, performance standards are requirements imposed on projects or project categories through conditional use permits to ensure compliance with general plan policies and local ordinances. These standards could apply to such project categories as distribution centers, very large gas dispensing facilities, autobody shops, dry cleaners, and metal platers. Land use agencies may wish to consider adding land use-based performance standards to zoning ordinances in existing mixed-use communities for certain air pollution project categories. Such standards would provide certainty and equitable treatment to all projects of a similar nature, and reserve the more resource intensive conditional or special use permits to projects that require a more detailed analysis. In developing project design or performance standards, land use agencies should consult with the local air district. Early and regular consultation can avoid duplication or inconsistency with local air district control requirements when considering the site-specific design and operation of a project.

---

[17] A land use agency has the authority to condition or deny a project based upon information collected and evaluated through the land use decision-making process. However, any denial would need to be based upon identifiable, generally applicable, articulated standards set forth in the local government's General Plan and zoning codes. One way of averting this is to conduct early and regular outreach to the community and the local air district so that community and environmental concerns can be addressed and accommodated into the project proposal.

AR0069364

Examples of land use-based air quality-specific performance standards include the following:

- Placing a process vent away from the direction of the local playground that is nearby or increasing the stack height so that emissions are dispersed to reduce the emissions impact on surrounding homes or schools.
- Setbacks between the project fence line and the population center.
- Limiting the hours of operation of a facility to avoid excess emissions exposure or foul odors to nearby individuals.
- An ordinance that requires fleet operators to use cleaner vehicles before project approval (if a new business), or when expanding the fleet (if an existing business); and
- Providing alternate routes for truck operations that discourage detours into residential neighborhoods.

Outreach to Other Agencies

When questions arise regarding the air quality impacts of projects, including potential cumulative impacts, land use agencies should consult the local air district. Land use agencies should also consider the following suggestions to avoid creating new incompatible land uses:

- Consult with the local air district to help determine if emissions from a particular project will adversely impact sensitive individuals in the area, if existing or future effective regulations or permit requirements will affect the proposed project or other sources in the vicinity of the proposed project, or if additional inspections should be required.
- Check with ARB for new information and modeling tools that can help evaluate projects seeking to site within your jurisdiction.
- Become familiar with ARB's Land Use-Air Quality Linkage Report to determine whether approaches and evaluation tools contained in the Report can be used to reduce transportation-related impacts on communities.
- Contact and collaborate with other state agencies that play a role in the land use decision-making process, e.g., the State Department of Education, the California Energy Commission, and Caltrans. These agencies have information on mitigation measures and mapping tools that could be useful in addressing local problems.

- **Information Clearinghouse**

  - Land use agencies can refer to the ARB statewide electronic information clearinghouse for information on what measures other jurisdictions are using to address comparable issues or sources.[13]

[13] This information can be accessed from ARB's website by going to: http://www.arb.ca.gov/ch/clearinghouse.htm

The next section addresses available air quality assessment tools that land use agencies can use to evaluate the potential for localized or cumulative impacts in their communities

AR0069366

5. Available Tools to Evaluate Cumulative Air Pollution Emissions and Risk

Until recently, California has traditionally approached air pollution control from the perspective of assessing whether the pollution was regional, category-specific, or from new or existing sources. This methodology has been generally effective in reducing statewide and regional air pollution impacts and risk levels. However, such an incremental, category-by-category, source-by-source approach may not always address community health impacts from multiple sources - including mobile, industrial, and commercial facilities.

As a result of air toxics and children's health concerns over the past several years, ARB and local air districts have begun to develop new tools to evaluate and inform the public about cumulative air pollution impacts at the community level. One aspect of ARB's programs now underway is to consolidate and make accessible air toxics emissions and monitoring data by region, using modeling tools and other analytical techniques to take a preliminary look at emissions, exposure, and health risk in communities.

ARB has developed multiple tools to assist local air districts perform assessments of cumulative emissions, exposure, and risk on a neighborhood scale. These tools include:

- Regional risk maps that show trends in potential cancer risk from toxic air pollutants in southern and central California between 1990 and 2010. These maps are based on the U.S. EPA's ASPEN model. These maps provide an estimate of background levels of toxic air pollutant risk but are not detailed enough to assess individual neighborhoods or facilities.[14]

- The Community Health Air Pollution Information System (CHAPIS) is a user-friendly, Internet-based system for displaying information on emissions from sources of air pollution in an easy to use mapping format. CHAPIS contains information on air pollution emissions from selected large facilities and small businesses that emit criteria and toxic air pollutants. It also contains information on air pollution emissions from motor vehicles. When released in 2004, CHAPIS did not contain information on every source of air pollution or every air pollutant. However, ARB continues to work with local air districts to include all of the largest air pollution sources and those with the highest documented air pollution risk. Additional facilities will be added to CHAPIS as more data become available.[15]

---

[14] For further information on these maps, please visit ARB's website at: http://www.arb.ca.gov/toxics/cti/hlthrisk/hlthrisk.htm

[15] For further information on CHAPIS, please click on: http://www.arb.ca.gov/ch/chapis1/chapis1.htm

- The Hot Spots Analysis and Reporting Program (HARP) is a software database package that evaluates emissions from one or more facilities to determine the overall health risk posed by the facility(-ies) on the surrounding community. Proper use of HARP ensures that the risk assessment meets the latest risk assessment guidelines published by the State Office of Environmental Health Hazard Assessment (OEHHA). HARP is designed with air quality professionals in mind and is available from the ARB.

- The Urban Emissions Model (URBEMIS) is a computer program that can be used to estimate emissions associated with land development projects in California such as residential neighborhoods, shopping centers, office buildings, and construction projects. URBEMIS uses emission factors available from the ARB to estimate vehicle emissions associated with new land uses.

Local air districts and others can use these tools to assess a new project or plan revision. For example, these tools can be used to:

- Identify if there are multiple sources of air pollution in the community;
- Identify the major sources of air pollution in the area under consideration;
- Identify the background potential cancer risk from toxic air pollution in the area under consideration;
- Estimate the risk from a new facility and how it adds to the overall risk from other nearby facilities; and
- Provide information to decision-makers and key stakeholders on whether there may be significant issues related to cumulative emissions, exposure, and health risk due to a permitting or land use decision.

If an air agency wishes to perform a cumulative air pollution impact analysis using any of these tools, it should consult with the ARB and/or the local air district to obtain information or assistance on the data inputs and procedures necessary to operate the program. In addition, land use agencies could consult with local air districts to determine the availability of land use and air pollution data for entry into an electronic Geographical Information System (GIS) format. GIS is an easier mapping tool than the more sophisticated models described in Appendix C. GIS mapping makes it possible to superimpose land use with air pollution information so that the spatial relationship between air pollution sources, sensitive receptors, and air quality can be visually represented. Appendix C provides a general description of the impact assessment process and micro-scale, or community level modeling tools that are available to evaluate potential cumulative air pollution impacts. Modeling protocols will be accessible on ARB's website as they become available. The ARB will also provide land use agencies and local air districts with statewide regional modeling results and information regarding micro-scale modeling.

AR0069368

6. ARB Programs to Reduce Air Pollution in Communities

ARB's regulatory programs reduce air pollutant emissions through statewide strategies that improve public health in all California communities. ARB's overall program addresses motor vehicles, consumer products, air toxics, air-quality planning, research, education, enforcement, and air monitoring. Community health and environmental justice concerns are a consideration in all these programs. ARB's programs are statewide but recognize that extra efforts may be needed in some communities due to historical mixed land-use patterns, limited participation in public processes in the past, and a greater concentration of air pollution sources in some communities.

ARB's strategies are intended to result in better air quality and reduced health risk to residents throughout California. The ARB's priority is to prevent or reduce the public's exposure to air pollution, including from toxic air contaminants that pose the greatest risk, particularly to infants and children who are more vulnerable to air pollution.

In October 2003, ARB updated its statewide control strategy to reduce emissions from source categories within its regulatory authority. A primary focus of the strategy is to achieve federal and state air quality standards for ozone and particulate matter throughout California, and to reduce health risk from diesel PM. Along with local air districts, ARB will continue to address air toxics emissions from regulated sources (see Table 6-1 for a summary of ARB activities). As indicated earlier, ARB will also provide analytical tools and information to land use agencies and local air districts to help assess and mitigate cumulative air pollution impacts.

The ARB will continue to consider the adoption of or revisions to needed air toxics control measures as part of the state's ongoing air toxics assessment program.[16]

As part of its effort to reduce particulate matter and air toxics emissions from diesel PM, the ARB has developed a Diesel Risk Reduction Program[17] that lays out several strategies in a three-pronged approach to reduce emissions and their associated risk:

- Stringent emission standards for all new diesel-fueled engines;
- Aggressive reductions from in-use engines; and
- Low sulfur fuel that will reduce PM and still provide the quality of diesel fuel needed to control diesel PM.

[16] For continuing information and updates on state measures, the reader can refer to ARB's website at http://www.arb.ca.gov/toxics/toxics.htm.
[17] For a comprehensive description of the program, please refer to ARB's website at http://www.arbB.ca.gov/diesel/dieselrrp.htm.

Table 6-1
ARB ACTIONS TO ADDRESS
CUMULATIVE AIR POLLUTION IMPACTS IN COMMUNITIES

Information Collection

- Improve emission inventories, air monitoring data, and analysis tools that can help to identify areas with high cumulative air pollution impacts
- Conduct studies in coordination with OEHHA on the potential for cancer and non-cancer health effects from air pollutants emitted by specific source categories
- Establish web-based clearinghouse for local land use strategies

Emission Reduction Approaches (2004-2006)*

- Through a public process, consider development and/or amendment of regulations and related guidance to reduce emissions, exposure, and health risk at a statewide and local level for the following sources:
  - Diesel PM sources such as stationary diesel engines, transport refrigeration units, portable diesel engines, on-road public fleets, off-road public fleets, heavy-duty diesel truck idling, harbor craft vessels, waste haulers
  - Other air toxics sources, such as formaldehyde in composite wood products, hexavalent chromium for chrome plating and chromic acid anodizing, thermal spraying, and perchloroethylene dry cleaning
- Develop technical information for the following:*
  - Distribution centers
  - Modeling tools such as HARP and CHAPIS
- Adopt rules and pollution prevention initiatives within legal authority to reduce emissions from mobile sources and fuels, and consumer products
- Develop and maintain Air Quality Handbook as a tool for use by land use agencies and local air districts to address cumulative air pollution impacts

Other Approaches

- Establish guidelines for use of statewide incentive funding for high priority mobile source emission reduction projects

*Because ARB will continue to review the need to adopt or revise statewide measures, the information contained in this chart will be updated on an ongoing basis.

A number of ARB's diesel risk reduction strategies have been adopted. These include measures to reduce emissions from refuse haulers, urban buses, transport refrigeration units, stationary and portable diesel engines, and idling trucks and school buses. These sources are all important from a community perspective.[18]

[18] The reader can refer to ARB's website for information on its mobile source-related programs at: http://www.arb.ca.gov/msprog/msprog.htm, as well as regulations adopted and under consideration as part of the Diesel Risk Reduction Program at: http://www.arb.ca.gov/diesel/dieselrrp.htm

The ARB will continue to evaluate the health effects of air pollutants while implementing programs with local air districts to reduce air pollution in all California communities.

Local air districts also have ambitious programs to reduce criteria pollutants and air toxics from regulated sources in their region. Many of these programs also benefit air quality in local communities as well as in the broader region. For more information on what is being done in your area to reduce cumulative air pollution impacts through air pollution control programs, you should contact your local air district.[19]

[19] Local air district contacts can be found on the inside cover to this Handbook.

AR0069371

7. Ways to Enhance Meaningful Public Participation

Community involvement is an important part of the land use process. The public is entitled to the best possible information about the air they breathe and what is being done to prevent or reduce unhealthful air pollution in their communities. In particular, information on how land use decisions can affect air pollution and public health should be made accessible to all communities, including low-income and minority communities.

Effective community participation consistently relies on a two-way flow of information – from public agencies to community members about opportunities, constraints and impacts, and from community members back to public officials about needs, priorities, and preferences. The outreach process needed to build understanding and local neighborhood involvement requires data, methodologies and formats tailored to the needs of the specific community. More importantly, it requires the strong collaboration of local government agencies that review and approve projects and land uses to improve the physical and environmental surroundings of the local community.

Many land use agencies, especially those in major metropolitan areas, are familiar with, and have a long established public review process. Nevertheless public outreach can often be improved. Active public involvement requires engaging the public in ways that do not require their previous interest in or knowledge of the land use or air pollution control requirements, and a commitment to taking action where appropriate to address the concerns that are raised.

- **Direct Community Outreach**

In conjunction with local air districts, land use agencies should consider designing an outreach program for community groups, other stakeholders, and local government agency staffs that address the problem of cumulative air pollution impacts, and the public and government role in reducing them. Such a program could consider analytical tools that assist in the preparation and presentation of information in a way that supports sensible decision-making and public involvement. Table 7-1 contains some general outreach approaches that might be considered.

AR0069372

Table 7-1
Public Participation Approaches

- Staff and community leadership awareness training on environmental justice programs and community-based issues
- Surveys to identify the website information needs of interested community-based organizations and other stakeholders
- Information materials on local land use and air district authorities
- Community-based councils to facilitate and invite resident participation in the planning process
- Neighborhood CEQA scoping sessions that allows for community input prior to technical analysis
- Public information materials on existing issues are under review including materials written for the affected community and in different media that widens accessibility
- Public meetings
- Identify other opportunities to include community-based organizations in the process

To improve outreach, local land use agencies should consider the following activities.

- Hold meetings in communities affected by agency programs, policies, and projects at times and in places that encourage public participation, such as evenings and weekends at centrally located community meeting rooms, libraries, and schools.
- Assess the need for and provide translation services at public meetings.
- Hold community meetings to update residents on the results of any special air monitoring programs conducted in their neighborhood.
- Hold community meetings to discuss and evaluate the various options to address cumulative impacts in their community.
- In coordination with local air districts, make staff available to attend meetings of community organizations and neighborhood groups to listen to and, where appropriate, act upon community concerns.
- Establish a specific contact person for environmental justice issues.
- Increase student and community awareness of local government land use activities and policies through outreach opportunities.
- Make air quality and land use information available to communities in an easily understood and useful format, including fact sheets, mailings, brochures, public service announcements, and web pages, in English and other languages.
- On the local government web-site, dedicate a page or section to what the land use program is doing regarding environmental justice and cumulative environmental impacts, and, as applicable, activities conducted with local air districts such as neighborhood air monitoring studies, pollution prevention, air pollution sources in neighborhoods, and risk reduction.

AR0069373

- Allow, encourage, and promote community access to land use activities including public meetings, General Plan or Community Plan updates, zoning changes, special studies, CEQA reviews, variances, etc.
- Distribute information in multiple languages, as needed, on how to contact the land use agency or local air district to obtain information and assistance regarding environmental justice programs, including how to participate in public processes
- Create and distribute a simple, easy-to-read, and understandable public participation handbook, which may be based on the "Public Participation Guidebook" developed by ARB.

- **Other Opportunities for Meaningful Public Outreach**

  - Community-Based Planning Committees

Neighborhood-based or community planning advisory councils could be established to invite and facilitate direct resident participation into the planning process. With the right training and technical assistance, such councils can provide valuable input and a forum for the review of proposed amendments to plans, zone changes, land use permits, and suggestions as to how best to prevent or reduce cumulative air pollution impacts in their community.

  - Regional Partnerships

Consider creating regional coalitions of key growth-related organizations from both the private and public sectors, with corporations, communities, other jurisdictions, and government agencies. Such partnerships could facilitate agreement on common goals and win-win solutions tailored specifically for the region. With this kind of dialogue, shared vision, and collaboration barriers can be overcome and locally acceptable sustainable solutions implemented. Over the long term, such strategies will help to bring about clean air in communities as well as regionally.

AR0069374

LAND USE CLASSIFICATIONS AND ASSOCIATED FACILITY CATEGORIES THAT COULD EMIT AIR POLLUTANTS

(1) Land Use Classifications – by Activity[1]	(2) Facility or Project Examples	(3) Key Pollutants[2,3]	(4) Air Pollution Permits[4]
COMMERCIAL/ LIGHT INDUSTRIAL: SHOPPING, BUSINESS, AND COMMERCIAL			
▲ Primarily retail shops and stores, office commercial activities, and light industrial or small business	Dry cleaners, drive-through restaurants, gas dispensing facilities, auto body/ auto mechanical, metal plating shops, photographic processing shops, textiles, apparel and furniture, upholstery, leather and leather products, appliance repair shops, mechanical assembly cleaning, printing shops	VOCs, air toxics including diesel PM, NOx, CO, SOx	Limited Rules for applicable equipment
▲ Goods storage or handling activities, characterized by loading and unloading goods at warehouses, large storage structures, movement of goods, shipping, and trucking	Warehousing, freight forwarding centers, drop off and loading areas, distribution centers	VOCs, air toxics including diesel PM, NOx, CO, SOx	No
LIGHT INDUSTRIAL/ RESEARCH AND DEVELOPMENT			
▲ Medical waste at research hospitals and labs	Incineration, surgical and medical instrument manufacturers, pharmaceutical manufacturing, biotech research facilities	Air toxics, NOx, CO, SOx	Yes
▲ Electronics, electrical apparatus, components, and accessories	Computer manufacturer, integrated circuit board manufacturer, semiconductor production	Air toxics, VOCs	Yes
▲ College or university lab or research center	Medical waste incinerators, lab chemicals handling, storage and disposal	Air toxics, NOx, CO, SOx, PM10	Yes
▲ Research and development labs	Satellite manufacturer, fiber optics manufacturer, defense contractors, space research and technology, new vehicles and fuels testing labs	Air toxics, VOCs	Yes
▲ Commercial testing labs	Consumer products, chemical handling, storage and disposal	Air toxics, VOCs	Yes

AR0069375

(1) Land Use Classifications – by Activity[1]	(2) Facility or Project Examples	(3) Key Pollutants[2,3]	(4) Air Pollution Permits[4]
INDUSTRIAL: NON-ENERGY-RELATED			
▲ Assembly plants manufacturing facilities industrial machinery	Adhesives, chemical, textiles, apparel and furniture upholstery, clay, glass, and stone products production, asphalt materials, cement manufacturers, wood products, paperboard containers and boxes, metal coating, metal and canned food product fabrication, auto manufacturing, food processing, printing and publishing, drug, vitamins and pharmaceuticals, dyes, paints, pesticides, photographic chemicals, polish and wax, consumer products, metal and mineral smelters and foundries, fiberboard, floor tile and cover, wood and metal furniture and fixtures, rubber and leather products, general, industrial and metalworking machinery, musical instruments, office supplies, rubber products and plastics production, sawmills, solvent recycling, shingle and siding, surface coatings	VOCs, air toxics, including diesel PM, NOx, PM, CO, SOx	Yes
INDUSTRIAL: ENERGY AND UTILITIES			
▲ Water and sewer operations	Pumping stations, vents, treatment	VOCs, air toxics, NOx, CO, SOx, PM10	Yes
▲ Power generation and distribution	Power plant boilers and heaters, portable diesel engines, gas turbine engines	NOx, diesel PM, NOx, CO, SOx, PM10, VOCs	Yes
▲ Refinery operations	Refinery boilers and heaters, coke cracking units, valves and flanges, flares	VOCs, air toxics, including diesel PM, NOx, CO, SOx, PM10	Yes
▲ Oil and gas extraction	Oil recovery systems, uncovered wells	NOx, diesel PM, VOCs, CO, SOx, PM10	Yes
▲ Gasoline storage, transmission, and marketing	Above and below ground storage tanks, floating roof tanks, tank farms, pipelines	VOCs, air toxics, including diesel PM, NOx, CO, SOx, PM10	Yes
▲ Solid and hazardous waste treatment, storage, and disposal activities	Landfills, methane digester systems, process recycling facility for concrete and asphalt materials	VOCs, air toxics, NOx, CO, SOx, PM10	Yes
CONSTRUCTION (NON-TRANSPORTATION)			
	Building construction, demolition sites	PM (particulate road dust), asbestos, diesel PM, NOx, CO, SOx, PM10, VOCs	Limited state and federal off-road equipment standards

AR0069376

(1) Land Use Classifications – by Activity[1]	(2) Facility or Project Examples	(3) Key Pollutants[2,3]	(4) Air Pollution Permits[4]
DEFENSE			
	Ordnance and explosives demolition range and testing activities, chemical production, degreasing, surface coatings, vehicle refueling, vehicle and engine operations and maintenance	VOCs, air toxics including diesel PM, NOx, CO, SOx, PM10	Limited prescribed burning, equipment and solvent rules
TRANSPORTATION			
▲ Vehicular movement	Residential area circulation systems, parking and idling at parking structures, drive-through establishments, car washes, special events, schools, shopping malls, etc.	VOCs, NOx, PM (re-entrained road dust), air toxics (e.g., benzene, diesel PM, formaldehyde, acetaldehyde, 1,3 butadiene), CO, SOx, PM10	No
▲ Road construction and surfacing	Street paving and repair, new highway construction and expansion	VOCs, air toxics including diesel PM, NOx, CO, SOx, PM10	No
▲ Trains	Railroads, switch yards, maintenance yards		
▲ Marine and port activities	Recreational sailing, commercial marine operations, refueling operations, loading and unloading, servicing, shipping operations, dredging, marina expansion, truck idling	VOCs, NOx, CO, SOx, PM10, air toxics, refueling diesel PM	Limited Applicable state and federal MV standards and possible equipment rules
▲ Aircraft	Takeoff, landing, and taxiing, aircraft maintenance, ground support activities		
▲ Mass transit and school buses	Bus repair and maintenance		
NATURAL RESOURCES			
▲ Farming operations	Agricultural burning, diesel operated engines and heaters, small food processors, pesticide application, agricultural off-road equipment	Diesel PM, VOCs, NOx, PM10, CO, SOx, pesticides	Limited[5], Agricultural burning requirements, applicable state and federal mobile source standards, pesticide rules
▲ Livestock and dairy operations	Dairies and feed lots	Ammonia, VOCs, PM10	Yes
▲ Logging	Off-road equipment (e.g., diesel fueled skippers, crush trackers, etc.)	Diesel PM, NOx, CO, SOx, PM10, VOCs	Limited Applicable state/federal mobile source standards
▲ Mining operations	Quarrying or stone cutting, mining, drilling or dredging	PM10, CO, SOx, VOCs, NOx, and asbestos in some geographical areas	Applicable equipment rules and dust controls

AR0069377

(1) Land Use Classifications – by Activity[i]	(2) Facility or Project Examples	(3) Key Pollutants[ii,iii]	(4) Air Pollution Permits[iv]
RESIDENTIAL			
Housing	Housing developments; retirement developments; affordable housing	Fireplace emissions (PM10, NOx, VOCs, CO, air toxics); Water heater combustion (NOx, VOCs, CO)	No[vi]
ACADEMIC AND INSTITUTIONAL			
▲ Schools, including school-related recreational activities	Schools; school yards; vocational training labs/classrooms such as auto repair/painting and aviation mechanics	Air toxics	Yes/No[vii]
▲ Medical waste	Incineration	Air toxics, NOx, CO, PM10	Yes
▲ Clinics, hospitals, convalescent homes		Air toxics	Yes

[i] These classifications were adapted from the American Planning Association's "Land Based Classification Standards." The Standards provide a consistent model for classifying land uses based on their characteristics. The model classifies land uses by refining traditional categories into multiple dimensions, such as activities, functions, building types, site development character, and ownership constraints. Each dimension has its own set of categories and subcategories. These multiple dimensions allow users to have precise control over land-use classifications. For more information, the reader should refer to the Association's website at http://www.planning.org/LBCS/GeneralInfo/.

[ii] This column includes key criteria pollutants and air toxic contaminants that are most typically associated with the identified source categories.

Additional information on specific air toxics that are attributed to facility categories can be found in ARB's Emission Inventory Criteria and Guidelines Report for the Air Toxics Hot Spots Program (May 15, 1997). This information can be viewed at ARB's web site at http://www.arb.ca.gov/ab2588/final96/guide96.pdf.

Criteria air pollutants are those air pollutants for which acceptable levels of exposure can be determined and for which an ambient air quality standard has been set. Criteria pollutants include ozone (formed by the reaction of volatile organic compounds and nitrogen oxides in the presence of sunlight), particulate matter, nitrogen dioxide, sulfur dioxide, carbon monoxide, and lead.

Volatile organic compounds (VOCs) combine with nitrogen oxides to form ozone, as well as particulate matter. VOC emissions result primarily from incomplete fuel combustion and the evaporation of chemical solvents and fuels. On-road mobile sources are the largest contributors to statewide VOC emissions. Stationary sources of VOC emissions include processes that use solvents (such as dry-cleaning, degreasing, and coating operations) and petroleum-related processes (such as petroleum refining, gasoline marketing and dispensing, and oil and gas extraction). Areawide VOC sources include consumer products, pesticides, aerosols and paints, asphalt paving and roofing, and other evaporative emissions.

Nitrogen oxides (NOx) are a group of gaseous compounds of nitrogen and oxygen, many of which contribute to the formation of ozone and particulate matter. Most NOx emissions are produced by the combustion of fuels. Mobile sources make up about 80 percent of the total statewide NOx emissions. Mobile sources include on-road vehicles and trucks, aircraft, trains, ships, recreational boats, industrial and construction equipment, farm

AR0069378

equipment, off-road recreational vehicles, and other equipment. Stationary sources of NOx include both internal and external combustion processes in industries such as manufacturing, food processing, electric utilities, and petroleum refining. Areawide sources, which include residential fuel combustion, waste burning, and fires, contribute only a small portion of the total statewide NOx emissions, but depending on the community, may contribute to a cumulative air pollution impact.

Particulate matter (PM) refers to particles small enough to be breathed into the lungs (under 10 microns in size). It is not a single substance, but a mixture of a number of highly diverse types of particles and liquid droplets. It can be formed directly, primarily as dust from vehicle travel on paved and unpaved roads, agricultural operations, construction and demolition.

Carbon monoxide (CO) is a colorless and odorless gas that is directly emitted as a by-product of combustion. The highest concentrations are generally associated with cold, stagnant weather conditions that occur during winter. CO problems tend to be localized.

An Air Toxic Contaminant (air toxic) is defined as an air pollutant that may cause or contribute to an increase in mortality or in serious illness, or which may pose a present or potential hazard to human health. Similar to criteria pollutants, air toxics are emitted from stationary, areawide, and mobile sources. They contribute to elevated regional and localized risks near industrial and commercial facilities and busy roadways. The ten compounds that pose the greatest statewide risk are: acetaldehyde, benzene, 1,3-butadiene, carbon tetrachloride, diesel particulate matter (diesel PM), formaldehyde, hexavalent chromium, methylene chloride, para-dichlorobenzene, and perchloroethylene. The risk from diesel PM is by far the largest, representing about 70 percent of the known statewide cancer risk from outdoor air toxics. The exhaust from diesel-fueled engines is a complex mixture of gases, vapors, and particles, many of which are known human carcinogens. Diesel PM is emitted from both mobile and stationary sources. In California, on-road diesel-fueled vehicles contribute about 26 percent of statewide diesel PM emissions, with an additional 72 percent attributed to other mobile sources such as construction and mining equipment, agricultural equipment, and other equipment. Stationary engines in shipyards, warehouses, heavy equipment repair yards, and oil and gas production operations contribute about two percent of statewide emissions. However, when this number is disaggregated to a sub-regional scale such as neighborhoods, the risk factor can be far greater.

The level of pollution emitted is a major determinant of the significance of the impact.

[1] Indicates whether facility activities listed in column 4 are generally subject to local air district permits to operate. This does not include regulated products such as solvents and degreasers that may be used by sources that may not require an operating permit per se, e.g., a gas station or dry cleaner.

[2] Generally speaking, warehousing or distribution centers are not subject to local air district permits. However, depending on the district, motor vehicle fleet rules may apply to trucks or off-road vehicles operated and maintained by the facility operator. Additionally, emergency generators or internal combustion engines operated on the site may require an operating permit.

[3] Authorized by recent legislation SB700.

[4] Local air districts do not require permits for woodburning fireplaces inside private homes. However, some local air districts and land use agencies do have rules or ordinances that require new housing developments or home re-sales to install U.S. EPA–certified stoves. Some local air districts also ban residential woodburning during weather inversions that concentrate smoke in residential areas. Likewise, home water heaters are not subject to permits; however, new heaters could be subject to emission limits that are imposed by federal or local agency regulations.

[5] Technical training schools that conduct activities normally permitted by a local air district could be subject to an air permit.

AR0069379

LAND USE-BASED REFERENCE TOOLS TO EVALUATE NEW PROJECTS FOR POTENTIAL AIR POLLUTION IMPACTS

Land use agencies generally have a variety of tools and approaches at hand, or accessible from local air districts that can be useful in performing an analysis of potential air pollution impacts associated with new projects. These tools and approaches include:

- Base map of the city or county planning area and terrain elevations.
- General Plan designations of land use (existing and proposed).
- Zoning maps.
- Land use maps that identify existing land uses, including the location of facilities that are permitted or otherwise regulated by the local air district. Land use agencies should consult with their local air district for information on regulated facilities.
- Demographic data, e.g., population location and density, distribution of population by income, distribution of population by ethnicity, and distribution of population by age. The use of population data is a normal part of the planning process. However, from an air quality perspective, socioeconomic data is useful to identify potential community health and environmental justice issues.
- Emissions, monitoring, and risk-based maps created by the ARB or local air districts that show air pollution-related health risk by community across the state.
- Location of public facilities that enhance community quality of life, including parks, community centers, and open space.
- Location of industrial and commercial facilities and other land uses that use hazardous materials, or emit air pollutants. These include chemical storage facilities, hazardous waste disposal sites, dry cleaners, large gas dispensing facilities, auto body shops, and metal plating and finishing shops.
- Location of sources or facility types that result in diesel on-road and off-road emissions, e.g., stationary diesel power generators, forklifts, cranes, construction equipment, on-road vehicle idling, and operation of transportation refrigeration units. Distribution centers, marine terminals and ports, rail yards, large industrial facilities, and facilities that handle bulk goods are all examples of complex facilities where these types of emission sources are frequently concentrated.[1] Very large facilities, such as ports, marine terminals, and airports, could be analyzed regardless of proximity to a receptor if they are within the modeling area.
- Location and zoning designations for existing and proposed schools, buildings, or outdoor areas where sensitive individuals may live or play.
- Location and density of existing and proposed residential development.
- Zoning requirements, property setbacks, traffic flow requirements, and idling restrictions for trucks, trains, yard hostlers[2], construction equipment, or school buses.
- Traffic counts (including diesel truck traffic counts), within a community to validate or augment existing regional motor vehicle trip and speed data.

---

[1] The ARB is currently evaluating the types of facilities that may act as complex point sources and developing methods to identify them.

[2] Yard hostler means a tractor less than 300 horsepower that is used to transfer semi-truck or tractor-trailer containers in and around storage, transfer, or distribution yards or areas and is often equipped with a hydraulic lifting fifth wheel for connection to trailer containers.

AR0069381

ARB AND LOCAL AIR DISTRICT INFORMATION AND TOOLS CONCERNING CUMULATIVE AIR POLLUTION IMPACTS

It is the ARB's policy to support research and data collection activities toward the goal of reducing cumulative air pollution impacts. These efforts include updating and improving the air toxics emissions inventory, performing special air monitoring studies in specific communities, and conducting a more complete assessment of non-cancer health effects associated with air toxics and criteria pollutants.[1] This information is important because it helps us better understand links between air pollution and the health of sensitive individuals – children, the elderly, and those with pre-existing serious health problems affected by air quality.

ARB is working with CAPCOA and OEHHA to improve air pollutant data and evaluation tools to determine when and where cumulative air pollution impacts may be a problem. The following provides additional information on this effort.

How are emissions assessed?

Detailed information about the sources of air pollution in an area is collected and maintained by local air districts and the ARB in what is called an emission inventory. Emission inventories contain information about the nature of the business, the location, type and amount of air pollution emitted, the air pollution producing processes, the type of air pollution control equipment, operating hours, and seasonal variations in activity. Local districts collect emission inventory data for most stationary source categories.

Local air districts collect air pollution emission information directly from facilities and businesses that are required to obtain an air pollution operating permit. Local air districts use this information to compile an emission inventory for areas within their jurisdiction. The ARB compiles a statewide emission inventory based on the information collected by the ARB and local air districts. Local air districts provide most of the stationary source emission data, and ARB provides mobile source emissions as well as some areawide emission sources such as consumer products and paints. ARB is also developing map-based tools that will display information on air pollution sources.

Criteria pollutant data have been collected since the early 1970's, and toxic pollutant inventories began to be developed in the mid-1980's.

[1] A criteria pollutant is any air pollutant for which EPA has established a National Ambient Air Quality Standard or for which California has established a State Ambient Air Quality Standard, including: carbon monoxide, lead, nitrogen oxides, ozone, particulates and sulfur oxides. Criteria pollutants are measured in each of California's air basins to determine whether the area meets or does not meet specific federal or state air quality standards. Air toxics or air toxic contaminants are listed pollutants recognized by California or EPA as posing a potential risk to health.

How is the toxic emission inventory developed?

Emissions data for toxic air pollutants is a high priority for communities because of concerns about potential health effects. Most of ARB's air toxics data is collected through the toxic "Hot Spots" program. Local air districts collect emissions data from industrial and commercial facilities. Facilities that exceed health-based thresholds are required to report their air toxics emissions as part of the toxic "Hot Spots" program and update their emissions data every four years. Facilities are required to report their air toxics emissions data if there is an increase that would trigger the reporting threshold of the hotspots program. Air toxics emissions from motor vehicles and consumer products are estimated by the ARB. These estimates are generally regional in nature, reflecting traffic and population.

The ARB also maintains chemical speciation profiles that can be used to estimate toxics emissions when no toxic emissions data is available.

What additional toxic emissions information is needed?

In order to assess cumulative air pollution impacts, updated information from individual facilities is needed. Even for sources where emissions data are available, additional information such as the location of emissions release points is often needed to better model cumulative impacts. In terms of motor vehicles, emissions data are currently based on traffic models that only contain major roads and freeways. Local traffic data are needed so that traffic emissions can be more accurately assigned to specific streets and roads. Local information is also needed for off-road emission sources, such as ships, trains, and construction equipment. In addition, hourly maximum emissions data are needed for assessing acute air pollution impacts.

What work is underway?

ARB is working with CAPCOA to improve toxic emissions data, developing a community health air pollution information system to improve access to emission information, conducting neighborhood assessment studies to better understand toxic emission sources, and conducting surveys of sources of toxic pollutants.

How is air pollution monitored?

While emissions data identify how much air pollution is going into the air, the state's air quality monitoring network measures air pollutant levels in outdoor air. The statewide air monitoring network is primarily designed to measure regional exposure to air pollutants, and consists of more than 250 air monitoring sites.

The air toxics monitoring network consists of approximately 20 permanent sites. These sites are supplemented by special monitoring studies conducted by ARB and local air districts. These sites measure approximately sixty toxic air pollutants. Diesel PM, which is the major driver of urban air toxic risk, is not monitored directly. Ten of the

60 toxic pollutants, not including diesel, account for most of the remaining potential cancer risk in California urban areas

What additional monitoring has been done?

Recently additional monitoring has been done to look at air quality at the community level. ARB's community monitoring was conducted in six communities located throughout the state. Most sites were in low-income, minority communities located near major sources of air pollution, such as refineries or freeways. The monitoring took place for a year or more in each community, and included measurements of both criteria and toxic pollutants.

What is being learned from community monitoring?

In some cases, the ARB or local air districts have performed air quality monitoring or modeling studies covering a particular region of the state. When available, these studies can give information about regional air pollution exposures.

The preliminary results of ARB's community monitoring are providing insights into air pollution at the community level. Urban background levels are a major contributor to the overall risk from air toxics in urban areas, and this urban background tends to mask the differences between communities. When localized elevated air pollutant levels were measured, they were usually associated with local ground-level sources of toxic pollutants. The most common source of this type was busy streets and freeways. The impact these ground-level sources had on local air quality decreased rapidly with distance from the source. Pollutant levels usually returned to urban background levels within a few hundred meters of the source.

These results indicate that tools to assess cumulative impacts must be able to account for both localized, near-source impacts, as well as regional background air pollution. The tools that ARB is developing for this purpose are air quality models.

How can air quality modeling be used?

While air monitoring can directly measure cumulative exposure to air pollution, it is limited because all locations cannot be monitored. To address this, air quality modeling provides the capability to estimate exposure when air monitoring is not feasible. Air quality modeling can be refined to assess local exposure, identify locations of potential hot spots, and identify the relative contribution of emission sources to exposure at specific locations. The ARB has used this type of information to develop regional cumulative risk maps that estimate the cumulative cancer air pollution risk for most of California. While these maps only show one air pollution-related health risk, it does provide a useful starting point.

What is needed for community modeling?

Air quality models have been developed to assess near-source impacts, but they have very exacting data requirements. These near-source models estimate the impact of local sources, but do not routinely include the contribution from regional air pollution background. To estimate cumulative air pollution exposure at a neighborhood scale, a modeling approach needs to combine features of both micro-scale and regional models.

In addition, improved methods are needed to assess near-source impacts under light and variable wind conditions, when high local concentrations are more likely to occur. A method for modeling long-term exposure to air pollutants near freeways and other high traffic areas is also needed.

What modeling work has ARB developed?

A key component of ARB's Community Health Program is the Neighborhood Assessment Program (NAP). As described later in this section, the NAP studies are being conducted to better understand pollution impacts at the community level. Through two such studies conducted in Barrio Logan (San Diego) and Wilmington (Los Angeles), ARB is refining community-level modeling methodologies. Regional air toxics modeling is also being performed to better understand regional air pollution background levels.

In a parallel effort, ARB is developing modeling protocols for estimating cumulative emissions, exposure, and risk from air pollution. The protocols will cover modeling approaches and uncertainties, procedures for running the models, the development of statewide risk maps, and methods for estimating health risks. The protocols are subject to an extensive peer review process prior to release.

How are air pollution impacts on community health assessed?

On a statewide basis, ARB's toxic air contaminant program identifies and reduces public exposure to air toxics. The focus of the program has been on reducing potential cancer risk, because monitoring results show potential urban cancer risk levels are too high. ARB has also looked for potential non-cancer risks based on health reference levels provided by OEHHA. On a regional basis, the pollutants measured in ARB's toxic monitoring network are generally below the OEHHA non-cancer reference exposure levels.

As part of its community health program, the ARB is looking at potential cancer and non-cancer risk. This could include chronic or acute health effects. If the assessment work shows elevated exposures on a localized basis, ARB will work with OEHHA to assess the health impacts.

What tools has ARB developed to assess cumulative air pollution impacts?

ARB has developed the following tools and reports to assist land use agencies and local air districts assess and reduce cumulative emissions, exposure, and risk on a neighborhood scale.

Statewide Risk Maps

ARB has produced regional risk maps that show the statewide trends for Southern and Central California in estimated potential cancer risk from air toxics between 1990 and 2010.[2] These maps will supplement U.S. EPA's ASPEN model and are available on the ARB's Internet site. These maps are best used to obtain an estimate of the regional background air pollution health risk and are not detailed enough to estimate the exact risk at a specific location.

ARB also has maps that focus in more detail on smaller areas that fall within the Southern and Central California regions for these same modeled years. The finest visual resolution available in the maps on this web site is two by two kilometers. These maps are not detailed enough to assess individual neighborhoods or facilities.

Community Health Air Pollution Information System (CHAPIS)

CHAPIS is an Internet-based procedure for displaying information on emissions from sources of air pollution in an easy to use mapping format. CHAPIS uses Geographical Information System (GIS) software to deliver interactive maps over the Internet. CHAPIS relies on emission estimates reported to the ARB's emission inventory database - California Emissions Inventory Development and Reporting System, or CEIDARS.

Through CHAPIS, air district staff can quickly and easily identify pollutant sources and emissions within a specified area. CHAPIS contains information on air pollution emissions from selected large facilities and small businesses that emit criteria and toxic air pollutants. It also contains information on air pollution emissions from motor vehicle and areawide emissions. CHAPIS does not contain information on every source of air pollution or every air pollutant. It is a major long-term objective of CHAPIS to include all of the largest air pollution sources and those with the highest documented air pollution risk. CHAPIS will be updated on a periodic basis and additional facilities will be added to CHAPIS as more data becomes available.

CHAPIS is being developed in stages to assure data quality. The initial release of CHAPIS will include facilities emitting 10 or more tons per year of nitrogen oxides, sulfur dioxide, carbon monoxide, PM10, or reactive organic gases; air toxics from refineries and power plants of 50 megawatts or more; and facilities that conducted health risk

[2]ARB maintains state trends and local potential cancer risk maps that show statewide trends in potential inhalable cancer risk from air toxics between 1990 and 2010. This information can be viewed at ARB's web site at http://www.arb.ca.gov/toxics/cti/hlthrisk/hlthrisk.htm)

assessments under the California Air Toxics "Hot Spots" Information and Assessment Program.[3]

CHAPIS can be used to identify the emission contributions from mobile, area, and point sources on that community.

"Hot Spots" Analysis and Reporting Program (HARP)

HARP[4] is a software package available from the ARB and is designed with air quality professionals in mind. It models emissions and release data from one or more facilities to estimate the potential health risk posed by the selected facilities on the neighboring community. HARP uses the latest risk assessment guidelines published by OEHHA.

With HARP, a user can perform the following tasks:

- Create and manage facility databases;
- Perform air dispersion modeling;
- Conduct health risk analyses;
- Output data reports; and
- Output results to GIS mapping software.

HARP can model downwind concentrations of air toxics based on the calculated emissions dispersion at a single facility. HARP also has the capability of assessing the risk from multiple facilities, and for multiple locations of concern near those facilities. While HARP has the capability to assess multiple source impacts, there had been limited application of the multiple facility assessment function in the field at the time of HARP's debut in 2003. HARP can also evaluate multi-pathway, non-inhalation health risk resulting from air pollution exposure, including skin and soil exposure, and ingestion of meat and vegetables contaminated with air toxics, and other toxics that have accumulated in a mother's breast milk.

Neighborhood Assessment Program (NAP)

The NAP[5] has been a key component of ARB's Community Health Program. It includes the development of tools that can be used to perform assessments of cumulative air pollution impacts on a neighborhood scale. The NAP studies have been done to better understand how air pollution affects individuals at the neighborhood level. Thus far, ARB has conducted neighborhood scale assessments in Barrio Logan and Wilmington.

As part of these studies, ARB is collecting data and developing a modeling protocol that can be used to conduct cumulative air pollution impact assessments. Initially these

---

[3] California Health & Safety Code section 44300, et seq.
[4] More detailed information can be found on ARB's website at: http://www.arb.ca.gov/toxics/harp/harp.htm
[5] For more information on the Program, please refer to: http://www.arb.ca.gov/ch/programs/nap/nap.htm

assessments will focus on cumulative inhalation cancer health risk and chronic non-cancer impacts. The major challenge is developing modeling methods that can combine both regional and localized air pollution impacts, and identifying the critical data necessary to support these models. The objective is to develop methods and tools from these studies that can ultimately be applied to other areas of the state. In addition, the ARB plans to use these methods to replace the ASPEN regional risk maps currently posted on the ARB Internet site.

Urban Emissions Model (URBEMIS)

URBEMIS[6] is a computer program that can be used to estimate emissions associated with land development projects in California such as residential neighborhoods, shopping centers, office buildings, and construction projects. URBEMIS uses emission factors available from the ARB to estimate vehicle emissions associated with new land uses. URBEMIS estimates sulfur dioxide emissions from motor vehicles in addition to reactive organic gases, nitrogen oxides, carbon monoxide, and PM10.

Land-Use Air Quality Linkage Report[7]

This report summarizes data currently available on the relationships between land use, transportation and air quality. It also highlights strategies that can help to reduce the use of the private automobile. It also briefly summarizes two ARB-funded research projects. The first project analyzes the travel patterns of residents living in five higher density, mixed use neighborhoods in California, and compares them to travel in more auto-oriented areas. The second study correlates the relationship between travel behavior and community characteristics, such as density, mixed land uses, transit service, and accessibility for pedestrians.

[6] For more information on this model, please refer to ARB's website at http://www.arb.ca.gov/html/soft.htm.
[7] To access this report, please refer to ARB's website or click on: http://www.arb.ca.gov/ch/programs/link97.pdf

LAND USE AND AIR QUALITY AGENCY ROLES IN THE LAND USE PROCESS

A wide variety of federal, state, and local government agencies are responsible for regulatory, planning, and siting decisions that can have an impact on air pollution. They include local land use agencies, regional councils of government, school districts, local air districts, ARB, the California Department of Transportation (Caltrans), and the Governor's Office of Planning and Research (OPR) to name a few. This Section will focus on the roles and responsibilities of local and state agencies. The role of school districts will be discussed in Appendix E.

Local Land Use Agencies

Under the State Constitution, land use agencies have the primary authority to plan and control land use.[1] Each of California's incorporated cities and counties are required to adopt a comprehensive, long-term General Plan.[2]

The General Plan's long-term goals are implemented through zoning ordinances. These are local laws adopted by counties and cities that describe for specific areas the kinds of development that will be allowed within their boundaries.

Land use agencies are also the lead for doing environmental assessments under CEQA for new projects that may pose a significant environmental impact, or for new or revised General Plans.

Local Agency Formation Commissions (LAFCOs)

Operating in each of California's 58 counties, LAFCOs are composed of local elected officials and public members who are responsible for coordinating changes in local governmental boundaries, conducting special studies that review ways to reorganize, simplify, and streamline governmental structures, and preparing a sphere of influence for each city and special district within each county. Each Commission's efforts are directed toward seeing that local government services are provided efficiently and economically while agricultural and open-space lands are protected. LAFCO decisions strive to balance the competing needs in California for efficient services, affordable housing, economic opportunity, and conservation of natural resources.

---

[1] The legal basis for planning and land use regulation is the "police power" of the city or county to protect the public's health, safety and welfare. The California Constitution gives cities and counties the power to make and enforce all local police, sanitary and other ordinances and regulations not in conflict with general laws. State law reference: California Constitution, Article XI §7.

[2] OPR General Plan Guidelines, 2003: http://www.opr.ca.gov/planning/PDFs/General_Plan_Guidelines_2003.pdf

Councils of Government (COG)

COGs are organizations composed of local counties and cities that serve as a focus for the development of sound regional planning, including plans for transportation, growth management, hazardous waste management, and air quality. They can also function as the metropolitan planning organization for coordinating the region's transportation programs. COGs also prepare regional housing need allocations for updates of General Plan housing elements.

Local Air Districts

Under state law, air pollution control districts or air quality management districts (local air districts) are the local government agencies responsible for improving air quality and are generally the first point of contact for resolving local air pollution issues or complaints. There are 35 local air districts in California[3] that have authority and primary responsibility for regional clean air planning. Local air districts regulate stationary sources of air pollutants within their jurisdiction, including but not limited to industrial and commercial facilities, power plants, construction activities, outdoor burning, and other non-mobile sources of air pollution. Some local air districts also regulate public and private motor vehicle fleet operators such as public bus systems, private shuttle and taxi services, and commercial truck depots.

- **Regional Clean Air Plans**

Local air districts are responsible for the development and adoption of clean air plans that protect the public from the harmful effects of air pollution. These plans incorporate strategies that are necessary to attain ambient air quality standards. Also included in these regional air plans are ARB and local district measures to reduce statewide emissions from mobile sources, consumer products, and industrial sources.

- **Facility-Specific Considerations**

Permitting. In addition to the planning function, local air districts adopt and enforce regulations, issue permits, and evaluate the potential environmental impacts of projects.

Pollution is regulated through permits and technology-based rules that limit emissions from operating units within a facility or set standards that vehicle fleet operators must meet. Permits to construct and permits to operate contain very specific requirements and conditions that tell each regulated source what it must do to limit its air pollution in compliance with local air district rules, regulations, and state law. Prior to receiving a permit, new facilities must go through a New Source Review (NSR) process that establishes air pollution control requirements for the facility. Permit conditions are typically contained in the permit to operate and specify requirements that businesses must follow; these may include limits on the amount of pollution that can be emitted, the

[3] Contact information for local air districts in California is listed in the front of this Handbook.

type of pollution control equipment that must be installed and maintained, and various record-keeping requirements.

Local air districts also notify the public about new permit applications for major new facilities, or major modifications to existing facilities that seek to locate within 1,000 feet of a school.

Local air districts can also regulate other types of sources to reduce emissions. These include regulations to reduce emissions from the following sources:

- hazardous materials in products used by industry such as paints, solvents, and de-greasers;
- agricultural and residential burning;
- leaking gasoline nozzles at service stations;
- public fleet vehicles such as sanitation trucks and school buses; and
- fugitive or uncontrolled dust at construction sites.

However, while emissions from industrial and commercial sources are typically subject to the permit authority of the local air district, sensitive sites such as a day care center, convalescent home, or playground are not ordinarily subject to an air permit. Local air district permits address the air pollutant emissions of a project but not its location.

Under the state's air toxics program, local air districts regulate air toxic emissions by adopting ARB air toxic control measures, or more stringent district-specific requirements, and by requiring individual facilities to perform a health risk assessment if emissions at the source exceed district-specific health risk thresholds[4], [5] (See the section on ARB programs for a more detailed summary of this program).

One approach by which local air districts regulate air toxics emissions is through the "Hot Spots" program.[6] The risk assessments submitted by the facilities under this

---

[4] Cal/EPA's Office of Environmental Health Hazard Assessment has published "A Guide to Health Risk Assessment" for lay people involved in environmental health issues, including policymakers, businesspeople, members of community groups, and others with an interest in the potential health effects of toxic chemicals. To access this information, please refer to http://www.oehha.ca.gov/pdf/HRSguide2001.pdf

[5] Section 44306 of the California Health & Safety Code defines a health risk assessment as a detailed comprehensive analysis that a polluting facility uses to evaluate and predict the dispersion of hazardous substances in the environment and the potential for exposure of human populations, and to assess and quantify both the individual and population-wide health risks associated with those levels of exposure.

[6] AB-2588 (the Air Toxics "Hot Spots" Information and Assessment Act) requires local air districts to prioritize facilities by high, intermediate, and low priority categories to determine which must perform a health risk assessment. Each district is responsible for establishing the prioritization score threshold at which facilities are required to prepare a health risk assessment. In establishing priorities for each facility, local air districts must consider the potency, toxicity, quantity, and volume of hazardous materials released from the facility, the proximity of the facility to potential receptors, and any other factors that the district determines may indicate that the facility may pose a significant risk. All facilities within the highest category must prepare a health risk assessment. In addition, each district may require facilities in the intermediate and low priority categories to also submit a health risk assessment.

Table D-1
Local Sources of Air Pollution, Responsible Agencies, and Associated Regulatory Programs

Source	Examples	Primary Agency	Applicable Regulations
Large Stationary	Refineries, power plants, chemical facilities, certain manufacturing plants	Local air districts	Operating permit rules Air Toxics "Hot Spots" Law (AB 2588) Local district rules Air Toxic Control Measures (ATCMs)* New Source Review rules Title V permit rules
Small Stationary	Dry cleaners, auto body shops, welders, chrome plating facilities, service stations, certain manufacturing plants	Local air districts	Operating permit conditions. Air Toxics "Hot Spots" Law (AB 2588) Local district rules ATCMs* New Source Review rules
Mobile (non-fleet)	Cars, trucks, buses	ARB	Emission standards Cleaner-burning fuels (e.g., unleaded gasoline, low-sulfur diesel) Inspection and repair programs (e.g., Smog Check)
Mobile Equipment	Construction equipment	ARB, U.S. EPA	ARB rules U.S. EPA rules
Mobile (fleet)	Truck depots, school buses, taxi services	Local air districts, ARB	Local air district rules ARB urban bus fleet rule
Areawide	Paints and consumer products such as hair spray and spray paint	Local air district, ARB	ARB rules Local air district rules

*ARB adopts ATCMs, but local air districts have the responsibility to implement and enforce these measures or more stringent ones.

program are reviewed by OEHHA and approved by the local air district. Risk assessments are available by contacting the local air district.

Enforcement. Local air districts also take enforcement action to ensure compliance with air quality requirements. They enforce air toxic control measures, agricultural and residential burning programs, gasoline vapor control regulations, laws that prohibit air pollution nuisances, visible emission limits, and many other requirements designed to

AR0069394

clean the air. Local districts use a variety of enforcement tools to ensure compliance. These include notices of violation, monetary penalties, and abatement orders. Under some circumstances, a permit may be revoked.

- **Environmental Review**

As required by the California Environmental Quality Act (CEQA), local air districts also review and comment on proposed land use plans and development projects that can have a significant effect on the environment or public health.[7]

California Air Resources Board

The ARB is the air pollution control agency at the state level that is responsible for the preparation of air plans required by state and federal law. In this regard, it coordinates the activities of all local air districts to ensure all statutory requirements are met and to reduce air pollution emissions for sources under its jurisdiction.

Motor vehicles are the single largest emissions source category under ARB's jurisdiction as well as the largest overall emissions source statewide. ARB also regulates emissions from other mobile equipment and engines as well as emissions from consumer products such as hair sprays, perfumes, cleaners, and aerosol paints.

Air Toxics Program

Under state law, the ARB has a critical role to play in the identification, prioritization, and control of air toxic emissions. The ARB statewide comprehensive air toxics program was established in the early 1980's. The Toxic Air Contaminant Identification and Control Act of 1983 (AB 1807, Tanner 1983) created California's program to reduce exposure to air toxics.[8] The Air Toxics "Hot Spots" Information and Assessment Act (Hot Spots program) supplements the AB 1807 program, by requiring a statewide air toxics inventory, notification of people exposed to a significant health risk, and facility plans to reduce these risks.

Under AB 1807, the ARB is required to use certain criteria to prioritize the identification and control of air toxics. In selecting substances for review, the ARB must consider criteria relating to emissions, exposure, and health risk, as well as persistence in the atmosphere, and ambient concentrations in the community. AB 1807 also requires the ARB to use available information gathered from the Hot Spots program when prioritizing compounds.

The ARB identifies pollutants as toxic air contaminants and adopts statewide air toxic control measures (ATCMs). Once ARB adopts an ATCM, local air districts must

[7] Section 4 of this Handbook contains more information on the CEQA process.
[8] For a general background on California's air toxics program, the reader should refer to ARB's website at http://www.arb.ca.gov/toxics/tac/appendxb.htm.

implement the measure, or adopt and implement district-specific measures that are at least as stringent as the state standard. Taken in the aggregate, these ARB programs will continue to further reduce emissions, exposure, and health risk statewide.

With regard to the land use decision-making process, ARB, in conjunction with local air districts, plays an advisory role by providing technical information on land use-related air issues.

Other Agencies

Governor's Office of Planning and Research (OPR)

In addition to serving as the Governor's advisor on land use planning, research, and liaison with local government, OPR develops and implements the state's policy on land use planning and coordinates the state's environmental justice programs. OPR updated its General Plan Guidelines in 2003 to highlight the importance of sustainable development and environmental justice policies in the planning process. OPR also advises project proponents and government agencies on CEQA provisions and operates the State Clearinghouse for environmental and federal grant documents.

California Department of Housing and Community Development

The Department of Housing and Community Development (HCD) administers a variety of state laws, programs and policies to preserve and expand housing opportunities, including the development of affordable housing. All local jurisdictions must update their housing elements according to a staggered statutory schedule, and are subject to certification by HCD. In their housing elements, cities and counties are required to include a land inventory which identifies and zones sites for future residential development to accommodate a mix of housing types, and to remove barriers to the development of housing.

An objective of state housing element law is to increase the overall supply and affordability of housing. Other fundamental goals include conserving existing affordable housing, improving the condition of the existing housing stock, removing regulatory barriers to housing production, expanding equal housing opportunities, and addressing the special housing needs of the state's most vulnerable residents (frail elderly, disabled, large families with children, farmworkers, and the homeless).

Transportation Agencies

Transportation agencies can also influence mobile source-related emissions in the land use decision-making process. Local transportation agencies work with land use agencies to develop a transportation (circulation) element for the General Plan. These local government agencies then work with other transportation-related agencies, such as the Congestion Management Agency (CMA), Metropolitan Planning Organization

(MPO), Regional Transportation Planning Agency (RTPA), and Caltrans to develop long and short range transportation plans and projects.

Caltrans is the agency responsible for setting state transportation goals and for state transportation planning, design, construction, operations and maintenance activities. Caltrans is also responsible for delivering California's multibillion-dollar state Transportation Improvement Program, a list of transportation projects that are approved for funding by the California Transportation Commission in a 4-year cycle.

When safety hazards or traffic circulation problems are identified in the existing road system, or when land use changes are proposed such as a new residential subdivision, shopping mall or manufacturing center, Caltrans and/or the local transportation agency ensure the projects meet applicable state, regional, and local goals and objectives.

Caltrans also evaluates transportation-related projects for regional air quality impacts, from the perspective of travel-related emissions as well as road congestion and increases in road capacity (new lanes).

California Energy Commission (CEC)

The CEC is the state's CEQA lead agency for permitting large thermal power plants (50 megawatts or greater). The CEC works closely with local air districts and other federal, state and local agencies to ensure compliance with applicable laws, ordinances, regulations and standards in the permitting, construction, operation and closure of such plants. The CEC uses an open and public review process that provides communities with outreach and multiple opportunities to participate and be heard. In addition to its comprehensive environmental impact and engineering design assessment process, the CEC also conducts an environmental justice evaluation. This evaluation involves an initial demographic screening to determine if a qualifying minority or low-income population exists in the vicinity of the proposed project. If such a population is present, staff considers possible environmental justice impacts including from associated project emissions in its technical assessments.[9]

Department of Pesticides Regulation (DPR)

Pesticides are industrial chemicals produced specifically for their toxicity to a target pest. They must be released into the environment to do their job. Therefore, regulation of pesticides focuses on using toxicity and other information to ensure that when pesticides are used according to their label directions, potential for harm to people and the environment is minimized. DPR imposes strict controls on use, beginning before pesticide products can be sold in California, with an extensive scientific program to ensure they can be used safely. DPR and county enforcement staff tracks the use of pesticides to ensure that pesticides are used properly. DPR collects periodic

[9] See California Energy Commission, "Environmental Performance Report," July 2001 at http://www.energy.ca.gov/reports/2001-11-20_700-01-001.PDF

measurements of any remaining amounts of pesticides in water, air, and on fresh produce. If unsafe levels are found, DPR requires changes in how pesticides are used, to reduce the possibility of harm. If this cannot be done - that is, if a pesticide cannot be used safely - use of the pesticide will be banned in California.[10]

Federal Agencies

Federal agencies have permit authority over activities on federal lands and certain resources, which have been the subject of congressional legislation, such as air, water quality, wildlife, and navigable waters. The U.S. Environmental Protection Agency generally oversees implementation of the federal Clean Air Act, and has broad authority for regulating certain activities such as mobile sources, air toxics sources, the disposal of toxic wastes, and the use of pesticides. The responsibility for implementing some federal regulatory programs such as those for air and water quality and toxics is delegated by management to specific state and local agencies. Although federal agencies are not subject to CEQA they must follow their own environmental process established under the National Environmental Policy Act (NEPA).

[10] For more information, the reader is encouraged to visit the Department of Pesticide Regulation web site at www.cdpr.ca.gov/docs/empm/pubs/tacmenu.htm.

SPECIAL PROCESSES THAT APPLY TO SCHOOL SITING

The California Education Code and the California Public Resources Code place primary authority for siting public schools with the local school district, which is the 'lead agency' for purposes of CEQA. The California Education Code requires public school districts to notify the local planning agency about siting a new public school or expanding an existing school. The planning agency then reports back to the school district regarding a project's conformity with the adopted General Plan. However, school districts can overrule local zoning and land use designations for schools if they follow specified procedures. In addition, all school districts must evaluate new school sites using site selection standards established in Section 14010 of Title 5 of the California Code of Regulations. Districts seeking state funding for school site acquisition must also obtain site approval from the California Department of Education.

Before making a final decision on a school site acquisition, a school district must comply with CEQA and evaluate the proposed site acquisition/new school project for air emissions and health risks by preparing and certifying an environmental impact report or negative declaration. Both the California Education Code section 17213 and the California Public Resources Code section 21151.8 require school districts to consult with administering agencies and local air districts when preparing the environmental assessment. Such consultation is required to identify both permitted and non-permitted "facilities" that might significantly affect health at the new site. These facilities include, but are not limited to, freeways and other busy traffic corridors, large agricultural operations, and rail yards that are within one-quarter mile of the proposed school site, and that might emit hazardous air emissions, or handle hazardous or acutely hazardous materials, substances, or waste.

As part of the CEQA process and before approving a school site, the school district must make a finding that either it found none of the facilities or significant air pollution sources, or alternatively, if the school district finds that there are such facilities or sources, it must determine either that they pose no significant health risks, or that corrective actions by another governmental entity would be taken so that there would be no actual or potential endangerment to students or school workers.

In addition, if the proposed school site boundary is within 500 feet of the edge of the closest traffic lane of a freeway or traffic corridor that has specified minimum average daily traffic counts, the school district is required to determine through specified risk assessment and air dispersion modeling that neither short-term nor long term exposure poses significant heath risks to pupils.

State law changes effective January 1, 2004 (SB352, Escutia 2003, amending Education Code section 17213 and Public Resources Code section 21151.8) also provides for cases in which the school district cannot make either of those two findings and cannot find a suitable alternative site. When this occurs, the school district must adopt a statement of over-riding considerations, as part of an environmental impact

report that the project should be approved based on the ultimate balancing of the merits.

Some school districts use a standardized assessment process to determine the environmental impacts of a proposed school site. In the assessment process, school districts can use maps and other available information to evaluate risk, including a local air district's database of permitted source emissions. School districts can also perform field surveys and record searches to identify and calculate emissions from non-permitted sources within one-quarter mile radius of a proposed site. Traffic count data and vehicular emissions data can also be obtained from Caltrans for major roadways and freeways in proximity to the proposed site to model potential emissions impacts to students and school employees. This information is available from the local COG, Caltrans, or local cities and counties for non-state maintained roads.

GENERAL PROCESSES USED BY LAND USE AGENCIES TO ADDRESS AIR POLLUTION IMPACTS

There are several separate but related processes for addressing the air pollution impacts of land use projects. One takes place as part of the planning and zoning function. This consists of preparing and implementing goals and policies contained in county or city General Plans, community or area plans, and specific plans governing land uses such as residential, educational, commercial, industrial, and recreational activities. It also includes recommending locations for thoroughfares, parks and other public improvements.

Land use agencies also have a permitting function that includes performing environmental reviews and mitigation when projects may pose a significant environmental impact. They conduct inspections for zoning permits issued, enforce the zoning regulations and issue violations as necessary, issue zoning certificates of compliance, and check compliance when approving certificates of occupancy.

Planning

- **General Plan**[1]

The General Plan is a local government "blueprint" of existing and future anticipated land uses for long-term future development. It is composed of the goals, policies, and general elements upon which land use decisions are based. Because the General Plan is the foundation for all local planning and development, it is an important tool for implementing policies and programs beneficial to air quality. Local governments may choose to adopt a separate air quality element into their General Plan or to integrate air quality-beneficial objectives, policies, and strategies in other elements of the Plan, such as the land use, circulation, conservation, and community design elements.

More information on General Plan elements is contained in Appendix D.

- **Community Plans**

Community or area plans are terms for plans that focus on a particular region or community within the overall general plan area. It refines the policies of the general plan as they apply to a smaller geographic area and is implemented by ordinances and other discretionary actions, such as zoning.

[1] In October 2003, OPR revised its General Plan Guidelines. An entire chapter is now devoted to a discussion of how sustainable development and environmental justice goals can be incorporated into the land use planning process. For further information, the reader is encouraged to obtain a copy of OPR's General Plan Guidelines, or refer to their website at: http://www.opr.ca.gov/planning/PDFs/General_Plan_Guidelines_2003.pdf

- **Specific Plan**

A specific plan is a hybrid that can combine policies with development regulations or zoning requirements. It is often used to address the development requirements for a single project such as urban infill or a planned community. As a result, its emphasis is on concrete standards and development criteria.

- **Zoning**

Zoning is the public regulation of the use of land. It involves the adoption of ordinances that divide a community into various districts or zones. For instance, zoning ordinances designate what projects and activities can be sited in particular locations. Each zone designates allowable uses of land within that zone, such as residential, commercial, or industrial. Zoning ordinances can address building development standards, e.g. minimum lot size, maximum building height, minimum building setback, parking, signage, density, and other allowable uses.

Land Use Permitting

In addition to the planning and zoning function, land use agencies issue building and business permits, and evaluate the potential environmental impacts of projects. To be approved, projects must be located in a designated zone and comply with applicable ordinances and zoning requirements.

Even if a project is sited properly in a designated zone, a land use agency may require a new source to mitigate potential localized environmental impacts to the surrounding community below what would be required by the local air district. In this case, the land use agency could condition the permit by limiting or prescribing allowable uses including operating hour restrictions, building standards and codes, property setbacks between the business property and the street or other structures, vehicle idling restrictions, or traffic diversion.

Land use agencies also evaluate the environmental impacts of proposed land use projects or activities. If a project or activity falls under CEQA, the land use agency requires an environmental review before issuing a permit to determine if there is the potential for a significant impact, and if so, to mitigate the impact or possibly deny the project.

- **Land Use Permitting Process**

In California, the authority to regulate land use is delegated to city and county governments. The local land use planning agency is the local government administrative body that typically provides information and coordinates the review of development project applications. Conditional Use Permits (CUP) typically fall within a land use agency's discretionary authority and therefore are subject to CEQA. CUPs are

intended to provide an opportunity to review the location, design, and manner of development of land uses prior to project approval. A traditional purpose of the CUP is to enable a municipality to control certain uses that could have detrimental environmental effects on the community.

The process for permitting new discretionary projects is quite elaborate, but can be broken down into five fundamental components:

- Project application
- Environmental assessment
- Consultation
- Public comment
- Public hearing and decision

Project Application

The permit process begins when the land use agency receives a project application with a detailed project description, and support documentation. During this phase, the agency reviews the submitted application for completeness. When the agency deems the application to be complete, the permit process moves into the environmental review phase.

Environmental Assessment

If the project is discretionary and the application is accepted as complete, the project proposal or activity must undergo an environmental clearance process under CEQA and the CEQA Guidelines adopted by the California Resources Agency.[2] The purpose of the CEQA process is to inform decision-makers and the public of the potential significant environmental impacts of a project or activity, to identify measures to minimize or eliminate those impacts to the point they are no longer significant, and to discuss alternatives that will accomplish the project goals and objectives in a less environmentally harmful manner.

What is a "Lead Agency"?

A lead agency is the public agency that has the principal responsibility for carrying out or approving a project that is subject to CEQA. In general, the land use agency is the preferred public agency serving as lead agency because it has jurisdiction over general land uses. The lead agency is responsible for determining the appropriate environmental document, as well as its preparation.

What is a "Responsible Agency"?

A responsible agency is a public agency with discretionary approval authority over a portion of a CEQA project (e.g., projects requiring a permit). As a responsible agency, the agency is available to the lead agency and project proponent for early consultation on a project to apprise them of applicable rules and regulations, potential adverse impacts, alternatives, and mitigation measures, and provide guidance as needed on applicable methodologies or other related issues.

What is a "Commenting Agency"?

A commenting agency is any public agency that comments on a CEQA document, but is neither a lead agency nor a responsible agency. For example, a local air district, as the agency with the responsibility for comprehensive air pollution control, could review and comment on an air quality analysis in a CEQA document for a proposed distribution center, even though the project was not subject to a permit or other pollution control requirements.

[2] Projects and activities that may have a significant adverse impact on the environment are evaluated under CEQA Guidelines set forth in title 14 of the California Code of Regulations, sections 15000 et seq.

To assist the lead agency in determining whether the project or activity may have a significant effect that would require the preparation of an EIR, the land use agency may consider criteria, or thresholds of significance, to assess the potential impacts of the project, including its air quality impacts. The land use agency must consider any credible evidence in addition to the thresholds, however, in determining whether the project or activity may have a significant effect that would trigger the preparation of an EIR.

The screening criteria to determine significance is based on a variety of factors, including local, state, and federal regulations, administrative practices of other public agencies, and commonly accepted professional standards. However, the final determination of significance for individual projects is the responsibility of the lead agency. In the case of land use projects, the lead agency would be the City Council or County Board of Supervisors.

A new land use plan or project can also trigger an environmental assessment under CEQA if, among other things, it will expose sensitive sites such as schools, day care centers, hospitals, retirement homes, convalescence facilities, and residences to substantial pollutant concentrations.[3]

CEQA only applies to "discretionary projects." Discretionary means the public agency must exercise judgment and deliberation when deciding to approve or disapprove a particular project or activity, and may append specific conditions to its approval. Examples of discretionary projects include the issuance of a CUP, re-zoning a property, or widening of a public road. Projects that are not subject to the exercise of agency discretion, and can therefore be approved administratively through the application of set standards are referred to as ministerial projects. CEQA does not apply to ministerial projects.[4] Examples of typical ministerial projects include the issuance of most building permits or a business license.

Once a potential environmental impact associated with a project is identified through an environmental assessment, mitigation must be considered. A land use agency should incorporate mitigation measures that are suggested by the local air district as part of the project review process.

Consultation

Application materials are provided to various departments and agencies that may have an interest in the project (e.g., air pollution, building, police, fire, water agency, Fish and Game, etc.) for consultation and input.

---

[3] Readers interested in learning more about CEQA should contact OPR or visit their website at http://www.opr.ca.gov/.

[4] See California Public Resources Code section 21080(b)(1).

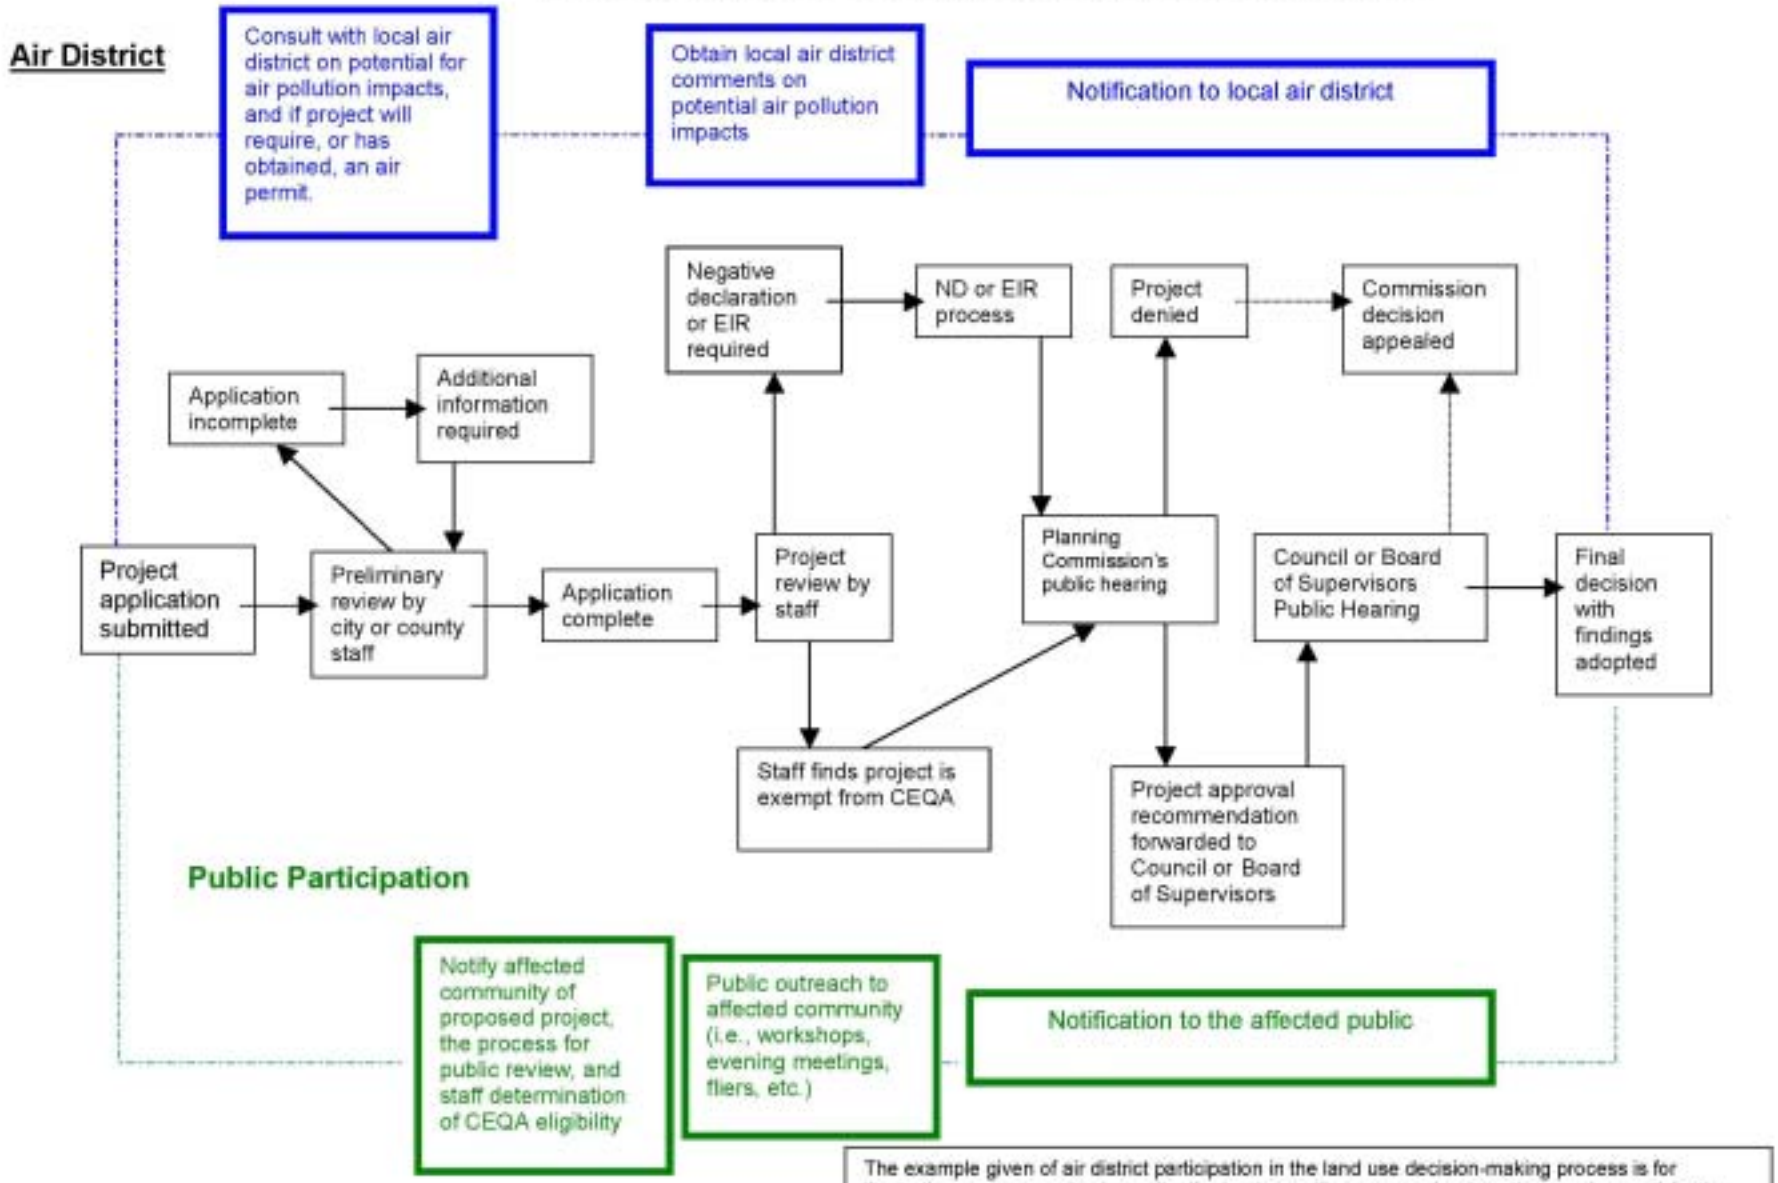
Pub ic Comment

Fo low ng the environmental rev ew process, the P anning Commission reviews application along with the staff's report on the project assessment and a public comment period is set and input s solicited.

Pub ic Hearing and Decis on

Permit rules vary depending on the particular permit authority in question but the process generally involves comparing the proposed project with the land use agency standards or policies The procedure usually leads to a pub ic hearing which is followed by a written decision by the agency or its designated off cer Typically, a project is approved denied, or approved subject to specified condit ons

USE PERMIT (DISCRETIONARY ACTION) REVIEW PROCESS*



The example given of air district participation in the land use decision-making process is for illustrative purposes only. In reality, the land use siting process involves the ongoing participation of multiple affected agencies and stakeholders throughout the process.

GLOSSARY OF KEY AIR POLLUTION TERMS

Air Pollution Control Board or Air Quality Management Board: Serves as the governing board for local air districts. It consists of appointed or elected members from the public or private sector. It conducts public hearings to adopt local air pollution regulations.

Air Pollution Control Districts or Air Quality Management Districts (local air district): A county or regional agency with authority to regulate stationary and area sources of air pollution within a given county or region. Governed by a district air pollution control board.

Air Pollution Control Officer (APCO): Head of a local air pollution control or air quality management district.

Air Toxic Control Measures (ATCM): A control measure adopted by the ARB (Health and Safety Code section 39666 et seq.), which reduces emissions of toxic air contaminants.

Ambient Air Quality Standards: An air quality standard defines the maximum amount of a pollutant that can be present in the outdoor air during a specific time period without harming the public's health. Only U.S. EPA and the ARB may establish air quality standards. No other state has this authority. Air quality standards are a measure of clean air. More specifically, an air quality standard establishes the concentration at which a pollutant is known to cause adverse health effects to sensitive groups within the population, such as children and the elderly. Federal standards are referred to as National Ambient Air Quality Standards (NAAQS), state standards are referred to as California ambient air quality standards (CAAQS).

Area-wide Sources: Sources of air pollution that individually emit small amounts of pollution, but together add up to significant quantities of pollution. Examples include consumer products, fireplaces, road dust, and farming operations.

Attainment vs. Nonattainment Area: An attainment area is a geographic area that meets the National Ambient Air Quality Standards for the criteria pollutants and a non-attainment area is a geographic area that doesn't meet the NAAQS for criteria pollutants.

Attainment Plan: Attainment plans lay out measures and strategies to attain one or more air quality standards by a specified date.

California Clean Air Act (CCAA): A California law passed in 1988, which provides the basis for air quality planning and regulation independent of federal regulations. A major element of the Act is the requirement that local air districts in violation of the CAAQS

must prepare attainment plans which identify air quality problems, causes, trends, and actions to be taken to attain and maintain California's air quality standards by the earliest practicable date.

California Environmental Quality Act (CEQA): A California law that sets forth a process for public agencies to make informed decisions on discretionary project approvals. The process helps decision-makers determine whether any potential, significant, adverse environmental impacts are associated with a proposed project and to identify alternatives and mitigation measures that will eliminate or reduce such adverse impacts.[1]

California Health and Safety Code: A compilation of California laws, including state air pollution laws, enacted by the Legislature to protect the health and safety of people in California. Government agencies adopt regulations to implement specific provisions of the California Health and Safety Code.

Clean Air Act (CAA): The federal Clean Air Act was adopted by the United States Congress and sets forth standards, procedures, and requirements to be implemented by the U.S. Environmental Protection Agency (U.S. EPA) to protect air quality in the United States.

Councils of Government (COGs): There are 25 COGs in California made up of city and county elected officials. COGs are regional agencies concerned primarily with transportation planning and housing; they do not directly regulate land use.

Criteria Air Pollutant: An air pollutant for which acceptable levels of exposure can be determined and for which an ambient air quality standard has been set. Examples include ozone, carbon monoxide, nitrogen dioxide, sulfur dioxide, and PM10 and PM2.5. The term "criteria air pollutants" derives from the requirement that the U.S. EPA and ARB must describe the characteristics and potential health and welfare effects of these pollutants. The U.S. EPA and ARB periodically review new scientific data and may propose revisions to the standards as a result.

District Hearing Board: Hears local air district permit appeals and issues variances and abatement orders. The local air district board appoints the members of the hearing board.

Emission Inventory: An estimate of the amount of pollutants emitted into the atmosphere from mobile, stationary, area-wide, and natural source categories over a specific period of time such as a day or a year.

Environmental Impact Report (EIR): The public document used by a governmental agency to analyze the significant environmental effects of a proposed project, to identify

[1] To track the submittal of CEQA documents to the State Clearinghouse within the Office of Planning and Research, the reader can refer to CEQAnet at http://www.ceqanet.ca.gov.

alternatives and to disclose possible ways to reduce or avoid the possible negative environmental impacts

Environmental Justice: California law defines environmental justice as the "fair treatment of people of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies (California Government Code sec.65040.12(c)).

General Plans: A statement of policies developed by local governments, including text and diagrams setting forth objectives, principles, standards, and plan proposals for the future physical development of the city or county

Hazardous Air Pollutants (HAPs): An air pollutant listed under section 112 (b) of the federal Clean Air Act as particularly hazardous to health. U.S. EPA identifies emission sources of hazardous air pollutants, and emission standards are set accordingly. In California, HAPs are referred to as toxic air contaminants

Land Use Agency: Local government agency that performs functions associated with the review, approval, and enforcement of general plans and plan elements, zoning, and land use permitting. For purposes of this Handbook, a land use agency is typically a local planning department

Mobile Source: Sources of air pollution such as automobiles, motorcycles, trucks, off-road vehicles, boats, and airplanes.

National Ambient Air Quality Standard (NAAQS): A limit on the level of an outdoor air pollutant established by the US EPA pursuant to the Clean Air Act. There are two types of NAAQS. Primary standards set limits to protect public health and secondary standards set limits to protect public welfare

Negative Declaration (ND): When the lead agency (the agency responsible for preparing the EIR or ND) under CEQA, finds that there is no substantial evidence that a project may have a significant environmental effect, the agency will prepare a "negative declaration" instead of an EIR.

New Source Review (NSR): A federal Clean Air Act requirement that state implementation plans must include a permit review process, which applies to the construction and operation of new or modified stationary sources in nonattainment areas. Two major elements of NSR to reduce emissions are best available control technology requirements and emission offsets.

Office of Planning and Research (OPR): OPR is part of the Governor's office. OPR has a variety of functions related to local land-use planning and environmental programs. It provides General Plan Guidelines for city and county planners, and coordinates the state clearinghouse for Environmental Impact Reports

Ordinance: A law adopted by a City Council or County Board of Supervisors. Ordinances usually amend, repeal or supplement the municipal code, provide zoning specifications, or appropriate money for specific purposes.

Overriding Considerations: A ruling made by the lead agency in the CEQA process when the lead agency finds the importance of the project to the community outweighs potential adverse environmental impacts.

Public Comment: An opportunity for the general public to comment on regulations and other proposals made by government agencies. You can submit written or oral comments at the public meeting or send your written comments to the agency.

Public Hearing: A public hearing is an opportunity to testify on a proposed action by a governing board at a public meeting. The public and the media are welcome to attend the hearing and listen to, or participate in, the proceedings.

Public Notice: A public notice identifies the person, business, or local government seeking approval of a specific course of action (such as a regulation). It describes the activity for which approval is being sought, and describes the location where the proposed activity or public meeting will take place.

Public Nuisance: A public nuisance, for the purposes of air pollution regulations, is defined as a discharge from any source whatsoever of such quantities of air contaminants or other material which cause injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public, or which endanger the comfort, repose, health, or safety of any such persons or the public, or which cause, or have a natural tendency to cause, injury or damage to business or property. (Health and Safety Code section 41700)

Property Setback: In zoning parlance, a setback is the minimum amount of space required between a lot line and a building line.

Risk: For cancer health effects, risk is expressed as an estimate of the increased chances of getting cancer due to facility emissions over a 70 year lifetime. This increase in risk is expressed as chances in a million (e.g. 10 chances in a million).

Sensitive Individuals: Refers to those segments of the population most susceptible to poor air quality (i.e., children, the elderly, and those with pre-existing serious health problems affected by air quality).

Sensitive Sites or Sensitive Land Uses: Land uses where sensitive individuals are most likely to spend time, including schools and schoolyards, parks and playgrounds, day care centers, nursing homes, hospitals, and residential communities.

Setback: An area of land separating one parcel of land from another that acts to soften or mitigate the effects of one land use on the other.

State Implementation Plan (SIP): A plan prepared by state and local agencies and submitted to U.S. EPA describing how each area will attain and maintain national ambient air quality standards. SIPs include the technical information about emission inventories, air quality monitoring, control measures and strategies, and enforcement mechanisms. A SIP is composed of local air quality management plans and state air quality regulations.

Stationary Sources: Non-mobile sources such as power plants, refineries, and manufacturing facilities.

Toxic Air Contaminant (TAC): An air pollutant identified in regulation by the ARB, which may cause or contribute to an increase in deaths or in serious illness, or which may pose a present or potential hazard to human health. TACs are considered under a different regulatory process (California Health and Safety Code section 39650 et seq.) than pollutants subject to State Ambient Air Quality Standards. Health effects associated with TACs may occur at extremely low levels. It is often difficult to identify safe levels of exposure, which produce no adverse health effects.

Urban Background: The term is used in this Handbook to represent the ubiquitous elevated, regional air pollution levels observed in large urban areas in California.

Zoning ordinances: City councils and county boards of supervisors adopts zoning ordinances that set forth land use classifications, divides the county or city into land use zones as delineated on the official zoning maps, and set enforceable standards for future develop

Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards [1]		National Standards [2]		
		Concentration [3]	Method [4]	Primary [3,5]	Secondary [3,6]	Method [7]
Ozone (O_3)	1 Hour	0.09 ppm (180 µg/m^3)	Ultraviolet Photometry	—	Same as Primary Standard	Ultraviolet Photometry
	8 Hour	0.070 ppm (137 µg/m^3)		0.075 ppm (147 µg/m^3)		
Respirable Particulate Matter (PM10)[8]	24 Hour	50 µg/m^3	Gravimetric or Beta Attenuation	150 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	20 µg/m^3		—		
Fine Particulate Matter (PM2.5)[8]	24 Hour	—	—	35 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	12 µg/m^3	Gravimetric or Beta Attenuation	12.0 µg/m^3	15 µg/m^3	
Carbon Monoxide (CO)	1 Hour	20 ppm (23 mg/m^3)	Non-Dispersive Infrared Photometry (NDIR)	35 ppm (40 mg/m^3)	—	Non-Dispersive Infrared Photometry (NDIR)
	8 Hour	9.0 ppm (10 mg/m^3)		9 ppm (10 mg/m^3)	—	
	8 Hour (Lake Tahoe)	6 ppm (7 mg/m^3)		—	—	
Nitrogen Dioxide (NO_2)[9]	1 Hour	0.18 ppm (339 µg/m^3)	Gas Phase Chemiluminescence	100 ppb (188 µg/m^3)	—	Gas Phase Chemiluminescence
	Annual Arithmetic Mean	0.030 ppm (57 µg/m^3)		0.053 ppm (100 µg/m^3)	Same as Primary Standard	
Sulfur Dioxide (SO_2)[10]	1 Hour	0.25 ppm (655 µg/m^3)	Ultraviolet Fluorescence	75 ppb (196 µg/m^3)	—	Ultraviolet Flourescence; Spectrophotometry (Pararosaniline Method)
	3 Hour	—		—	0.5 ppm (1300 µg/m^3)	
	24 Hour	0.04 ppm (105 µg/m^3)		0.14 ppm (for certain areas)[10]	—	
	Annual Arithmetic Mean	—		0.030 ppm (for certain areas)[10]	—	
Lead[11,12]	30 Day Average	1.5 µg/m^3	Atomic Absorption	—	—	High Volume Sampler and Atomic Absorption
	Calendar Quarter	—		1.5 µg/m^3 (for certain areas)[12]	Same as Primary Standard	
	Rolling 3-Month Average	—		0.15 µg/m^3		
Visibility Reducing Particles[13]	8 Hour	See footnote 13	Beta Attenuation and Transmittance through Filter Tape	No National Standards		
Sulfates	24 Hour	25 µg/m^3	Ion Chromatography			
Hydrogen Sulfide	1 Hour	0.03 ppm (42 µg/m^3)	Ultraviolet Fluorescence			
Vinyl Chloride[11]	24 Hour	0.01 ppm (26 µg/m^3)	Gas Chromatography			

See footnotes on next page …

1. California standards for ozone, carbon monoxide (except 8-hour Lake Tahoe), sulfur dioxide (1 and 24 hour), nitrogen dioxide, and particulate matter (PM10, PM2.5, and visibility reducing particles) are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.

2. National standards (other than ozone, particulate matter, and those based on annual arithmetic means) are not to be exceeded more than once per year. The ozone standard is attained when the fourth-highest 8-hour concentration measured at each site in a year, averaged over three years, is equal to or less than the standard. For PM10, the 24-hour standard is attained when expected number of days per calendar year with a 24-hour average concentration above 150 µg/m^3 is equal to or less than one. For PM2.5, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over three years, are equal to or less than the standard. Contact the U.S. EPA for further clarification and current national policies.

3. Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25°C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this standard refers to ppm by volume, or micromoles of pollutant per mole of gas.

4. Any equivalent measurement method which can be shown to the satisfaction of the ARB to give equivalent results at or near the level of the air quality standard may be used.

5. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health.

6. National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

7. Reference method as described by the U.S. EPA. An "equivalent method" of measurement may be used but must have a correlation, relationship, or conversion factor that has been approved by the U.S. EPA.

8. On December 14, 2012, the national annual PM2.5 primary standard was lowered from 15 µg/m^3 to 12.0 µg/m^3. The existing national 24-hour PM2.5 standards (primary and secondary) were retained at 35 µg/m^3, as was the annual secondary standard of 15 µg/m^3. The existing 24-hour PM10 standards (primary and secondary) of 150 µg/m^3 also were retained. The form of the annual primary and secondary standards is the annual mean, averaged over 3 years.

9. To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 0.12 ppm. Note that the national 1-hour standard is in units of parts per million (ppm). To directly compare the national 1-hour standard to the California standards the units can be converted from ppm to pphm. To convert from ppm to pphm, move the decimal point one place to the right (0.12 ppm = 12 pphm).

10. On June 2, 2010, a new 1-hour SO2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO2 national standards (24-hour and annual) remain in effect until 1 year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standard, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standard are approved.

   Note that the 1-hour national standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the 1-hour national standard to the California standards the units can be converted to ppm. To convert from the 1-hour national standard of 75 ppb, move the decimal point three places to the left (75 ppb = 0.075 ppm).

11. The ARB has identified sulfates, hydrogen sulfide, vinyl chloride, and visibility reducing particles as toxic air contaminants with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.

12. The national standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 µg/m^3 as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.

13. In 1989, the ARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are "extinction of 0.23 per kilometer" and "extinction of 0.07 per kilometer" for the statewide and Lake Tahoe Air Basin standards, respectively.

ppm - Parts Per Million parts of air, by volume ppb – Parts Per Billion parts of air, by volume AAM = Annual Arithmetic Mean --- Pollutant not monitored

** Salton Sea Air Basin

- In 2010, the State and Federal Ambient Air Quality Standards were met for the gaseous pollutants CO, NO2 and SO2 at all District regular monitoring sites, listed above.
  a) - The federal 8-hour standard is 8-hour average CO > 9 ppm and state 8-hour standard is 8-hour average CO > 9.0 ppm. The federal and state 1-hour standards are 35 ppm and 20 ppm.
  b) - The NO2 federal 1-hour standard is 100 ppb and the annual standard is annual arithmetic mean NO_2 > 0.0534 ppm. The state 1-hour and annual standards are 0.18 ppm and 0.030 ppm.
  c) - The federal SO2 1-hour standard is 75 ppb (0.075 ppm). The state standards are 1-hour average SO_2 > 0.25 ppm and 24-hour average SO_2 > 0.04 ppm.
- Revised/New Standards in 2010:
  -- U.S. EPA established the new NO2 1-hour federal standard of 100 ppb (0.100 ppm), effective April 7, 2010.
  -- U.S. EPA revised the SO2 federal standard by establishing the new 1-hour standard of 75 ppb (0.075 ppm) and revoking the existing annual (0.03 ppm) and 24-hour (0.14 ppm) standards, effective August 2, 2010.

** Salton Sea Air Basin µg/m³ - Micrograms per cubic meter of air AAM = Annual Arithmetic Mean -- - Pollutant not monitored

- In 2010, Particulate Matter concentrations met the Ambient Air Quality Standard levels for the federal PM10 Standard, the State and Federal Lead Standards, and the State Sulfate standard at the regular monitoring sites, listed above.

d) - PM10 samples were collected every 6 days at all sites except for Station Numbers 4144 and 4157, where samples were collected every 3 days. The Federal annual PM10 standard (AAM > 50 µg/m³) was revoked in 2006. State standard is annual average (AAM) > 20 µg/m³.

e) - PM2.5 samples were collected every 3 days at all sites except for station numbers 069, 072, 077, 087, 3176, 4144 and 4165, where samples were taken daily, and station number 5818 where samples were taken every 6 days. Federal annual PM2.5 standard is annual average (AAM) > 15.0 µg/m³. State standard is annual average (AAM) > 12.0 µg/m³.

f) - TSP Particulate, Lead and Sulfate samples were taken every 6 days at all sites monitored.

- Federal Equivalent Method (FEM) continuous monitoring instruments were operated at some of the above locations for PM10 and PM2.5 monitoring. The Federal Reference Method (FRM) data is used for the above statistics.

Printed on Recycled Paper

For information on the current standard levels and most recent revisions please refer to the previous year "Air Quality" summary card or access the "Ambient Air Quality Standards" chart at http://www.arb.ca.gov/research/aaqs/aaqs2.pdf.

Maps showing the source/receptor area boundaries can be accessed via the Internet by entering your address in the AQMD Current Hourly Air Quality Map, accessed from http://www2.aqmd.gov/webappl/pisaq2/VEMap3D.aspx or at http://www.aqmd.gov/map/MapAQMD2.pdf. A map is also available free of charge from the AQMD Public Information Center at 1-800-CUT-SMOG.

ppm - Parts Per Million parts of air, by volume. AAM = Annual Arithmetic Mean -- - Pollutant not monitored.

** Salton Sea Air Basin.

+ Site was relocated.

a) - The federal 8-hour standard (8-hour average CO > 9 ppm) and state 8-hour standard (8-hour average CO > 9.0 ppm) were not exceeded. The federal and state 1-hour standards (35 ppm and 20 ppm) were not exceeded, either.

b) - The federal 1-hour ozone standard was revoked and replaced by the 8-hour average ozone standard effective June 15, 2005. U.S. EPA has revised the federal 8-hour ozone standard from 0.084 ppm to 0.075 ppm, effective May 27, 2008.

c) - The 8-hour average California ozone standard of 0.070 ppm was established effective May 17, 2006.

d) - The federal standard is annual arithmetic mean NO_2 > 0.0534 ppm. California Air Resources Board has revised the NO_2 1-hour state standard from 0.25 ppm to 0.18 ppm and has established a new annual standard of 0.030 ppm, effective March 20, 2008. U.S. EPA has established a new NO2 1-hour standard of 100 ppb (0.100 ppm), effective April 7, 2010.

e) - The state standards are 1-hour average SO_2 > 0.25 ppm and 24-hour average SO_2 > 0.04 ppm. U.S. EPA has revised the federal standard by establishing a new SO2 1-hour standard of 75 ppb (0.075 ppm) and revoking the existing annual (0.03 ppm) and 24-hour (0.14 ppm) SO2 standards, effective August 2, 2010. The federal and state SO_2 standards were not exceeded.

µg/m³ - Micrograms per cubic meter of air. AAM = Annual Arithmetic Mean -- = Pollutant not monitored.

** Salton Sea Air Basin.

+ Site was relocated.

f) - PM10 samples were collected every 6 days at all sites except for Station Numbers 4144 and 4157 where samples were collected every 3 days.

g) - PM2.5 samples were collected every 3 days at all sites except for the following sites: Station Numbers 069, 072, 077, 087, 3176, 4144 and 4165 where samples were taken every day, and Station Number 5818 where samples were taken every 6 days.

h) - Federal annual PM10 standard (AAM > 50 µg/m³) was revoked effective December 17, 2006. State standard is annual average (AAM) > 20 µg/m³.

i) - Federal PM2.5 standard is annual average (AAM) > 15.0 µg/m³. State standard is annual average (AAM) > 12.0 µg/m³.

j) - Federal lead standards are rolling 3-month average > 0.15 µg/m3, and quarterly average > 1.5 µg/m³. State standard is monthly average ≥ 1.5 µg/m³.

ppm - Parts Per Million parts of air, by volume. AAM = Annual Arithmetic Mean -- - Pollutant not monitored.

* Less than 12 full months of data; may not be representative. ** Salton Sea Air Basin.

\+ Site was relocated.

a) - The federal 8-hour standard (8-hour average CO > 9 ppm) and state 8-hour standard (8-hour average CO > 9.0 ppm) were not exceeded. The federal and state 1-hour standards (35 ppm and 20 ppm) were not exceeded, either.

b) - The federal 1-hour ozone standard was revoked and replaced by the 8-hour average ozone standard effective June 15, 2005. U.S. EPA has revised the federal 8-hour ozone standard from 0.084 ppm to 0.075 ppm, effective May 27, 2008.

c) - The 8-hour average California ozone standard of 0.070 ppm was established effective May 17, 2006.

d) - The federal standard is annual arithmetic mean NO_2 > 0.0534 ppm. California Air Resources Board has revised the NO_2 1-hour state standard from 0.25 ppm to 0.18 ppm and has established a new annual standard of 0.030 ppm, effective March 20, 2008.

e) - The state standards are 1-hour average SO_2 > 0.25 ppm and 24-hour average SO_2 > 0.04 ppm. The federal standards are annual arithmetic mean SO_2 > 0.03 ppm, 24-hour average > 0.14 ppm, and 3-hour average > 0.50 ppm. The federal and state SO_2 standards were not exceeded.

µg/m³ - Micrograms per cubic meter of air. AAM = Annual Arithmetic Mean -- - Pollutant not monitored.

* Less than 12 full months of data; may not be representative. ** Salton Sea Air Basin.

\+ Site was relocated.

f) - PM10 samples were collected every 6 days at all sites except for Station Numbers 4144 and 4157 where samples were collected every 3 days.

g) - PM2.5 samples were collected every 3 days at all sites except for the following sites: Station Numbers 060, 072, 077, 087, 3176, and 4144 where samples were taken every day, and Station Number 5818 where samples were taken every 6 days.

h) - Total suspended particulates, lead, and sulfate were determined from samples collected every 6 days by the high volume sampler method, on glass fiber filter media.

i) - Federal annual PM10 standard (AAM > 50 µg/m³) was revoked effective December 17, 2006. State standard is annual average (AAM) > 20 µg/m³.

j) - U.S. EPA has revised the federal 24-hour PM2.5 standard from 65 µg/m³ to 35 µg/m³; effective December 17, 2006.

k) - Federal PM2.5 standard is annual average (AAM) > 15 µg/m³. State standard is annual average (AAM) > 12 µg/m³.

l) - Federal lead standard is quarterly average > 1.5 µg/m³; and state standard is monthly average ≥ 1.5 µg/m³. U.S. EPA has established the federal standard of 0.15 ug/m3, rolling 3-month average, as of October 15, 2008.

Maps showing the source/receptor area boundaries can be accessed via the Internet by entering your address in the AQMD Current Hourly Air Quality Map, accessed from http://www2.aqmd.gov/webappl/gissql2/VEMap3D.aspx or at http://www.aqmd.gov/map/MapAQMD2.pdf . A map is also available free of charge from the AQMD Public Information Center at 1-800-CUT-SMOG.

ppm - Parts Per Million parts of air, by volume. AAM = Annual Arithmetic Mean -- - Pollutant not monitored.

** Salton Sea Air Basin.

+ Site was relocated.

a) - The federal 8-hour standard (8-hour average CO > 9 ppm) and state 8-hour standard (8-hour average CO > 9.0 ppm) were not exceeded. The federal and state 1-hour standards (35 ppm and 20 ppm) were not exceeded, either.

b) - The federal 1-hour ozone standard was revoked and replaced by the 8-hour average ozone standard effective June 15, 2005. U.S. EPA has revised the federal 8-hour ozone standard from 0.084 ppm to 0.075 ppm, effective May 27, 2008.

c) - The 8-hour average California ozone standard of 0.070 ppm was established effective May 17, 2006.

d) - The federal standard is annual arithmetic mean NO_2 > 0.0534 ppm. California Air Resources Board has revised the NO_2 1-hour state standard from 0.25 ppm to 0.18 ppm and has established a new annual standard of 0.030 ppm, effective March 20, 2008. U.S. EPA has established a new NO2 1-hour standard of 100 ppb (0.100 ppm), effective April 7, 2010.

e) - The state standards are 1-hour average SO_2 > 0.25 ppm and 24-hour average SO_2 > 0.04 ppm. U.S. EPA has revised the federal standard by establishing a new SO2 1-hour standard of 75 ppb (0.075 ppm) and revoking the existing annual (0.03 ppm) and 24-hour (0.14 ppm) SO2 standards, effective August 2, 2010. The federal and state SO_2 standards were not exceeded.

µg/m³ - Micrograms per cubic meter of air. AAM = Annual Arithmetic Mean -- = Pollutant not monitored.

** Salton Sea Air Basin.

+ Site was relocated.

f) - PM10 samples were collected every 6 days at all sites except for Station Numbers 4144 and 4157 where samples were collected every 3 days.

g) - PM2.5 samples were collected every 3 days at all sites except for the following sites: Station Numbers 069, 072, 077, 087, 3176, 4144 and 4165 where samples were taken every day, and Station Number 5818 where samples were taken every 6 days.

h) - Federal annual PM10 standard (AAM > 50 µg/m³) was revoked effective December 17, 2006. State standard is annual average (AAM) > 20 µg/m³.

i) - Federal PM2.5 standard is annual average (AAM) > 15.0 µg/m³. State standard is annual average (AAM) > 12.0 µg/m³.

j) - Federal lead standards are rolling 3-month average > 0.15 µg/m3, and quarterly average > 1.5 µg/m³. State standard is monthly average ≥ 1.5 µg/m³.

Printed on Recycled Paper

Maps showing the source/receptor area boundaries can be accessed via the Internet by entering your address in the AQMD Current Hourly Air Quality Map, accessed from http://www2.aqmd.gov/webappl/ajaxqi2/YEMap3D.aspx or at http://www.aqmd.gov/map/Map/AQMD2.pdf. A map is also available free of charge from the AQMD Public Information Center at 1-800-CUT-SMOG.

APPENDIX C

MAPS AND TABLES OF AREA DESIGNATIONS FOR STATE AND NATIONAL AMBIENT AIR QUALITY STANDARDS

[This page intentionally left blank]

APPENDIX C

MAPS AND TABLES OF AREA DESIGNATIONS FOR STATE AND NATIONAL AMBIENT AIR QUALITY STANDARDS

This attachment fulfills the requirement of Health and Safety Code section 40718 for ARB to publish maps that identify areas where one or more violations of any State ambient air quality standard (State standard) or national ambient air quality standard (national standard) have been measured. The national standards are those promulgated under section 109 of the federal Clean Air Act (42 U.S.C. 7409).

This attachment is divided into three parts. The first part comprises a table showing the levels, averaging times, and measurement methods for each of the State and national standards. This is followed by a section containing maps and tables showing the 2012 area designations for each pollutant for which there is a State standard in the California Code of Regulations, title 17, section 70200. The last section contains maps and tables showing the most current area designations for the national standards.

AR0069425

Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards [1]		National Standards [2]		
		Concentration [3]	Method [4]	Primary [3,5]	Secondary [3,6]	Method [7]
Ozone (O_3)	1 Hour	0.09 ppm (180 µg/m³)	Ultraviolet Photometry	—	Same as Primary Standard	Ultraviolet Photometry
	8 Hour	0.070 ppm (137 µg/m³)		0.075 ppm (147 µg/m³)		
Respirable Particulate Matter (PM10)	24 Hour	50 µg/m³	Gravimetric or Beta Attenuation	150 µg/m³	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	20 µg/m³		—		
Fine Particulate Matter (PM2.5)	24 Hour	—	—	35 µg/m³	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	12 µg/m³	Gravimetric or Beta Attenuation	15 µg/m³		
Carbon Monoxide (CO)	1 Hour	20 ppm (23 mg/m³)	Non-Dispersive Infrared Photometry (NDIR)	35 ppm (40 mg/m³)	—	Non-Dispersive Infrared Photometry (NDIR)
	8 Hour	9.0 ppm (10 mg/m³)		9 ppm (10 mg/m³)	—	
	8 Hour (Lake Tahoe)	6 ppm (7 mg/m³)		—	—	
Nitrogen Dioxide (NO_2)[8]	1 Hour	0.18 ppm (339 µg/m³)	Gas Phase Chemiluminescence	100 ppb (188 µg/m³)	—	Gas Phase Chemiluminescence
	Annual Arithmetic Mean	0.030 ppm (57 µg/m3)		53 ppb (100 µg/m³)	Same as Primary Standard	
Sulfur Dioxide (SO_2)[9]	1 Hour	0.25 ppm (655 µg/m³)	Ultraviolet Fluorescence	75 ppb (196 µg/m³)	—	Ultraviolet Flourescence; Spectrophotometry (Pararosaniline Method)
	3 Hour	—		—	0.5 ppm (1300 µg/m³)	
	24 Hour	0.04 ppm (105 µg/m³)		0.14 ppm (for certain areas)[9]	—	
	Annual Arithmetic Mean	—		0.030 ppm (for certain areas)[9]	—	
Lead[10,11]	30 Day Average	1.5 µg/m³	Atomic Absorption	—	—	High Volume Sampler and Atomic Absorption
	Calendar Quarter	—		1.5 µg/m³ (for certain areas)[11]	Same as Primary Standard	
	Rolling 3-Month Average	—		0.15 µg/m³		
Visibility Reducing Particles[12]	8 Hour	See footnote 12	Beta Attenuation and Transmittance through Filter Tape	No National Standards		
Sulfates	24 Hour	25 µg/m³	Ion Chromatography			
Hydrogen Sulfide	1 Hour	0.03 ppm (42 µg/m³)	Ultraviolet Fluorescence			
Vinyl Chloride[16]	24 Hour	0.01 ppm (26 µg/m³)	Gas Chromatography			

See footnotes on next page ...

For more information please call ARB-PIO at (916) 322-2990

California Air Resources Board (2/7/12)

AR0069426

1. California standards for ozone, carbon monoxide (except 8-hour Lake Tahoe), sulfur dioxide (1 and 24 hour), nitrogen dioxide, and particulate matter (PM10, PM2.5, and visibility reducing particles), are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.

2. National standards (other than ozone, particulate matter, and those based on annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration measured at each site in a year, averaged over three years, is equal to or less than the standard. For PM10, the 24 hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 $\mu g/m^3$ is equal to or less than one. For PM2.5, the 24 hour standard is attained when 98 percent of the daily concentrations, averaged over three years, are equal to or less than the standard. Contact the U.S. EPA for further clarification and current national policies.

3. Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25°C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.

4. Any equivalent measurement method which can be shown to the satisfaction of the ARB to give equivalent results at or near the level of the air quality standard may be used.

5. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health.

6. National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

7. Reference method as described by the U.S. EPA. An "equivalent method" of measurement may be used but must have a "consistent relationship to the reference method" and must be approved by the U.S. EPA.

8. To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb. Note that the national standards are in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the national standards to the California standards the units can be converted from ppb to ppm. In this case, the national standards of 53 ppb and 100 ppb are identical to 0.053 ppm and 0.100 ppm, respectively.

9. On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO_2 national standards (24-hour and annual) remain in effect until one year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved.

   Note that the 1-hour national standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the 1-hour national standard to the California standard the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.

10. The ARB has identified lead and vinyl chloride as 'toxic air contaminants' with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.

11. The national standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 $\mu g/m^3$ as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.

12. In 1989, the ARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are "extinction of 0.23 per kilometer" and "extinction of 0.07 per kilometer" for the statewide and Lake Tahoe Air Basin standards, respectively.

[This page intentionally left blank]

AR0069428

Area Designations for the State Ambient Air Quality Standards

The following maps and tables show the area designations for each pollutant with a State standard set forth in the California Code of Regulations Title 17 section 60200. Each area is identified as attainment, nonattainment, nonattainment-transitional, or unclassified for each pollutant, as shown below:

Attainment	A
Nonattainment	N
Nonattainment-Transitional	NA-T
Unclassified	U

In general, ARB designates areas by air basin for pollutants with a regional impact and by county for pollutants with a more local impact. However, when there are areas within an air basin or county with distinctly different air quality deriving from sources and conditions not affecting the entire air basin or county, ARB may designate a smaller area. Generally, when boundaries of the designated area differ from the air basin or county boundaries, the description of the specific area is referenced at the bottom of the summary table.

Area Designations for the National Ambient Air Quality Standards

The following maps and tables show the area designations for each pollutant with a national ambient air quality standard. Additional information about the federal area designations is available on the U.S. EPA website

http://www.epa.gov/airprogm/oar/oaqps/greenbk

Over the last several years U.S. EPA has been reviewing the levels of the various national standards. The agency has already promulgated new standard levels for some pollutants and is considering revising the levels for others. Information about the status of these reviews is available on the U.S. EPA website:

http://epa.gov/airquality/urbanair/

Designation Categories

Ozone and Suspended Particulate Matter (PM_{10}). The U.S. EPA uses three categories to designate areas with respect to ozone and PM_{10}

- Attainment
- Nonattainment
- Unclassifiable

The national 1-hour ozone standard was revoked effective June 15, 2005, and the current area designations reflect the 2008 national 8-hour ozone standard of 0.075 ppm. These designations were finalized on April 30, 2012.

Fine Suspended Particulate Matter ($PM_{2.5}$), Carbon Monoxide (CO), and Nitrogen Dioxide (NO_2). The U.S. EPA uses two categories to designate areas with respect to these standards

- Nonattainment
- Unclassifiable/Attainment

New national area designations for $PM_{2.5}$ became effective December 14, 2009. These designations reflect both the annual average standard of 15 $\mu g/m^3$ and the recently revised (December 2006) 24-hour standard of 35 $\mu g/m^3$.

On January 22, 2010, the U.S. EPA established a new national 1-hour NO_2 standard of 100 parts per billion (ppb) and retained the annual average standard of 53 ppb. New designations for the primary NO_2 standard became effective on February 29, 2012. All areas of California meet this standard.

AR0069450

Sulfur Dioxide (SO_2) The U.S. EPA uses four categories to designate areas with respect to the 24-hour and annual average sulfur dioxide standards. These designation categories are

- Does not meet the primary standards.
- Does not meet the secondary standards,
- Cannot be classified and
- Better than the national standards

In California, the first two designation categories listed above are not applicable because all areas of California either meet the primary and secondary standards or are unclassifiable. The map and summary table for sulfur dioxide show areas that cannot be classified as "U" for unclassifiable and areas that are better than the national standards as "A" for attainment.

On June 2, 2010, the U.S. EPA established a new primary 1-hour SO_2 standard of 75 parts per billion (ppb). At the same time, U.S. EPA revoked the 24-hour and annual average standards. U.S. EPA is currently in the process of designating areas for the 2010 national 1-hour SO_2 standard of 75 ppb. However, these designations are not expected to be finalized until June 2012.

Lead (particulate) The U.S. EPA promulgated a new lead standard in October 2008 of 0.15 $\mu g/m^3$ for a 3 month average. This new standard is ten times lower than the former lead standard. Effective December 31, 2010, several areas in the nation became nonattainment for lead, based on data collected during 2007 through 2009. All other areas were designated as unclassified. These unclassified designations will be resolved over the next several years as data from a new, source-oriented monitoring network become available.

Designated Areas

From time to time, the boundaries of the California air basins have been changed to facilitate the planning process. ARB generally initiates these changes, and they are not always reflected in the U.S. EPA's area designations. For purposes of consistency, the maps in this attachment reflect area designation boundaries and nomenclature as promulgated by the U.S. EPA. In some cases, these may not be the same as those adopted by ARB. For example, the national area designations reflect the former Southeast Desert Air Basin. In accordance with Health and Safety Code section 39606.1, ARB redefined this area in 1996 to be the Mojave Desert Air Basin and Salton Sea Air Basin. The definitions and boundaries for all areas designated for the national standards can be found in Title 40, Code of Federal Regulations (CFR) Chapter I, Part 81.305. They are available on the web at:

http://www.access.gpo.gov/nara/cfr/waisidx_05/40cfr81_05.html

Once at this website, scroll down to Part 81.305 to view the California area designations.

* Definitions and references for Areas can be found in 40 CFR, Chapter I, Part 81.300.
Although U.S. EPA established a new 1-hour standard of 75 ppb for SO2, current area designations still reflect the revoked 24-hour and annual average standards as U.S. EPA has not finalized the designations for the revised standard.

(1) South Central Coast Air Basin Channel Islands:

Santa Barbara County includes Santa Cruz, San Miguel, Santa Rosa and Santa Barbara Islands.

Ventura County includes Anacapa and San Nicolas Islands.

Note that the San Clemente and Santa Catalina Islands are considered part of Los Angeles County, and therefore are included as part of the South Coast Air Basin.

Office of
HISTORIC RESOURCES

Frequently Asked Questions (FAQs)

FREQUENTLY ASKED QUESTIONS (FAQs) ABOUT THE HISTORIC-CULTURAL MONUMENT DESIGNATION PROCESS

Who may submit a nomination?

A nomination for City of Los Angeles Historic-Cultural Monument status may be submitted by any person or organization. The City Council may also nominate a resource for Monument status, typically through the introduction of a motion by an individual Councilmember. The Cultural Heritage Commission itself may also initiate a nomination.

The application requires considerable research to determine the age of buildings and structures, property ownership history, former inhabitants, past uses, and other known facts about the resource. Many applicants choose to retain historic preservation consultants to prepare nominations, but it is also possible for non-professionals to research and prepare successful nominations. The Los Angeles Conservancy has prepared a helpful guide to researching and preparing Historic-Cultural Monument applications, at Los Angeles Conservancy.

Is there an age requirement?

In the City of Los Angeles, there is no requirement that a resource be a certain age before it can be designated. In general, enough time needs to have passed since the resource's completion to provide sufficient perspective that would allow an evaluation of its significance within a historical context. The youngest structure to be designated in Los Angeles was built in 1909 – it is Claes Oldenburg and Coosje van Bruggen's Binoculars at the Chiat/Day Building in Venice (the rest of the building, designed by Frank Gehry, is not yet designated).

What can be nominated?

The criteria for designation allow for numerous types of Monuments. Buildings make up the great majority of Historic-Cultural Monuments – including many examples of residential, commercial, institutional, and industrial structures. Structures like bridges, stairways, and median strips have also become Monuments. Open spaces such as Echo Park and Banning Park (which, in these cases, also feature historic structures) have been declared Monuments, as have individual trees or groups of trees, and natural features such as Eagle Rock.

What makes a resource historically significant?

See What Makes a Resource Historic for information on the criteria for Historic-Cultural Monument status and for the types of questions that help staff and the Cultural Heritage Commission evaluate a nomination for Historic-Cultural Monument status.

Must the property owner be notified about the nomination?

Under the City of Los Angeles' Cultural Heritage Ordinance, the property owner is not required to support the nomination, but the owner typically does participate in the designation process. To avoid preemptive demolition or alteration before the nomination can be heard, the Commission does not notify the owner that an application has been filed until after the first hearing. If the Commission takes the nomination under consideration at that hearing, no permits for demolition or significant alterations may be issued. Even if a demolition permit has already been issued when the Commission takes the nomination under consideration, no actual demolition may occur while the nomination is being considered by the Commission and City Council.

What happens when a building is designated? Is it protected forever?

In Los Angeles, designation as a Historic-Cultural Monument does not guarantee that the building cannot be demolished, but it does allow the Commission to delay demolition in order to create opportunities for preservation solutions to emerge. The ordinance allows the Cultural Heritage Commission to object formally to the issuance of a demolition permit, delaying the demolition for up to 180 days, plus another possible 180-day extension if approved by the City Council, to allow for time to preserve the monument. Designation also ensures that Office of Historic Resources staff trained in preservation and architecture reviews and approves proposals for work on HCMs before any permits for alteration are issued. A Monument is also presumed to be a significant historical resource under the California Environmental Quality Act (CEQA), triggering the requirement to perform an environmental review that could lead to the preparation of an Environmental Impact Report (EIR) before demolition can occur. For more information on what Historic-Cultural Monument status accomplishes, visit Historic-Cultural Monument Status. [illegible]

Attachment: AA 2000-1 (Parking Policy)

No. AA 2000-1
RESIDENTIAL PARKING POLICY

New Condominiums:

A. Up to 5 units

1. 2 per du
2. Minimum 1/4 guest per du[1]

B. Six units or more

1. 2 per du
2. 1/4 guest in non-parking congested areas[1]
   1/2 guest in parking congested areas[1]
3. For side-by-side parking in private garages with direct entries into the units, 1/4 guest parking per unit will be permitted in parking congested areas.

Condominium Conversions:

A. Minimum of 2 parking spaces per unit for projects if the building is more than five years old from a temporary issuance of its Certificate of Occupancy.

B. For projects where the building is five or less years old from the Certificate of Occupancy, standards for new condominiums will apply.

EXCEPTIONS

Exceptions will be considered by the Advisory Agency pursuant to LAMC Section 12.22-A.26 ("Adaptive Reuse Projects in the Greater Downtown Los Angeles Area," Ordinance No. 172,571). Stock Cooperative Conversions will be considered on case-by-case basis.

---

[1]Determinations on required parking by the Advisory Agency are not intended to supercede more restrictive requirements contained in other adopted City ordinances such as adopted specific plans and "Q" conditions. Further, additional guest parking will be considered in special areas of the City which are either subject to unusual public access demands (such as the beach areas) or areas where on-street parking is highly restricted (Major highways, such as Barham Boulevard).

CIVIL CITATION
COUNTY OF ORANGE, CODE ENFORCEMENT

1. TO COMPLY:

A. PAYMENT MUST BE MADE WITHIN TEN CALENDAR DAYS OF THE ISSUANCE OF THIS CITATION. PAYMENT MAY BE SENT TO, AND MADE PAYABLE TO, "COUNTY OF ORANGE – CODE ENFORCEMENT". DO NOT SEND CASH. PAYMENT MAY ALSO BE MADE IN PERSON AT THE COUNTY OF ORANGE. PLEASE NOTE A NOTICE OF VIOLATION MAY BE RECORDED ON YOUR PROPERTY. PAYMENT MAY ALSO BE MADE VIA ONLINE BY CREDIT CARD AT WWW.OCAPPSERVICES.COM/CODE OR BY CALLING (800) 290-6155. USE THE CITATION NUMBER AS YOUR REFERENCE NUMBER. PAYMENT MUST BE FOLLOWING ADDRESS:

COUNTY OF ORANGE
C/O CITATION PROCESSING CENTER
P.O. BOX 2935
ANAHEIM, CA 92803

B. IF THIS CIVIL CITATION IS YOUR FIRST NOTICE, YOU ARE NOT REQUIRED TO PAY ANY PENALTY IF YOU CORRECT THE VIOLATION WITHIN THE TIME GIVEN ON THE FRONT OF THIS CITATION. YOU MAY BE CITED FOR ADDITIONAL VIOLATIONS FOR EACH DAY THE VIOLATION EXISTS AFTER THE END OF THE 30-DAY CORRECTION PERIOD. YOU CAN FILE A REQUEST IN WRITING FOR AN EXTENSION OF THIS 30-DAY CORRECTION PERIOD WITH THE ISSUING DEPARTMENT. SUBMIT A COPY OF THIS CIVIL CITATION AND A LETTER STATING WHY THE EXTENSION IS REQUESTED. MAIL TO CODE ENFORCEMENT, 1501 E. EDINGER #E, SANTA ANA, CA 92705 OR P.O. BOX 1438, SANTA ANA, CA 92702. EXTENSIONS MAY BE GRANTED IN UNUSUAL CIRCUMSTANCES WHERE REASONABLE.

2. TO CONTEST:

A. ADMINISTRATIVE REVIEW: YOU MAY REQUEST AN ADMINISTRATIVE REVIEW TO CONTEST THE CIVIL CITATION WITHIN 10 DAYS OF THE DATE OF ISSUANCE BY MAILING A SIGNED COPY OF THIS CIVIL CITATION WITH THE REQUESTED CHANGES TO CODE ENFORCEMENT, 1501 E. EDINGER #E, SANTA ANA, CA 92705 OR P.O. BOX 1438, SANTA ANA, CA 92702. YOU MUST SPECIFY IN WRITING WHY YOU ARE REQUESTING AN ADMINISTRATIVE REVIEW BY CLICKING ON ONE OF THE BOXES IN ITEM 2.C. BELOW. WITHIN 10 DAYS TO OBTAIN A HEARING YOU MUST DEPOSIT THE FULL AMOUNT OF THE FINE WITH YOUR REQUEST UNLESS YOU ALSO REQUEST A FINANCIAL HARDSHIP WAIVER ON THE FORM BELOW AND THE WAIVER IS GRANTED PRIOR TO THE LOCATION OF THE HEARING IS APPEALED. IF THE CITATION IS NOT APPEALED IN THIS MANNER, THE CITATION IS FINAL. YOU ARE REQUIRED TO ATTEND THE HEARING SCHEDULED FOR YOU AT THE TIME YOU CONTACT THE CODE ENFORCEMENT OFFICER. IF THE HEARING OFFICER WILL BE IN THE FIELD, THEIR CONTACT INFORMATION WILL BE PROVIDED AT THE TIME OF THE HEARING. IF THE HEARING OFFICER DECIDES THAT THERE WAS A CODE VIOLATION AND THAT YOU ARE RESPONSIBLE FOR THE VIOLATION, NOTICE OF A VIOLATION MAY BE RECORDED ON THE PROPERTY. THE CITATION AMOUNT MAY BE INCREASED WHICH MUST BE PAID BY YOU.

B. COURT APPEAL: YOU MAY APPEAL FROM THE DECISION OF THE HEARING OFFICER TO THE SUPERIOR COURT WITHIN 90 DAYS AFTER THE DATE OF THE DECISION. TO APPEAL, YOU MUST PAY A $25 FILING FEE TO THE COURT. IMPORTANT: NOT ALL UNPAID PENALTIES AND/OR ORIGINAL CITATION AMOUNTS CAN BE SUSPENDED AS A CONDITION TO APPEAL. YOU MAY BE RESPONSIBLE FOR PAYING ALL OR PART OF THE ORIGINAL CITATION AMOUNT. UNPAID ASSESSMENTS CAN RESULT IN A LIEN ON YOUR PROPERTY THAT LASTS FOR THREE YEARS OR LONGER. YOU MAY BE CHARGED INTEREST AT 10% PER YEAR ON THE CITATION AMOUNT. A FULL EXPLANATION OF THE CIVIL PENALTY PROCEDURES FOR CODE ENFORCEMENT CITATIONS AND VIOLATIONS AND YOUR RIGHTS TO CONTEST ARE AVAILABLE IN ORANGE COUNTY CODE SECTION 1-6-81 THROUGH 1-6-101.

1

C. IF YOU NEED FURTHER CLARIFICATION ABOUT PAYMENT, APPEAL OF THIS CITATION, PLEASE CALL (800) 290-6155. IF YOU NEED FURTHER INFORMATION ABOUT HOW TO COMPLY WITH THE ORANGE COUNTY CODIFIED ORDINANCE VIOLATIONS, PLEASE CONTACT THE COUNTY CODE ENFORCEMENT AT (714) 796-0177.

FORM TO CONTEST THIS CIVIL CITATION (FILL OUT SECTIONS 1 AND 2)

1. ☐ I HEREBY REQUEST AN ADMINISTRATIVE REVIEW OF THE CIVIL CITATION. I HAVE ATTACHED A COPY OF THE CITATION WITH THE REQUESTED CHANGES TO THE CITATION.

☐ I HEREBY REQUEST A HEARING BEFORE A HEARING OFFICER.

☐ I HAVE ATTACHED A REQUEST FOR A FINANCIAL HARDSHIP WAIVER.

2. ☐ I HAVE ENCLOSED THE FULL AMOUNT OF THE CITATION WITH THIS REQUEST.

☐ I HEREBY REQUEST A FINANCIAL HARDSHIP WAIVER OF THE DEPOSIT REQUIREMENT.

RE: PROFESSIONAL CONSULTING SERVICES AGREEMENT
CLIENT-DIRECTED BULK SAMPLING FOR ASBESTOS
1750 NORTH VINE, HOLLYWOOD, CA 90028
CTL PROPOSAL #A-057-3485

Dear Mr. Piro:

CTL is pleased to present the following consulting services agreement for the above-referenced project. CTL understands the scope of work to include the following:

SCOPE OF WORK

- Provision of client-directed bulk sampling for asbestos at the above-referenced property, with 24 hour verbal results with fax transmittal and submission of report 1 week from authorization. CTL will collect bulk samples of suspect asbestos-containing material from the subject property. If additional building area is requested to be surveyed, you will be contacted for authorization prior to any additional work.

FEE SCHEDULE

ASBESTOS SAMPLING		
Technician	4 @ $50.00/hr	$200.00
Project Manager	.50 @ $80.00/hr	$40.00
PLM Sample Analysis	3 @ $15.00/ea*	$45.00
Report	Lump Sum	$35.00
TOTAL		**$320.00**

*Estimated maximum of 3 samples. Additional samples can be collected and analyzed at $15.00 each.

This proposal is valid for 60 days from correspondence date.

Should you have any questions regarding the information contained herein, please do not hesitate to contact me directly at (310) 530-5006. Thank you for allowing CTL the opportunity to be of service to Capital Records.

Respectfully Submitted,

CTL Environmental Services

REF: Bulk Sample Analysis
Mail Room

PROJECT SUMMARY

CTL Environmental Services (CTL) collected and analyzed bulk samples for asbestos content from the Capitol Records facility located at 1750 N. Vine Street, Hollywood, California. The sampling was conducted on October 17, 1996 by Perry Adams, a Certified Site Surveillance Technician employed by CTL.

ANALYTICAL METHODOLOGY

The samples collected for analysis of asbestos content were analyzed by Polarized Light Microscopy (PLM). Analysis was conducted as described in United States Environmental Protection Agency (EPA) Method for the Determination of Asbestos in Bulk Building Materials: EPA/600/R-93/116, July 1993, at our NVLAP-accredited laboratory in South Gate, California.

RESULTS

The following samples were collected and analyzed for asbestos content:

MATERIAL	SAMPLE #	MATERIAL LOCATION	ASBESTOS CONTENT
Off-White/Gray Fibrous Material	56254	Sample Collected by Client	10% Chrysotile 25% Amosite <1% Crocidolite
Off-White/Gray Fibrous Material	56255	Sample Collected by Client	15% Chrysotile 25% Amosite
Off-White/Gray Fibrous Material	56256	North Wall by Pipe Penetration	5% Chrysotile 30% Amosite <1% Crocidolite
Off-White Fibrous Material	56257	Pipe Insulation Above Duct in Mail Room	12% Chrysotile
Off-White Fibrous Material	56258	Pipe Insulation Above Duct in Mail Room	10% Chrysotile

When a sample is "layered", the Total Asbestos % represents the composite percentage of all sample layers. If the asbestos percentage of an individual layer is required, the detailed lab report should be referenced, or the layer should be reanalyzed as a separate sample. Samples reported as Not detected, or less than 1% (<1%), are non-asbestos containing according to PLM method definitions.

The report applies only to the sample, or samples, investigated and is not necessarily indicative of the quality or condition of apparently identical or similar materials or products. As a mutual protection to clients, the public and these Laboratories, this report is submitted and accepted for the exclusive use of the client to whom it is addressed and upon the condition that it is not to be used, in whole or in part, in any advertising or publicity matter without prior written authorization from these Laboratories.

RE: **Clearance Air Sampling**
Mail Room

INTRODUCTION

CTL Environmental Services performed clearance air sampling, following the removal of asbestos contaminated ceiling tile from the mail room of the Capitol Records facility at 1750 North Vine Street, Hollywood, California. Clearance air sampling was conducted on October 24, 1996

Samples were collected and analyzed in accordance with the National Institute of Occupational Safety and Health (NIOSH) Method 7400 utilizing Phase Contrast Microscopy (PCM).

All samples were consistent at less than 0.01 fibers per cubic centimeter (f/cc) of air, the level recommended by the Environmental Protection Agency (EPA) for reoccupancy of non-protected personnel following an asbestos response action

CTL Environmental Services is an environmental consulting firm, registered to practice under the State of California Department of Safety and Health. Its laboratories are accredited by the American Industrial Hygiene Association (AIHA) and the National Voluntary Laboratory Accreditation (NVLAP) programs.

Sincerely,
CTL Environmental Services

SUBJECT Final Air Testing - Capitol Records (Mailroom)

DATE 05-24-96 (06:15)

MESSAGE

At the request of QHI-Stevens, CTL conducted final air testing after the cleaning and removal of asbestos contaminated ceiling tile. The area appears to be clear of all dust and debris. The area appears to have been encapsulated and allowed to dry.

CTL have conducted air testing in the work area and, found the sample to be 0.01 f/cc or less. The samples were collected using PCM (Phase Contrast Microscopy). The samples were analyzed using the NIOSH 7400 method. The level of airborne fibers are below the 0.1 f/cc which is the permissible exposure level set by the OSHA (Occupational Safety and Health Administration).

REF: Bulk Sample Analysis
Mail Room

PROJECT SUMMARY

CTL Environmental Services (CTL) analyzed bulk samples of plaster and wall packing from the mail room of the Capitol Records facility located at 1750 N. Vine Street, Hollywood, California. The samples were submitted to CTL by a Capitol Records representative on October 24, 1996.

ANALYTICAL METHODOLOGY

The samples collected for analysis of asbestos content were analyzed by Polarized Light Microscopy (PLM). Analysis was conducted as described in United States Environmental Protection Agency (EPA) Method for the Determination of Asbestos in Bulk Building Materials: EPA/600/R-93/116, July 1993, at our NVLAP-accredited laboratory in South Gate, California.

RESULTS

The following samples were analyzed for asbestos content:

MATERIAL	SAMPLE #	SAMPLE LOCATION	MATERIAL LOCATION	ASBESTOS CONTENT
Off-White Crumbly Packing & Plaster with Black Paint	001	In Pipe Penetration, North Side of Mail Room	Recreation Room	9% Chrysotile 15% Amosite <1% Crocidolite
Plaster with Light Green Paint	002	Boiler Room Stack Wall, North Side of Mail Room	Recreation Room	None Detected
Plaster with Black Paint	003	West Wall of Mail Room	Recreation Room	None Detected

PROJECT NO: 92-0553 **REPORTED:** January 29, 1992

CLIENT: Capital Records
1750 North Vine Street
Hollywood, California 90028

ATTENTION: Mr. John McKenna

REF: **Investigation for asbestos-containing materials of the Capital Records Building located at 1750 North Vine Street, Hollywood, California.**

A. Introduction

On January 25th, 1992, CTL Environmental Services (CTL) conducted a limited asbestos investigation survey of the property located at 1750 North Vine Street, in Hollywood, California for Capital Records.

The survey was conducted by Doug Coburn, an EPA accredited building inspector employed by CTL. The purpose of the survey was to identify and sample all accessible friable and non-friable building materials suspected to contain asbestos that may be impacted by the installation of fire sprinklers in the building.

At the request of the building management, sampling was to be conducted in a discrete and non-destructive manner. Also, to provide the description and locations of these materials and provide estimated quantities of those materials found to contain asbestos.

This document is intended to identify the asbestos-containing materials in the building as a result of this asbestos survey. The quantity estimates given herein are **estimates only** and should not be used for asbestos removal bidding purposes.

B. Description of Survey Site

The Property surveyed is located at 1750 North Vine Street, in Hollywood, California. The Building consists of thirteen stories, constructed on a concrete foundation with concrete slabs separating floors and supported by concrete columns and beams. Interior walls are constructed of drywall and plaster.

C. Field Survey and Analytical Methods

Prior to sampling suspect material, a visual inspection was conducted during which accessible areas of the building were visited.

This report applies only to the samples tested and is not necessarily representative of other similar or dissimilar materials.

methods cont...

By request of the building management, sampling was conducted in an non-destructive manner to preserve the current integrity of all building materials. As a result, some areas were not readily accessible unless destructive means were employed to gain access. These areas were considered inaccessible and are considered exempt from this report. Examples of such areas include: areas under carpeting, between walls, wall pipe chases, elevator and air shafts, areas between suspended gypsum board ceilings and hard decks, adhesives between acoustic tiles and substrates, and materials behind wall coverings (i.e. wallpaper, wood paneling).

Prior to any renovation or demolition that may affect these areas, it is recommended that further investigating be conducted for suspect materials by a qualified building inspector.

Samples were collected from suspect materials and subsequently analyzed by Polarized Light Microscopy (PLM) in accordance with U.S. Environmental Protection Agency Interim Method of the Determination of Asbestos in Bulk Insulation Samples: Polarized Light Microscopy, 40 CFR Ch. 1 Pt. 763, Subpart. F, Appendix A, 7/1/87 edition.

D. Survey Results

A complete listing of all samples collected is in the following section of this report. The materials listed below were determined to contain asbestos. Quantities are approximations only and should not be used for bidding purposes.

ASBESTOS-CONTAINING MATERIAL	LOCATION	EST. QTY.
Acoustic spray on ceiling	1st floor, elevator lobby	500 square ft.
White gasket material (plugging holes in walls)	Mezzanine, walls	10 sq. ft.
Pipe insulation S-2 (Chill water)	Above 1st floor in crawlspace	100 linear feet
Pipe insulation S-1 (Hot water)	Mail room, above dropped ceiling	100 linear feet
Pipe insulation S-2 (Hot water)	1st floor, boiler room	75 linear feet

E. Discussion

Currently, the Environmental Protection Agency E.P.A. considers those materials that contain more than one (1) percent of asbestos by volume to be treated as asbestos-containing material (ACM).

As previously discussed, this survey was conducted in a non-destructive manner. Although every attempt was made to access friable suspect materials in the buildings, the possibility exists that additional materials may be exposed during renovation and/or demolition activities. Visually suspect materials not listed in this report and exposed during renovation or demolition should be sampled and analyzed prior to further disturbance.

Prior to the demolition of the building or any other activity that may disturb known asbestos containing materials (ACM), removal of such materials is advised. Removal should be performed by a qualified and licensed asbestos removal contractor.

Should you have any further questions regarding this investigation report or would like more information describing our wide range of environmental services, please feel free to contact me at (310) 530-5006.

Respectfully submitted,
CTL Environmental Services,

David R. Schack
Sr. Project Coordinator

City Water Sources 6
Report for All Water Quality Areas 8
About this Report & Contact Information 15

AR0069548

1 Beginning of L.A. Aqueducts

Lee Vining Intake

The beginning of the Los Angeles Aqueducts. Water is collected from creeks in the Mono Basin and the Owens River in the Owens Valley and then carried to the City of Los Angeles by the Los Angeles Aqueducts, which operate completely by gravity, making clean hydroelectric energy along the way.

A Message to Our Customers

In 2009, the 200 billion gallons of water supplied to the City's 4.1 million residents met or surpassed all health-based drinking water standards. These standards are set by the U.S. Environmental Protection Agency (USEPA) and the State of California Department of Public Health (CDPH) Drinking Water Program.

Year after year, LADWP proves that it has what it takes to provide the City of Los Angeles with high-quality, low cost drinking water. It's no easy task to achieve such high quality water. Hundreds of employees and countless hours are spent protecting our water sources, managing state-of-the-art water treatment processes, maintaining and operating our facilities, and vigilantly monitoring and testing the water we serve. We continuously strive to surpass the legal requirements and do so in an effective and affordable way for our customers.

In 2009, LADWP collected over 25,000 water samples across the city, and performed more than 240,000 water quality tests—not just for compliance, but also for research and operational improvements. We tested for over 200 different contaminants throughout the year including both, regulated contaminants such as arsenic, chromium, lead, and disinfection by-products, as well as unregulated contaminants of concern such as sodium and boron.

This report summarizes the results of the water quality tests conducted in 2009 and provides specific information about the quality of water served in your neighborhood. You will see that most contaminants have not been detected in our water sources and those that are (see tables I-IV) are safely within the regulatory limits for drinking water.

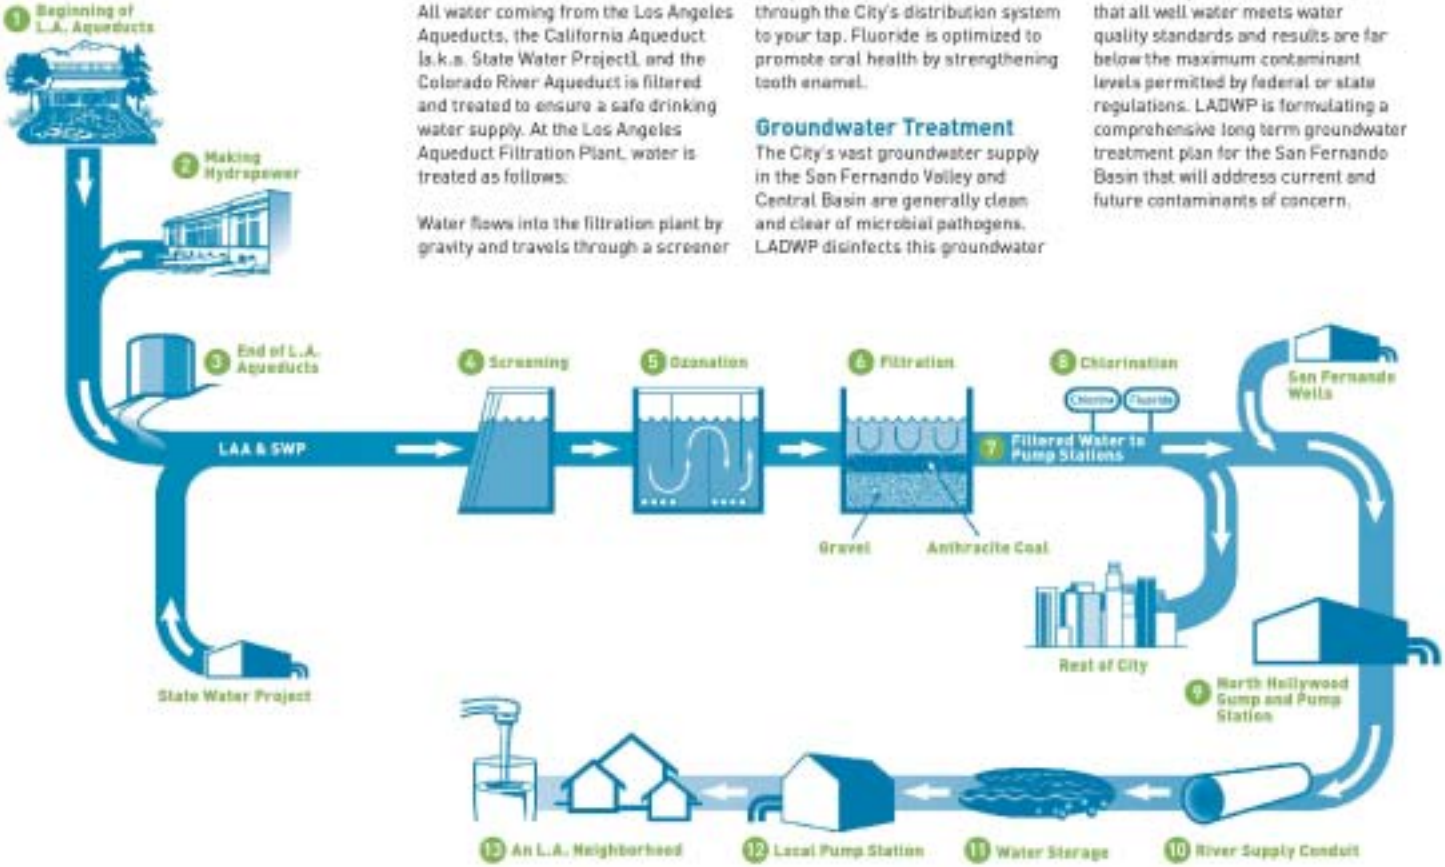
James B. McDaniel
Senior Assistant General Manager - Water

Dr. Pankaj Parekh
Director of Water Quality

The Journey of a Drop of a Water

From the Mountains to Your Tap...

A drop of melted snow trickles into a stream and gathers strength as it travels down mountains and into streams and rivers in a land of blue skies. This is where City of Los Angeles drinking water comes from. To most people, the journey water takes to get to their business or residence is a mystery. The photos in this report will reveal the mystery by sharing snapshots of where a drop of water travels before it splashes over your baby's head at bathtime or streams into your water bottle before your evening walk. Because, when it's all said and done, **it really is that good!**



Water Treatment Processes

Surface Water Treatment

LADWP water comes from four very different water sources—three are from surface water sources like lakes and rivers, and the other is groundwater from local wells and springs. The taste and appearance of surface water can vary seasonally and groundwater generally contains more minerals. All these factors make for different tasting water. Despite these variations, LADWP water meets all drinking water standards for health and aesthetics.

All water coming from the Los Angeles Aqueducts, the California Aqueduct (a.k.a. State Water Project), and the Colorado River Aqueduct is filtered and treated to ensure a safe drinking water supply. At the Los Angeles Aqueduct Filtration Plant, water is treated as follows:

Water flows into the filtration plant by gravity and travels through a screener to remove environmental debris such as twigs and dead leaves. The process injects ozone, a super-charged oxygen molecule and a powerful disinfecting agent into the water to destroy bacteria and other impurities that affect taste, odor and color. Treatment chemicals are quickly dispersed into the water to make fine particles called floc. A six-foot-deep filter (crushed coal over gravel) removes the floc and previously added chemicals. Chlorine added during the final step ensures lasting disinfection and protects the water as it travels through the City's distribution system to your tap. Fluoride is optimized to promote oral health by strengthening tooth enamel.

Groundwater Treatment

The City's vast groundwater supply in the San Fernando Valley and Central Basin are generally clean and clear of microbial pathogens. LADWP disinfects this groundwater with chlorine as a safeguard against microorganisms and adds optimal amounts of fluoride to promote oral health. In December, 2009, the federal Ground Water Rule went into effect. This regulation now requires all water agencies across the country to disinfect groundwater sources, a standard practice that LADWP has had for decades.

Because of man-made contaminants found in San Fernando Valley groundwater wells, LADWP continuously monitors and ensures that all well water meets water quality standards and results are far below the maximum contaminant levels permitted by federal or state regulations. LADWP is formulating a comprehensive long term groundwater treatment plan for the San Fernando Basin that will address current and future contaminants of concern.

AR0069549

Making Hydropower 2

San Francisquito Power Plant 1

Water generates electricity as it passes through the hydroelectric plant.

Water Quality News and Updates

Safeguarding Our Surface Water

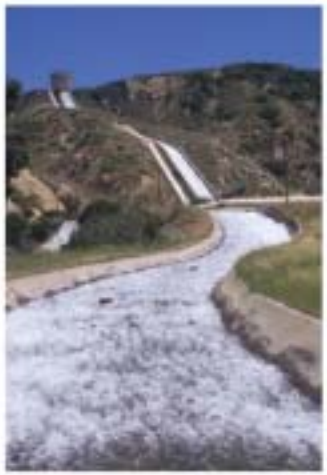
The Surface Water Treatment Rule (SWTR), administered by CDPH, is a drinking water regulation designed to help safeguard reservoir supplies from microbiological contamination that may occur when rain runoff from nearby hillsides and slopes enters the water. In Los Angeles, SWTR applied to four open water reservoirs – Lower Stone Canyon, Encino, and Upper and Lower Hollywood.

LADWP successfully met the compliance deadlines and treatment requirements for all four open reservoirs that were subject to SWTR. Upper and Lower Hollywood Reservoirs were successfully removed in July 2001 and replaced with two 30 million gallon buried tanks. New support facilities were successfully commissioned to serve filtered water from Encino Reservoir in January, 2006 and Lower Stone Canyon Reservoir in September, 2008.

The latest drinking water regulation related to the treatment of surface water is the Long Term 2 Enhanced Surface Water Treatment Rule (LT2). This rule requires that LADWP cover or remove from service the remaining six uncovered distribution reservoirs, or provide additional treatment to achieve prescribed inactivation or removal of viruses, Cryptosporidium, and Giardia by April 1, 2009 or be in compliance with a state-approved schedule to meet the same requirements. The six reservoirs are Los Angeles, Upper Stone Canyon, Santa Ynez, Ivanhoe, Silver Lake, and Elysian Reservoirs.

On April 1, 2008, LADWP notified CDPH that it is fully committed to complying with the new regulations and requested an extension of the April 1, 2009 deadline. LADWP submitted an interim operations plan, a schedule for the required reservoir improvements, and executed a Compliance Agreement with CDPH on March 31, 2009. LADWP is working diligently to bring all reservoirs into compliance as quickly as possible and will provide the public with project updates in the annual water quality report. The estimated cost to modify the six reservoirs is $1.65 billion.

LT2 improves on the SWTR by requiring further protection of open distribution reservoirs from microbial pathogens like Cryptosporidium and Giardia. In preparation for compliance with this rule, LADWP has been routinely monitoring its water sources for microbial pathogens since 2005. Cryptosporidium and Giardia are occasionally detected in very low numbers in some of our reservoirs and in the L.A. Aqueduct and we are fully committed to achieving compliance with the LT2. To further educate our customers on this topic, we have included a statement from CDPH regarding Cryptosporidium.



End of LA Aqueducts 3

The Cascades

Seen along Interstate 5, this is the terminus (end) of the Aqueducts. Water flows over the "steps" to release some of the water's energy.

"Cryptosporidium is a microbial pathogen found in surface water throughout the U.S. Although filtration removes Cryptosporidium, the most commonly used filtration methods cannot guarantee 100 percent removal. Our monitoring indicates the presence of these organisms in our source water and finished water. Current test methods do not allow us to determine if the organisms are dead or if they are capable of causing disease. Ingestion of Cryptosporidium may cause cryptosporidiosis, an abdominal infection. Symptoms of infection include nausea, diarrhea, and abdominal cramps. Most healthy individuals can overcome the disease within a few weeks. However, immunocompromised persons are at greater risk of developing life-threatening illness. We encourage immunocompromised individuals to consult their doctor regarding appropriate precautions to take to avoid infection. Cryptosporidium must be ingested to cause disease, and it may be spread through means other than drinking water."

Water Quality Team Regulatory Affairs

Among the employees responsible for the maintenance and compliance of the City's drinking water, is a little known group of highly trained and educated water quality experts. Known as the LADWP Regulatory Affairs Unit, this elite group knows everything there is to know about the implementation and adherence to all drinking water regulations to protect our water quality. They field hundreds of calls each year from customers and provide input to management about everything water quality.

A diverse group of employees, the unit includes chemists, biologists, environmental specialists, and environmental engineers who work closely with State and County public health departments on ongoing and emerging public health issues related to water quality. They implement

Screening 4

Los Angeles Aqueduct Filtration Plant (LAAFP) Inlet Structure

Water flows through the inlet of the LAAFP, where large pieces of debris or algae are removed by screens.

Ozonation 5

Ozone Contact Chamber, LAAFP

Water is exposed to ozone gas, a disinfectant that prepares the water for filtration.

Filtration 6

Anthracite Coal Filters, LAAFP

Water passes through 60 inches of anthracite coal filters, which remove particles as small as microns.

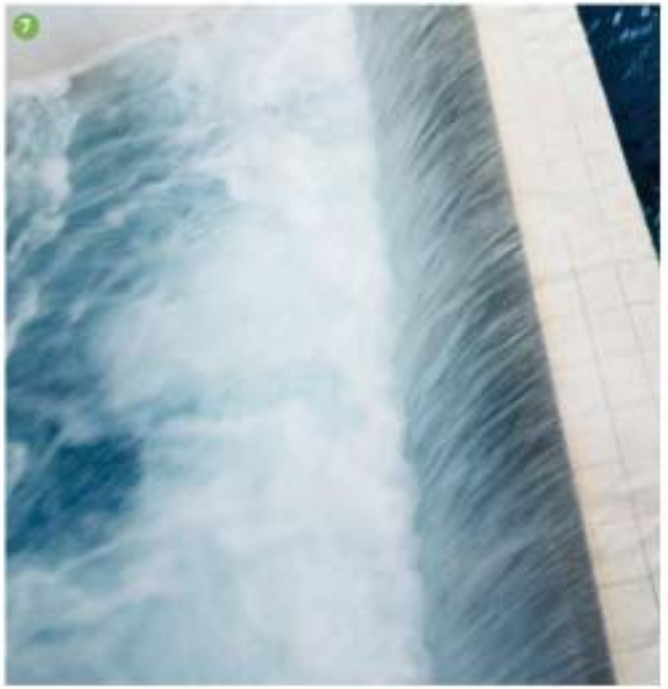
new regulations as well as perform annual and multi-year compliance activities for the City of Los Angeles including: Residential Lead and Copper monitoring; the Watershed Sanitary Survey of the Owens Valley and Mono Basin; system-wide changes to improve water quality, and the updating of water quality data and statistics at ladwp.com. The team works continuously to find new ways to improve water quality above and beyond what is currently required by law.

As LADWP customers themselves, the Regulatory Affairs group has a first-hand understanding of the importance of water quality in our daily lives. It takes a team to complete the various jobs related to water quality.

A Better Understanding of Radon

Radon is a naturally occurring radioactive gas that is not a significant issue in most of California. In 2009, very low levels of radon were detected in some of our water supplies that serve the Central Los Angeles area (see Table III on page 12). There is no established drinking water standard or monitoring requirement for radon. In general, radon entering a home through tap water is a very small contributor to radon in indoor air. Although the radon levels were well below what the EPA currently considers as standard, the EPA has asked us to share the following general information with you to help you better understand radon.

"Radon is a radioactive gas that you can't see, taste, or smell. It is found throughout the U.S. Radon can move up through the ground and into a home through cracks and holes in the foundation. Radon can build up to high levels in all types of homes. Radon can also get into indoor air when released from tap water from showering, washing dishes, and other household activities. Compared to radon entering the home through soil, radon entering the home through tap water is, in most cases, a small source of radon in indoor air. Radon is a known human carcinogen. Breathing air containing radon can lead to lung cancer. Drinking water containing radon may also cause increased risk of stomach cancer. If you are concerned about radon in your home, test the air in your home. Testing is inexpensive and easy. Fix your home if the level of radon in your air is 4 picoCuries per liter of air (pCi/L) or higher. There are simple ways to fix a radon problem that aren't too costly. For additional information, call your State radon program or call EPA's Radon Hotline (800-SOS-RADON)."



7 Filtered Water to Pump Stations

Filter Weir
Water from each of the 24 filters combine at the Filter Weir before leaving the Filtration Plant.

8 Chlorination

Chlorination Station
Chlorinator controls the amount of chlorine added to protect against bacteria and pathogens as water travels through the distribution system.

AR0069551

Report for All Water Quality Areas

Tables I–IV list the results of water tests performed by LADWP and MWD from January to December 2009. LADWP tests for over 200 contaminants. These tables include only contaminants with values that are equal to or greater than the limit of detection.

How to Read the Tables

The constituents/contaminants found in the water served in your area are listed as follows:

- For San Fernando Valley Area – water test results are under the Los Angeles Aqueduct Filtration Plant, the Northern Combined Wells, and MWD Jensen Filtration Plant columns
- For Western Los Angeles Area – water test results are under the Los Angeles Aqueduct Filtration Plant column
- For Central Los Angeles Area – water test results are under the Los Angeles Aqueduct Filtration Plant and the Southern Combined Wells columns
- For Harbor/Eastern Los Angeles Area – water test results are under the MWD Jensen, Weymouth, and Diemer Filtration Plants columns

Some constituents/contaminants detected are reported on a citywide basis as required by the California Department of Public Health.
The unregulated contaminants reported on an area-wide basis are included for additional information on the water served in your area.

Shade Balls Minimize Bromate in City Reservoirs

LADWP continues to minimize bromate levels in open reservoirs, keeping them within regulatory requirements. A creative short-term intervention LADWP recently implemented was the use of "shade balls" to decrease the formation of Bromate. In 2008, shade balls were used to shade the water surfaces of Elysian and Ivanhoe Reservoirs. As a result, bromate levels have been consistently well below the current drinking water standard of 10 parts per billion.

In the long term, LADWP intends to permanently cover or replace all remaining uncovered reservoirs by 2022 as required by the LT2 regulation (please see Safeguarding our Surface Water, page 4). Meanwhile, all water served to our customers continues to meet all public health standards.

Public Health Goals Report

Prepared once every three years, the Public Health Goals Report focuses on drinking water contaminants found at levels above a California Public Health Goal (PHG). A PHG is a level identified as having no adverse health effects. PHGs are not strict standards, but are used in the regulatory process to establish a drinking water standard for contaminants that are currently

9 North Hollywood Sump and Pump Station

Well Water Blending

Water flows by gravity from the LAAFP to the North Hollywood Pump Station. Well water from the San Fernando Valley mixes with the aqueduct water in the North Hollywood Sump before it is sent by large pumps to the central city.

Abbreviations and Footnotes

mg/L = milligrams per liter (equivalent to ppm)
µg/L = micrograms per liter (equivalent to ppb)
ng/L = nanograms per liter (equivalent to ppt)
pCi/L = picoCuries per liter
% = percentage
µS/cm = microSiemens per centimeter
NTU = nephelometric turbidity unit
TON = threshold odor number
CFU = colony-forming unit
ACU = apparent color unit
< = less than

NA = not applicable
NT = not tested
HRAA = highest running annual average

(a) Values reflect Highest Running Annual Average (HRAA). HRAA is the highest of all Running Annual Averages (RAAs). RAA is a calculated average of all the samples collected within twelve months period.

(b) Bromate is tested in water treated with ozone. Bromate has also been found in chloraminated treated water of some LADWP reservoirs exposed to sunlight. Metropolitan Water District of Southern California (MWD) only tests bromate at Jensen Filtration Plant.

(c) Radiological monitoring is performed in cycles of various periods of time. LADWP performed all radiological testing in 2009 for samples collected at Los Angeles Aqueduct Filtration Plant, Northern Combined Wells blend points, and Southern Combined Wells blend points. MWD performed all radiological testing in 2008 for samples collected at Weymouth, Diemer, and Jensen Filtration Plants.

(d) Turbidity is a measure of the cloudiness of the water and is a good indicator of water quality and filtration performance. High turbidity can hinder the effectiveness of disinfectants. The Primary Drinking Water Standard for turbidity level at water filtration plants is less than or equal to 0.3 NTU in at least 95% of the measurements taken in any month and shall not exceed 1.0 NTU at any time. The reporting requirement for treatment plant turbidity is: report the highest single measurement in the calendar year and the lowest monthly percentage of measurements that are less than or equal to 0.3 NTU.

(e) At-the-tap monitoring of lead and copper is conducted every three years as required by the Lead and Copper Rule. LADWP performed at-the-tap testing in 2009. A system is out of compliance if the Regulatory Action Level is exceeded in the 90th percentile of all samples at the customers' taps. Although the City's treated water has little, if any, detectable lead, studies were conducted and corrosion control is scheduled for implementation.

(f) Values reflect annual range and average of samples collected from six open reservoirs: Elysian, Ivanhoe, Los Angeles, Santa Ynez, Silver Lake, and Upper Stone.

(g) Values reflect testing at entry to distribution system.

10 River Supply Conduit

Water Travels through the City

Water from the pump station is carried through a 78" water main to Ivanhoe Reservoir in the Silver Lake area of the City.

unregulated, and are used to revise standards for regulated contaminants. While PHGs are based solely on health effects, primary drinking water standards are based on health effects, technical feasibility and cost.

The report includes health effects from exposure to the contaminant, the relative risk associated with each contaminant, the best available treatment technology to remove or reduce the contaminant down to the PHG, and the cost associated with such treatments. For Los Angeles, the contaminants in water that pose the highest risks are arsenic and disinfection by-products. By prioritizing water quality improvements on contaminants that pose the greatest risks to health, LADWP effectively and efficiently achieves the highest risk reduction at the lowest cost.

LADWP's 2009 Public Health Goals report was completed in July 2010 and can be downloaded from www.ladwp.com or mailed to customers upon request.

Commonly Used Terms

Compliance: A drinking water standard based on the health risk (primary standards) and aesthetic (secondary standards) exposure of a contaminant to consumers. For example, bacteria and nitrate have strict limits that must be met at all times due to the acute effects they can cause. Other standards, like small amounts of disinfection by-products and man-made chemicals, have standards that are based on a lifetime of exposure because the risk to consumers is very low. Compliance with most standards is based on an average of samples collected within a year. This allows for some fluctuation above and below the numerical standard, while still protecting public health.

Detection Limit for Reporting Purpose (DLR): DLR means the designated minimum level at or above which any analytical finding of a contaminant in drinking water resulting from monitoring required under Title 22 Code of Regulations shall be reported to the California Department of Public Health (CDPH).

Maximum Contaminant Level (MCL): MCL is the highest level of a contaminant that is allowed in drinking water. Primary MCLs are set as close to the Public Health Goals (PHGs) or Maximum Contaminant Level Goals (MCLGs) as is economically and technologically feasible. Secondary MCLs are set to protect odor, taste, and appearance of drinking water. For certain contaminants, compliance with the MCL is based on the average of all samples collected throughout the year.

Maximum Contaminant Level Goal (MCLG): MCLG is the level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs are set by the U.S. Environmental Protection Agency (USEPA).

Maximum Residual Disinfectant Level (MRDL): MRDL is the highest level of a disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.

Maximum Residual Disinfectant Level Goal (MRDLG): MRDLG is the level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs do not reflect the benefits of the use of disinfectants to control microbial contaminants. MRDLGs are set by the USEPA.

Notification Level (NL): NL is the Health-based advisory levels established by CDPH for chemicals in drinking water that lack maximum contaminant levels (MCLs).

Primary Drinking Water Standard (PDWS): MCLs and MRDLs for contaminants that affect health along with their monitoring and reporting requirements, and water treatment requirements.

Public Health Goal (PHG): PHG is the level of a contaminant in drinking water below which there is no known or expected risk to health. PHGs are set by the California Environmental Protection Agency, Office of Environmental Health Hazard Assessment (OEHHA).

Regulatory Action Level (AL): AL is the concentration of a contaminant which, if exceeded, triggers treatment or other requirements that a water system must follow. ALs are set by the USEPA.

Treatment Technique (TT): TT is a required process intended to reduce the level of a contaminant in drinking water. For example, the filtration process is a treatment technique used to reduce turbidity (the cloudiness in water) and microbial contaminants from surface water. High turbidities may be indicative of poor or inadequate filtration.

Table IV Calendar Year 2009 Water Quality Monitoring Results

Drinking Water Disinfection By-Products Reported on Area-Wide Basis

Additional chlorine is added before large pumps send the water to L.A. neighborhoods, east of Ivanhoe Reservoir.

continued from page 11

Impact of Public Water System Contaminants

Lead Exposure from Plumbing Materials

LADWP monitors lead contents in source water and the distribution system and has not found detectable amounts. If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with lead service lines and home plumbing. The LADWP is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting in the pipes for several hours, you can minimize the potential for lead exposure by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. This water can be collected and used to water plants. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at http://www.epa.gov/safewater/lead.

Pharmaceutical and Personal Care Products

Very low levels of pharmaceutical and personal care products (PPCPs) are increasingly being detected in U.S. drinking water supplies. PPCPs include medicines, shampoos, soaps, detergents, lotions, and perfumes. Currently, neither the state or federal government require LADWP to test for PPCPs. However, as a forward looking utility, LADWP conducts its own monitoring for these compounds.

In 2009, LADWP tested its source and treated waters for PPCPs. The amount of PPCPs detected was so minute that no adverse health effect from exposure has been reported. LADWP continues to study the issue with several other utilities and the Water Research Foundation. Customers can do their part by disposing unwanted medications into a waste receptical—not down a toilet or drain.

13 An L.A. Neighborhood

The Journey Ends

Water passes through the interior plumbing of a home to be used for many purposes, including drinking, cooking, bathing, laundry, toilet flushing and as an eco-friendly alternative to bottled water.

About This Report

The 2009 Water Quality Report was prepared by the Los Angeles Department of Water and Power (LADWP). This report is required by the California Department of Public Health (CDPH) and was prepared in accordance with CDPH guidelines. It was prepared, printed and mailed to you at a cost of 35 cents.

Contact Information

LADWP, the largest municipal utility in the nation, was established more than 100 years ago to provide a reliable and safe water and electric supply to the City's 4 million residents and businesses.

LADWP is governed by a five-member Board of Water and Power Commissioners, appointed by the Mayor and confirmed by the City Council. The Board meets regularly on the first and third Tuesdays of each month at 1:30 p.m. Meetings are held at:

Los Angeles Department of Water and Power
111 North Hope Street, Room 1555H
Los Angeles, CA 90012-2694

The meeting agenda is available to the public on the Thursday prior to the week of the meeting. You can access the Board agenda at www.ladwp.com or by calling (213) 367-1351.

For general information about LADWP, call 1-800-DIAL DWP (1-800-342-5397) or visit www.ladwp.com.

For questions regarding water quality, call the LADWP Water Quality Customer Services Group at (213) 367-3182.

For questions regarding this report, please call Dr. Langford Book at (213) 367-3199.

Want to know more about your drinking water and related regulations?

Los Angeles Department of Water and Power	www.ladwp.com

AR0069558

Introduction

The City through its Bureau of Sanitation in the Department of Public Works has provided solid resources management services to residential households within the City of Los Angeles since 1890. Every week three collection vehicles visit each of our 720,000 customers to separately collect recyclables, yard trimmings and refuse at curbside. The Bureau also provides special residential collection services such as bulky item, appliance and bulky brush collection.

The City's collection of solid waste has changed dramatically since its inception in 1890 when the first solid waste crematory (incinerator) was constructed and the City provided disposal service. In later years food and organic waste was collected for delivery to hog ranches, metals and other materials were reused or recycled, and combustible rubbish was burned in backyard incinerators or collected and disposed by private contractors.

In 1943, residential collection was turned over to City forces. In 1957 after backyard incineration was banned as a part of the smog control program, the City added the collection and disposal of combustible rubbish as part of its refuse collection program. Beginning in 1957 the City used only landfill disposal sites located in and around the City to dispose of all materials collected at curbside.

In 1961, Sam Yorty was elected Mayor of Los Angeles. Part of his campaign platform was the promise that, if elected, he would end the requirement to separate refuse at the curb. He accused his opponent, the incumbent Norris Poulson, of *"forcing Los Angeles housewives to perform coolie labor for a salvage firm."* After his election, in 1964 all household refuse was then collected in a single container and disposed in local City, County and private landfills rather than being recycled. During the 1970s and 1980s, local City landfills began closing and new landfill sites became harder to secure. In the early 1980s the Bureau of Sanitation began investigating recycling and waste to energy technology as a way to reduce our reliance on landfills.

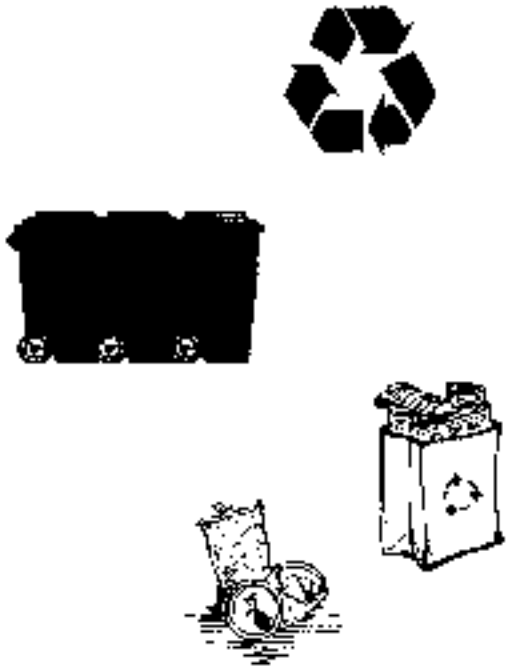
City Rubbish Collection 1943

A waste to energy facility was authorized for study in 1979, but in 1987, after eight years of development, the project was canceled. Also, during this time pilot curbside recycling operations were initiated in West Los Angeles in 1985 and expanded to the San Fernando Valley in 1987 and into all Council Districts in 1989, finally reaching a total of 95,000 households.

In order to control the growing waste stream and improve operational efficiency, the Mayor and City Council approved the implementation of a full curbside recycling and automated refuse and yard trimmings collection program in early 1990, with the program roll out starting later that same year. The yellow bin recycling program and the automated collection system became a Citywide program in 1995. In 1997, just two years after the five year implementation of the yellow bin system, the City embarked on the next generation of curbside recycling and began the implementation of the automated blue container recycling system. This new system, which is the state of the art in recycling, was completely rolled out Citywide by December 1998 in a record 18 month period of time.

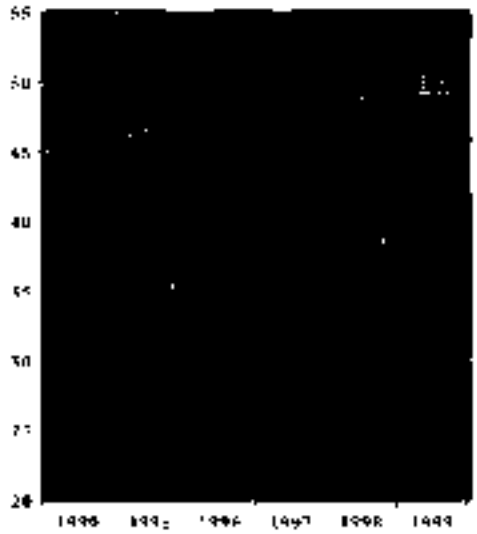
AR0069559

Current Solid Resources Operations



The City's solid waste management practices have come a long way since 1890 and have transitioned from a collection and disposal oriented structure to a recycling operation back to a disposal operation and since 1990 returning whole heartedly back to recycling. Even the term for the materials we collect and manage has changed from solid *waste* to solid *resources*. Programs have been established throughout the City that have contributed to a Citywide waste diversion rate of 49% in 1999, and the City is expected to surpass the mandated 50% diversion rate in 2000. Innovative programs must be implemented to reach the City's 70% diversion goal in 2020.

The shift in emphasis in the Bureau's solid resources business has also affected our need for support facilities. Where, for example, the City used to own and operate several landfills which provided disposal services to our collection staff, the Bureau now disposes of the remaining refuse it collects in three landfills, two operated by private entities and one by the Los Angeles County Sanitation Districts. The City's involvement in its landfills is now focused on closure, maintenance, and ultimate restoration of the six inactive City owned landfills. Recycling and Transfer facilities provide the necessary link between the collection of solid waste and its ultimate disposal.



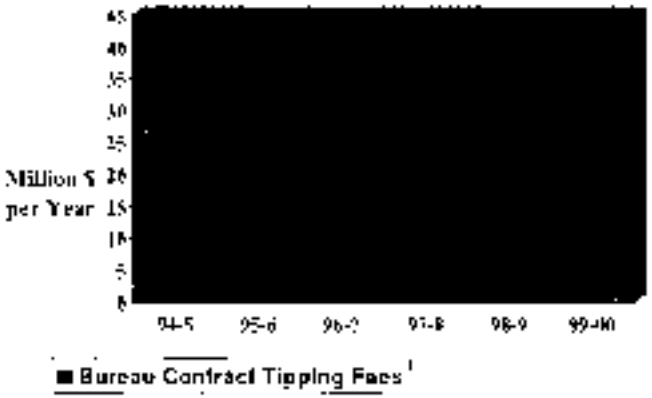
Diversion increases yearly

The doubling of the recyclables collected at curbside has resulted in the City contracting with several Material Recovery Facilities owned and operated by the private sector to receive, clean, process, and market the recyclables. The Bureau also has three City operations and several contracts with private contractors to accept, clean, grind, and mulch or compost our yard trimmings which is a significant element in our achieving such a high recycling rate. The City now needs to invest in infrastructure to support these new solid resources management activities. Acquiring City-owned and operated facilities may provide more control over future cost increases and more options for managing the materials we collect at curbside. The development of infrastructure, in most cases, could result in a net cost savings when compared to future private sector contract costs.

AR0069560

Current issues in solid resources management

The waste management industry has recently experienced unprecedented consolidation, transitioning from many companies to a few mega-companies. For example, after the merger between giants Waste Management, inc and USA Waste, a trade paper reported that prices have been raised at many Waste Management disposal facilities across the nation--- increases such as 40 percent in Pennsylvania, 29 percent in Virginia, and 136 percent at a landfill in Ohio! Analysts predict that other companies will follow with price hikes. Also, Allied Industries, a waste management giant based in Phoenix, Arizona, acquired Browning Ferris Industries, the owners of the Falcon Transfer Station and Sunshine Canyon Landfill (both used by the City), for a price totaling about $9.1 *billion* dollars. **Future prices for transfer and disposal in Los Angeles are expected to only go higher.**



The City does not own the supporting infrastructure facilities such as transfer stations and Material Recovery Facilities which are critical to support our core business of servicing 720,000 households with waste management services. This situation exposes the City to capricious changes in prices and control by these large private waste management companies. The Bureau's attempt to exercise its purchase option for the Central Los Angeles Recycling and Transfer Station was met by the owner reporting that a sale of the facility was made to Republic Industries for over $70 million! Through the sale of the property at that price, the new owner will need to recoup its costs through higher contract rates in the future. City ownership of facilities could provide us with both cost control and greater operating efficiencies. **We must aggressively pursue cost effective contract services or the siting and construction of City-owned facilities to contain costs to City residents.**

AR0069561

Solid Resources Plan Development

Plan Development

On July 28, 1995, the Bureau was directed by the City Council to prepare an Action Plan to examine: (1) the waste disposal alternatives available when the Lopez Canyon Landfill closed, (2) measures to increase waste diversion, and (3) revenue raising alternatives to finance new solid resources projects. On December 13, 1995 the Action Plan prepared by the Bureau was considered by the City Council and the Bureau was directed by the City Council to develop a plan to procure/construct City-owned transfer facilities in the West Los Angeles, Valley, and Central City areas so that the City could gain greater control over the management of its waste stream and future cost increases.

After investigating the City's long-term needs for these solid resources management services, the Bureau presented a preliminary report (August 27 1997) to the Board of Public Works containing several recommendations recommending the acquisition and development of City-owned solid resources management facilities, and other capital improvements. Upon review of that report the Board directed the Bureau to hold a series of public workshops in October, 1997 to gather additional input and foster discussion of the items with concerned agencies, the industry and the public. The Bureau also formed a Process Action Team (PAT) composed of staff, union representatives, and Solid Waste Citizens Advisory Group (SWCAG) members to discuss and provide direction concerning the proposed recommended actions.

In response to the comments received at the workshops and further investigation by the Bureau, the previous report and recommendations were revised to reflect the changing emphasis of waste management and recycling within the City and the industry.

AR0069562

Plan Objectives

As a result of further review and the comments received on the draft Solid Resources Infrastructure Plan, the following twelve key strategies were identified.

(1) *Develop a Transfer facility and/or Recycling Center in the Central Los Angeles area.* The Bureau has launched an aggressive program to acquire, permit and construct a state of the art transfer facility in the downtown Los Angeles area which is environmentally sound and cost effective.

(2) *Develop a Transfer and/or Recycling facility to serve the West Los Angeles area.* This state of the art, cost-effective facility will serve the West Los Angeles area, possibly other nearby City collection routes and may serve other area cities by contract to manage recyclables collected in their curbside programs.

(3) *Relocate the East Valley Collection Yard. Develop a new East Valley collection yard facility as approved by the Mayor and Council on August 5, 1998 (CF 96-0705-S2).* This larger site will allow collection yard operations, truck maintenance shops, container warehouse facilities and residential drop-off.

(4) *Develop permanent Household Hazardous Waste (HHW) drop-off facilities for City residents to provide year-round services and encourage safe disposal of these materials.* These new facilities will ultimately replace the existing Mobile Program.

(5) *Continue to pursue the development of yard trimmings processing, mulching and shipping facilities and marketing of the finished product within the City.* Successful programs have already been established in the San Fernando Valley and Harbor areas.

(6) *Continue to research and develop the use of Material Recovery Facilities to preprocess all residual waste prior to delivery to a disposal site.*

(7) *Establish a capital improvement expenditure program to upgrade all collection yard facilities to meet current environmental and health and safety standards, and to provide an adequate working environment for our employees.* New regulations requiring treatment of stormwater runoff and purchase of alternative fuel collection trucks will drive the cost of yard upgrades.

(8) *Perform closure construction at all six inactive landfill sites owned by the City within the next four years. Post-Closure monitoring and maintenance will continue after closure construction.*

(9) *Acquire the minimal long-term disposal capacity that the City will need beyond the year 2001.*

(10) *Develop a financing plan with the assistance of the Office of Administrative and Research Services for the recommended Solid Resources capital improvement program.*

(11) *Identify a method of receiving Citywide public review of plans and actions in the Solid Resources programs similar to the Solid Waste Citizen's Advisory Group.*

(12) *Develop a comprehensive and continual Public Education & Community Outreach program designed to educate and inform the public about the City's solid resources programs and strategies.* The Bureau will report back with the plan and budget costs.

These are the key objectives of the Plan that will provide the City with the necessary solid resources management infrastructure to serve our customers into the next Century. As other changes take place over time further actions will be necessary to bring the City the best possible services at the lowest cost.

AR0069563

2.0 Solid Resources Programs And Facilities Objectives

2.1 Plan Objective No. 1 - Central Los Angeles Transfer Station Development

Although the amount of refuse collected and disposed by the Bureau has decreased from over 1,200,000 tons in fiscal year 1993-94 to 863,500 tons in fiscal year 1999-00, the City must still maintain disposal contracts to provide guaranteed disposal capacity. Although our disposal needs will continue to decrease with the implementation of more intensive recycling efforts, disposal capacity needs will continue for the foreseeable future.

The City no longer owns and operates its own landfills. To provide cost containment and control for the future, the Bureau believes that a publicly owned and operated transfer station is essential. This facility can be used as a focal point for the gathering and shipping of materials to more remote landfills. On July 28, 1995, the Bureau was directed by the City Council to prepare an Action Plan with an examination of the waste disposal alternatives available when the Lopez Canyon Landfill closed, measures to increase waste diversion, and revenue raising alternatives to finance new solid resources projects. The Action Plan was considered by the City Council on December 13, 1995. On December 19, 1995, the Bureau was directed by the City Council to procure/construct City-owned transfer facilities in the West Los Angeles, Valley, and Central City areas so that the City can maintain greater control over its waste stream (Council File #95-0859). The Bureau is involved in the following projects in response to the Council directive:

2.1.1 Central Los Angeles Recycling and Transfer Station

To reduce contract costs of transfer services and increase our flexibility in providing services in the Central City area, the City is seeking to establish a recycling and transfer facility in Central Los Angeles.

In August, 1997, the Board of Public Works as a result of a report from the Bureau began consideration of recommendations to develop recycling and transfer facilities in the Central Los Angeles and Valley areas of the City. The recommendations included the acquisition of the Central Los Angeles Recycling and Transfer Station (Central L.A.) currently under contract to the City. The current contract includes a buy-out clause that gave the City the option to purchase the facility under certain conditions in December 1998, and again in December 2003. The buy-out clause includes procedures for valuation of the property.

AR0069564

On June 16, 1998, the City Council approved the issuance of Letters of Interest to BLT Enterprises, the owner, and Browning-Ferris Industries, the operator, stating that the City intended to exercise its purchase option with respect to the Central L.A. facility. The City followed up by conducting a land and business appraisal of the facility. The owner in a separate action negotiated an option and sale of the Central L.A. facility to Republic Industries. The owner has stated that the sale price was approximately $70 million. The sale of the facility at this price has excluded the City from the sale process.

A task force was formed within the Bureau to examine the potential for City operation of the Central L.A. facility. The Task Force recommended several actions in its final report to make the implementation of City owned and operated transfer facilities a success. Task Force staff also worked with employee unions and other City departments.

Estimated costs for operation of a City-owned facility, as of late 1999, are as follows:

City Operation of Recycling and Transfer Station
2,000 tons per day

Personnel	Salary	Benefits	Indirect	Cost per year
Full Time City Staff	$1,601,095	$605,578	$758,758	$3,965,431
Scheduled Overtime				$200,419
Operating Costs within Transfer Station				$284,929
Hauling Costs				$661,170
Equipment Maintenance				$1,178,257
Capital Costs - Equipment				$632,714
Retipping (Any Top)				$26,867
Total Yearly Estimated Cost				$6,887,525
Total Cost per Ton				$11.28

New Transfer Station
(Oxnard, California)

AR0069565

The Task Force also recommended that staff investigate the procurement of suitable land/property in downtown Los Angeles to construct a City-owned and operated recycling and/or transfer facility. The Bureau estimates that the permitting, design and construction of a new transfer facility to manage City-collected material would be approximately $12 million with an additional $5 million for equipment including transfer vehicles, significantly lower than the stated purchase price of the Central L.A. facility.

The Bureau is now on an aggressive course to site and develop a recycling and transfer station within the Central L.A. service area. In late 1999, the Bureau was approached by the L.A. County Sanitation Districts to discuss the development of a potential joint recycling and transfer facility. The resulting Joint Powers Agreement (JPA) will lay the groundwork for a facility that will serve the City as well as private haulers well into the 21st century through a cooperative equity partnership.

The development of a transfer station would be approximately $17 million as shown above. If the development of the facility was through a JPA with the L.A. County Sanitation Districts, the City may be able to reduce its up-front investment costs by paying capital development costs through tipping fees, while remaining an equity partner.

2.1.2 Other Transfer Station Services

The Bureau will also continue to procure or acquire transfer station services throughout the City as needed. For example:

(1) The Bureau currently contracts with the Falcon/BFI transfer station in the Harbor for refuse transfer services.

(2) The Bureau currently contracts with Southern California Disposal for refuse transfer services at their facility in Santa Monica.

(3) To further serve the West Los Angeles area, the Bureau has a new program to use direct transfer trailers - where the material is pushed directly from the collection vehicle into a trailer without the need for a transfer facility. This small scale transfer activity could serve as a bridge during development of larger, permanent transfer facilities.

(4) The Bureau is investigating the potential of developing a recycling and/or transfer facility at 5000 West Jefferson to serve the West Los Angeles area.

(5) To serve the San Fernando Valley when local disposal is not available, the Bureau will continue the planning process for a City-owned transfer station.

(6) The Bureau will continue to investigate options to procure cost-effective transfer station services through contract.

AR0069566

2.2 Plan Objective No. 2 - Western Facility Development

The Bureau should develop a Recycling and/or Transfer Center in the Western portion of the City to process and/or transfer the materials collected in this area. Siting is the greatest challenge in the Western area of Los Angeles, as the amount of industrial zoned land is limited. In 1996, the Bureau acquired a five acre parcel of land on Jefferson Boulevard zoned M1-1, located in the City and less than one mile from the Culver City transfer station. Three acres of the site have been graded and paved for parking of recycling and employee vehicles, and a temporary office trailer has been installed.

Prior to 1994 there was no Recycling Center located in the Western District. The recyclables from this District were transported to Recycling Centers located in either downtown L.A. or the San Fernando Valley. The current contractor built a Recycling Center on Jefferson Boulevard near the City property which transfers the recyclables collected in the Western District. Currently the recyclables are shipped from the contractor's facility to another location to be processed.

The Bureau has run pilot programs to utilize both the City of Culver City transfer station and the Southern California Disposal transfer station in Santa Monica. Both are currently utilized for about 100 tons per day of the refuse and 50 tons per day of the yard trimmings collected in the Western District.

Develop a Transfer and Recycling Center to serve the West Los Angeles area.

-Prepare a feasibility report and construction estimate for services to be provided at the site.

-Acquire financing and begin site assessments of available properties.

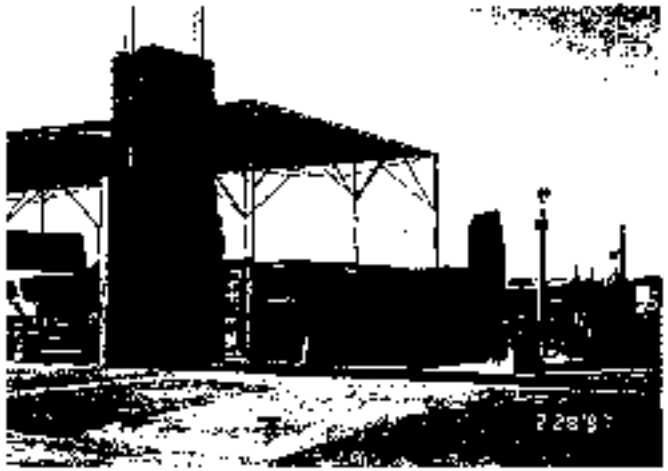
AR0069567

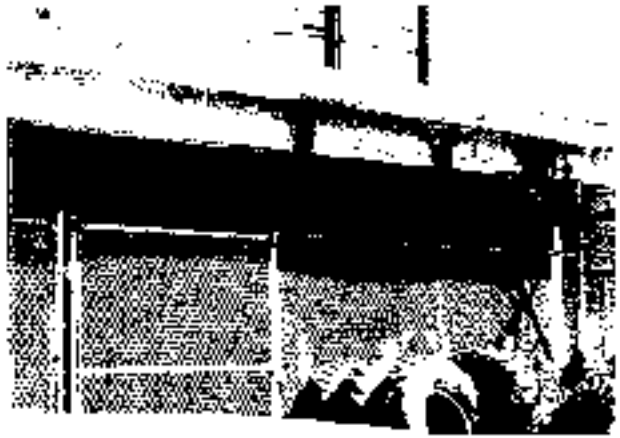
2.3 Plan Objective No. 3- East Valley Solid Resources Yard Relocation

The Northridge Earthquake in January 1994 caused an estimated $25 billion in damage. The current East Valley Collection Yard, located on San Fernando Road in Sun Valley, was damaged by the event as follows:

The entrance gate wall was damaged beyond repair;
The Maintenance/repair garage was partly demolished, and a 'temporary' carport-type building erected in its place;
Roof structures were deformed;
Employee parking was structurally damaged; and
I-beam and wall connections in the tire store and garage buildings were damaged.

The City qualified for reimbursement of approximately $750,000 from the Federal Emergency Management Agency (FEMA) for the replacement and repair of earthquake-damaged buildings at the East Valley Collection Yard. This money will be used for construction of a new yard at another site. The City has chosen to relocate the yard to a new site which is larger and more suitable for this use, leaving the site on San Fernando road available for development.





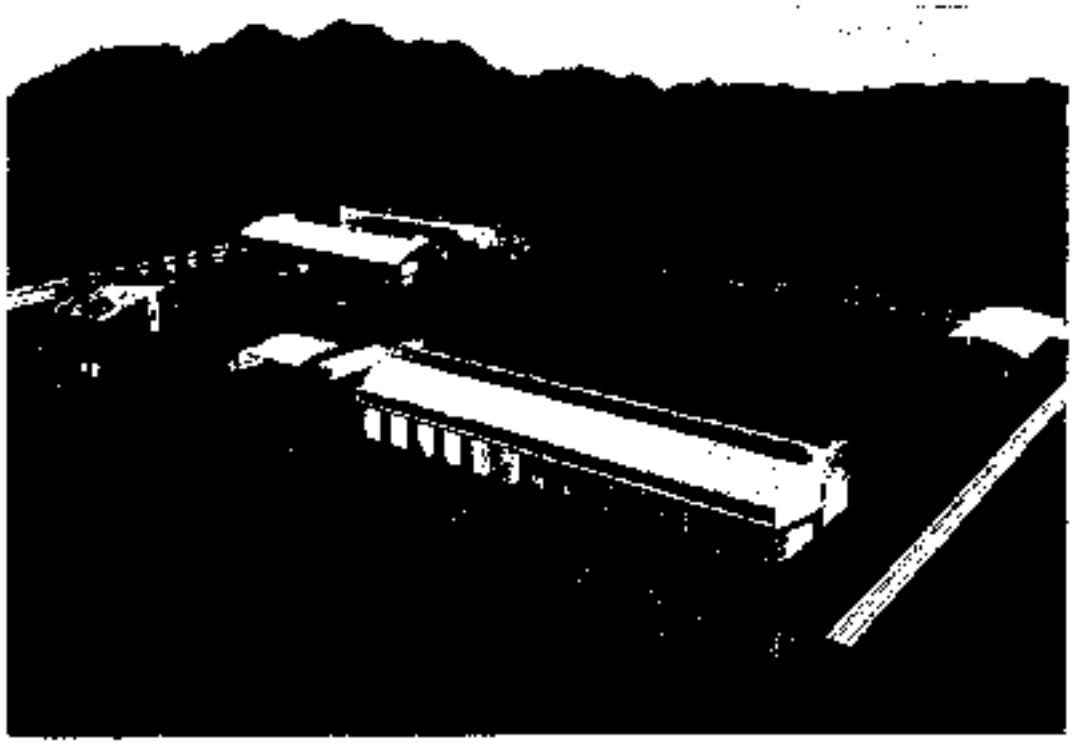
East Valley Earthquake Damage

AR0069568

The Bureau investigated the potential for using another site to develop a new East Valley collection yard facility, and a site was found in Sun Valley at 11050 Pendleton Street which is properly zoned and large enough (about 14 acres) to provide other services on the same site that will result in increased efficiency for our collection programs and expanded services to the local residents. The Bureau has acquired the property from the Department of Water and Power (DWP) to on Pendleton Street to develop as a new East Valley collection yard.

The expanded services to residents will include the development of residential drop-off facilities for recyclables, bulky items, and a special area for Household Hazardous Waste (HHW). A transfer facility can be developed if it becomes necessary. Both the development and the operation of the site are cost-effective when compared to the redevelopment of the current site on San Fernando Road.

East Valley Administration Building
Conceptual Design



On August 5th, 1998, the City Council authorized the Department of General Services to negotiate with the DWP for lease and transfer of jurisdiction for the property at 11050 Pendleton Street to the Department of Public Works. An authorization was also given to the Bureaus of Sanitation and Engineering to begin the environmental review process for the development of the new collection yard.

The Bureaus of Sanitation and Engineering have worked together to prepare the design for the site and to prepare required environmental documentation and permits. Development of the site is proceeding on schedule, with site preparation/excavation (to be performed by City crews) scheduled to begin in mid 2000, and construction beginning in mid 2001. Estimated capital needs for the relocation of the East Valley Collection Yard is approximately $25 million.

AR0069569

2.4 Plan Objection No. 4 - Permanent Household Hazardous Waste Facilities

Under the agreement with the County of Los Angeles, the Bureau has been operating its Household Hazardous Waste (HHW) collection program since 1989, serving over 150,000 households and disposing of 12 million pounds of HHW. Through this agreement, the City educates and informs City and County residents about HHW and local collection events. The City is reimbursed for its costs through a $.34 per ton fee on each ton of refuse disposed in the County, administered by the County Department of Public Works. At the request of the Mayor's Office, the Bureau began the Conditionally Exempt Small Quantity Generator program (CESQG) in 1998. The CESQG program provides small businesses with a legal and affordable solution to hazardous waste disposal,as the generators pay only the fees charged to the City by our HHW contractors.

The City conducts approximately two multi-day collection events per month. Three full-time City personnel handle the planning, siting, permitting, and logistics and two contractors handle the on-site operations at each event. Public notifications is done using event flyers and mailing of postcards. Public Service Announcements are sent to radio and television stations and press releases are mailed to newspapers, both dailies and non-dailies. All of these efforts are documented and used to request reimbursement from the County.

In order to meet the needs of residents and businesses and remove HHW from refuse and landfills, the Bureau will develop up to five HHW/Used Oil facilities throughout the City. These facilities will complement and in some areas replace the existing Mobile Program. Some of the potential facilities are as follows:

(1) The City of Santa Monica has an existing HHW drop-off facility for their residents. A Memorandum of Understanding is being drafted to allow City and County residents to dispose of HHW at this site.

(2) A grant of $290,000 was awarded to the City and six other jurisdictions including the cities of Bell, Bell Garden, Cudahy, Huntington Park, South Gate and Vernon by the California Integrated Waste Management Board for the development of a permanent HHW facility. This facility must be on-line by mid-2001 due to the grant restrictions. The Bureau is proposing to site a facility at the South Central District Yard.

(3) Through the relocation of the East Valley Collection yard, the Bureau has included in the design a permanent HHW facility. Construction is scheduled to take place in mid 2001.

(4) Other potential sites may be in the West Valley and Harbor areas, possibly in conjunction with other Bureau Solid Resources projects.

AR0069570

2.5 Plan Objective No. 5 - Yard Trimmings Processing Facilities

The Bureau currently uses a combination of contract and City-owned facilities to process and beneficially reuse the yard trimmings collected by City crews at curbside. Successful new programs operated by City employees in partnership with the Bureau of Street Services and the Harbor Department now process an average of 250 tons of yard trimmings per day at the Van Norman Reservoir in the North San Fernando Valley and a similar mulching site in the Harbor area. To further reduce contract costs associated with processing and transportation of yard trimmings for beneficial reuse, the Bureau intends to take positive steps to reduce the City's dependence on private service contracts when such use will lower program costs.

The Bureau collects over 400,000 tons of yard trimmings per year separated at curbside by our residents. Over the last several years, yard trimmings diversion programs have contributed 30% to the diversion rate for residents receiving curbside service. The 1,600 tons of yard trimmings collected per day are taken to several processors which clean the material of residue, chip it into small pieces, and either mulch the material on-site or transport it to other distant locations where the material is beneficially reused. Currently, nine contracts are held by the Bureau for a range of services to handle yard trimmings. The estimated cost for yard trimmings processing and reuse in the 2000 - 01 Fiscal Year budget is over $16 million dollars, even with the cost savings provided by the City operated facilities.

Acquire and Develop sites for the Processing, Mulching and/or Composting of Yard Trimmings

- Expand Processing Operations to Provide material.

- Develop joint programs for processing and/or spreading mulch with other agencies or private contractors where possible.

- Pursue other contractual opportunities to lower program costs for yard trimmings.

Several actions have been taken to lower the Bureau's contract costs and to control future cost increases. Actions include a new contract with a transfer station in the Central L.A. area that allows material that had a high cost due to 'double transfer' to now be received by one processor at a lower cost, reducing the Bureau's contract costs by over $700,000 per year. Other yard trimmings contract costs have been renegotiated at a lower rate to remain competitive in the current marketplace.

AR0069571

2.5.1 Van Norman Joint Processing Facility

A joint mulching operation with the Bureau of Street Services at the Van Norman Dam receives Sanitation-collected yard trimmings delivered to the site where it is cleaned, processed, and spread at the site for weed and erosion control or transported to farms for use as mulch. The site manages approximately 200 tons per day of Sanitation collected yard trimmings for a contract cost savings over $1.4 million per year. Staff is also accomplishing the objective of using mulch from the site at City parks and facilities whenever possible.

2.5.2 Harbor Processing Facility

The Bureau has established a yard trimmings processing site located on Harbor Department property. 50-70 tons per day of yard trimmings from the Harbor area collected by the Bureau are cleaned, processed and delivered by the Bureau for use as weed and erosion control in the Harbor area. This program reuses material from the immediate area, provides aesthetic benefits for the Harbor Beautification Project, and saves over $600,000 per year in contract costs.

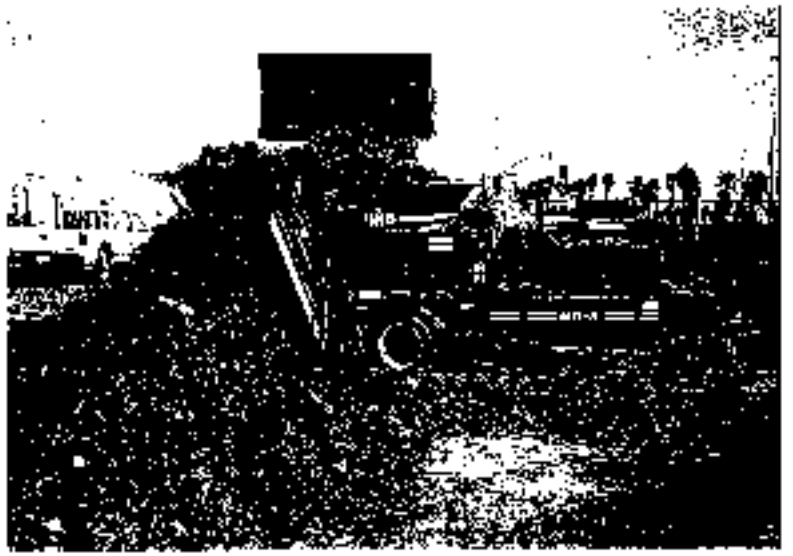
2.5.3 Sites for Mulch Application

After the yard trimmings collected at curbside are cleaned and processed, the material can be used as a soil amendment, or for erosion and dust control. The Bureau has established a Process Action Team (PAT) to work with other agencies to locate additional sites to spread the mulch created by the Van Norman facility and other potential sources. These sites may include:

(1) City Parks - The Department of Recreation and Parks has tested mulch application at several sites and is interested in using the material, which is shipped from the Van Norman site. The demand for this material is expected to increase. The Bureau also provides the department with 50% of the TopGro produced at the Griffith Park Composting Facility.

(2) CalTrans. The Bureau is delivering mulch to freeway right-of-ways.

(3) Harbor - The Harbor Department allows the Bureau to compost mulch on a site near Anchorage Street. This compost material is delivered to CalTrans, will also be made available to Rec and Parks for soil amendment and eventually to the general public through composting workshops.



City Yard Trimmings-Grindor Operation

AR0069572

(4) City golf courses - The Bureau is pursuing the use of mulch at City golf courses

(5) L.A. County Sanitation - has designated small pilot sites in landscaped areas for application of mulch

(6) Palmdale Airport site - The City's Department of Airports owns twenty-six square miles of unimproved property east of the City of Palmdale. Some small acreage is leased for agriculture. The cleaned, processed yard trimmings could be applied and/or tilled into the soil to anchor sand dunes and provide nutrients to the soil to increase the agricultural value of the property

(7) Owens Valley revegetation project - The use of cleaned, processed yard trimmings as a soil amendment could decrease soil erosion due to wind and increase the soil's moisture retaining ability, therefore increasing the success rate of revegetation of a portion of the dry lake bed. The Bureau is working with the Department of Water and Power to develop an initial pilot test to determine the suitability of the TopGro compost and yard trimmings material for use in the revegetation project. Initial tests show that mulch is chemically clean and able to be land-applied for this purpose.

2.5.4 Opportunities for Public/Private partnership

The Bureau has successfully utilized contractors for the beneficial reuse of the majority of the yard trimmings collected from City residents. The private contractors have provided excellent service to the City. Recently, the contract cost to the City for management of yard trimmings has dropped due to both the City-operated mulching facilities and the increases in the markets for end use of the material. The Bureau will continue to utilize private contractors for a portion of the yard trimmings collected using the City's competitive bid process and will continue to seek potential facilities to receive, clean, process and ship to end use, and/or receive and mulch or compost the material. The Bureau will continue to beneficially reuse all yard trimmings collected in the Curbside Yard Trimmings Program.

2.5.5 Other Potential Programs

Processed yard trimmings have many applications. The demand for the material is increasing due to its soil enhancing properties. Development of processing operations will provide more material for mulching or composting. Some other potential programs include:

(1) The development of a Recycling and Transfer facility in the central Los Angeles area can provide yard trimmings processing capacity if space is available.

(2) A small-scale project with the City of Culver City provides a lower price for shipping and processing 50 tons per day of the yard trimmings collected in the Western area of the City. This program could be expanded to provide more processing services.

(3) Yard Trimmings may be used to remediate 'brownfields', or areas of vacant land which have been contaminated by petroleum. Studies have indicated that blending yard trimmings into the soil helps release hydrocarbons and possibly remediate the contamination.

(5) The Bureau can pursue the establishment of more composting or vermicomposting facilities to create a compost product with our processed yard trimmings

(4) The Bureau will pursue the marketing of mulch and compost products to help offset the cost of processing yard trimmings.

AR0069573

2.6 Plan Objective No.6 – Material Recovery Facility Development

The Bureau of Sanitation, through the Curbside Recycling Program, collects over 800 tons per day of commingled, source separated recyclables. Through existing contracts, these materials are taken to private contractors to sort, bale and market. Although opportunities exist for residents and businesses to recycle, many are unable to provide source separation because of location, size, or other impediments. To increase the recycling rate in the City, the Bureau believes that the City should promote and support the development of Material Recovery Facilities (MRF) which can accept mixed loads of construction/demolition debris, office and commercial bin waste, and potentially mixed residential waste. The City in October 1993 adopted the goal of 70% diversion Citywide by 2020. This goal has received continued support from the Mayor and City Council.

Inert landfills accept only rocks, dirt, etc., not organic materials such as wood and paper. Any 'mixed loads' which contain some organic material, are disposed at the same landfills used by the City for residential waste (Class III). By pre sorting this material, it reduces the amount sent to the Class III landfills and can preserve space for more appropriate materials. From commercial and industrial customers, a mixed waste MRF can recover mixed paper, cardboard, metals, and other easily marketed materials. Sorting waste from residences such as those in apartment complexes with a large trash bin can increase the recovery of glass, plastics and all types of paper.

A series of pilot programs are being implemented by the Bureau to study additional potential recovery using mixed waste processing. This information, along with the comprehensive waste characterization study now underway, will allow the Bureau to target specific mixed wastestreams and types of MRF's which will be the most cost-effective in diverting material from disposal. Funding for the development of MRF's accesible to both the public and private sector could be made available through both private and public sources. A portion of the money collected from a hauler permitting system could be directed towards such development.

Facility in Oxnard, California

AR0069574

2.7 Plan Objective No.7 - Upgrade Collection Yard Facilities to meet health and safety standards

Our fleet of collection vehicles are parked and maintained at a total of six collection yards located throughout the City. North Central, South Central, Harbor, East Valley, West Valley, and Western. The collection yards have all been used continually for up to 40 years, with only minor repair and maintenance done to the facilities. Repaving of the parking areas to collect and treat stormwater runoff and prevent petroleum from reaching the storm drains is one of several major improvements needed at these yards. Also, the need for modern facilities and clean vehicles is a Bureau priority.

To create a better working environment for our staff and reduce environmental impacts, the Bureau should undertake a series of small capital improvements at the Sanitation collection yards to refurbish and provide more modern facilities

Below are listed the types of upgrades and repairs needed in the short term at the Solid Resources Collection yards:

General Improvements

Stormwater Management improvements will decrease the amount of contamination reaching the storm drain system and, ultimately, the Pacific Ocean. Stormwater improvements will be made to all yards including, canopy covers over fuel dispensing areas, clarifiers to treat oily-water run-off and drainage improvements such as regrading and repaving to facilitate collection of run-off

Improved truck wash facilities will be installed at all yards including structural modifications to the existing facility at Western, West Valley and Harbor yards and asbestos abatement at West Valley and Harbor yards. A new truck wash structure will be constructed at the North Central yard. Truck wash improvements at the South Central yard are in process.

Specific Improvements by Collection yard are as follows:

AR0069575

Yard Specific Improvements needed at Solid Resources Collection Yards

West Valley
Repair Facility: Construct additional repair bays and enclosed parts storage area.
Truck Parking Area: Replace existing deteriorated asphalt pavement with concrete surface.

South Central Satellite Yard
Reconstruction/evaluation after completion of Alameda Corridor project

Harbor
Reconstruct substandard yard facilities to improve operational efficiency
Replace repair facilities which are inadequate for current needs

Harbor Yard Example:
Automated Collection Vehicles do not fit into maintenance bays

Western Yard Example - Trucks and cars share parking space

North Central
Reconstruct existing Street Services transfer station to add operational capacity for curbside collected material

Western
Provide additional employee parking either by acquiring additional property or construction of a parking structure.

East Valley
Relocation and reconstruction in progress (See 2.2)

Western Satellite Yard
Redevelopment for use as a Recycling and/or Transfer Center (See 2.3)

AR0069576

2.7.1 Alternative Fueling for City Collection Vehicles

In June 2000, the South Coast Air Quality Management District voted to impose new regulations on all refuse collection fleets of 15 or more vehicles. These regulations require the City to begin purchasing either dual-fuel or alternative fuel collection vehicles beginning in 2001 to reduce diesel pollutants in Los Angeles. The Bureau of Sanitation has 18 months to prepare their collection yards to receive the first deliveries of new dual-fuel vehicles arriving in December 2001. In addition a recently adopted Council motion requires all diesel powered City over-the- road vehicles over a two year period be retrofitted with particulate exhaust traps and use low sulfur diesel.

Specialized infrastructure must be installed to fuel these vehicles with one of the alternative fuel compounds allowed by the California Air Resources Board. Also, these types of fuel require specialized safety equipment and modifications to the maintenance facilities to repair and maintain these trucks. The estimated cost per collection yard for the new fueling infrastructure is $1.7 million per facility, and maintenance facility improvements are estimated to reach $1 million per collection yard.

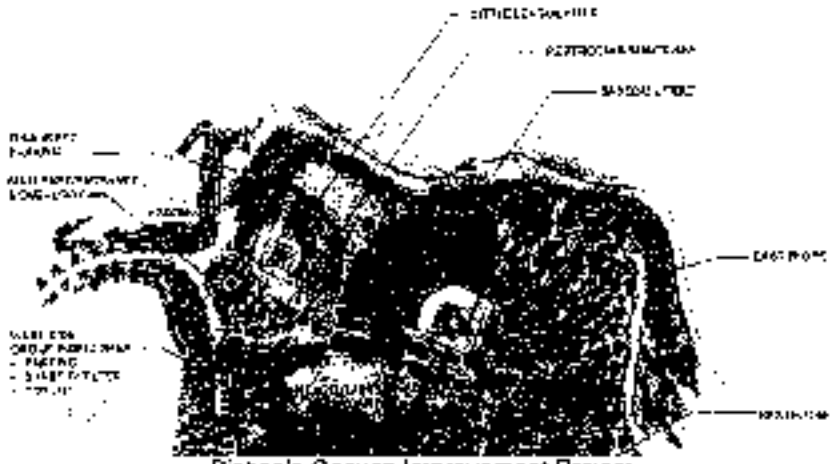
The preliminary plan will entail ordering 400 new dual-fuel collection vehicles over the next two fiscal years and modifying two of our existing collection yards for these vehicles. Also, the new collection facility to be constructed in Sun Valley has been designed to accommodate dual-fuel vehicles and is expected to be in use at the end of 2002 (Objective No.3).

The Bureau is procuring the services of a consultant to evaluate the needs for each facility and the feasibility of installing and using alternative fuels. At the same time, we will be testing several dual-fuel collection vehicles to make sure that they can be used to collect materials at curbside in Los Angeles. These additional costs will be included in the financing plan developed for all Solid Resources capital needs (see Objective No.9).

AR0069577

2.8 Plan Objective No.8 - Closure of Inactive City Owned Landfills

The City of Los Angeles owns and maintains six inactive landfill sites. In accordance with State regulations, all landfills that ceased accepting refuse after November 1984 are required to completed final closure in compliance with prescribed minimum standards. The minimum standards for closure include a multiple layer final cover typically consisting of a foundation soil layer, a low permeable layer, with a vegetative soil layer on top. The regulations allow an alternative final cover design if it is shown to be equivalent or superior to the prescribed final cover.



Bishop's Canyon Improvement Project

2.8.1 Lopez Canyon and Toyon Canyon

Since both the Lopez Canyon and Toyon Canyon Landfills ceased accepting refuse after November 1984, they must be formally closed in compliance with State regulations. Each of these landfills is currently undergoing closure construction. The Bureau has received Regional Water Quality Control Board (RWQCB) approval to use an alternative engineered cover system known as a monolithic or single layer system at both the Lopez Canyon and Toyon Canyon landfills. The monolithic system will perform better, and cost less to construct and maintain as compared to the prescriptive cover system. It will also be easier and quicker to construct, thus reducing the closure time line. Lopez Canyon and Toyon Canyon closure construction are expected to be completed by mid 2002.

2.8.2 Four Other Landfills

The City also owns and maintains four other inactive landfills: Bishops Canyon, Branford, Gaffey Street, and Sheldon-Arleta. These landfills ceased accepting refuse prior to November 1984 and are not subject to current closure regulations. However, the RWQCB has advised the Bureau that these landfills are still required to formally close in compliance with the requirements stipulated in each facility's Waste Discharge Requirements (WDRs) issued by the RWQCB. It is also be prudent for the City to formally close these landfills to minimize any liabilities the City may have for owning unofficially closed landfills. In order to formally rescind the WDRs and officially close each landfill, the City must show the RWQCB that the landfill does not impact the local groundwater by a Solid Waste Assessment Test (SWAT), and that it satisfies the requirements for soil cover and drainage. The City must also satisfy health and safety concerns of the CIWMB and the Local Enforcement Agency (LEA).

AR0069578

Phase I of the Bishops Canyon Site Improvements Project was completed in mid 1997, with the installation of recreational baseball fields on the north edge of the site and surface drainage improvements on the front face. Phase II of the project will include additional park facilities, landscaping and irrigation. Plans for Phase II were finalized, with construction anticipated to begin in the spring of 2000 and to be completed by January 2001. An estimated total of $2,500,000 is needed to complete the Phase II construction. Bond funds of $600,000 are available for Bishops Canyon Landfill Closure. The Bureau received a grant of $1,900,000 from the Los Angeles County Park and Open Space District, as one of the projects approved in the 1996 Proposition A, Safe Neighborhood Parks.

Since the SWAT indicates no impact to the groundwater, the Bureau will, at the completion of the Phase II project, request the RWQCB to officially rescind the WDR for Bishops Canyon. The Bureau will also identify for the CIWMB and LEA the actions addressing any potential health and safety concerns. No additional closure work is anticipated in order for the regulatory agencies to acknowledge the official closure of the Bishops Canyon Landfill.

For the Gaffey Street Landfill, closure plans were prepared and submitted to the RWQCB and the Local Enforcement Agency. In February 1999, the office of Councilman Rudy Svorinich requested the Bureau to investigate the possibility of reclaiming the landfill site into an active recreational facility. The Bureau performed a technical evaluation and found it to be feasible for park development.

Lopez Canyon - Monofill Construction
Toyon Canyon will receive similar closure
Estimated completion date 2002

AR0069579

Currently, the Caffey Landfill is undergoing closure construction in accordance with detailed closure plans that provide for the following mitigation and improvements:

(1) A final cover with a minimum thickness of six feet over the entire landfill boundary.
(2) A subdrain system to prevent the percolation of the rain and irrigation water into the system.
(3) Drainage collection system for controlling surface runoff and minimizing erosion.
(4) Installation of a gas migration control system.
(5) Reclamation of the landfill into an active recreational facility known as the "Field of Dreams Athletic Complex"

At the conclusion of the closure construction, scheduled for completion in late 2000, the Bureau will turn over the 15-acre site to the Department of Recreation and Parks for development. The estimated cost for closure is $708,000. Bond funds are available for the closure construction materials

Closure plans for the Branford Landfill were prepared and submitted to the LEA & RWQCB. The SWAT indicates no impacts on the groundwater, however, there is the need for proper drainage of the site. The Bureau is in the process of purchasing a different site for the relocation of the existing adjacent East Valley Yard. Once this relocation is complete, the drainage at the Branford site can be improved to formally close the landfill Closure construction cost is estimated at $875,000, and could begin in FY 2001-02. The Mayor's Office of Economic Development is also in the process of negotiating with a private developer to purchase the landfill site and the current East Valley Collection yard site for development into an industrial complex

Since the SWAT for the Sheldon-Arleta Landfill is outdated, the Bureau has prepared the closure plans to include additional groundwater sampling and analysis. This sampling should be completed by January 2001. If the results are satisfactory, an official request can then be submitted to the RWQCB to rescind the WDR. Closure construction is necessary to correct some drainage problems and gas migration areas. This construction cost is estimated at $1,000,000, and could begin in FY 2002-03.

AR0069580

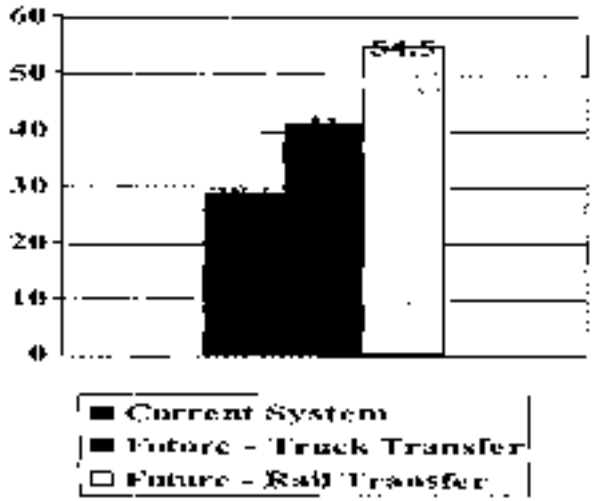
2.9 Plan Objective No. 9 - Disposal Options

The Bureau currently disposes about 3,300 tons per day of refuse in two landfill sites, down from 5,500 tons per day in 1990 as discussed below

The Bradley Landfil, owned and operated by Waste Management, Inc. (WMX), receives approximately 2,200 tons per day of refuse under a contract with the City which expires July 1, 2001

The Sunshine Canyon Landfill owned and operated by Browning Ferris Industries (BFI), receives approximately 1,100 tons per day of refuse under a contract which expires in February, 2004.

The South East Resources Recovery Facility in Long Beach, through a pilot program, receives about 100 tons per day of the refuse collected in the Harbor area. This pilot has a potential tip fee savings over $160,000 per year.



TIP FEE ESTIMATES PER OPTION
(in Million $ per year)

The future availability of close-in refuse disposal facilities can affect the timing of development of a transfer facility in the San Fernando Valley

The Bradley Landfill does not have a closure date, but will close when it reaches a final elevation and capacity This may allow the facility to remain open past mid-2001 for 1-2 more years, thus delaying the need for a transfer facility at this time;

The Sunshine Canyon Landfill has received a General Plan amendment and zone change to expand their disposal facility into the City of Los Angeles. This will allow landfilling to take place at a higher rate for a longer period than the previous landfill site in the County of Los Angeles

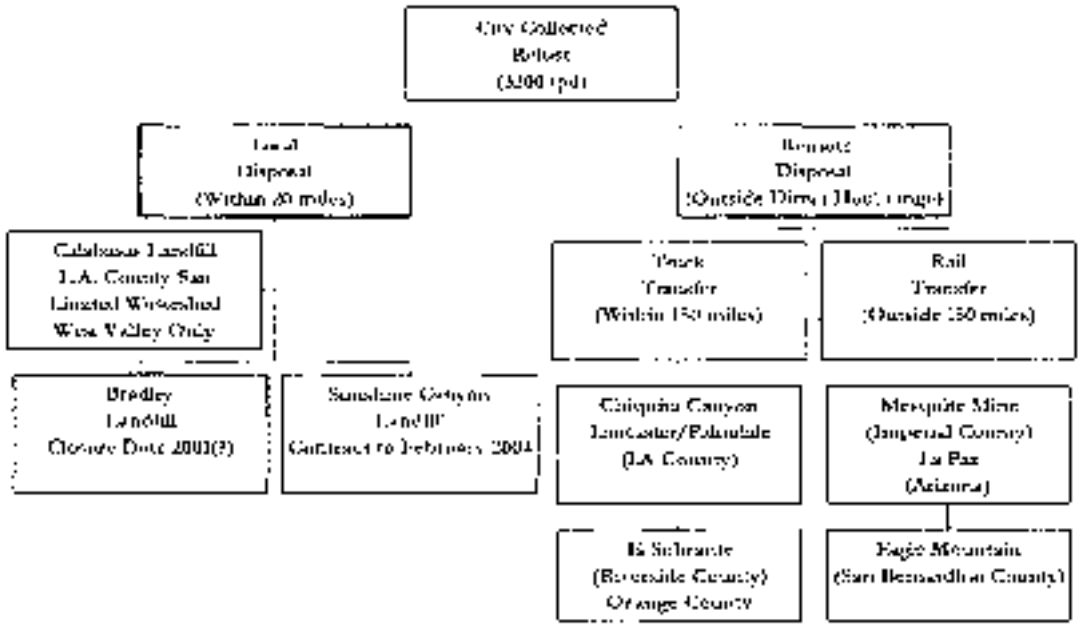
The Bureau must acquire additional disposal capacity for approximately 2,300 tons per day of refuse before 2001, and another 1,000 tons per day by 2004. Disposal capacity in the region is affected both by permit restrictions and the difficulty in siting new facilities Permitting of new disposal facilities can take 15 years, with no guarantee of success.

After the Bradley Landfill is closed for refuse disposal, and if Sunshine Canyon is not available to the City after the current contract expires, the Bureau will be faced with higher transportation costs to transfer refuse to more distant disposal facilities As an example, the Chiquita Canyon landfill will have available capacity, but is 19 miles further from the Central L.A. facility than the Bradley Landfill, thus increasing transportation costs Other facilities such as El Sobrante Landfil in Riverside, Lancaster Landfill in the Antelope Valley, and Bowerman Landfill in south Orange County could have available disposal capacity but it will cost considerably more because the average distance from the central Los Angeles area to these more remote located landfills is 60-70 miles (one way).

AR0069581

A contract amendment to extend the current refuse disposal contract for the Sunshine Canyon Landfill will extend local disposal in five year increments at the City's sole option until 2021.

To prepare for long-term disposal capacity after local capacity is exhausted, the Bureau has recommended a Joint Powers Agreement with the Los Angeles County Sanitation Districts (County San) to develop a transfer station in the central Los Angeles area that will allow Los Angeles access to desert rail-haul disposal facilities (Objective #1). County San announced in August 2000 that it had acquired both the fully permitted Mesquite Mine and almost permitted Eagle Mountain landfills. This acquisition gives the agency control over long term rail disposal options for the Southern California area well into this century



County San may begin in the next fiscal year to levelize the tip fees it charges to users of its disposal options to begin to create a resource to fund future cost increases associated with rail haul. County San may add several dollars per ton for disposal at the Puente Hills landfill to create this resource fund that will make the transition from the current $18 per ton disposal fee at Puente Hills to the $55 or more per ton for rail haul disposal more gradual. The agency expects to have rail disposal fully operational by 2013. The agency will continue to build and/or acquire rail-compatible transfer facilities to serve all Los Angeles County haulers, including those within the City of Los Angeles

The City should also consider establishing a sinking fund to set aside monies now to pay for the significant cost impact of rail haul in the future.

AR0069582

2.10 Plan Objective No.10 - Develop a Financing Strategy with the assistance of the Office of Administrative and Research Services (OARS) for the Solid Resources Capital Improvement Program

Prior to 1983 the City has historically provided the bulk of the funding for its Solid Resources program activites through the General Fund. In 1983 the Sanitation Equipment Charge (SEC), a fee used for the purchase and maintenance of collection/disposal vehicles/equipment was adopted. The SEC rate is currently $6 per single family residence and $4 per multi-family unit per month.

The funds generated by the SEC are limited in use for the following purposes:

1. Purchase of collection and disposal vehicles (including alternative fuel trucks), other equipment, and collection containers;
2. Maintenance of these vehicles, equipment and collection containers;
3. Purchase of real property to park and maintain the vehicles, equipment and collection containers, and
4. Landfill improvements and closure construction

The Solid Resources Program Objectives identified in this Plan could require funds of over $200 million over the next 7 to 10 years. It is unlikely that the Sanitation Equipment Charge can provide this level of funding needed to provide the Solid Resources Management infrastructure needed for the future. Because of these realities, the Bureau believes that the funding for these infrastructure needs be generated through a combination of debt financing using the SEC, an increase in the SEC and possible reallocation of existing SEC revenues from related costs to infrastructure needs as the mechanisms to finance the proposed infrastructure improvements and facilities development. Other sources of funds may include grants, loan programs, and federal appropriations

The Bureau recommends with the assistance of the Office of Administrative and Research Services, the development of a comprehensive financing plan that over the next 7 to 10 years can accommodate the proposed capital improvements. The great majority of the proposed solid resources infrastructure projects will have 20+ years of useful life and as such any debt payments of the principle and interest can be spread over the life of the facilities, thus minimizing yearly debt payments. The amount of debt that the current SEC revenues can support are not sufficient to finance the projects identified in this Plan.

AR0069583

2.11 Plan Objective No. 11 - Solid Waste Citizens Advisory Group (SWCAG)

The City has in the past utilized the Solid Waste Citizen's Advisory Group (SWCAG) formed by the City Council with representatives from each Council district as a forum for the presentation of information concerning the City's Solid Resources Management Program. This group has been consulted many times in the past and has provided comments on many solid resources issues. The Bureau believes that a public review panel should exist in some form for the presentation and review of Citywide solid resources issues. This panel could be a group similar to the SWCAG or could be incorporated with the community input process resulting from the City Charter reform.

AR0069584

2.12 Plan Objective No.12 - Public Education/Community Outreach

The Solid Resources Public Outreach program began in 1990 with the implementation of the automated collection system. At that time seven City staff members handled outreach with a budget of $3.5 million. Over time the public education staff within the Bureau were absorbed into the Department of Public Works, but several public information functions have remained with Bureau staff.

Outreach programs in the Bureau include those administered by the Solid Resources Citywide Recycling Division, as follows: the Used Oil Collection Program, the Household Hazardous Waste mobile collection program, Business and Technical outreach for AB939 mandated diversion goals, home Composting workshops, seasonal programs such as grasscycling, clean your files, etc., and program-specific information which has been developed for each of these programs. Other current Solid Resources education and outreach programs of the Solid Resource Collection Division include the Service Request Line which can be accessed by any resident, information programs such as the development of a new comprehensive service brochure mailed to all 720,000 residential customers and informational signs on all City solid resources collection vehicles. The City's various webpages describe programs, services, and information. Outreach to schools and community groups are currently limited to request only, based on the total educational budget of $500,000 for printing and contractual services.

The Bureau will investigate other successful programs within the City and seek partnering opportunities with other similar programs. Integration of environmental protection messages will help maximize their impact and can potentially reduce the overall cost of programs.

The Bureau can reach more residents with an expansion of existing programs. Additional staff is needed to provide hands on technical assistance to private sector generators to help increase diversion. The Bureau would like to increase the schools program to reach all schools in the City, and provide information on other City environmental programs as well. Another asset would be the development of a Speaker's Bureau, including collection truck operators, to participate in community meetings. A team is needed to provide one-on-one interaction with City residents to reduce contamination and increase diversion through the Blue Container recycling program.

A comprehensive report is being prepared for the potential implementation of a private hauler fee which could finance the above programs. The Bureau will present this report intended to increase our ability to reach residents with the specific information they need to make our environmental programs a success.

AR0069585

DUE DILIGENCE REPORT
For the Capitol Records Tower
1750 N. Vine Street
Hollywood, Ca.
January 24, 1994

DUE DILIGENCE REPORT

CAPITOL RECORDS TOWER
1750 N. Vine St.
Hollywood, CA.

FOR

CAPITOL RECORDS INC.
1750 N. Vine St.
Hollywood, CA.
ATTN: Mr. Charles Goldstuck

BY

DON PROHASKA & ASSOCIATES

January 24, 1994

AR0069595

APPENDIX 1

The appendix contains copies of all permits, variances and other documents on file with the Los Angeles Department of Building and Safety. The original core & shell building permit could not be located and therefore was not on file. The approved soils report was on file. There are two documents which should be given attention.

1) A 1988 zoning memorandum which requires all properties listed to obtain written clearance from the Cultural Heritage Commission for any applications to obtain a building permit or perform any demolition. 1750 N. Vine Street is listed.

2) An unapproved request for a 2 year extension to provide elevator lobby vestibules. Such extension expired on December 20, 1993. Another extension should be applied for to avoid an Order to Comply from the Fire Safety Division.

BUILDING PROFILE

1. ARCHITECTURAL FINISHES:
   a. Exterior: Painted concrete, glass in aluminum frames and porcelain-enameled metal louvers.
   b. Interior:
      1. Lobby: Marble walls and floor, painted plaster ceiling.
      2. Typical floor: Plaster on concrete, gypsum board, carpet and acoustic ceiling tile

2. BUILDING DATA:
   a. Floor-to-floor Height:
      1. Ground Floor: Varies from 16'-6" to 22'-0"
      2. Typical tower floor: 10'-9".

   b. Floor-to-ceiling Height:
      1. Ground floor: Varies 14'-6" (lobby) to 26'-0" (Studio A&B).
      2. Typical tower floor: 9'-0".

   c. Window Height:
      1. Floor-to-sill: 2'-11"
      2. Window height: 5'-0"
      3. Window head to ceiling: 2'-1"

   d. Perimeter Window Module: 3'-6" on center.

   e. Perimeter Column Module: 22'-11" on center

3. ROOFING:
   a. Type: Asphaltic built-up membrane (installed 1984) at T-2 and Penthouse levels.
   b. Condition: Fair

FINDINGS:
Exterior finishes are in good condition. No rust is evident on the porcelain-enameled metal louvers. Painted concrete walls have no significant cracks or spalling. Aluminum windows have some corrosion which can be easily cleaned.

The roofs have considerable ponding due to inadequate slope to drains. This will lead to premature failure of the membrane. The 10 year joint and several guarantee of the roof by the manufacturer expires in 1994. At time of next re-roof, consider providing sloped insulation and additional drains to eliminate ponding and prolong roof life.

AR0069597

BUILDING STATISTICS

1. GROSS LOT AREA: 43,460 SF
   FAR: 2.12:1

2. BUILDING AREAS:
   a. Gross Area: 92,246 SF / 86,617 RSF
      (reverb chambers below grade not included)

   b. Typical Floor Area:
      T2: 4,915 GSF / 4,415 RSF
      T3-T8: 6,030 GSF / 6,030 RSF
      P2: 1,697 GSF

   c. Ground Floor Area: 15,006 GSF / 14,076 RSF
      Studios A & B: 5,535 GSF
      Studio C: 1,880 GSF

3. BUILDING DATA:
   a. Number of floors:
      The building contains 12 floors of offices (T2-T8) in the tower above a ground floor base structure containing recording studios and support areas, lobby, mailroom and physical plant. A mechanical penthouse is located on the roof. There are 8 subterranean reverberation chambers under the parking lot connected by a corridor. Each chamber is approximately 336 SF.

   b. Parking Spaces: 374 Total (4.3/1000 RSF)
      On-site: 97 spaces
      Off-site: 277 spaces

4. DESIGN CONSULTANTS
   a. Architect:
      Base Building: Welton Becket
      Space Planner: Tichenor & Thorp/Others

   b. Structural Engineer
      Base Building: Murray Erick Associates

   c. Mechanical/Electrical/Plumbing
      Base Building: Welton Becket

5. YEAR COMPLETED: 1956

AR0069598

ELECTRICAL PROFILE

1. SERVICE ENTRANCE:
   Electrical service is provided by the Department of Water and Power through transformers located under the parking lot near the Yucca St. entrance. Service entrance is underground at northeast corner of ground floor.

2. SERVICE CAPACITY:
   a. 1 - 800 A, 480Y 3P, 3 wire. Main switchboard servicing the physical plant and some equip. in Studio A.
   b. 5 - 800 A, 120/240V 1P, 3 wire. Main switchboards providing lighting and power for offices and studios. Wattage per square foot (demand) distributed in risers equals approximately 5.4 w/sf. 2.4 w/sf lighting and 3 w/sf convenience power.

3. DISTRIBUTION:
   a. Floor duct system (flrs. 2-8 only): 3 concentric rings of floor duct with outlet inserts 24" o.c. Top of duct 2-7/8" below top of slab.
   b. Conduit: All conductors are in rigid steel conduit, EMT or flexible armored cable.
   c. Conductors: All wire sizes No. 8 AWG or smaller is type TH (heat-resistant thermoplastic insulation). All wire sizes No. 6 AWG or larger is type RHW (heat and moisture-resistant rubber insulated).

5. EMERGENCY POWER:
   a. Capacity: 150 kw, 3P.
   b. Fuel: 100 gallons (diesel)
   c. Cummins driver/Onan generator.

FINDINGS:
The convenience power capacity as calculated in watts/sf is not ample by present standards (5.4 watts/sf). Expansion of the building which adds electrical equipment or demand on the power system may require adding additional capacity. However, it may be that with diversity, that actual power usage is much less than the connected load and service switch capacity. Consider taking measured readings from the service panels to determine actual usage.

AR0069599

ELEVATOR PROFILE

1. ELEVATORS:
   a. Mfgr. / Type: Otis / gearless passenger
   b. Number / Capacity: 3 / 2500 lb.
   c. Speed: 500 feet per minute
   d. Dedicated freight elevator: None
   e. Control System: Otis Autotronic original group supervisory control system utilizing six basic traffic programs:
      1. Up Peak
      2. Two-Way - Balanced
      3. Two-Way - Heavier Down
      4. Two Way - Heavier Up
      5. Down Peak
      6. Light and Intermittent
   f. Platform Dimensions: 5' x 7'
   g. Entrance Size: 3'-6" wide x 7'-0" high
   h. Freemans' Service: Phase I & Phase II
   i. Alternate Floor Recall: No
   j. Disabled Access Compliance: Poor
   k. Floors Served: All

NOTE: **See attached Elevator Report by Lerch, Bates & Associates dated April 23, 1993.**

2. DUMBWAITER
   a. Mfgr / Type: Otis / geared
   b. Number / Capacity: 1 / 300 lb.
   c. Speed: 100 feet per minute
   d. Floors Served: All

3. DOCK LIFT:
   a. Mfgr / Type: Unknown/ hydraulic
   b. Size / Capacity: 6' x 6' / 6,000 lb.
   c. Speed / Travel: 7 feet per minute / 4 feet

FINDINGS:
The Lerch Bates report recommends a modernization program to upgrade the system dispatch controls, motor controls, motor generators, door operation components and cab finishes. This office concurs with their recommendations. Much of the existing elevator system components have reached the end of their useful lives and will require higher and costlier levels of maintenance and repair to keep operating.

Title 24/ADA requirements for disabled access are mandated by state law and are required in order to obtain building permits for remodeling. These are considerably more limited and less costly to provide than a modernization program. Consider doing this required work during the modernization of such a program is undertaken. Otherwise, the existing equipment can be retrofitted to comply.

ENVIRONMENTAL PROFILE

1. ASBESTOS CONTAINING MATERIALS:
   ACM was detected in piping insulation in various locations and spray-on acoustic ceiling of the ground floor lobby. **See attached report by CTL Environmental Services dated January 29, 1992.**

2. UNDERGROUND FUEL TANK:
   None known to exist.

3. OTHER:
   Some older fluorescent light fixture ballasts may contain PCB's. These fixtures are being replaced over time.

FINDINGS:
It does not appear that hazardous materials such as asbestos will be encountered during the remodeling program contemplated.

MECHANICAL PROFILE

1. STANDARD HOURS OF OPERATION:
   6:30 am to 1 am Weekdays

2. DESIGN CONDITIONS:
   a. Cooling
      1. Inside: 72° DB / 50% RH
      2. Outside: 90° DB / 70° WB
   b. Heating:
      1. Inside: 70°
      2. Outside: 35°

3. HEATING/COOLING SYSTEM:
   a. 3-3 - 7FGround floor
      Generic Type: 4 - pipe air and water using compressive refrigeration.
      A central plant produces chilled and heated water which are pumped to fan coils of both central and individual air handlers. Central air handlers are double-duct type and serve the interior zones and ground floor. Individual units at the periphery are single-duct type and serve perimeter zones in the Tower.

   b. Studios/T-2 Editing rooms
      Generic type: Direct refrigerant package units. Studio units are single package type and are located on the 1st floor roof. Editing room units are split system type with the fan coils in the perimeter soffit and the compressors located outside on the 1st floor roof.

   c. Refrigeration Plant
      1. Number of machines and tonnage:
         1 - 160 ton chiller (installed 1978)
         1 - 40 ton chiller (installed 1990)
         (chilled and condensing water circulated by 2 Worthington centrifugal pumps (10 hp) each. Pumps were installed in 1988.
         Type: reciprocating
         Manufacturer: Carrier
         Cooling Tower: Baltimore Air Coil, 200 ton capacity (installed 1982).
         Automatic Controls: Johnson Controls pneumatic temperature control system.
      2. Package units
         Studio A: 1 - Trane 6 ton unit (installed 1991) for performance area
                   1 - Trane 5 ton unit (installed 1991) for control room.
                   1 - Trane 3 ton unit (installed 1991) for lounge area/electrical room.
         Studio B: 1 - Carrier 5 ton unit (installed 1985) in performance area only. Control room on central system.
         Studio C: 1 - Carrier 5 ton unit (installed 1981) for performance area and control room.

   d. Heating Plant
      2 - 1,250,000 BTU gas fired boilers with 2 circulating pumps by Chicago Pump
      Manufacturer: Aerco
      Efficiency: 80%

   e. Air Handling Equipment
      1. Number and location of central fan coils and served areas:
         1 - 13,955 CFM unit at ground floor. Serving ground floor areas including Studio B performing area (all other studio areas on package units).

AR0069602

1 - 6,030 CFM unit at ground floor. Serving interior zones of floors T2-T6.
1 - 10,265 CFM unit at penthouse. Serving interior zones of floors T7-TE.
Manufacturer/Model: Westinghouse/AHZ

2. Individual fan-coil units at periphery vary in size from 350 CFM to 880 CFM. Units (zones) per floor vary from 6 to 11 depending on office layout.
Manufacturer/Model: Wat International. Units on floors T-9 (1992) and TE (1990) were replaced by MagicAire units in 1993.

3. Exhaust fans
Location/size and served areas:

E-1 Ground floor	780 CFM	Gr. flr. areas on north side
E-2 Ground floor	12,950 CFM	Gr. flr. recirculation
E-3 Penthouse	13,400 CFM	Tower toilets
E-4 Penthouse	250 CFM	Kitchen on TE
E-5 Penthouse	2,500 CFM	Elevator room
E-6 Ground floor	1,060 CFM	Reverberation chambers
E-7 Ground floor	280 CFM	Record. studio toilets

4. PLUMBING SYSTEM
   a. Domestic water system: Cold water riser to 2500 gallon pressure storage tank on roof. Hot water riser pumped from 2 - 100 gallon (4 years old) hot water heaters on T-1 to TE. Individual hot and cold supply drops feed men's and women's restroom fixtures. 4 floor shut off valves on T-9 and T-12 only. All water supply distribution piping was originally installed as Schedule 40 galvanized steel pipe with threaded joints. The hot water riser and drops have been replaced with copper piping. The old piping was abandoned and the janitorial sinks on each floor removed.

   b. Hydronic / Condenser water loops: There are 6 hot / chilled water supply and return risers at the tower perimeter. The condenser riser runs one story to the new cooling tower on the roof of T-1. The original installation located the cooling tower on the Penthouse level and condenser riser piping was located in stairwell #2. Hydronic loop piping is Schedule 40 black steel pipe.

FINDINGS:

HVAC:

The system is generally in good condition. The refrigeration plant and some fan coil unit in the tower are relatively new. The balance of the system is nearly 40 years old and reaching the end of its useful life. The double duct system provides superior comfort control to VAV and is still considered to be the "Cadillac" system. Where system upgrading should be considered is in the automatic controls. The existing system does not allow the plant to be as efficient or as flexible as it could be. The condition of the controls particularly at the penthouse fan coil unit is fair to poor.

Plumbing:

The cold water distribution piping and hydronic loop piping has chronic leaking problems due to the age of the steel piping. Consider replacing this piping with new copper piping and providing floor shut-off valves at the hot and cold water drops.

STRUCTURAL PROFILE

1. GENERIC TYPE: Reinforced Concrete
The round Tower is constructed as a reinforced concrete frame. The floor slabs, perimeter columns and spandrels are of 3000 psi, poured-in-place concrete. The first floor rectangular "base" structure is composed of two systems: 1) the round tower structure flanked by (2), a rectangular steel frame and concrete structure for the studios and mechanical/support areas.

The Tower floor slabs are cantilevered from 8 1/4" at the center to 8" at the column line and 7 1/2" at the perimeter slab edge.

2. DESIGN LIVE LOADS
   a. Tower floors: 50 PSF.
   b. Ground floor roof areas: 20 PSF

3. CONTROL DIMENSIONS
   a. Slab-to-slab height
      Tower: 10'-9"
      Ground floor: varies between 16'-6"(north side) and 22'-0"(south side)
   b. Slab thickness
      Tower: 8"- 8 1/4"
      Ground floor: 6 1/2"
      "L roof": 7 1/2"
   c. Tower floor plate size: 95'-6" diameter (90'-8" enclosed).

4. SEISMIC
   a. Seismic zone: 4
   b. Seismic upgrades: none

FINDINGS:
The building is constructed as two independent structures: the base and the tower. The tower is a very rigid frame designed to resist large lateral forces from wind and earthquake. The base has considerable resistance as well due the shear capacity of long windowless walls. The perimeter spandrel beam system is designed to span continuously from column to column. Any perceptions of this beam to accomodate new traffic patterns on the 2nd floor must compensate for the loss in continuity.

Consider reviewing seismic capability with a structural engineer specializing in such design. As the recent Northridge earthquake has shown, even recently designed buildings have areas of vulnerability which only a disaster will reveal. Further, even if the main building frame is found to be satisfactory, there may be secondary yet important members and connections which need reinforcement. For example, while the tower and base are shown on the drawings to have a separation joint between them, this may not be adequate to prevent the separate structures from 'banging' against one another in a larger or closer earthquake and causing significant damage in the studio areas.

This report is a qualitative evaluation based upon a general review of the architectural and structural drawings. Not calculations or other quantitative analysis was performed. Such analysis should be done by a structural engineer.

AR0069608

Foreword

Groundwater is one of California's greatest natural resources. In an average year, groundwater meets about 30 percent of California's urban and agricultural water demands. In drought years, this percentage increases to more than 40 percent. In 1995, an estimated 12 million Californians, nearly 45 percent of the State's population, were served by groundwater. The demand on groundwater will increase significantly as California's population grows to a projected 46 million by the year 2020. In many basins, our ability to optimally use groundwater is affected by overdraft and water quality impacts, or limited by a lack of data, management, and coordination between agencies.

Over the last few years, California voters and the Legislature have provided significant funding to local agencies for conjunctive use projects, groundwater recharge facilities, groundwater monitoring, and groundwater basin management activities under Proposition 13 and the Local Groundwater Management Assistance Act of 2000. Most recently, the 2002 passage of Propositions 50 will result in additional resources to continue recent progress toward sustaining our groundwater resources through local agency efforts. We are beginning to see significant benefits from these investments.

The State Legislature recognizes the need for groundwater data in making sound local management decisions. In 1969, the Legislature approved funding and directed the Department of Water Resources (DWR) to update the inventory of groundwater basins contained in Bulletin 118 (1975), *California's Ground Water* and Bulletin 118-80 (1980), *Ground Water Basins in California*. In 2001, the Legislature passed AB 599, requiring the State Water Resources Control Board to establish a comprehensive monitoring program to assess groundwater quality in each groundwater basin in the State and to increase coordination among agencies that collect groundwater contamination information. In 2002, the Legislature passed SB 1938, which contains new requirements for local agency groundwater management plans to be eligible for public funds for groundwater projects.

Effective management of groundwater basins is essential because groundwater will play a key role in meeting California's water needs. DWR is committed to assisting local agencies statewide in developing and implementing effective, locally planned and controlled groundwater management programs. DWR is also committed to federal and State interagency efforts and to partnerships with local agencies to coordinate and expand data monitoring activities that will provide necessary information for more effective groundwater management. Coordinated data collection at all levels of government and local planning and management will help to ensure that groundwater continues to serve the needs of Californians.

Acknowledgments

Successful completion of this update and continued implementation of this program would not be possible without the dedicated efforts of the Central, Northern, San Joaquin, and Southern District Offices of the California Department of Water Resources. The information in this report is the result of contributions from many local, state, and federal agencies outside DWR. We would like to acknowledge the contributions of the following agencies.

California Department of Pesticide Regulation
California Department of Toxic Substances Control
California Department of Health Services
California State Water Resources Control Board
California Regional Water Quality Control Boards
United States Geological Survey
United States Bureau of Reclamation

We also wish to thank numerous reviewers who provided valuable comments on the April 2009 public review draft of this [illegible]

AR0069622

Findings

Major Findings

1. **Groundwater provides about 30% of the State's water supply in an average year, yet in many basins the amount of groundwater extracted annually is not accurately known.**
   - In some regions, groundwater provides 60% or more of the supply during dry years.
   - Many small to moderate sized towns and cities are entirely dependent on groundwater for drinking water supplies.
   - 40% to 90% of Californians rely on groundwater for part of their water supply.
   - In many basins, groundwater use is indirectly estimated by assessing crop evapotranspiration demands and surveying the acreage of each crop type.

2. **Opportunities for local agencies to manage their groundwater resources have increased significantly since the passage of Assembly Bill 3030 in 1992. (Water Code § 10750 et seq.). In the past several years more agencies have developed management programs to facilitate conjunctive use, determine the extent of the resource, and protect water quality.**
   - The act provides the authority for many local agencies to manage groundwater.
   - The act has resulted in more than 200 local agencies adopting groundwater management plans to date.
   - The act encourages regional cooperation in basins and allows private water purveyors to participate in groundwater management through memorandums of understanding with public agencies.
   - Many local agencies are recognizing their responsibility and authority to better manage groundwater resources.

3. **Agencies in some areas have not yet developed groundwater management plans.**
   - Concerns about cooperative management, governance, and potential liabilities have kept some agencies from developing management plans.
   - Development of management programs to the basin's sustainable groundwater supply for local use has not been accomplished throughout the State.

4. **A comprehensive assessment of overdraft in the State's groundwater basins has not been conducted since Bulletin 118-80, but it is estimated that overdraft is between 1 million and 2 million acre-feet annually.**
   - Historical overdraft in many basins is evident in hydrographs that show a steady decline in groundwater over a number of years.
   - Other basins may be subject to overdraft in the future if current water management practices are continued.
   - Overdraft can result in increased water production costs, land subsidence, water quality impairment, and environmental degradation.
   - Few basins have detailed water budgets by which to estimate overdraft.
   - While the most extensively developed basins tend to have information, many basins have insufficient data for effective management or the data have not been evaluated.
   - The extent and impacts of overdraft must be fully evaluated to determine whether groundwater will provide a sustainable water supply.
   - Modern computer hardware and software enable rapid manipulation of data to develop and test conditions such as groundwater storage changes or groundwater extraction, but a lack of essential data limits the ability to make such calculations.
   - Adequate statewide land use data for making groundwater extraction estimates are not available in electronic format.

AR0069624

5. Surface water and groundwater are connected and can be effectively managed as integrated resources
   - Groundwater originates as surface water.
   - Groundwater extraction can affect flow in streams.
   - Changes in surface water flow can affect groundwater levels.
   - Legal systems for surface water and groundwater rights can make coordinated management complex.

6. Groundwater quality and groundwater quantity are interdependent and are increasingly being considered in an integrated manner.
   - Groundwater quantity and groundwater quality are inseparable.
   - Groundwater in some aquifers may not be usable because of contamination with chemicals either from natural or human sources.
   - Unmanaged groundwater extraction may cause migration of poor quality water.
   - Monitoring and evaluating groundwater quality provides managers with the necessary data to make sound decisions regarding storage of water in the groundwater basin.
   - State agencies conduct several legislatively mandated programs to monitor different aspects of groundwater quality.
   - California Department of Water Resources (DWR) monitors general groundwater quality in many basins throughout the State for regional evaluation.

7. Land use decisions affecting recharge areas can reduce the amount of groundwater in storage and degrade the quality of that groundwater.
   - In many basins, little is known about the location of recharge areas and their effectiveness.
   - Protection and preservation of recharge areas are seldom considered in land use decisions.
   - If recharge areas are altered by paving, channelizing, or other land use changes, available groundwater will be reduced.
   - Potentially contaminating activities can degrade the quality of groundwater and require well-head treatment or aquifer remediation before use.
   - There is no coordinated effort to inform the public that recharge areas should be protected against contamination and preserved so that they function effectively.

Additional Important Findings

8. Funding to assist local groundwater management has recently been available in unprecedented amounts.
   - Proposition 13 (Water Code § 79000 et seq.) authorized $230 million in loans and grants for local groundwater programs and projects, almost all of which has been allocated.
   - The Local Groundwater Management Assistance Act of 2000 (Water Code § 10795) has resulted in more than $15 million in grants to local agencies in fiscal years 2001, 2002, and 2003.
   - Proposition 50 (Water Code, § 79500 et seq.) will provide funding for many aspects of water management, including groundwater management and groundwater recharge projects.
   - Funding for the California Bay-Delta program has provided technical and facilitation assistance to numerous local groundwater planning efforts.

AR0069625

9. **Local governments are increasingly involved in groundwater management.**
   - Twenty-four of the 27 existing county groundwater management ordinances have been adopted since 1990.
   - Most ordinances require the proponents of groundwater export to demonstrate that a proposed export will not cause subsidence, degrade groundwater quality, or deplete the water supply before the county will issue an export permit.
   - While the ordinances generally require a permit for export of groundwater, most do not require a comprehensive groundwater management plan designed to ensure a sustainable water resource for local use.
   - Some local governments are coordinating closely with local water agencies that have adopted groundwater management plans.
   - Many local governments are monitoring and conducting studies in an effort to better understand groundwater resources.

10. **Despite the increased groundwater management opportunities and activities, the extent of local efforts is not well known.**
    - There is no general requirement that groundwater management plans be submitted to DWR, so the number of adopted plans and status of groundwater management throughout the State are not currently known.
    - There are no requirements for evaluating the effectiveness of adopted plans other than during grant proposal review.
    - No agency is responsible for tracking implementation of adopted plans.
    - Unlike urban water management plans, groundwater management plans are not required to be submitted to DWR, making such information unavailable for updating the California Water Plan.

11. **Despite the fact that several agencies often overlie each groundwater basin, there are few mechanisms in place to support and encourage agencies to manage the basin cooperatively.**
    - Some local agencies have recognized the benefits of integrating basin-wide and regional planning for groundwater management and have recorded many successes.
    - Regional cooperation and coordination depends on the ability of local agencies to form such efforts.
    - There is no specific State or federal program to fund and support coordination efforts that would benefit multiple water users in a region and statewide.

12. **The State Legislature has recognized the need to consider water supplies as part of the local land use planning process.**
    - Three bills—Senate Bill 221[1], SB 610[2], and AB 901[3]—were enacted in 2001 to improve the assessment of water supplies. The new laws require the verification of sufficient water supply as a condition for approving certain developments and compel urban water suppliers to provide more information on the reliability of groundwater as an element of supply.
    - The Government Code does not specifically require local governments to include a water resources element in their general plans.

[3] Water Code Sections 10910-12, 10631, 10604

AR0069626

13. The need to monitor groundwater quality and contamination of groundwater continues to grow
    - As opportunities for developing additional surface water supplies become more limited, subsequent growth will increasingly rely on groundwater.
    - Human activities are likely the cause of more than half the exceedances of a basin plan contaminant level in public water supply wells.
    - New contaminants are being regulated and standards are becoming more stringent, for others, requiring more load monitoring and better management of water quality.

14. Monitoring networks for groundwater levels and groundwater quality have not been evaluated in all basins to ensure that the data accurately represent conditions in the aquifer(s).
    - Groundwater levels are monitored in about 10,000 active wells, including those basins where most of the groundwater is used.
    - Groundwater levels are not monitored in approximately 200 basins where population is sparse and groundwater use is generally low.
    - Groundwater quality monitoring networks are most dense near population centers and may not be representative of the basin as a whole.
    - Many of the wells being monitored are not ideally constructed to provide water level or water quality information that is representative of a specific aquifer.
    - Many wells are too deep to monitor changes in the unconfined (water table) portion of basins.

15. The coordination of groundwater data collection and evaluation by local, State, and federal agencies is improving.
    - The State Water Resources Control Board (SWRCB) recently formed the Groundwater Resources Information Sharing Team (GRIST) consisting of several State and federal agencies with groundwater-related programs.
    - DWR established a website in 1998 that has provided water level data and hydrographs for more than 35,000 active and inactive wells monitored by DWR and cooperating agencies.
    - DWR collects and maintains water level data in part through partnerships with local agency cooperators.
    - DWR staff consulted with many local, State, and federal agencies in developing this update of Bulletin 118.
    - SWRCB recently formed an interagency task force to develop a comprehensive groundwater quality monitoring program for assessing every groundwater basin in the State as required by the Groundwater Quality Monitoring Act of 2001 (AB 599, Water Code, § 10780 et seq.).
    - Water purveyors have concerns about balancing public access to data with water supply security.

AR0069627

16. **Boundaries of groundwater basins have been determined using the best available geologic and hydrologic information. These boundaries are important in determining the availability of local water supplies.**
    - Basin boundaries were developed primarily by identifying alluvial sediments on geologic maps using the best available information, but are subject to change when new information becomes available
    - The Water Code requires the use of basin boundaries defined in Bulletin 118 in groundwater management plans and urban water management plans.
    - The location of basin boundaries will become more critical as the demand for water continues to increase.
    - Subbasin boundaries may be delineated for management convenience rather than based on hydrogeologic conditions.

17. **Little is known about the stream-aquifer interaction in many groundwater basins.**
    - Groundwater and surface water are closely linked in the hydrologic cycle.
    - The relationship between stream flow and extraction of groundwater is not fully understood in most basins and is generally not considered.
    - Groundwater extraction in many basins may affect stream flow.
    - Interaction of groundwater flow and surface water may affect environmental resources in the hyporheic zone.
    - An understanding of stream aquifer interaction will be essential to evaluating water transfers in many areas of the State.

18. **Although many new wells are built in fractured rock areas, insufficient hydrogeologic information is available to ensure the reliability of groundwater supplies.**
    - Population is increasing rapidly in foothill and mountain areas in which groundwater occurs in fractured rock.
    - The cumulative effect of groundwater development may reduce the yield of individual wells, lower the flow of mountain streams, and impact local habitat.
    - Characterization of groundwater resources in fractured rock areas can be very expensive and complex.
    - Many groundwater users in these areas have no other water supply alternatives.
    - Recent dry years have seen many wells go dry in fractured rock areas throughout the State.
    - Groundwater management in these areas is beginning, but there is insufficient data to support quantitative conclusions about the long-term sustainable yield.

19. **When new wells are built, drillers are required to file a Well Completion Report with DWR. That report contains a lithologic log, the usability of which varies considerably from driller to driller.**
    - The Well Completion Reports are confidential and not available to the public, as stipulated by the Water Code, unless the owner's permission is obtained.
    - The usefulness of the information in Well Completion Reports varies but is not fully realized.
    - Public access to Well Completion Reports would increase understanding of groundwater conditions and issues.
    - There is no provision in the Water Code that requires submission of geophysical logs, which would provide an accurate log of the geologic materials within the aquifer.
    - Geophysical logs would provide a greatly improved database for characterization of aquifers.

AR0069628

Recommendations

Major Recommendations

1. Local or regional agencies should develop groundwater management plans if groundwater constitutes part of their water supply. Management objectives should be developed to maintain a sustainable long-term supply for multiple beneficial uses. Management should integrate water quantity and quality, groundwater and surface water, and recharge area protection.
   - Groundwater management in California is a local agency responsibility.
   - In basins where there is more than one management agency, those agencies should coordinate their management objectives and program activities.
   - A water budget should be completed that includes recharge, extraction and change in storage in the aquifer(s).
   - Changes in groundwater quality should be monitored and evaluated.
   - Stakeholders should be identified and included in development of groundwater management plans.

2. The State of California should continue programs to provide technical and financial assistance to local agencies to develop monitoring programs, management plans, and groundwater storage projects to more efficiently use groundwater resources and provide a sustainable supply for multiple beneficial uses. DWR should:
   - Post information about projects that have successfully obtained funding through various grant and loan programs.
   - Provide additional technical assistance to local agencies in the preparation of grant and loan applications.
   - Continue outreach efforts to inform the public and water managers of grant and loan opportunities.
   - Participate, when requested, in local efforts to develop and implement groundwater management plans.
   - Continue to assess, develop, and modify its groundwater programs to provide the greatest benefit to local agencies.
   - Develop grant criteria to ensure funding supports local benefits as well as Statewide priorities, such as development of the California Water Plan and meeting Bay-Delta objectives.

3. DWR should continue to work with local agencies to more accurately define historical overdraft and to more accurately predict future water shortages that could result in overdraft.
   - A water budget should be developed for each basin.
   - The annual change in storage should be determined for each basin.
   - The amount of annual recharge and discharge, including pumping, should be determined.
   - Changes in groundwater quality that make groundwater unusable or could allow additional groundwater to be used should be included in any evaluation of overdraft.

4. Groundwater management agencies should work with land use agencies to inform them of the potential impacts various land use decisions may have on groundwater, and to identify, prioritize, and protect recharge areas.
   - Local planners should consider recharge areas when making land use decisions that could reduce recharge or pose a risk to groundwater quality.
   - Recharge areas should be identified and protected from land uses that limit recharge rates, such as paving or lining of channels.

AR0069630

- Both local water agencies and local governments should pursue education and outreach to inform the public of the location and importance of groundwater.
- DWR should inform local agencies of the availability of grant funding and technical assistance that could support these efforts.

5. DWR should publish a report by December 31, 2004 that identifies those groundwater basins or subbasins that are being managed by local or regional agencies and those that are not, and should identify how local agencies are using groundwater resources and protecting groundwater quality.
   - Such information will be necessary to confirm whether agencies are meeting the requirements of SB 1938 (Water Code Section 10753.7).
   - Collection and summary of existing groundwater management plans will provide a better understanding of the distribution and coordination of groundwater management programs throughout the State.
   - Successful strategies employed by specific local agencies should be highlighted to assist others in groundwater management efforts.
   - Similarly, the impact of groundwater management ordinances throughout the State should be evaluated to provide a better understanding of the effect of ordinances on groundwater management.

6. Water managers should include an evaluation of water quality in a groundwater management plan, recognizing that water quantity and water quality are inseparable.
   - Local water managers should obtain groundwater quality data from federal, state, and local agencies that have collected such data in their basin.
   - Local agencies should evaluate long-term trends in groundwater quality.
   - Local agencies should work closely with the SWRCB and DWR in evaluating their groundwater basins.
   - Local agencies should establish management objectives and monitoring programs that will maintain a sustainable supply of good quality groundwater.

7. Water transfers that involve groundwater (or surface water that will be replaced with groundwater) should be consistent with groundwater management in the source area that will assure the long-term sustainability of the groundwater resource.

8. Continue to support coordinated management of groundwater and surface water supplies and integrated management of groundwater quality and groundwater quantity.
   - Future bond funding should be provided for conjunctive use facilities to improve water supply reliability.
   - Funding for feasibility and pilot studies, in addition to construction of projects will help maximize the potential for conjunctive use.
   - DWR should continue and expand its efforts to form partnerships with local agencies to investigate and develop locally controlled conjunctive use programs.

9. Local, State, and federal agencies should improve data collection and analyses to better estimate groundwater basin conditions used in Statewide and local water supply reliability planning. DWR should:
   - Assist local agencies in the implementation of SB 221, SB 610, and AB 901 to help determine water supply reliability during the local land use planning process.
   - Provide and continue to update information on groundwater basins, including basin boundaries, groundwater levels, monitoring data, aquifer yield, and other aquifer characteristics.

AR0069631

- Identify areas of rapid development that are heavily reliant on groundwater and prioritize monitoring activities in these areas to identify potential impacts on these basins.
- Evaluate the existing network of wells monitored for groundwater elevations, eliminate wells of questionable value from the network, and add wells where data are needed.
- Work cooperatively with local groundwater managers to evaluate the groundwater basins of the State with respect to overdraft and its potential impacts. Beginning with the most heavily used basins.
- Expand DWR and its cooperating monitoring programs to provide a better understanding of the interaction between groundwater and surface water.
- Work with SWRCB to investigate temporal trends in water quality to identify areas of water quality degradation that should receive additional attention.
- Estimate groundwater extraction using a land use based method for over 200 basins with little or no groundwater budget information.
- Integrate groundwater budgets into the California Water Plan Update process.

10 **Increase coordination and sharing of groundwater data among local, State, and federal agencies and improve data dissemination to the public. DWR should:**

- Use the established website to continually update new groundwater basin data collected after the publication of California's Groundwater (Bulletin 118-Update 2003).
- Publish a summary update of Bulletin 118 every five years coincident with the California Water Plan (Bulletin 160).
- Publish in cooperation with SWRCB, a biennial groundwater report that addresses current groundwater quantity and quality conditions.
- Coordinate the collection and storage of its groundwater quality monitoring data with programs of SWRCB and other agencies to ensure maximum coverage statewide and reduce duplication of effort.
- Make groundwater basin information more compatible with other Geographic Information System-based resource data to improve local integrated resources planning efforts.
- Compile data collected by projects funded under grant and loan programs and make data available to the public on the DWR website.
- Encourage local agency cooperators to submit data to the DWR database.
- Maximize the accuracy and usefulness of data and develop guidelines for quality assurance and quality control, consistency, and format compatibility.
- Expand accessibility of groundwater data by the public after considering appropriate security measures.
- State, federal, and local agencies should expand accessibility of groundwater data by the public after considering appropriate security measures.
- Local agencies should submit copies of adopted groundwater management plans to DWR.

Additional Important Recommendations

11 **Local water agencies and local governments should be encouraged to develop cooperative working relationships at basinwide or regional levels to effectively manage groundwater. DWR should:**

- Provide technical and financial assistance to local agencies in the development of basinwide groundwater management plans.
- Provide a preference in grant funding for groundwater projects for agencies that are part of a regional or basinwide planning effort.
- Provide Proposition 50 funding preferences for projects that are part of an integrated regional water management plan.

AR0069632

12. Groundwater basin boundaries identified in Bulletin 118 should be updated as new information becomes available and the basin becomes better defined. DWR should:
    - Identify basin boundaries that are based on limited data.
    - List the kind of information that is necessary to better define basin boundaries.
    - Develop a systematic procedure to obtain and evaluate stakeholder input on groundwater basin boundaries.

13. Improve the understanding of groundwater resources in fractured rock areas of the State.
    - DWR, in cooperation with local and federal agencies, should conduct studies to determine the amount of groundwater that is available in fractured rock areas, including water quality assessment, identification of recharge rates and amounts, and if water can be obtained when needed.
    - Local agencies and local governments should conduct studies in their areas to quantify the local demands on groundwater and project future demands.
    - The Legislature should consider expanding the groundwater management authority in the Water Code to include areas outside of alluvial groundwater basins.
    - DWR should include information on the most significant fractured rock groundwater sources in future updates of Bulletin 118.

14. Develop a program to obtain geophysical logs in areas where additional data are needed.
    - DWR should encourage submittal of geophysical logs, when they are conducted, as a part of the Well Completion Report.
    - The geophysical logs would be available for use by public agencies to better understand the aquifer, but would be confidential as stipulated by the Water Code.
    - DWR should seek funding to work with agencies and property owners to obtain geophysical logs of new wells in areas where additional data are needed.
    - Geophysical logs would be used to better characterize the aquifers within each groundwater basin.

15. Educate the public on the significance of groundwater resources and on methods of groundwater management.
    - DWR should continue to educate the public on statewide groundwater issues and assist local agencies in their public education efforts.
    - Local agencies should expand their outreach efforts during development of groundwater management plans under AB 3030 and other authority.
    - DWR should develop educational materials to explain how they quantify groundwater throughout the State as well as the utility and limitations of the information.
    - DWR should continue its efforts to educate new dug well owners and small water systems that are entirely dependent on groundwater.

AR0069633

AR0069634

Introduction

AR0069635

Introduction

Groundwater is one of California's greatest natural resources. In an average water supply year, groundwater meets about 30 percent of California's urban and agricultural demand. In drought years, this percentage increases to 40 percent or even higher (DWR 1998). Some cities, such as Fresno, Davis, and Lodi, rely solely on groundwater for their drinking water supply. In 1995, an estimated 13 million Californians (nearly 43 percent of the State's population) used groundwater for at least a portion of their public supply needs (Solley and others 1998). With a projected population of nearly 46 million by the year 2020, California's demand on groundwater will increase significantly. In many basins, our ability to optimally use groundwater is affected by overdraft and water quality, or limited by a lack of data, lack of management, and coordination between agencies.

In the last few years, California has provided substantial funds to local agencies for groundwater management. For example, the nearly $2 billion Water Bond 2000 (Proposition 13) approved by California voters in March 2000 specifically authorizes funds for two groundwater programs: $200 million for grants for feasibility studies, project design, and the construction of conjunctive use facilities; and $50 million for loans for local agency acquisition and construction of groundwater recharge facilities and grants for feasibility studies for recharge projects. Additionally, the Local Groundwater Management Assistance Act of 2000 (AB 303) resulted in $15 million in fiscal years 2001, 2002, and 2003 for groundwater studies and data collection intended to improve basin and subbasin groundwater management. These projects focus on improving groundwater monitoring, coordinating groundwater basin management, and conducting groundwater studies.

The State Legislature has increasingly recognized the importance of groundwater and the need for monitoring in making sound groundwater management decisions. Significant legislation was passed in 2000, 2001 and 2002. AB 303 authorizes grants to help local agencies develop better groundwater management strategies. AB 599 (2001) requires, for the first time, that the State Water Resources Control Board (SWRCB), in cooperation with other agencies, develop a comprehensive monitoring program capable of assessing groundwater quality in every basin in the State with the intent of maintaining a safe groundwater supply. SB 610 (2001) and SB 901 (2001) together require urban water suppliers, in their urban water management plans, to determine the adequacy of current and future supplies to meet demands. Detailed groundwater information is required for those suppliers that use groundwater. SB 221 (2001) prohibits approval of certain developments without verification of an available water supply. These bills are significant with respect to groundwater because much of California's new development will rely on groundwater for its supply.

Finally, SB 1938 (2002) was enacted to provide incentives to local agencies for improved groundwater management. The legislation modified the Water Code to require that specific elements be included in a groundwater management plan for an agency to be eligible for certain State funding administered by the Department of Water Resources for groundwater projects. AB 303 is exempt from that requirement.

AR0069636

History of Bulletin 118

DWR has long recognized the need for collection, summary, and evaluation of groundwater data as tools in planning optimal use of the groundwater resource. An example of this is DWR's Bulletin 118 series. Bulletin 118 presents the results of groundwater basin evaluations in California. The Bulletin 118 series was preceded by Water Quality Investigations Report No. 3, *Ground Water Basins in California* (referred to in this bulletin as Report No. 3), published in 1952 by the Department of Public Works, Division of Water Resources (the predecessor of DWR). The purpose of Report No. 3 was to create a base/index map of the "more important ground water basins" for carrying out DWR's mandate in Section 229 of the Water Code. Sect on 229 directed Public Works to

> ... investigate conditions of the quality of all waters within the State, including saline waters, coastal and inland, as related to all sources of pollution of whatever nature and shall report thereon to the Legislature and to the appropriate regional water pollution control board annually, and may recommend any steps which might be taken to improve or protect the quality of such waters.

Report No. 3 identified 233 alluvium-filled valleys that were believed to be basins with usable groundwater in storage. A statewide numbering system was created in cooperation with the State Water Pollution Control Board (now the State Water Resources Control Board) based on the boundaries of the nine Regional Water Quality Control Boards. In 1992, Water Code Section 229 was amended, resulting in the elimination of the annual reporting requirements.

In 1975, DWR published Bulletin 118, *California's Ground Water* (referred to in this report as Bulletin 118-75). Bulletin 118-75 summarized available information from DWR, U.S. Geological Survey, and other agencies for individual groundwater basins to "help those who must make decisions affecting the protection, additional use, and management of the State's ground water resources."

Bulletin 118-75 contains a summary of technical information for 248 of the 461 identified groundwater basins, subbasins, and what were referred to as "areas of potential ground water storage" in California as well as maps showing their location and extent. The Bulletin 118-75 basin boundaries were based on geologic and hydrogeologic conditions except where basins were defined by a court decision.

In 1976, Section 12924 was added to the California Water Code:

> The Department shall, in cooperation with other public agencies, conduct an investigation of the State's groundwater basins. The Department shall identify the State's groundwater basins on the basis of geologic and hydrogeologic conditions and consideration of political boundary lines whenever practical. The Department shall also investigate existing general patterns of groundwater pumping and groundwater recharge within such basins to the extent necessary to identify basins which are subject to critical conditions of overdraft.

DWR published the report in 1980 as *Ground Water Basins in California, A Report to the Legislature in Response to Water Code Section 12924* (referred to in this report as Bulletin 118-80). The bulletin included 36 groundwater basins with boundaries different from Bulletin 118-75. The changed boundaries resulted by combining several basins based on geologic or political considerations and by dividing the San Joaquin Valley groundwater basin into many smaller subbasins based primarily on political boundaries. These changes resulted in the identification of 447 groundwater basins, subbasins, and areas of potential groundwater storage. Bulletin 118-80 also identified 11 basins as subject to critical conditions of overdraft.

AR0069637

Box A: Which Bulletin 118 Do You Mean?

Mention of an update to Bulletin 118 causes some confusion about which Bulletin 118 the California Department of Water Resources (DWR) has updated. In addition to the statewide Bulletin 118 series (Bulletin 118-75, Bulletin 118-80, and Bulletin 118-03), DWR released several other publications in the 118 series that evaluate groundwater basins in specific areas of the State. Regional specific Bulletin 118 reports are listed below:

- Bulletin 118-1: Evaluation of Ground Water Resources: South San Francisco Bay
  - Appendix A: Geology, 1967
  - Volume 1: Fremont Study Area, 1968
  - Volume 2: Additional Fremont Study Area, 1973
  - Volume 3: Northern Santa Clara County, 1975
  - Volume 4: South Santa Clara County, 1991
- Bulletin 118-2: Evaluation of Ground Water Resources: Livermore and Sunol Valleys, 1974
  - Appendix A: Geology, 1966
- Bulletin 118-3: Evaluation of Ground Water Resources: Sacramento County, 1974
- Bulletin 118-4: Evaluation of Ground Water Resources: Sonoma County
  - Volume 1: Geologic and Hydrologic Data, 1975
  - Volume 2: Santa Rosa Plain, 1982
  - Volume 3: Petaluma Valley, 1982
  - Volume 4: Sonoma Valley, 1982
  - Volume 5: Alexander Valley and Healdsburg Area, 1983
- Bulletin 118-5: Bulletin planned but never completed
- Bulletin 118-6: Evaluation of Ground Water Resources: Sacramento Valley, 1978

The Need for Bulletin 118 Update 2003

Despite California's heavy reliance on groundwater, basic information for many of the groundwater basins is lacking. Particular essential data necessary to provide for both the protection and optimal use of this resource is not available. To this end, the California Legislature mandated in the Budget Act of 1999 that DWR prepare:

> "...the statewide update of the inventory of groundwater basins contained in Bulletin 118-80, which includes, but is not limited to, the following: the review and summary of boundaries and hydrographic features, hydrogeologic units, yield data, water budgets, well production characteristics, and water quality and active monitoring data; development of a water budget for each groundwater basin; development of a format and procedures for publication of water budgets on the Internet; development of the model groundwater management ordinance; and development of guidelines for evaluating local groundwater management plans."

AR0069638

The information on groundwater basins presented in Bulletin 118 Update 2003 is mostly limited to the acquisition and compilation of existing data previously developed by federal, State, and local water agencies. While this bulletin is a good starting reference for basic data on a groundwater basin, more recent data and more information about the basin may be available in recent studies conducted by local water management agencies. Those agencies should be contacted to obtain the most recent data.

Report Organization

Bulletin 118 Update 2003 includes this report and supplemental material consisting of individual descriptions and a Geographic Information System-compatible map of each of the delineated groundwater basins in California. The basin descriptions will be updated as new information becomes available, and can be viewed or downloaded at http://www.waterplan.water.ca.gov/groundwater/118index.htm (Appendix A). Basin descriptions will not be published in hard copy.

This report is organized into the following topics:

- Groundwater is one of California's most important natural resources, and our reliance on it has continued to grow (Chapter 1).
- Groundwater has a complex legal and institutional framework in California that has shaped the groundwater management system in place today (Chapter 2).
- Groundwater management occurs primarily at the local water agency level, but may also be instituted at the local government level. At the request of the Legislature, DWR has developed some recommendations for a model groundwater management ordinance and components for inclusion in a groundwater management plan (Chapter 3).
- Groundwater has had a flurry of activity in the Legislature and at the ballot box in recent years that will affect the way groundwater is managed in California (Chapter 4).
- Groundwater programs with a variety of objectives exist in many State and federal agencies (Chapter 5).
- Groundwater concepts and definitions should be made available to a wide audience (Chapter 6).
- Groundwater basins with a wide range of characteristics and concerns exist in each of California's 10 hydrologic regions (Chapter 7).

AR0069639

Chapter 1
Groundwater California's Hidden Resource

Chapter 1
Groundwater – California's Hidden Resource

In 1975, *California's Ground Water – Bulletin 118* described groundwater as "California's hidden resource." Today, those words ring as true as ever. Because groundwater cannot be directly observed, except under a relatively few conditions such as at a spring or a wellhead, most Californians do not give much thought to the value that California's vast groundwater supply has added to the State. It is unlikely that California could have achieved its present status as the largest food and agricultural economy in the nation and fifth largest overall economy in the world without groundwater resources. Consider that about 43 percent of all Californians obtain drinking water from groundwater. California is not only the single largest user of groundwater in the nation, but the estimated 14.5 million acre-feet (maf) of groundwater extracted in California in 1995 represents nearly 20 percent of all groundwater extracted in the entire United States (Solley and others 1998).

California's Hydrology

California's climate is dominated by the Pacific storm track. Numerous mountain ranges cause orographic lifting of clouds, producing precipitation mostly on the western slopes and leaving a rain shadow on most eastern slopes (Figure 1 and Figure 2). These storms also leave tremendous accumulations of snow in the Sierra Nevada during the winter months. While the average annual precipitation in California is about 23 inches (DWR 1998), the range of annual rainfall varies greatly from more than 140 inches in the northwestern part of the State to less than 4 inches in the southeastern part of the State.

Snowmelt and rain falling on the mountains flow into creeks, streams, and rivers. The average annual runoff in California is approximately 71 maf (DWR 1998). As these flows make their way into the valleys, much of the water percolates into the ground. The vast majority of California's groundwater that is accessible in significant amounts is stored in alluvial groundwater basins. These alluvial basins, which are the subject of this report, cover nearly 40 percent of the geographic area of the State (Figure 3).

This bulletin focuses on groundwater resources, but in reality groundwater and surface water are inextricably linked in the hydrologic cycle. As an example, groundwater may be recharged by spring runoff in streams, but later in the year the base flow of a stream may be provided by groundwater. So, although the land surface is a convenient division for categorizing water resources, it is a somewhat arbitrary one. It is essential that water managers recognize and account for the relationship between groundwater and surface water in their planning and operations.

AR0069642

AR0069645

California's Water Supply System

The economic success achieved in California could not have been foreseen a century ago. California's natural hydrologic system appeared too limited to support significant growth in population, industry, and agriculture. The limitations revolved around not only the relative aridity of the State, but the geographic, seasonal, and climatic variability that influences California's water supply. Approximately 70 percent of the State's average annual runoff occurs north of Sacramento, while about 75 percent of the State's urban and agricultural water needs are to the south. Most of the State's precipitation falls between October and April with half of it occurring December through February in average years. Yet, the peak demand for this water occurs in the summer months. Climatic variability includes dramatic deviations from average supply conditions by way of either droughts or flooding. In the 20th century alone, California experienced multi-year droughts in 1912–1913, 1918–1920, 1922–1924, 1929–1934, 1947–1950, 1959–1961, 1976–1977, and 1987–1992 (DWR 1998).

California has dealt with the limitations resulting from its natural hydrology and achieved its improbable growth by developing an intricate system of reservoirs, canals, and pipelines under federal, State and local projects (Figure 4). However, a significant portion of California's water supply needs is also met by groundwater. Typically, groundwater supplies about 30 percent of California's urban and agricultural uses. In dry years, groundwater use increases to about 40 percent statewide and 60% or more in some regions.

The importance of groundwater to the State's development may have been underestimated at the beginning of the 20th century. At that time, groundwater was seen largely as just a convenient resource that allowed for settlement in nearly any part of the State, given groundwater's widespread occurrence. Significant artesian flow from confined aquifers in the Central Valley allowed the early development of agriculture. When the Water Commission Act defined the allocation of surface water rights in 1914, it did not address allocation of the groundwater resource. In the 1950s, the development of the deep-well turbine pump and the increased availability of electricity led to a tremendous expansion of agriculture, which used these high-volume pumps and increased forever the significance of groundwater as a component of water supply in California.

AR0069646

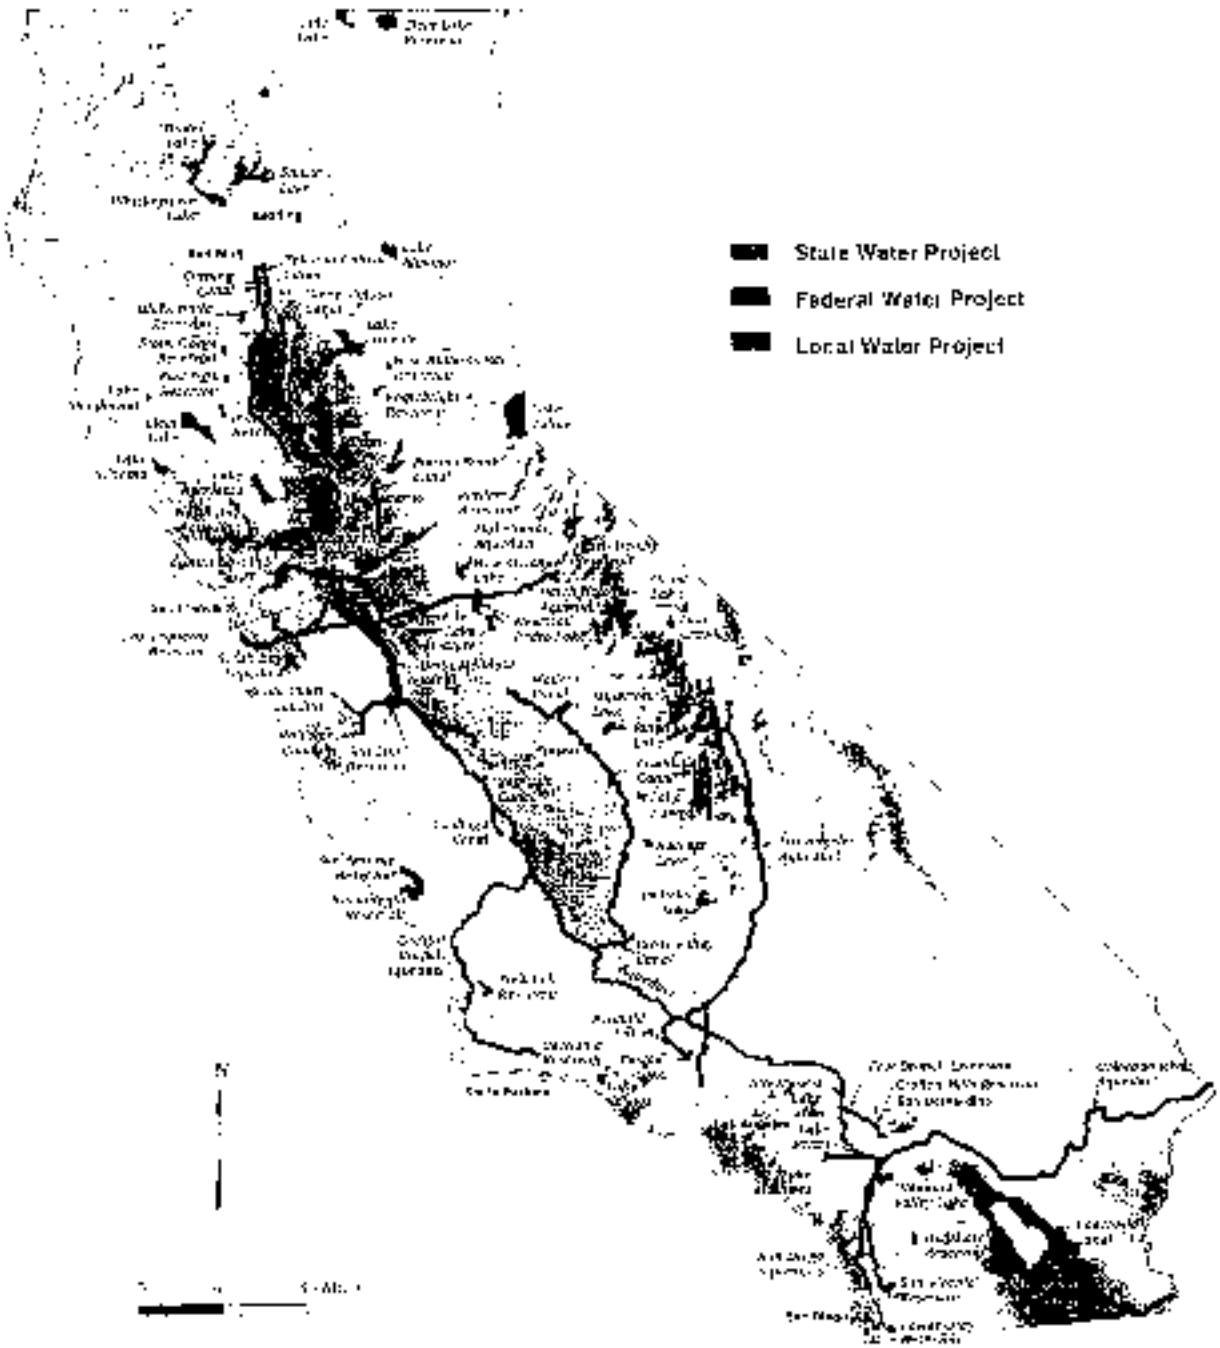

Figure 4 Water projects in California

AR0069647

Box 8 Will Climate Change Affect California's Groundwater?

California's water storage and delivery system can be thought of as including three reservoir systems—the snowpack of the Sierra Nevada, an extensive system of dams, lakes, and conveyance systems for surface water, and finally the aquifers that store groundwater. Precipitation in the form of snow is stored in the Sierra in winter and early spring and under ideal conditions melts in a manner that allows dams to capture the water for use during California's dry season. When snow melts faster, the dams act as flood control structures to prevent high runoff from flooding lowland areas. Water storage and delivery infrastructure—dams and canals—has been designed largely around the historical snowpack, while aquifers have played a less formal and less recognized role.

What will be the affect of climate change on California's water storage system? How will groundwater basins and aquifers be affected?

The latest report of the Intergovernmental Panel on Climate Change (2001) reaffirms that climate is changing in ways that cannot be accounted for by natural variability and that "global warming" is occurring. Studies by the National Water Assessment Team for the U.S. Global Change Research Program's National Assessment of the Potential Consequences of Climate Variability and Change identify potential changes that could affect water resources systems. For California, these include higher snow levels leading to more precipitation in the form of rain (or runoff) and rise in sea level, and possibly larger floods. In addition to affecting the balance between storage and flood control of our reservoirs, such changes in hydrology would affect wetlands, resulting in fauna and flora displacement and resulting changes in vegetative water consumption. These changes would also affect patterns of both irrigated and dryland farming.

A warmer, wetter winter would increase the amount of runoff available for groundwater recharge, however this additional runoff in the winter would be occurring at a time when some basins, particularly in Northern California, are either being recharged at their maximum capacity or are already full. Conversely, reductions in spring runoff and higher evapotranspiration because of warmer temperatures could reduce the amount of water available for recharge and surface storage.

The extent to which climate will change and the impact of that change are both unknown. A reduced snowpack, coupled with increased seasonal rainfall and earlier snowmelt, may require a change in the operating procedures for existing dams and conveyance facilities. Furthermore, these changes may require more active development of successful conjunctive management programs in which the aquifers are more effectively used as storage facilities. Water managers might want to evaluate their systems to better understand the existing snowpack surface water/groundwater relationship and identify opportunities that may exist to optimize groundwater and other storage capability under a new hydrologic regime that may result from climate change. If more water was stored in aquifers or in new or reoperated surface storage, the additional water could be used to meet water demands when the surface water supply was not adequate because of reduced snowmelt.

AR0069648

Recent Groundwater Development Trends

While development of California's surface water storage system has slowed significantly, groundwater development continues at a strong pace. A review of well completion reports submitted to the California Department of Water Resources (DWR) provides data on the number and type of water wells drilled in California since 1987. For the 14-year period, DWR received 127,616 well completion reports for water supply wells that were newly constructed, reconditioned, or deepened — an average of 9,115 annually[1]. Of these, 82 percent were drilled for individual domestic uses; 14 percent for irrigation; and about 4 percent for a combined group of municipal and industrial uses (figure 5). Although domestic wells predominate, individual domestic use makes up a small proportion of total groundwater use in the State.

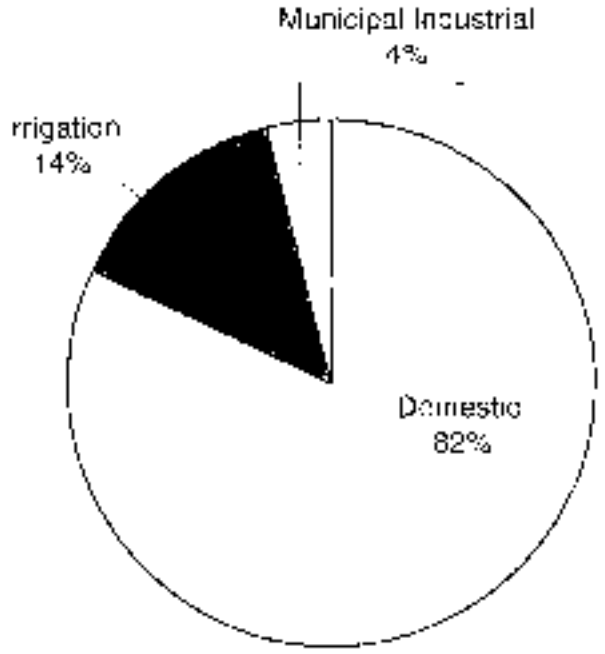

Figure 5 Well completion reports filed with DWR from 1987 through 2000

The most evident influence on the number of wells constructed is hydrologic conditions. The number of wells constructed and modified increases dramatically with drought conditions (figure 6). The number of wells constructed and modified annually from 1987 through 1992 is more than double the annual totals for 1993 through 2000. Each year from 1987 through 1992 was classified as either dry or critically dry; water years 1993 through 2000 were either above normal or wet, based on measured unimpaired runoff in the Sacramento and San Joaquin valleys. In addition to providing an indication of the growth of groundwater development, well completion reports are a valuable source of information on groundwater basin conditions.

[1] DWR also received an average of 1,225 well completion reports for monitoring, which were not included above because they do not extract groundwater for supply purposes.

AR0069649

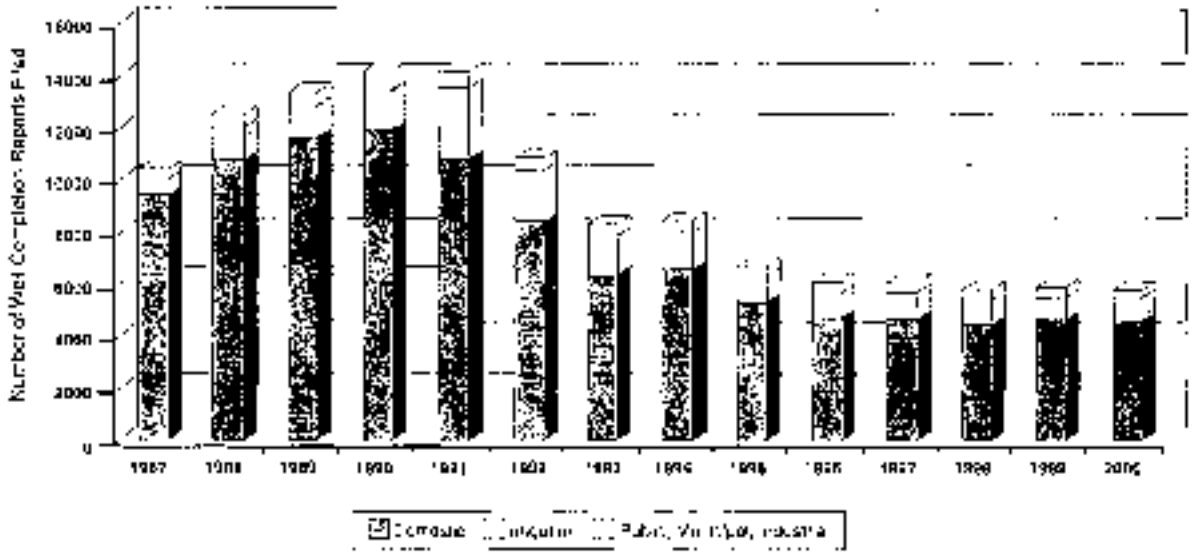

Figure 6 Well completion reports filed annually from 1987 through 2000

The Need for Groundwater Monitoring and Evaluation

Some 34 million people called California their home in the year 2000, and a population of nearly 46 million is expected by 2020. The increased population and associated commercial, industrial, and institutional growth will bring a substantially greater need for water. This need will be met in part by improved water use efficiency, opportunities to reoperate or expand California's surface water system, and increased desalination and recycling of water sources not currently considered usable. This need will also be met by storing and extracting additional groundwater. However, the sustainability of the groundwater resource, both in terms of what is currently used and future increased demand, cannot be achieved without effective groundwater management. In turn, effective groundwater management cannot be achieved without a program of groundwater data collection and evaluation.

Perhaps surprising to many, California does not have a comprehensive monitoring network for evaluating the health of its groundwater resource, including quantity and quality of groundwater. The reasons for this are many with the greatest one being that information on groundwater levels and groundwater quality is primarily obtained by drilling underground, which is relatively expensive. Given that, delineated groundwater basins cover about 40 percent of the State's vast area, the cost of a dedicated monitoring network would be prohibitive. The other important reason for the lack of a comprehensive network is that, as will be discussed later in this report, groundwater is a locally controlled resource. State and federal agencies become involved only when a groundwater issue is directly related to the mission of a particular agency or if a local agency requests assistance. For these and other reasons, California lacks a cohesive, dedicated monitoring network.

AR0069650

Box C What about Overdraft?

Overdraft is the condition of a groundwater basin in which the amount of water withdrawn by pumping over the long term exceeds the amount of water that recharges the basin. Overdraft is characterized by groundwater levels that decline over a period of years and do not fully recover even in wet years. Overdraft can lead to increased pumping costs, land subsidence, water quality degradation, and environmental impacts.

The California Water Plan Update, Bulletin 160-98 (DWR 1998) estimated that groundwater overdraft in California in 1995 was nearly 1.5 million acre-feet annually, with most of the overdraft occurring in the Tulare Lake, San Joaquin River, and Central Coast hydrologic regions. The regional and statewide estimates of overdraft are currently being revised for the 2003 update of Bulletin 160. While these estimates are useful from a regional and statewide planning perspective, the basin water budgets calculated for this update of Bulletin 118 clearly indicate that information is insufficient in many basins to quantify overdraft, track how it has occurred, project future impacts on groundwater storage, and effectively manage groundwater. Further technical discussion of overdraft is provided in Chapter 6 of this bulletin.

When DWR and other agencies involved in groundwater began to collect data in the first half of the 20th century, it quickly became evident that there were insufficient funds to install an adequate number of monitoring wells to accurately determine changes in the condition of groundwater basins. Consequently, to create a serviceable monitoring network, the agencies asked owners of irrigation or domestic wells for permission to measure water levels and to a lesser extent to monitor water quality. These have been called "wells of opportunity." In many areas, this approach has led to a network of wells that provide adequate information to gain a general understanding of conditions in the subsurface and to track changes through time. In some areas, groundwater studies were conducted and often included the construction of a monitoring well network. These studies have gradually contributed to a more detailed understanding of some of California's groundwater basins, particularly the most heavily developed basins.

Given the combination of monitoring wells of opportunity and dedicated monitoring wells, it might be assumed that an adequate monitoring network in California will eventually accumulate. However, several factors contribute to reducing the effectiveness of the monitoring network for data collection and evaluation: (1) The funding for data programs in many agencies, which was generally insufficient in the first place, has been reduced significantly. (2) When private properties change ownership, some new owners rescind permission for agency personnel to enter the property and measure the well. (3) The appropriateness of using these private wells is questionable because they are often screened over long intervals encompassing multiple aquifers in the subsurface, and in some cases construction details for the well are unknown. (4) Some wells with long-term records actually reach the end of their usefulness because the casing collapses or something falls into the well, making it unusable. In some cases, groundwater levels may drop below the well depth. (5) As water quality or water quantity conditions change, the monitoring network may no longer be adequate to provide necessary data to manage groundwater.

AR0069651

The importance of long-term monitoring networks cannot be overstated. Sound groundwater management decisions require observation of trends in groundwater levels and groundwater quality. Only through these long-term evaluations can the question of sustainability of groundwater be answered. For example, this report contains a summary of groundwater contamination in public water supply wells throughout the State collected from 1994 through 2000. While this provides a "snap-shot" of the suitability of the groundwater currently developed for public supply needs, it does not address sustainability of groundwater for public uses. Sustainability can only be determined by observing groundwater quality over time. If conditions worsen, local managers will need to take steps to prevent further harm to groundwater quality. Long-term groundwater records require adequate funding and staff to develop groundwater monitoring networks and to collect, summarize, and evaluate the data.

Chapter 2
Groundwater Management in California

Chapter 2
Groundwater Management in California

Groundwater management, as defined in this report, is the planned and coordinated monitoring, operation, and administration of a groundwater basin or portion of a groundwater basin with the goal of long-term sustainability of the resource. Throughout the history of water management in California, local agencies have practiced an informal type of groundwater management. For example, since the early 20th century, when excess surface water was available, some agencies intentionally recharged groundwater to augment their natural water supply. In 1947, the amount of groundwater used was estimated at 8 million to 10 million acre-feet. By the beginning of the 21st century, the amount of groundwater used had increased to an estimated 15 million acre-feet. Better monitoring would provide more accurate information. This increased demand on California's groundwater resources, when coupled with estimates of population growth, has resulted in a need for more intensive groundwater management.

In 1914, California created a system of appropriating surface water rights through a permitting process (Stats. 1913, ch. 586), but groundwater use has never been regulated by the State. Though the regulation of groundwater has been considered on several occasions, the California Legislature has repeatedly held that groundwater management should remain a local responsibility (Sax 2002). Although they are treated differently legally, groundwater and surface water are closely interconnected in the hydrologic cycle. Use of one resource will often affect the other, so that effective groundwater management must consider surface water supplies and uses.

Figure 7 depicts the general process by which groundwater management needs are addressed under existing law. Groundwater management needs are identified at the local water agency level and may be directly resolved at the local level. If groundwater management needs cannot be directly resolved at the local agency level, additional actions such as enactment of ordinances by local governments, passage of laws by the Legislature, or decisions by the courts may be necessary to resolve the issues. Upon implementation, local agencies evaluate program success and identify additional management needs. The State's role is to provide technical and financial assistance to local agencies for their groundwater management efforts, such as through the Local Groundwater Assistance grant program (see Chapter 4, AB 303).

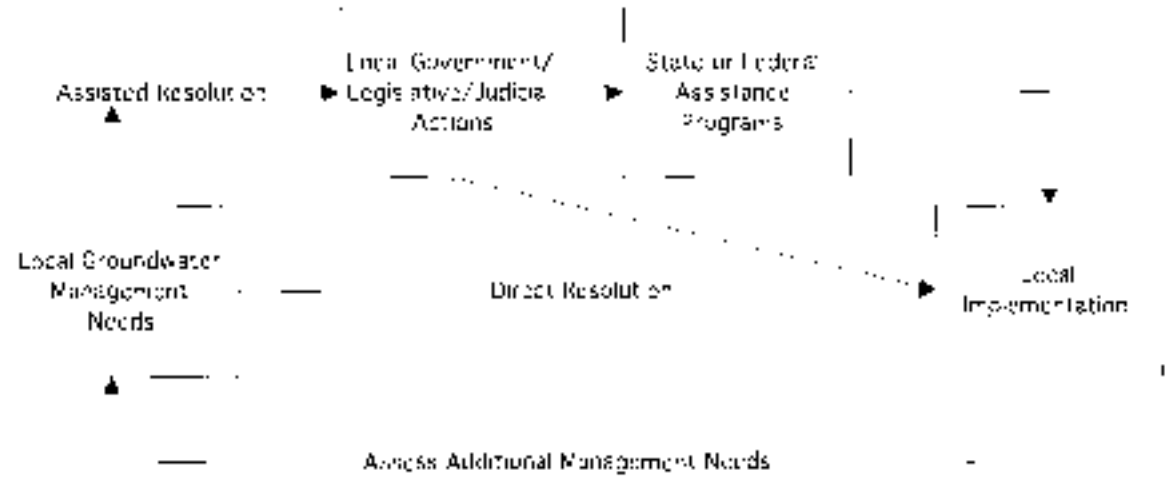

Figure 7 Process of addressing groundwater management needs in California

AR0069654

How Groundwater is Managed in California

There are three basic methods available for managing groundwater resources in California: (1) management by local agencies under authority granted in the California Water Code or other applicable State statutes, (2) local governmental groundwater ordinances or joint powers agreements, and (3) court adjudications. Table 1 shows how often each of these methods has been used, and each method is discussed briefly below. No law requires that any of these forms of management be applied in a basin. Management is often instituted after local agencies or landowners recognize a specific groundwater problem. The level of groundwater management in any basin or subbasin is often dependent on water availability and demand.

Table 1. Groundwater management methods

Method	Frequency of use[a]
Local water agencies	Undetermined number of agencies with authority to manage some types of groundwater under general powers associated with particular types of districts.
	Thirteen agencies with specially legislated authority to limit or regulate extraction.
	Seven agencies with adopted groundwater ordinances under Water Code Section 10750 et seq.[b] (As of 1991).
	More than 300 agencies with adopted plans with authority from Water Code Section 10753 et seq. (As of 1991).
Local ordinances, management and taxes	Currently adopted in 27 counties.
Court adjudication	Currently decided in 19 groundwater basins, mostly in Southern California. Three more basins are in court.

a. These figures do not include the many instances (typically within the California Department of Water Resources) in which
b. Section 10750 et seq. was amended in 1992.

Groundwater Management through Authority Granted to Local Water Agencies

More than 20 types of local agencies are authorized by statute to provide water for various beneficial uses. Many of these agencies also have statutory authority to institute some form of groundwater management. For example, a Water Replenishment District (Water Code, § 60000 et seq.) is authorized to establish groundwater replenishment programs and collect fees for that service. A Water Conservation District (Water Code, § 75500 et seq.) can levy groundwater extraction fees. Table 2 lists these and other types of local agencies that deliver water and may have authority to institute some form of groundwater management. Most of these agencies are identified in the Water Code, but their specific authority related to groundwater management varies. The Water Code does not require that the agencies report their activities to the California Department of Water Resources (DWR).

AR0069655

Table 2 Local agencies with authority to deliver water for beneficial uses, which may have authority to institute groundwater management

Local agency	Authority	Number of agencies[a]
Community Services District	Gov. Code § 61000 et seq.	115
County Sanitation District	Health and Safety Code § 4700 et seq.	91

Water Storage District	Water Code § 39000 et seq.	8

a From State Controller's Office Special Districts Annual Report, 1991 Edition.

Greater authority to manage groundwater has been granted to a small number of local agencies or districts created through special acts of the Legislature. For example, the Sierra Valley Groundwater Basin Act of 1980 (Water Code, App. 119) created the first two groundwater management districts in California. Currently, 13 local agencies have specific groundwater management authority as a result of being special act districts. The specific authority of each agency varies, but they can generally be grouped into two categories. Most of the agencies formed since 1980 have the authority to limit export and even control some in basin extraction upon evidence of overdraft or the threat of overdraft. These agencies can also generally levy fees for groundwater management activities and for water supply replenishment. Agencies formed prior to 1980 do not have authority to limit extraction from a basin. However, the groundwater users in these areas are generally required to report extractions to the agency, and the agency can levy fees for groundwater management or water supply replenishment. Some of these agencies have effectively used a tiered fee

AR0069656

structure to discourage excessive groundwater extraction in the basin. Table 1 lists the names of special act districts with legislative authority to manage groundwater.

Table 3 Special act districts with groundwater management authority in California

District or agency	Water Code citation[a]	Year agency established or Code[b]
Desert Water Agency	App. 100	1961
Fox Canyon Groundwater Management Agency	App. 121	1982
Honey Lake Groundwater Management District	App. 129	1989
Long Valley Groundwater Management District	App. 119	1980
Mendocino City Community Services District	Section 10700 et seq.	1987
Monte Vista/Lone Valley Groundwater Management District	App. 79	1989
Monterey Peninsula Water Management District	App. 118	1977
Ojai Groundwater Management Agency	App. 151	1991
Orange County Water District	App. 40.	1933
Pajaro Valley Water Management Agency	App. 120	1984
Santa Clara Valley Water District	App. 60.	1951
Sierra Valley Groundwater Management District	App. 119	1980
Willow Creek Groundwater Management Agency	App. 155	1993

a. Refers to West's Annotated California Codes (Deering's).
b. This is the year the agency was established. Also, Water Code Specific authorities, such as those for groundwater management activities, may have been granted through later amendments.

In 1992, AB 255 (Stats. 1991, Ch. 903) was enacted authorizing local agencies overlying basins subject to critical conditions of overdraft, as defined in DWR's Bulletin 118-80, to establish programs for groundwater management within their service areas. Water Code section 10750 et seq. provided these agencies with the powers of a water replenishment district to raise revenue for facilities to manage the basin for the purposes of extraction, recharge, conveyance, and water quality. Seven local agencies adopted plans under this authority.

The provisions of AB 255 were repealed in 1992 with the passage of AB 3030 (Stats. 1992, Ch. 947). This legislation was significant in that it greatly increased the number of local agencies authorized to develop a groundwater management plan and set forth a common framework for management by local agencies throughout California. AB 3030, which is codified in Water Code section 10750 et seq., provides a systematic procedure to develop a groundwater management plan by local agencies overlying the groundwater basins defined by Bulletin 118-75 (DWR 1975) and updates. Upon adoption of a plan, these agencies could possess the same authority as a water replenishment district to "fix and collect fees and assessments for groundwater management" (Water Code, § 10754). However, the authority to fix and collect these fees and assessments is contingent on receiving a majority of votes in favor of the proposal in a local election (Water Code, § 10754.3). More than 200 agencies have adopted an AB 3030 groundwater management plan. None of these agencies is known to have exercised the authority of a Water Replenishment District.

Water Code section 10753.2 expands groundwater management opportunities by encouraging coordinated plans and by authorizing public agencies to enter into a joint powers agreement or memorandum of understanding with public or private entities that provide water service. At least 20 coordinated plans have been prepared to date involving nearly 120 agencies, including cities and private water companies.

AR0069657

Local Groundwater Ordinances

A second general method of managing groundwater in California is through ordinances adopted by local governments such as cities or counties. Twenty-seven counties have adopted groundwater ordinances, and others are being considered (Figure 8). The authority of counties to regulate groundwater has been challenged, but in 1995 the California Supreme Court declined to review an appeal of a lower court decision, *Baldwin v. County of Tehama* (1994) that holds that State law does not occupy the field of groundwater management and does not prevent cities and counties from adopting ordinances to manage groundwater under their police powers. However, the precise nature and extent of the police power of cities and counties to regulate groundwater is uncertain.

The Public Policy Institute of California recently performed a study of California's water transfer market, which included a detailed investigation of the nature of groundwater ordinances by counties in California. The report found that 22 counties had adopted ordinances requiring a permit to export groundwater. In all but three cases, restricting out-of-county uses appears to be the only purpose (Hanak 2003). One ordinance, adopted recently in Glenn County (Box D, "Basin Management Objectives for Groundwater Management"), takes a comprehensive approach by establishing management objectives for the county's groundwater basins. Several other counties in Northern California are considering adopting similar management objective based ordinances.

Ordinances are mostly a recent trend in groundwater management, with 24 of the 27 ordinances enacted since 1990. Local ordinances passed during the 1990s have significantly increased the potential role of local governments in groundwater management. The intent of most ordinances has been to hold project proponents accountable for impacts that may occur as a result of proposed export projects. Because adoption of most of these ordinances is recent, their effect on local and regional groundwater management planning efforts is not yet fully known. However, it is likely that future groundwater development will take place within the constraints of local groundwater management ordinances. Table 4 lists counties with groundwater management ordinances and their key elements.

AR0069658

Figure 8 Counties with groundwater ordinances

AR0069659

Box D Basin Management Objectives for Groundwater Management

Most county groundwater management ordinances require that an export proponent prove the project will not deplete groundwater, cause groundwater quality degradation, or result in land subsidence. Although these factors could be part of any groundwater management plan, these ordinances do not require that a groundwater management plan be developed and implemented.

The only ordinance requiring development and adoption of objectives to be accomplished by management of the basin was adopted by the Glenn County Board of Supervisors in 2000. This action came after a citizen's committee spent five years working with stakeholders. The process of developing a groundwater management ordinance for Glenn County began in 1995 when local landowners and county residents became concerned about plans to export groundwater or substitute groundwater for exported surface water. Control of exports was the focus of early ordinance discussions.

After many discussions and technical advice from groundwater specialists, the committee realized that goals and objectives must be identified for effective management of groundwater in the county. What do the county want to accomplish by managing groundwater within the county? What did groundwater management really mean?

The concept of establishing basin management objectives emerged (BMOs). BMOs would establish threshold values for groundwater levels, groundwater quality, and land surface subsidence. When a threshold level is reached, the rules and regulations require that groundwater extraction be adjusted or stopped to prevent exceeding the threshold.

The Glenn County Board of Supervisors has adopted BMOs, which were developed by an advisory committee, for groundwater levels throughout the county. While currently there are 17 BMOs representing the 17 management areas in the county, the goal is to begin managing the entire county as a unit that benefits each of the local agencies and their landowners, as well as landowners outside of an Agency boundary. The committee is now developing BMOs for groundwater quality and land surface subsidence.

There is no single set of management objectives that will be successful in all areas. Groundwater management must be adapted to an area's political, institutional, legal, and technical constraints and uncertainties. Groundwater management must be tailored to each basin or subbasin's conditions and needs. Even within a single basin, the management objectives may change as more is learned about managing the resource within that basin. Flexibility is the key, but that flexibility must operate within a framework that ensures public participation, monitoring, evaluation, feedback on management alternatives, rules and regulations, and enforcement.

AR0069660

Table 4 Counties with ordinances addressing groundwater management

County	Year enacted	Key elements (refer to ordinances for exemptions and other details)
Butte	1990	Export permit required (extraction & substitute pumping), Water Commission and Technical Advisory Committee, groundwater planning reports (every 5 yrs monitoring program)
Calaveras	2007	Export permit required (extraction & substitute pumping)
Colusa	1998	Export permit required (extraction & substitute pumping)
Fresno	2008	Export permit required (extraction & substitute pumping)
Glenn	1998 ex. 2008	Water Advisory Committee and Technical Advisory Committee, basin management objectives and monitoring network, export permit required (1998)
Imperial	1996	Conservation district established to manage groundwater, discharge monitoring reports (permit required) over-draft, artificial recharge, and development projects
Inyo	1998	Regulates Owens Valley transfers pursuant to Water Code Section 1810, (2) cycles of control of the City of Los Angeles from within Inyo Co., (3) transfer or transport of water from basins within Inyo Co. to another basin with the County, and (4) transfers of water from basins within Inyo Co. to any area outside the County
Kern	1998	Conjunctive use permit for export of waters both outside county and within watershed area of underlying aquifer in question. Only applies to southeastern drainage of Sierra Nevada and Tehachapi mountains
Lake	1999	Export permit required (extraction & substitute pumping)
Lassen	1999	Export permit required (extraction & substitute pumping)
Madera	1999	Permit required for export, groundwater banking, and import for groundwater banking, purposes to areas outside local water agencies
Mendocino	1995	Mining of groundwater regulated for new developments in Town of Mendocino
Merced	2003	Export permit required for transfers out of basin
Mono	1998	Permit required for transfers out of basin
Monterey	1995	Water Resources Agency strictly regulates extractions facilities in zones with groundwater problems
Napa	1996	Permits for basin groundwater extractions. Exemptions for single parcels and agricultural use
Sacramento	1952 ex. 1986	Water Agency created to manage and protect groundwater management zones' replenishment charges
San Benito	1995	Mining groundwater (overdraft) for export prohibited, permit required for off-parcel use, affect up to 200 feet, influence of well for pump restrictions
San Bernardino	2007	Permit required for any new groundwater well within the desert region of the county
San Diego	1997	Provides for managing of groundwater impacted basins (drought), projects within impacted basins require groundwater investigations
San Joaquin	1996	Export permit required (extraction & substitute pumping)
Shasta	1997	Export permit required (extraction & substitute pumping)
Sierra	1998	Export permit required for off-parcel use
Siskiyou	1998	Permit required for transfers out of basin
Tehama	1995	Mining groundwater (overdraft) for export prohibited, permit required for off-parcel use, influence of well pumping restrictions
Tuolumne	2001	Export permit required (extraction & substitute pumping)
Yolo	1996	Export permit required (extraction & substitute pumping)

AR0069661

Adjudicated Groundwater Basins

A third general form of groundwater management in California is court adjudication. In some California groundwater basins, as the demand for groundwater exceeded supply, landowners and other parties turned to the courts to determine how much groundwater can rightfully be extracted by each user. The courts study available data to arrive at a distribution of the groundwater that is available each year, usually based on the California law of overlying use and appropriation. This court-directed process can be lengthy and costly. As noted in Table 5, the longest adjudication took 24 years. Many of these cases have been resolved with a court approved negotiated settlement, called a stipulated judgment. Unlike overlying and non-overlying rights to groundwater, such decisions guarantee to each party a proportionate share of the groundwater that is available each year. The intense technical focus on the groundwater supply and restrictions on groundwater extraction for all parties make adjudications one of the strongest forms of groundwater management in California.

There are 19 court adjudications for groundwater basins in California, mostly in Southern California (see Table 5). Eighteen of the adjudications were undertaken in State Superior Court and one in federal court. For each adjudicated groundwater basin, the court usually appoints a watermaster to oversee the court judgment. In 15 of these adjudications, the court judgment limits the amount of groundwater that can be extracted by all parties based on a court-determined safe yield of the basin. The basin boundaries are also defined by the court. The Santa Margarita Basin was adjudicated in federal court. That decision requires water users to report the amount of surface water and groundwater they use, but groundwater extraction is not restricted.

Most basin adjudications have resulted in either a reduction or no increase in the amount of groundwater extracted. As a result, agencies often import surface water to meet increased demand. The original court decisions provided watermasters with the authority to regulate extraction of the quantity of groundwater; however, they omitted authority to regulate extraction to protect water quality or to prevent the spread of contaminants in the groundwater. Because water quantity and water quality are inseparable, watermasters are recognizing that they must also manage groundwater quality.

AR0069662

Box F. Adjudication of Groundwater Rights in the Raymond Basin

The first basin-wide adjudication of groundwater rights in California was in the Raymond Basin in Los Angeles County in 1949 (*Pasadena v. Alhambra*). The first water well in Raymond Basin was drilled in 1887; 20 years later, the number of operating wells grew to about 140. Because of this pumping, the City of Pasadena began spreading water in 1914 to replenish the groundwater and during the next 10 years the city spread more than 20,000 acre-feet.

Pumping during 1930 through 1937 caused water levels to fall 30 to 60 feet in wells in Pasadena. After attempting to negotiate a reduction of pumping on a cooperative basis, the City of Pasadena, on September 25, 1937, filed a complaint in Superior Court against the City of Alhambra and 29 other purveyors to quiet title to the water rights within Raymond Basin. The court ruled that the city must amend its complaint, making defendants of all entities pumping more than 100 acre-feet per year, and that it was not a simple quiet title suit but a general adjudication of the water rights in the basin.

In February 1939, a court-ordered reference procedure under the State Water Code directed the State Division of Water Resources, Department of Public Works (predecessor to the Department of Water Resources) as referee to review all physical facts pertaining to the basin, determine the safe yield, and ascertain whether there was a surplus or an overdraft. The study took 2 1/2 years to complete and cost more than $53,000, which was paid by the parties. The resulting Report of Referee submitted to the court in July 1943 found that the annual safe yield of the basin was 21,900 acre-feet but that the actual pumping and claimed rights were 29,400 acre-feet per year.

Most parties agreed to appoint a committee of seven attorneys and engineers to work out a stipulated agreement. In 1944, the court designated the Division of Water Resources to serve as watermaster for the stipulated agreement, which all but one of the parties supported. On December 23, 1944, the judge signed the judgment that adopted the stipulation.

The stipulation provided that (1) the water was taken by each party openly, notoriously, and under a claim of right, which was asserted to be and was adverse to each and to other parties; (2) the safe yield would be divided proportionally among the parties; and (3) each party's right to a specified proportion of the safe yield would be declared and protected. It also established an arrangement for the exchange of pumping rights among parties.

Based on the stipulation, the court adopted a program of proportionate reductions. In so doing, the court developed the doctrine of mutual prescription, whereby the rights were essentially based on the highest continual amount of pumping during the five years following the beginning of the overdraft, and under conditions of overdraft, all of the overlying and appropriative water users had acquired prescriptive rights against each other, that is, mutual prescription."

In 1946, one party appealed the judgment, and in 1947, the District Court of Appeals reversed and remanded *Pasadena v. Alhambra*. However, on June 3, 1948, the State Supreme Court overturned the appellate court's decision and affirmed the original judgment. In 1950, the court granted a motion by the City of Pasadena that there be a review of the determination of safe yield, and in 1955, the safe yield and the total decreed rights were increased to 32,822 acre-feet per year. In 1984, watermaster responsibilities were assigned to the Raymond Basin Management Board.

In *City of Los Angeles v. City of San Fernando* (1975), the California Supreme Court rejected the doctrine of mutual prescription and held that a groundwater basin would be adjudicated based on the correlative rights of overlying users and prior appropriation among non-overlying users. For further discussion, see Appendix B.

19 Goleta	Goleta Central Basin; judgment reduces North Basin. Santa Barbara	3-16	1975	1989	No watermaster appointed; the court retains jurisdiction

AR0069665

How Successful Have Groundwater Management Efforts Been?

This chapter describes the opportunities for local agencies to manage their groundwater resources. Many have questioned whether these opportunities have led to an overall successful system of groundwater management throughout California. How successful groundwater management has been throughout the State is a difficult question and cannot be answered at present. While there are many examples of local agency successes (see Box B, "Managing through a Joint Powers Agreement," Box C, "Managing a Basin through Integrated Water Management," and Box G, "Managing Groundwater Using both Physical and Institutional Solutions"), there are neither mandates to prepare groundwater management plans nor reporting requirements when plans are implemented, so a comprehensive assessment of local planning efforts is not possible. Additionally, many plans have been adopted only recently, during a period of several consecutive wet years, so many of the plan components are either untested or not implemented.

At a minimum, successful groundwater management should be defined as maintaining and maximizing long-term reliability of the groundwater resource, focused on preventing significant depletion of groundwater in storage over the long term and preventing significant degradation of groundwater quality. A review of some of the groundwater management plans prepared under AB 3030 reveals that some plans are simply brief recitations about continuing the agency's existing programs. Not all agencies that enacted groundwater management plans under AB 3030 are actively implementing the plan.

Despite this apparent lack of implementation of groundwater management plans prepared under AB 3030, the bill has certainly increased interest in more effective groundwater management. With more than 200 agencies participating in plans and more than 120 of those involved in coordinated plans with other agencies, AB 3030 has resulted in a heightened awareness of groundwater management. Additionally, annual reports published by a few water agencies indicate that they are indeed moving toward better coordination throughout the basin and more effective management of all water supplies. Given the history of groundwater management in California, these seemingly small steps toward better management may actually represent giant strides forward.

More recently, financial incentives have played a large role in driving groundwater management activities. For example, under grant and loan programs resulting from Proposition 13 of 2000 (see description in Chapter 4), local agencies submitted applications proposing a total increase in annual water yield of more than 300,000 acre-feet through groundwater storage projects. Additional projects and programs would be developed with sufficient funding for feasibility and pilot studies. Unfortunately, not enough funding exists for all of the proposed projects, and many other legal and institutional barriers remain (see Box E, "Impediments to Conjunctive Management Programs in California"). It is clear, however, that further incentives would help agencies move ahead more aggressively in their groundwater management planning efforts.

Additional progress in groundwater management is reflected by passage of amendments to the Water Code (§§ 10753.4 and 10795.4 as amended, §§ 10753.7, 10753.8, and 10753.9 as amended and renumbered, and §§ 10753.1 and 10753.7 as added) through SB 1938 of 2002. The amendments require that groundwater management plans include specific components for agencies to be eligible for some public funds for groundwater projects. The provisions of SB 1938 (2001) are fully described in Chapters 3 and 4.

This evaluation of groundwater management success has not really considered ordinances and adjudications. Adjudications have been successful at maintaining the groundwater basin conditions, often restricting pumping for all basin users. In some cases, adjudication provides the necessary framework for more proactive management as well. Ordinances have successfully restricted exports from basins, but have not

AR0069666

Box F Managing through a Joint Powers Agreement

In 1993, representatives from business, environmental, public, and water purveyor interests formed the Sacramento Area Water Forum to develop a plan to protect the region's water resources from the effects of prolonged drought as the demand for water continues to grow. The Water Forum was founded on two co-equal objectives: (1) to provide a reliable and safe water supply for the region's economic health and planned development to the year 2030 and (2) to preserve the fishery, wildlife, recreational and aesthetic values of the lower American River.

After a six-year consensus-based process of education, analysis and negotiation, the participants signed a Water Forum agreement to meet these objectives. The agreement provides a framework for avoiding future water shortages, environmental degradation, groundwater contamination, threats to groundwater reliability, and limits to economic prosperity.

The Sacramento Groundwater Authority (SGA) was formed to fulfill a key Water Forum goal of protecting and managing the north-area groundwater basin. The SGA is a joint powers authority formed for the purpose of collectively managing the region's groundwater resources. This authority permits SGA to make contractual arrangements required to implement a conjunctive use program, and also provides potential partners with the legal and political certainty for entering into long-term agreements.

SGA's regional banking and exchange program is designed to provide long-term supply benefits for local needs, but also will have the potential to provide broader statewide benefits consistent with American River environmental needs. Water stored in Folsom Lake would be conjunctively used with groundwater in order to reduce surface water diversions in dry years and to achieve in-lieu recharge of the basin in wet years. The conjunctive use program participants include 16 water providers in northern Sacramento and southern Placer counties that serve water to more than half a million people.

Two of three implementation phases of the program are complete. In the first phase, program participants identified long-term water supply needs and conducted an inventory of existing infrastructure that could be used to implement the program. In the second phase, SGA completed two pilot banking and exchange projects, demonstrating the technical, legal, and institutional viability of a regional conjunctive use program. In the first pilot study, water agencies worked with the U.S. Bureau of Reclamation and the Sacramento Area Flood Control Agency to bank 2,100 acre-feet of groundwater, providing additional flood storage capacity in Folsom Lake. In the second pilot study, Citrus Heights and Fair Oaks water districts and the city of Sacramento extracted and used 7,143 acre-feet of groundwater, forgoing a portion of their rights to surface water, making this water available to the Environmental Water Account. The third phase of the SGA program is to further solidify the institutional frameworks and construct facilities to implement a full-scale regional conjunctive use program. These facilities, that will result in an average annual yield of 21,400 acre-feet, are currently under construction, funded in part by a $21.6 million grant under Proposition 13 of 2000.

AR0069667

Box C: Managing a Basin through Integrated Water Management

Orange County Water District (OCWD) was established in 1933 by an uncodified Act (Water Code App. 40) to manage Orange County's groundwater basin and protect the Santa Ana River rights of water users of north-central Orange County. The district manages the groundwater basin, which provides as much as 75 percent of the water supply for its service area. The district strives for a groundwater-based water supply with enough reserves to provide a water supply through drought conditions. An integrated set of water management practices helps achieve this, including the use of recharge, alternative sources, and conservation.

Recharge

The Santa Ana River provides the main natural recharge source for the county's groundwater basin. Increased groundwater use and lower than average rainfall during the late 1980s and early 1990s forced the district to rely on an aggressive program to enhance recharge of the groundwater basin. Programs used today to optimize water use and availability include:

- Construction of levees in the river channel to increase infiltration.
- Construction of additional recharge basins within the forebay.
- Development of an underwater basin cleaning vehicle that removes a clogging layer at the bottom of the recharge basin and extends the time between draining the basin for cleaning by a bulldozer.
- Use of stormwater captured behind Prado Dam that would otherwise flow to the ocean.
- Use of imported water from the State Water Project and Colorado River.
- Injection of treated recycled water to form a seawater intrusion barrier.

Alternative Water Use and Conservation

OCWD has successfully used nontraditional sources of water to help satisfy the growing need for water in Orange County. Projects that have added to the effective supply of groundwater are:

- Use of treated recycled water for irrigation and industrial use.
- In-lieu use to reduce groundwater pumping.
- Change to low-flow toilets and showerheads.
- Participation of 70 percent of Orange County hotels and motels in water conservation programs.
- Change to more efficient computerized irrigation.

Since 1975, Water Factory 21 has provided recycled water that meets all primary and secondary drinking water standards set by the California Department of Health Services. OCWD has proposed a larger, more efficient membrane purification project called the Groundwater Replenishment System (GWRS), which is scheduled to begin operating at 70,000 acre-feet per year in 2007. By 2020 the system will annually supply 131,000 acre-feet of high-quality water for recharge, for injection into the seawater intrusion barrier, and for direct industrial uses.

This facility will use a lower cost, microfiltration and reverse osmosis treatment process that produces water of near-distilled quality, which will help reverse the trend of rising total dissolved solids (TDS) in groundwater caused by the recharge of higher TDS-content Santa Ana River and Colorado River waters. The facility will use about half the energy required to import an equivalent amount of water to Orange County from Northern California. The GWRS will be funded, in part, by a $30 million grant under Proposition 13 of 2000.

AR0069668

Box H Managing Groundwater using both Physical and Institutional Solutions

Four agencies share responsibility for groundwater management in Ventura County. Coordination and cooperation between these agencies focus on regular meetings, attendance at each other's board meetings, joint projects, watershed committees, and ongoing personal contacts to discuss water-related issues. The agencies and their areas of responsibility are:

- United Water Conservation District – physical solutions: monitoring, modeling, recharging, administering management plans and adjudication;
- Fox Canyon Groundwater Management Agency – pumping allocations, credits and penalties, abandoned well destruction, data for irrigation efficiency
- County of Ventura – well permits, well construction regulations, tracking abandoned wells; and
- Calleguas Municipal Water District – groundwater storage of imported water

In Ventura County 75% to 80% of the extracted groundwater is for agriculture, the remainder is for municipal and industrial use. Seawater intrusion into the aquifers was recognized in the 1930s and was the driving force behind a number of groundwater management projects and policies in the county's groundwater basins. As groundwater issues became more complicated at the end of the 20th century, these groundwater management projects and policies were useful in solving a number of problems.

Physical Solutions

Physical solutions substitute supplemental surface water for groundwater pumping near coastal areas, increase basin recharge, and increase the reliability of imported water. Projects include:

- Winter flood-flow storage for dry season release
- Wells and pipelines to move pumping for drinking water away from the coast
- Diversion structures to supply surface water to spreading grounds and irrigation
- Pipelines to convey surface water to coastal areas
- Las Posas Basin Aquifer Storage and Recovery project

Institutional Solutions

Institutional solutions focus on developing and implementing effective groundwater management programs, reducing pumping demands, tracking groundwater levels and water quality, managing groundwater pumping patterns, and destroying abandoned wells to prevent cross-contamination of aquifers. Solutions include:

- Creation of Fox Canyon Groundwater Management Agency (GMA), which represents each major pumping constituency
- Use of irrigation efficiency (agricultural water conservation) and alternative sources of water (urban) to reduce pumping by 25%
- Manage pumping in the GMA area through an AB 3030 plan and a court adjudication
- Limit new permits for wells in specific aquifers to avoid seawater intrusion
- Creation of a program to destroy abandoned wells
- Creation of a database of historical groundwater levels and quality information collected since the 1920s
- Development of a regional groundwater flow model and a regional master plan for groundwater projects
- Creation of an irrigation weather station to assist in irrigation efficiency

Implementation of these physical and institutional management tools has resulted in the reversal of seawater intrusion in key coastal monitoring wells. These same tools are being used to mitigate saline intrusion (not seawater) in two inland basins and to reduce seasonal nitrate problems in the recharge area. Work is being expanded to help reduce loading of agricultural pesticides and nutrients. Without close coordination and cooperation of the county's water-related agencies, municipalities, and landowners, it would have been very difficult to implement most of these solutions. Although such coordination takes time, the investment has paid off in solutions that help provide a sustainable water supply for all water users in Ventura County.

Source: United Water Conservation District

AR0069669

necessarily improved groundwater management. The primary intent of most ordinances is to ensure that proponents of projects are held accountable for potential impacts of the proposed export projects. As studies lead to a better understanding of local water resources, development of pilot export and transfer projects, with appropriate monitoring, may lead to greater certainty in managing groundwater resources. Areas managed under adjudications and ordinances will continue to develop more active management approaches. Population growth and its accompanying increased demand on the resources is a certainty. Most geographic areas in California are not immune to this growth. As strategies for more than just maintaining existing groundwater supply through extraction or export restrictions need to be implemented.

Box I Impediments to Conjunctive Management Programs in California

In 1996 the National Water Research Institute in cooperation with the Association of Ground Water Agencies and the Metropolitan Water District of Southern California, conducted a workshop to determine the biggest impediments to implementing a cost effective conjunctive water management program in California.

Since that time, some steps have been taken to overcome those impediments, but several important barriers remain. Workshop participants identified the 10 most significant obstacles:

1) Inability of local and regional water management governance entities to build trust, resolve differences (internally and externally), and share control.
2) Inability to match benefits and funding burdens in ways that are acceptable to all parties, including third parties.
3) Lack of sufficient federal, State, and regional financial incentives to encourage groundwater conjunctive use to meet statewide water needs.
4) Legal constraints that impede conjunctive use, regarding storage rights, basin judgments, area of origin, water rights, and adjudication.
5) Lack of statewide leadership in the planning and development of conjunctive use programs as part of comprehensive water resources plans which recognize local, regional, and other stakeholders' interests.
6) Inability to address quality differences in "old" versus "new" standards for injection, export, and reclaimed water and unforeseeable future groundwater degradation.
7) Risk that water stored cannot be extracted when needed because of infrastructure, water quality or water level policies, and institutional or contractual provisions.
8) Lack of assurances to prevent third-party impacts and uncertainties to increase willingness of local citizens to participate.
9) Lack of creativity in developing "win-win" conjunctive use projects, agreements, and programs.
10) Supplemental suppliers and basin managers have different roles and expectations in relation to conjunctive use.

[Editor's note: The California Department of Water Resources' Conjunctive Water Management program has been significant steps to overcome several of these impediments, using a combination of California Bay-Delta Authority, IRWM, Proposition 13, and AB 303 funds to promote locally planned and controlled conjunctive use programs.]

AR0069670

Future Groundwater Management in California

Trying to predict what will happen with groundwater management in California is difficult given that actions by all of the involved groups—landowners, local governments, local, State, and federal agencies, and the courts—will continue to shape groundwater management in the future. However, the increasing population and the demands on California's water supply will accelerate the rate at which groundwater management issues become critical and require resolution. Some general conclusions are:

- Groundwater management will continue to be a local responsibility with increasing emphasis on how actions in one part of a basin impact groundwater resources throughout the basin. Regional cooperation and coordination of groundwater management activities will increase.

- As the State's population continues to grow, the increased reliance on groundwater will keep the topic of groundwater management at the forefront of legislative interest.

- Coordinated management of groundwater and surface water resources, through further development of conjunctive water management programs and projects, will become increasingly important.

- The increased reliance on groundwater in the future will necessitate a more direct link between land use planning, watershed management, floodplain management, and groundwater management plans.

- Current trends indicate that financial incentives in the form of loans and grants are increasing groundwater management planning and implementation at the local level. These successes will only continue at the current pace with increased funding to local agencies.

- Management of groundwater will increasingly include consideration of groundwater quality and groundwater quantity.

- Groundwater will be an important element in the trend toward an integrated water management approach that considers the full range of demand management and supply alternatives.

- Understanding of the relationship of groundwater and surface water and the role of groundwater in the environment will continue to grow.

AR0069671

Box 3 Managing Groundwater Quantity and Quality

When people hear the words "groundwater monitoring" they may think either of measuring groundwater levels or of analyzing for groundwater quality. In reality, monitoring and management of groundwater quantity and groundwater quality are inseparable components of a management plan.

Although the primary focus of the California Department of Water Resources (DWR) is on groundwater quantity and the measures taken by local agencies to manage supply, management must also consider groundwater quality. Natural or anthropogenic contamination and pumping patterns that are not managed to protect groundwater quality may limit the quantity of groundwater that is available for use in a basin.

Several State programs provide useful data as well as regulatory direction on groundwater quality that managers can use in managing their groundwater supply. One program is the Drinking Water Source Assessment and Protection Program prepared by the California Department of Health Services in response to 1996 amendments to the federal Safe Drinking Water Act. The DWSAP requires water purveyors to assess sources of drinking water, develop zones indicating direction of travel of groundwater, and identify potentially contaminating activities around supply wells. The goal is to ensure that the quality of drinking water sources is maintained and protected. Other useful water quality data for groundwater managers is collected by the agencies within the California Environmental Protection Agency, including the State Water Resources Control Board, Department of Pesticide Regulation and the Department of Toxic Substances Control, which are discussed in more detail in Chapter 5. Each of these agencies has a specific statutory responsibility to collect groundwater quality information and protect water quality.

Protection of Recharge Areas

Groundwater recharge areas, and the human activities that can reduce their ingestion, are an example of the need to coordinate land use activities to protect both groundwater quality and quantity. Protection of recharge areas, whether natural or man-made, is necessary if the quantity and quality of groundwater in the aquifer are to be maintained. Existing and potential recharge areas must be protected so that they remain functional, that is they continue to provide recharge to the aquifer and they are not contaminated with chemical or microbial constituents. Land-use practices should be implemented so that neither the quantity nor quality of groundwater is reduced. A lack of protection of recharge areas could decrease the availability of usable groundwater and require the substitution of a more expensive water supply.

Many potentially contaminating activities have routinely been practiced in recharge areas, leading to the presence of contaminants in groundwater. In many areas, groundwater obtained from aquifers now requires remediation. Recent studies in some areas show that recharge areas are contaminated, but down gradient wells are not, indicating that it is only a matter of time before contaminants in wells reach concentrations that require treatment of the groundwater.

In addition to quality impacts, urban development, consisting of pavement and buildings on former agricultural land, lining of flood control channels, and other land use changes have reduced the capacity of recharge areas to replenish groundwater, effectively reducing the safe yield of some basins.

AR0069672

Box 1 Managing Groundwater Quantity and Quality (continued)

To ensure that recharge areas continue to replenish high quality groundwater, water managers and land use planners should work together to:

- Identify recharge areas so the public and local zoning agencies are aware of the areas that need protection from paving and from contamination;
- Include recharge areas in zoning categories that diminish the possibility of contaminants entering the subsurface;
- Standardize guidelines for pre-treatment of the recharge water, including recycled water;
- Build monitoring wells to collect data on changes in groundwater quality that may be caused by recharge; and
- Consider the functions of recharge areas in land use and development decisions.

Chapter 3
Groundwater Management Planning and Implementation

AR0069675

Chapter 3
Groundwater Management Planning and Implementation

The 1990s were a very important decade in the history of groundwater management in California. In 1992, the State Legislature provided an opportunity for more formal groundwater management with the passage of AB 3030 (Water Code § 10750 et seq.). More than 200 agencies have adopted an AB 3030 groundwater management plan. Additionally, 24 of the 27 counties with ordinances related to groundwater management adopted these laws during the 1990s. Plans prepared under AB 3030 certainly brought unprecedented number of water agencies into the groundwater management arena, and counties are now heavily involved in groundwater management, primarily through ordinances. However, many plans prepared under AB 3030 have had little or no implementation, and many counties focus primarily on limiting exports rather than on a comprehensive management program. As a result, the California Budget Act of 1999 (Stats. 1999, ch. 50), which authorized this update to Bulletin 118, directed the California Department of Water Resources (DWR) to complete several tasks, including developing criteria for evaluating groundwater management plans and developing a model groundwater management ordinance. This chapter presents the results of these directives. The intent is to provide a framework that will assist local agencies in proactively planning and implementing effective groundwater management programs.

Criteria for Evaluating Groundwater Management Plans—Required and Recommended Components

In 2002, the Legislature passed SB 1938 (Stats 2002, ch 603), which amended Water Code section 10750 et seq to require that groundwater management plans adopted by local agencies include certain components to be eligible for public funds administered by DWR for construction of groundwater projects. The statute applies to funds authorized or appropriated after September 1, 2002. In addition to the required components, DWR worked with representatives from local water agencies to develop a list of additional recommended components that are common to effective groundwater management.

Both the "required" and the "recommended" components are tools that local agencies can use either to institute a groundwater management plan for the first time or to update existing groundwater management plans. These components are discussed below and listed in Appendix C, which can be used as a checklist by local agencies to assess whether their groundwater management plans are addressing these topics.

Required Components of Local Groundwater Management Plans

As of January 1, 2005, amendments to Water Code Section 10750 et seq. resulting from the passage of SB 1938, require new groundwater management plans prepared under section 10750, commonly referred to as AB 3030 plans, to include the first component listed below.

Groundwater management plans prepared under any statutory authority must include components 2 through 7 to be eligible for the award of public funds administered by DWR for the construction of groundwater projects or groundwater quality projects. These requirements apply to funds authorized or appropriated after September 1, 2002. Funds appropriated under Water Code section 10795 et seq. (AB 303 – Local Groundwater Assistance Fund) are specifically excluded.

1) Documentation that a written statement was provided to the public "describing the manner in which interested parties may participate in developing the groundwater management plan" (Water Code, § 10753.1(b)).

AR0069676

2) Basin management objectives (BMOs) for the groundwater basin that is subject to the plan (Water Code, § 10753.7 (a)(1)).
3) Components relating to the monitoring and management of groundwater levels, groundwater quality, inelastic land surface subsidence, and changes in surface flow and surface water quality that directly affect groundwater levels or quality or are caused by groundwater pumping (Water Code, § 10753.7 (a)(1)).
4) A plan by the managing entity to "involve other agencies that enables the local agency to work cooperatively with other public entities whose service area or boundary overlies the groundwater basin" (Water Code, § 10753.7 (a)(2)). A local agency includes "any local public agency that provides water service to all or a portion of its service area" (Water Code, § 10752 (g)).
5) Adoption of monitoring protocols (Water Code, § 10753.7 (a)(4)) for the components in Water Code section 10753.7 (a)(3). Monitoring protocols are not defined in the Water Code, but the section is interpreted to mean developing a monitoring program capable of tracking changes in conditions for the purpose of meeting BMOs.
6) A map showing the area of the groundwater basin as defined by DWR Bulletin 118 with the area of the local agency subject to the plan as well as the boundaries of other local agencies that overlie the basin in which the agency is developing a groundwater management plan (Water Code, § 10753.7 (a)(3)).
7) For local agencies not overlying groundwater basins, plans shall be prepared including the above listed components and using geologic and hydrologic principles appropriate to those areas (Water Code, § 10753.7 (a)(5)).

Recommended Components of Groundwater Management Plans

Although the seven components listed above are required only under certain conditions, they should always be considered for inclusion in any groundwater management planning process. In addition to the required components of a groundwater management plan resulting from the passage of SB 1938, it is recommended that the components listed below be included in any groundwater management plan adopted and implemented by a local managing entity. These additional components were developed in accord with the Budget Act of 1999 and with the assistance of stakeholder groups. The components should be considered and developed for specific application within the basin, subbasin, or agency service area covered by the plan. Additional components will likely be needed in specific areas. The level of detail for each component will vary from agency to agency. None of the suggested data reporting in the components should be construed to require disclosure of information that is confidential under State law. Local agencies should consider both the benefits of public dissemination of information and water supply security in developing reporting requirements.

Manage with the Guidance of an Advisory Committee

The managing entity should establish an advisory committee of interested parties that will help guide the development and implementation of the plan. The committee can benefit management in several ways. First, the committee can bring a variety of perspectives to the management team. As the intent of local groundwater management is to maintain and expand local benefits from the availability of the resource, it makes sense that the intended beneficiaries are a part of the management process. Second, the committee is free to focus on the specifics of groundwater management without being distracted by the many operational activities that the managing entity (such as a water district) must complete. Third, some parties could be negatively impacted by certain groundwater management decisions, and these actions and potential adverse impacts should be a part of the decision-making process to help reduce future conflicts. Finally, the advisory committee helps the managing entity gain the confidence of the local constituency by providing the opportunity for interested parties to participate in the management process.

AR0069677

Many managing entities have already elected to use advisory committees for implementation of their groundwater management plans. The composition of these committees varies widely. Some groups consist entirely of stakeholders; others add local or State government representatives or academic members as impartial third parties, and some have included consultants as technical advisors. Some plans use multiple advisory committees to manage unique subareas. Some plans appoint advisory committees with different objectives, such as one that deals with technical issues and another that deals with policy issues. There is no formula for the composition of an advisory committee because it should ultimately be based on local management needs and should include representation of diverse local interests.

The Tulare Lake Bed Coordinated Management Plan provides an example of the benefit of an advisory committee. The plan includes nine groups of participants, making coordination and communication a complicated issue. To allow for greater communication, an executive committee was established consisting of one voting member from each public agency participating in the plan and one voting member representing a combined group of private landowner plan participants. The committee administers groundwater management activities and programs for the plan (TLBWSD 2002).

Describe the Area to Be Managed under the Plan
The plan should include a description of the physical setting and characteristics of the aquifer system underlying the plan area in the context of the overall basin. The summary should also include a description of historical data, including data related to groundwater levels, groundwater quality, subsidence, and groundwater–surface water interaction, known issues of concern with respect to the above data, and a general discussion of historical and projected water demands and supplies. All of these data are critical to effective groundwater management because they demonstrate the current understanding of the system to be managed and serve as a point of departure for monitoring activities as part of plan implementation.

Create a Link Between Management Objectives and Goals and Actions of the Plan
The major goal of any groundwater management plan is to maintain a reliable supply of groundwater for long-term beneficial uses of groundwater in the area covered by the plan. The plan should clearly describe how each of the adopted management objectives helps attain that goal. Further, the plan should clearly describe how current and planned actions by the managing entity help meet the adopted management objectives. The plan will have a greater chance of success by developing an understanding of the relationship between each action, management objectives, and the goal of the groundwater management plan.

For example, prevention of contamination of groundwater from the land surface is a management objective that clearly supports the goal of groundwater sustainability. Management actions that could help support this objective include (1) educating the public through outreach programs that explain how activities at the surface ultimately impact groundwater, (2) developing wellhead protection programs or re-evaluating existing programs, (3) working with the local responsible agency to ensure that permitted wells are constructed, abandoned, and destroyed according to State well standards, (4) investigating whether local conditions necessitate higher standards than those adopted by the local permitting agency for the construction, abandonment, or destruction of wells, and (5) working with businesses engaged in practices that might impact groundwater to reduce the risks of contamination.

The concept of having a management objective is certainly not new. While many existing plans do not clearly include management objectives nor specifically identify actions to achieve objectives, some plans indirectly include these components. As an example, Eastern Municipal Water District's (EMWD) Groundwater Management Plan states that its goal includes maximizing "the use of groundwater for all beneficial uses in such a way as to lower the cost of water supply and to improve the reliability of the total

AR0069678

water supply for all users." To achieve this goal, EMWD has listed several issues to be addressed. One is the prevention of long-term depletion of groundwater. This can be defined as a management objective even though it is not labeled as such. Where this management objective is currently unmet in the North San Jacinto watershed portion of the plan area, EMWD has identified specific actions to achieve that objective, including the reduction of groundwater extraction coupled with pursuing the construction of a pipeline to act as an alternative source of surface water for the impacted area (EMWD 2002).

Describe the Plan Monitoring Program

The groundwater management plan should include a map indicating the locations of any applicable monitoring sites for groundwater levels, groundwater quality, subsidence, stream gaging, and other applicable monitoring. The groundwater management plan should summarize the type of monitoring (for example, groundwater level, groundwater quality, subsidence, streamflow, precipitation, evaporation, tidal influence), type of measurements, and the frequency of monitoring for each location. Site specific monitoring information should be included in each groundwater management plan. The plan should include the well depth, screened interval(s) and aquifer zone(s) monitored, and the type of well (public, irrigation, domestic, industrial, monitoring). These components will serve as a tool for the local managing entity to assess the adequacy of the existing monitoring network in tracking the progress of plan activities.

The groundwater management plan developed for the Scotts Valley Water District (SVWD) provides a detailed description of the monitoring program in Santa Cruz County (Todd Engineers 1994). Table 6 is SVWD's monitoring table, which serves as an example of the level of detail that is useful in a plan (Todd Engineers 2000a). Figure 9 shows the locations and types of monitoring points for each monitoring site. The monitoring table specifies in detail the data available and the planned monitoring. These serve as useful tools for SVWD to visualize the types and distribution of data available for their groundwater management activities. In addition to the minimum types of monitoring, SVWD summarizes other types of data that are relevant to their groundwater management effort.

Describe Integrated Water Management Planning Efforts

Water law in California treats groundwater and surface water as two separate resources with the result that they have largely been managed separately. Such management does not represent hydrologic reality. Recently, managers of a number of resources are becoming increasingly aware of how their planning activities could impact or be impacted by the groundwater system. Because of this, the local managing entity should describe any current or planned actions to coordinate with other land use, zoning, or water management planning entities.

Integrated management is addressed in existing groundwater management plans in several ways, including cooperatively managing groundwater with surface water supplies, recharging water from municipal sewage treatment plants, and working with local planning agencies to provide comments when a project is proposed that could impact the groundwater system.

Examples of planning efforts that should be integrated with groundwater management may include watershed management, protection of recharge areas, agricultural water management, urban water management, flood management, drinking water source assessment and protection, public water system emergency and disaster response, general plans, urban development, agricultural land preservation, and environmental habitat protection or restoration. Another example that may appear insignificant is transportation infrastructure. However, local impacts on smaller aquifers could be significant when landscaping of medians and interchanges requires groundwater pumping for irrigation or when paved areas are constructed over highly permeable sediments that act as recharge zones for the underlying aquifer.

Box K: What are Management Objectives?

Management objectives are the local managing entity's way of identifying the most important issues in meeting local resource needs. They can be seen as establishing a "value system" for the plan area. There is no fixed set of management objectives for any given plan area. Some of the more commonly recognized management objectives include the monitoring and managing of groundwater levels, groundwater quality, inelastic land subsidence, and changes in streamflow and surface water quality where they impact or are impacted by groundwater pumping. Management objectives may range from being entirely qualitative to strictly quantified.

Each management objective would have a locally determined threshold value associated with it which can vary greatly. For example, in establishing a management objective for groundwater quality, one area may simply choose to establish an average value of total dissolved solids as the indicator of whether a management objective is met, while another agency may choose to have no constituents exceeding the maximum contaminant level for public drinking water standards. While there is great latitude in establishing management objectives, local managers should remember that the objectives should serve to support the goal of a sustainable supply for the beneficial use of the water in their jurisdictional area.

An example of an alternative management objective is Orange County Water District's (OCWD) objective of maintaining available storage space in its management area at 200,000 acre-feet. The objective does not require that groundwater elevations be used at any particular location, although managing to this objective would likely have the net benefit of stabilizing water levels. Groundwater storage is a dynamic value, so attempting to meet this management objective is an ongoing challenge. OCWD has implemented many management actions directly aimed at managing the basin to meet this objective.

The Deer Creek and Tule River Authority provides an excellent example of how groundwater management activities can be coordinated with other resources. The authority, in conjunction with the U.S. Bureau of Reclamation, has constructed more than 200 acres of recharge basins as part of the Deer Creek Recharge-Wildlife Enhancement Project. When available, the project takes surplus water during winter months and delivers it to the basins, which serve as winter habitat for migrating waterfowl, creating a significant environmental benefit. Most of the water also recharges into the underlying aquifer, thereby benefiting the local groundwater system.

Report on Implementation of the Plan

The managing entity should produce periodic reports -- annually or at other frequencies determined by the local managing entity -- summarizing groundwater basin conditions and groundwater management activities for the period since the previous update. The reports should include:

- A summary of monitoring results, including historical trends,
- A summary of actual management actions,
- A summary, supported by monitoring results, of whether management actions are achieving progress in meeting management objectives,
- A summary of proposed management actions, and
- A summary of any plan component changes, including addition or modification of management objectives.

AR0069683

Unfortunately, many plans were prepared in the mid-1990s with little or no follow-up documentation of whether the plan is actually being implemented. This makes it difficult to determine what progress has been achieved in managing the groundwater resource. Periodic reports will serve as a tool for the managing entity to organize its many activities to implement the plan, act as a driving force for plan implementation, and help interested parties understand the progress made by local entities in managing their groundwater resource.

Progress reports on SVWD (Todd Engineers 2002) and EMWD (2002) groundwater management plans serve as excellent examples of the value of such an exercise. Both reports effectively portray the results of management actions, progress toward achieving objectives and specific recommendations for future management actions. An example of reporting on the modification of a management objective for water quality can be found in EMWD's 2000 Annual Report (EMWD 2001). A task force of more than 20 water suppliers and wastewater agencies, including EMWD, worked to update the Regional Water Quality Control Board's Region 8 Basin Plan objectives for nitrogen and total dissolved solids in water, effectively changing EMWD's management objectives for those constituents.

Evaluate the Plan Periodically

The managing entity and advisory committee should re-evaluate the entire plan. Periodic evaluation of the entire management plan is essential to delineate successes and failures under the plan and identify changes that may be needed. Additionally, re-evaluation of the plan should include assessment of changing conditions in the basin that may warrant modification of the plan or management objectives. Adjustment of components in the plan should occur on an ongoing basis if necessary. The re-evaluation of the plan should focus on determining whether the actions under the plan are meeting the management objectives and whether the management objectives are meeting the goal of sustaining the resource.

While there are several examples of existing groundwater management plans that demonstrate ongoing changes to plan activities, there are no known examples of such an approach to entirely re-evaluate an existing plan. This is likely due in part to the occurrence of several consecutive wet years in the mid- and late-1990s. The abundant surface water supplies reduced the need to actively manage groundwater supplies in many cases. More recent dry conditions and the recent passage of SB 1938 will create an excellent opportunity for managing entities to begin a re-evaluation of existing plans.

Model Groundwater Management Ordinance

As discussed in the previous chapter, ordinances are groundwater management mechanisms enacted by local governments through exercise of their police powers to protect the health and safety of their citizens. In Baldwin v. Tehama County (1994), the appellate court declared that State law does not preempt the field of groundwater management.

In the mid- to late-1990s, many counties adopted ordinances that effectively prevented export of groundwater from the county, even though none specifically prohibited export. The intent of most of these ordinances is to sustain groundwater as a viable local resource. To ensure that no local an export project proponent is required by most of the ordinances to show that the proposed project will not cause depletion of the groundwater, degradation of groundwater quality, or subsidence before a permit to export groundwater can be issued. Although these ordinances do not specifically require thresholds/limits for each of these potential negative impacts, a project proponent can really only show that these negative effects will not occur if the proponent develops a groundwater management plan.

AR0069684

Many of these ordinances were developed in response to the plans of some agencies or landowners to export groundwater or develop a groundwater substitution project where surface water is exported and groundwater is substituted for local use. In some cases, short-term export actually took place, leading to a number of claims of negative third party impacts. Residents of some counties became concerned because no one knew how much groundwater was available for local use and how much groundwater was available for export. In short, details of the hydrology of the basin, including surface water and groundwater availability, water quality, and the interaction of surface water and groundwater were not known. This lack of detailed knowledge about the operating potential of their groundwater resources led counties to take what they viewed as protective action, which consisted of requiring a permit before anyone could export groundwater from the county.

From the perspective of DWR, groundwater should be managed in a manner that ensures long-term sustainability of the resource for beneficial uses. Those beneficial uses are to be decided by the local stakeholders within the basin. In some areas there may be an ample supply of water, so groundwater exports or substitution projects are feasible while local beneficial uses of the water supply are maintained. In other areas, limiting exports may be necessary to maintain local beneficial uses. Such determinations can be made only after the data are collected and evaluated and the results are used to develop management objectives for the basin.

While developing both the criteria for evaluating groundwater management plans and the model groundwater management ordinance, DWR staff has some two principles in mind. First, the goal of groundwater management, whether accomplished by a plan or by an ordinance, is to sustain and often expand a groundwater resource. Second, groundwater management, whether accomplished by a plan or by an ordinance, requires that local agencies address and resolve the same or similar issues within the boundaries of the agencies. To say it in different words, whether it is a plan or an ordinance, good groundwater management should address the same issues and problems and arrive at the same conclusions and solutions to satisfy the needs of the local area. While some areas may allow or promote exports, others may not.

As stated above, the Legislature required a model ordinance as one of the elements of this update of Bulletin 118. The model ordinance is included as Appendix D and can be used by local governments that have identified a need to adopt a groundwater management ordinance. The model is an example of what a local ordinance might include. Local conditions will require some additions, modifications, or deletions. The variety of political, institutional, legal, technical, and economic opportunities and constraints throughout California guarantees that there will be differences in which the model will have to be adapted. Local governments interested in adopting a groundwater management ordinance are encouraged to consider all components included in the model.

Water Code section 10753.7(b)(1)(A) allows an agency to participate in or consent to be subject to a groundwater management plan, a basin-wide management plan, or other integrated regional water management plan in order to meet the funding eligibility requirements that resulted from passage of SB 1938 (2002). A local government that adopts an ordinance should consider whether or not it will have local agencies that do not have their own groundwater management plan, but consent to be managed under the ordinance. If this situation is anticipated, the ordinance should include the required components described in the Water Code so State funding can be pursued.

AR0069685

AR0069686

Chapter 4

Recent Actions Related to Groundwater Management

AR0069687

Chapter 4
Recent Actions Related to Groundwater Management

The past few years have seen significant actions that impact groundwater management in California. Below are several examples of recent actions including legislation, ballot measures, and executive orders that show the State Legislature and the citizens of California clearly recognize the importance of groundwater and its appropriate management in meeting the present and future water supply needs of the State.

Safe Drinking Water, Clean Water, Watershed Protection and Flood Protection Act of 2000 (Proposition 13)

On March 7, 2000, California voters approved a $1.97-billion general obligation bond known as the Safe Drinking Water, Clean Water, Watershed Protection and Flood Protection Act (Proposition 13). Of the nearly $2 billion, $230 million was earmarked for groundwater programs. The act authorizes $200 million for grants for feasibility studies, project design, and construction of conjunctive use facilities (Water Code, § 79170 et seq.) and $30 million in loans for local agency acquisition and construction of groundwater recharge facilities and feasibility study grants for projects potentially eligible for the loan program (Water Code, § 79160 et seq.). More than $120 million have been awarded in grants and loans to local agencies in the first two years of implementation of these programs.

California Bay-Delta Record of Decision

The goal of the California Bay-Delta (formerly CALFED) program is to restore ecosystem health and improve water management in the Bay-Delta system. The program has four primary objectives:

- Provide good water quality for all beneficial uses
- Improve and increase aquatic and terrestrial habitats and improve ecological functions in the Bay-Delta to support sustainable populations of diverse and valuable plant and animal species
- Reduce the mismatch between Bay-Delta water supplies and current and projected beneficial uses dependent on the Bay-Delta system
- Reduce the risk to land use and associated economic activities, water supply infrastructure, and the ecosystem from catastrophic breaching of Delta levees

The Record of Decision (ROD), released in August 2000, sets forth a 30-year plan to address ecosystem health and water supply reliability problems in the Bay-Delta system. The ROD lays out specific actions and investments over the first seven years to meet program goals. Most important, with respect to groundwater is the California Bay-Delta program's commitment to local groundwater management. The ROD states, "CALFED will work with local governments and affected stakeholders to develop legislation to strengthen AB 3030 and provide technical and financial incentives to encourage more effective basin-wide groundwater management plans ..." (CALFED 2000). The ROD encourages basin management that is developed at the subbasin level so that it addresses local needs, but is coordinated at the basin-wide level so that it considers impacts to other users in the basin. The ROD also commits Bay–Delta agencies to "facilitate and fund locally supported, managed, and controlled groundwater and conjunctive use projects with a total of 500,000 acre-feet to 1 million acre-feet (maf) of additional storage capacity by 2007" (CALFED 2000).

AR0069688

Local Groundwater Management Assistance Act of 2000 (AB 303, Water Code Section 10795 et seq.)

The goal of the Local Groundwater Management Assistance Act is to help local agencies better understand how to manage groundwater resources effectively to ensure the safe production, quality and proper storage of groundwater in the State. The act created the Local Groundwater Assistance Fund, which must be appropriated annually. In three years, more than $15 million in grants were awarded for 71 projects. Grants went to local agencies for groundwater studies and projects that contribute to basin and subbasin management objectives, including but not limited to groundwater monitoring and groundwater basin management. Grants are available to all geographic areas of the State. This act serves to emphasize that groundwater is recognized as an important local resource and, to the extent that groundwater is properly managed at the local level, serves to benefit all Californians.

Groundwater Quality Monitoring Act of 2001 (AB 599, Water Code Section 10780 et seq.)

Assembly Bill 599, known as the Groundwater Quality Monitoring Act of 2001, set a goal to establish comprehensive groundwater monitoring and increase the availability of information about groundwater quality to the public. The objective of the program is to highlight those basins in which contamination has occurred or is likely to occur and provide information that will allow local managers to develop programs to curtail, treat, or avoid additional contamination. The act required the State Water Resources Control Board (SWRCB), in coordination with an Interagency Task Force (ITF) and a Public Advisory Committee (PAC), to integrate existing monitoring programs and design new program elements, as necessary, to establish a comprehensive statewide groundwater quality monitoring program.

Through the ITF and PAC, the Comprehensive Groundwater Quality Monitoring Program was developed. The program will seek to:

- Accelerate the monitoring and assessment program already established by the SWRCB,
- Implement monitoring and assessment in accordance with a prioritization of basins/subbasins,
- Increase coordination and data sharing among groundwater agencies, and
- Maintain groundwater data in a single repository to provide useful access by the public while maintaining appropriate security measures.

The Comprehensive Groundwater Quality Monitoring Program is expected to provide the following key benefits:

- A common base communications medium for agencies to utilize and supply groundwater quality data at multiple levels,
- A mechanism to unite local, regional and statewide groundwater programs in a common effort,
- Better understanding of local, regional and statewide water quality issues and concerns that in turn can provide agencies at all levels with better information to deal with the concerns of consumers and consumer advocate groups,
- Groundwater agencies with near- and long-term forecasting information, essential for groundwater management plan preparation and implementation, and
- The motivation for small- and medium-sized agencies to begin or improve their own groundwater monitoring and management programs.

AR0069689

Water Supply Planning

Three bills enacted by the Legislature to improve water supply planning processes at the local level became effective January 1, 2002. In general, the new laws are intended to improve the assessment of water supplies during the local planning process before land use projects that depend on water are approved. The new laws require the verification of sufficient water supplies as a condition for approving developments, and they compel urban water suppliers to provide more information on the reliability of groundwater if used as a supply.

SB 221 (Gov. and Prof. Code, § 11010 as amended, Gov. Code, § 65867.5 as amended, Gov. Code, §§ 66455.3 and 66473.7) prohibits approval of subdivisions consisting of more than 500 dwelling units unless there is verification of sufficient water supplies for the project from the applicable water supplier(s). This requirement also applies to increases of 10 percent or more of service connections for public water systems with less than 500 service connections. The law defines criteria for determining "sufficient water supply," such as using normal, single-dry, and multiple-dry year hydrology and identifying the amount of water that the supplier can reasonably rely on to meet existing and future planned uses. Rights to extract additional groundwater must be substantiated if used for the project.

SB 610 (Water Code §§ 10631, 10656, 10910, 10911, 10912, and 10915 as amended; Pub. Resources Code, § 21151.9 as amended) and AB 901 (Water Code, §§ 10610.2 and 10631 as amended; Water Code § 10634) make changes to the Urban Water Management Planning Act to require additional information in Urban Water Management Plans (UWMPs) if groundwater is identified as a source available to the supplier. Required information includes a copy of any groundwater management plan adopted by the supplier, proof that the developer or agency has rights to the groundwater, a copy of the adjudication order or decree for adjudicated basins, and if not adjudicated, whether the basin has been identified as being overdrafted or projected to be overdrafted in the most current DWR publication on the basin. If the basin is in overdraft, the UWMP must include current efforts to eliminate any long-term overdraft. A key provision in SB 610 requires that any project subject to the California Environmental Quality Act supplied with water from a public water system be provided a water supply assessment, except as specified in the law. AB 901 requires the plan to include information relating to the quality of existing sources of water available to an urban water supplier over given periods and include the manner in which water quality affects water management strategies and supply reliability.

Emergency Assistance to the Klamath Basin

On May 1, 2001, the Governor proclaimed a State of Emergency in the Klamath Basin in Siskiyou and Modoc counties. The proclamation included disaster assistance of up to $5 million under authority of the State Natural Disaster Assistance Act. This assistance went directly into constructing wells to extract groundwater for use on cover crops to avoid loss of critical topsoil. The Governor's proclamation also included $1 million for a study of the Klamath River Basin to determine the long-term water supply in the California portion of the basin.

Governor's Drought Panel

The Governor's Advisory Drought Planning Panel was formed in 2000 to develop a contingency plan to address the impacts of critical water shortages in California. The panel formed with the recognition that critical water shortages may severely impact the health, welfare, and economy of California. Panel recommendations included securing funding for the Local Groundwater Management Assistance Act (described above), continued support of critical groundwater monitoring in basins with inadequate data, and the formation of a technical assistance and education program for "rural homeowners and small domestic water systems relying on self-supplied groundwater" (GADPP 2000).

AR0069690

Sacramento Valley Water Management Agreement

On May 22, 1995, SWRCB adopted the "Water Quality Control Plan for the San Francisco Bay/Sacramento San Joaquin Delta Estuary" (the 1995 WQCP). Following its action, SWRCB initiated a water rights hearing process with the intent of allocating responsibility for meeting the standards of the 1995 WQCP among water right holders in areas tributary to the Delta. The water rights hearing was conducted in phases with all phases being resolved with the exception of Phase 8, which involved water rights holders in the Sacramento Valley.

Proceeding with Phase 8 may have involved litigation and judicial review for years. That extended process could have resulted in adverse impacts to the environment and undermined progress on other statewide water management initiatives. To avoid the consequences of delay, the Sacramento Valley Water Users, DWR, the U.S. Bureau of Reclamation (USBR), and expert water users developed the Sacramento Valley Water Management Agreement. The agreement became effective April 20, 2001. At that time SWRCB issued an order staying the Phase 8 hearing for 18 months. The parties negotiated a short-term settlement agreement that obligated DWR and USBR to continue to fully meet the Bay Delta water quality standards while providing for the development of conjunctive use and system improvement projects by participating upstream water rights holders that would make water available to help meet water quality standards while improving the reliability of local water supplies. SWRCB has subsequently dismissed the Phase 8 proceedings, and work is being undertaken on both short-term and long-term activities included in the Sacramento Valley Water Management Agreement.

Groundwater Management Water Code Amendments

In September 2002, SB 1938 (Water Code, § 10753.4 and § 10795.4 as amended; Water Code, § 10753.7, § 10753.8 and § 10753.9 as amended and renumbered; Water Code, § 10753.1 and § 10753.7 as added) was signed into law. The act amends existing law related to groundwater management by local agencies. The law requires any public agency seeking State funds administered through DWR for the construction of groundwater projects or groundwater quality projects to prepare and implement a groundwater management plan with certain specified components. Prior to this, there were no required plan components. New requirements include establishing basin management objectives, preparing a plan to involve other local agencies in a cooperative planning effort, and adopting monitoring protocols that promote efficient and effective groundwater management. The requirements apply to agencies that have already adopted groundwater management plans as well as agencies that do not overlie groundwater basins identified in Bulletin 118 and its updates when these agencies apply for state funds. The requirements do not apply to funds administered through the AB 303 Local Groundwater Management Assistance Act (Water Code, § 10795 et seq.) or to funds authorized or appropriated prior to September 1, 2002. Further discussion of the requirements is included in Chapter 3 and Appendix C.

Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002 (Proposition 50)

California voters approved the Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002 (Proposition 50; Water Code, § 79500 et seq.) on the November 2002 elections. The initiative provides for more than $3.4 billion of funding, subject to appropriation by the Legislature, for a number of land protection and water management activities.

Several chapters of Proposition 50 allocate funds for specified water supply and water quality projects, including:

- Chapter 3 Water Security. Provides $50 million to protect State, local, and regional drinking water systems from terrorist attack or deliberate acts of destruction or degradation.

AR0069691

- Chapter 4 Safe Drinking Water. Provides $435 million for grants and loans for infrastructure improvements to meet safe drinking water standards.
- Chapter 5 Clean Water and Water Quality. Provides $390 million for a number of water quality and environmental improvements.
- Chapter 6 Contaminant and Salt Removal Technologies. Provides $100 million for desalination of ocean or brackish waters as well as treatment and removal of contaminants.
- Chapter 7 California Bay-Delta program. Provides $825 million for continuing implementation of all elements of the program.
- Chapter 8 Integrated Regional Water Management. Provides $500 million for many categories of water management projects that will protect communities from drought, protect and improve water quality, and reduce dependence on imported water supplies.
- Chapter 9 Colorado River. Provides $70 million for canal-lining projects necessary to reduce water use and to meet commitments related to California's allocation of water from the Colorado River.

AR0069692

Chapter 5

The Roles of State and Federal Agencies in California Groundwater Management

AR0069693

Chapter 5
The Roles of State and Federal Agencies in California Groundwater Management

Even though groundwater management is a local responsibility and mostly voluntary, several State and federal agencies have key roles in California groundwater management. Some of these roles may not be immediately recognized, but because they work toward the goal of maintaining a reliable groundwater supply, they are closely related to groundwater management. Some of the programs available through the California Department of Water Resources (DWR) and other agencies that assist local agencies in managing groundwater resources are described below.

Local Groundwater Management Assistance from DWR

DWR's role in groundwater management begins with the fundamental understanding that groundwater management is locally driven and management programs should respond to local needs and concerns. DWR recognizes that when groundwater is effectively managed at the local level, benefits are realized at a statewide level.

DWR has historically maintained many programs that directly benefit local groundwater management efforts including:

- Providing assistance to local agencies to assess basin hydrogeologic characteristics,
- Assisting local agencies to identify opportunities to develop additional groundwater supply,
- Monitoring groundwater levels and quality,
- Providing watermaster services for court-adjudicated basins,
- Providing standards for well construction and destruction,
- Managing the State's extensive collection of well completion reports, and
- Reviewing proposals and distributing grant funds and low-interest loans for conjunctive use projects, as well as local groundwater management and monitoring programs.

Conjunctive Water Management Program

DWR's Conjunctive Water Management Program consists of a number of integrated efforts to assist local agencies in improving groundwater management and increasing water supply reliability.

One goal of the Integrated Storage Investigations (ISI) Program, an element of the Bay-Delta program, is to increase water supply reliability statewide through the planned, coordinated management and use of groundwater and surface water resources. The effort emphasizes forming working partnerships with local agencies and stakeholders to share technical data and costs for planning and developing locally controlled and managed conjunctive water management projects.

Toward that end, the Conjunctive Water Management Program has:

- Developed a vision in which DWR would assist local agencies throughout the State so that these agencies can effectively manage groundwater resources,
- Adopted a set of working principles to ensure local planning, local control, operation, and management of conjunctive use projects; voluntary implementation of projects; and local benefits from the proposed projects,
- Executed memoranda of understanding with 30 local agency partners and provided technical and financial assistance to study groundwater basins and assess opportunities for conjunctive water management.

AR0069694

- Provided technical assistance in the form of groundwater monitoring, groundwater modeling, and local water management planning, as well as a review of numerous regional and statewide planning efforts on a variety of water issues, and
- Provided facilitation assistance to promote broad stakeholder involvement in regional water management planning processes.

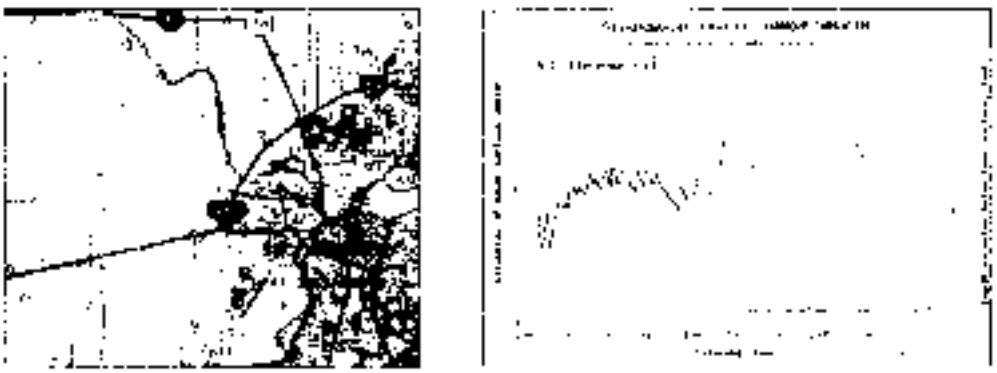
DWR staff review proposals and distribute grants pursuant to the Local Groundwater Management Assistance Act of 2000 (AB 303). To date, DWR has awarded more than $1.5 million to local agencies to fund 71 projects dealing with groundwater investigation, monitoring, or management.

With funds provided under Proposition 13, DWR has awarded more than $170 million in loans and grants for groundwater recharge and storage studies and projects to local agencies throughout the State. Applicant estimates of the water supply reliability increases that will be realized from these projects exceeds 150 thousand acre-feet annually. Recipients of loans and grants must provide progress reports to allow an evaluation of the successes of the various programs. Figure 16 shows the distribution of loan and grant awards throughout the State.

Both grant programs have active outreach efforts to inform and to assist agencies in preparation of applications. Selection of projects for funding relies in part on input from advisory committees composed of stakeholders from throughout the State.

Box L: Providing Data:
The Internet Makes Groundwater Elevation Data Readily Accessible to the Public

In 1995, the California Department of Water Resources (DWR) began providing Internet access to groundwater level data and hydrographs for wells in groundwater basins throughout California. The website, which distributes historical data for more than 35,000 wells monitored by DWR and its many cooperators has proven very popular with more than 60,000 visits to date. Options include a form or map interface to locate wells with water level data and the ability to download long-term water levels for specific wells or seasonal measurements for specific areas to create groundwater contour maps. The availability of this data makes it a significant resource for local agencies making sound groundwater management decisions. The address of the site is http://well.water.ca.gov/



Wells can be located with a map interface. By clicking on a well, a hydrograph with the latest data available is automatically generated.

AR0069695

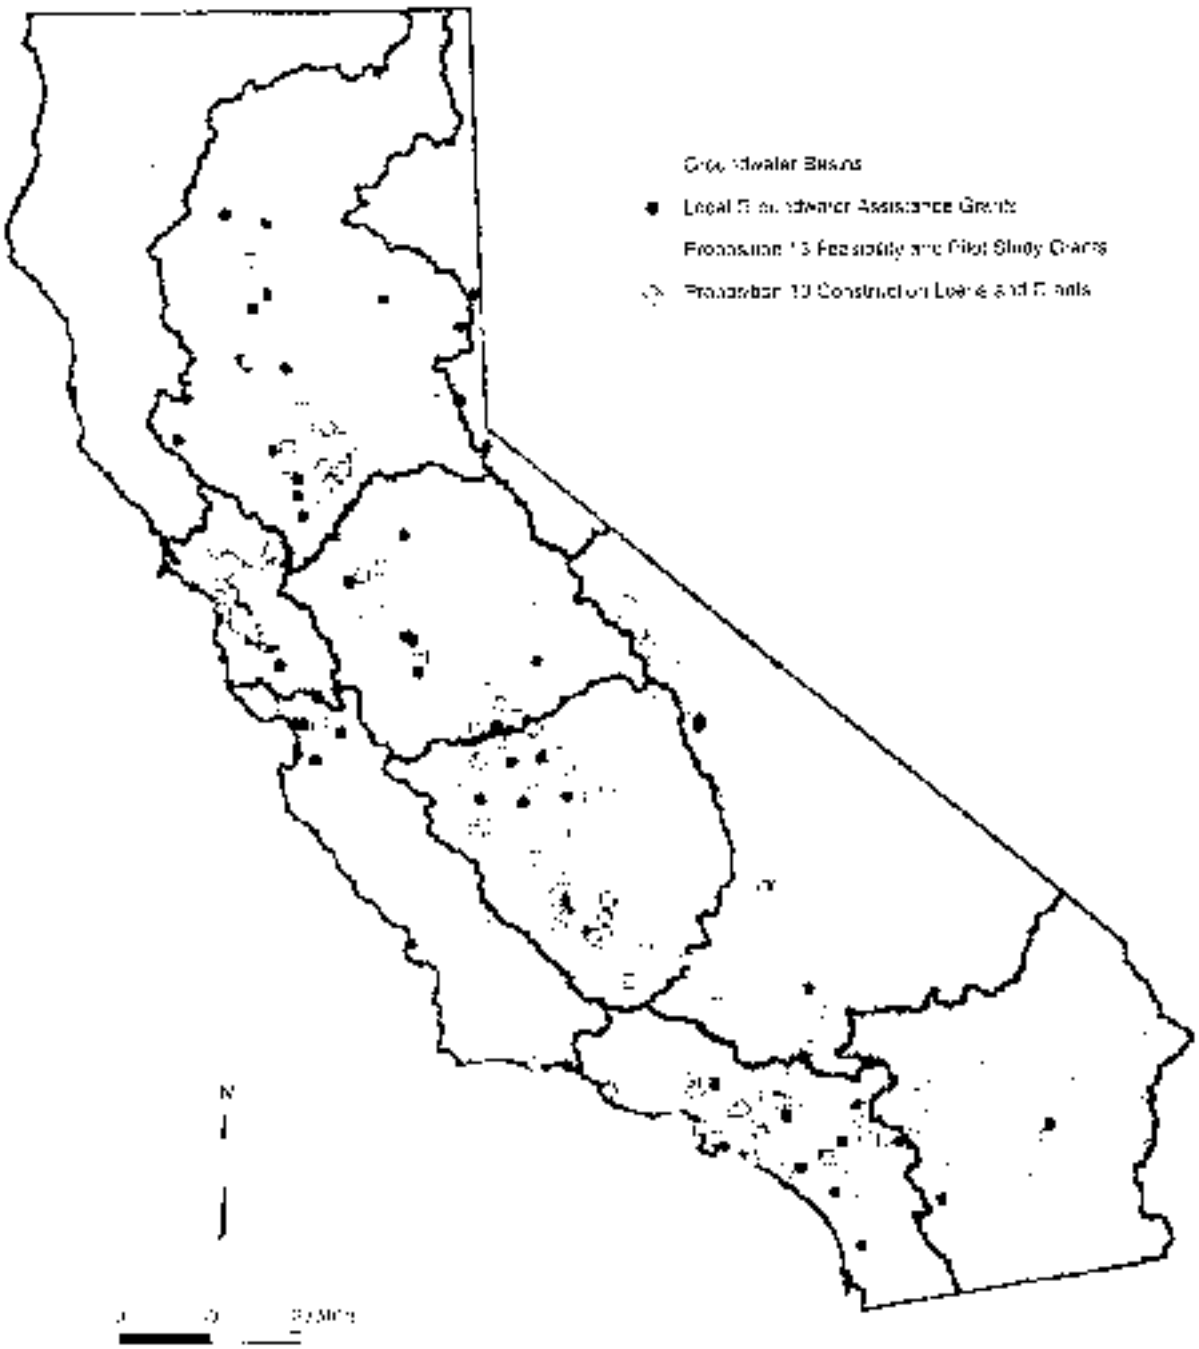


Figure 19 Broad distribution of grant and loan awardees for 2001 through 2003

AR0069696

Assistance from Other State and Federal Agencies

Many other State and federal agencies provide groundwater management assistance to local agencies. Some of those roles are described below. For more information on the roles of various agencies in protecting the groundwater resource, see the California Department of Health Services' Drinking Water Source Assessment and Protection Program Document (DHS 2000), California Groundwater Management (Jachens and others 1997), or the individual agency websites.

State Water Resources Control Board and Regional Water Quality Control Boards

http://www.swrcb.ca.gov The mission of the State Water Resources Control Board (SWRCB) is to ensure the highest reasonable quality of waters of the State, while allocating those waters to achieve the optimum balance of beneficial uses. In turn, the nine Regional Water Quality Control Boards (RWQCB) develop and enforce water quality objectives and implement plans to protect the beneficial uses of the State's waters, recognizing differences in climate, topography, geology, and hydrology.

SWRCB has many responsibilities regarding the protection of the groundwater resource. One of the more notable is the GroundWater Ambient Monitoring and Assessment (GAMA) Program. GAMA is a recently enacted program that will provide a comprehensive assessment of water quality in water wells throughout the state. GAMA has two main components: the California Aquifer Susceptibility (CAS) Assessment and the Voluntary Domestic Well Assessment Project.

The CAS combines age dating of water and sampling for low-level volatile organic compounds (VOCs), such as methyl tertiary-butyl ether (MTBE), to assess the relative susceptibility of all of approximately 16,000 public supply wells throughout the State. Age dating provides a general assessment of how quickly groundwater is moving through the system, while the sampling of low-level VOCs allows greater reaction time for potential remediation strategies before contaminants reach action levels. Sampling is being conducted by staff from the U.S. Geological Survey (USGS) and Lawrence Livermore National Laboratory. The CAS Assessment was developed cooperatively with DHS and DWR.

The Voluntary Domestic Well Assessment Project will provide a previously unavailable sampling of water quality in domestic wells, which will assist in assessing the relative susceptibility of California's groundwater. Because water quality in individual domestic wells is unregulated, the program is voluntary and will focus, as resources permit, on specific areas of the state. Constituents to be analyzed include nitrate, total and fecal coliform bacteria, MTBE, and minerals. Additional constituents will be added in areas with known water quality problems.

Other SWRCB/RWQCB activities related to groundwater protection include developing basin plans that identify existing and potential beneficial uses of marine water, groundwater, and surface waters; regulating the discharge of waste that may affect water quality in California; monitoring of landfills and hazardous waste facilities; establishing standards for the construction and monitoring of underground storage tanks; establishing management plans for control of nonpoint source pollutants; and issuing cleanup and abatement orders that require corrective actions by the responsible party for a surface water or groundwater pollution problem or nuisance.

The Groundwater Quality Monitoring Act of 2001 (AB599, Water Code, § 10780 et seq.) required the SWRCB to develop a comprehensive monitoring program in a report to the Legislature. See Chapter 4 for details.

AR0069697

California Department of Health Services

http://www.dhs.ca.gov/ps/ddwem The DHS Drinking Water Program, part of the Division of Drinking Water and Environmental Management, is responsible for DHS implementation of the federal Safe Drinking Water Act, as well as California statutes and regulations related to drinking water. As part of this responsibility, DHS inspects and provides regulatory oversight of approximately 8,500 public water systems (and approximately 16,000 drinking water wells) to assure delivery of safe drinking water to all California consumers.

Public water system operators are required to regularly monitor their drinking water sources for microbiological, chemical and radiological contaminants to show that drinking water supplies meet regulatory requirements (called primary maximum contaminant levels - MCLs). Among these contaminants are approximately 80 specific inorganic and organic chemical contaminants and six radiological contaminants that reflect the natural environment as well as human activities.

Public water system operators also monitor their water for a number of other contaminants and characteristics that deal with the aesthetic properties of drinking water (known as secondary MCLs). They are also required by regulation to analyze for certain unregulated contaminants (to allow DHS to collect information on emerging contaminants, for example), and to report findings of other contaminants that may be detected during routine monitoring. The DHS water quality monitoring database contains the results of analyses since 1984. These data, collected for purposes of regulatory compliance with drinking water laws, also provide an extensive body of information on the quality of groundwater throughout the State.

California Department of Pesticide Regulation

http://www.cdpr.ca.gov/dprprograms.htm The California Department of Pesticide Regulation (DPR) protects human health and the environment by regulating pesticide sales and use, and by promoting reduced-risk pest management. DPR plays a significant role in monitoring for the presence of pesticides and in preventing further contamination of the groundwater resource.

DPR conducts six types of groundwater monitoring:

1) Monitoring for pesticides on a DPR-determined Ground Water Protection List, which lists pesticides with the potential to pollute groundwater;
2) Post-sanitary survey monitoring to verify a reported detection and to help determine if a detected pesticide resulted from legal agricultural use;
3) Areal extent monitoring to identify the extent of contaminated wells;
4) Adjacent-section monitoring to identify additional areas sensitive to pesticide movement to groundwater;
5) Monitoring to repeatedly sample a network of wells to determine whether pesticide residues are declining; and
6) Special project monitoring.

When pesticides are found in groundwater, they are normally regulated in one-square-mile areas identified in regulation as sensitive to groundwater pollution. These pesticides are subject to permitting by the county agricultural commissioner and to use restrictions specified in regulation. DPR maintains an extensive database of pesticide sampling in groundwater and reports a summary of annual sampling and detections to the State Legislature.

AR0069698

California Department of Toxic Substances Control

http://www.dtsc.ca.gov The California Department of Toxic Substances Control (DTSC) has two programs related to groundwater resources protection: the Hazardous Waste Management Program and the Site Mitigation Program. These programs are authorized under Division 20 of the California Health and Safety Code, and implementing regulations are codified in Title 22 of the California Code of Regulations.

A critical element of both programs is maintaining environmental quality and economic vitality through the protection of groundwater resources. This is accomplished through hazardous waste facility permitting and design; oversight of hazardous waste handling, removal, and disposal; oversight of remediation of hazardous substances releases; funding of emergency removal actions involving hazardous substances, including the cleanup of illegal drug labs; cleanup of abandoned hazardous waste sites; oversight of the closure of military bases; and pollution prevention.

If groundwater is threatened or impacted by a hazardous substance release, DTSC provides technical oversight for the characterization and remediation of soil and groundwater contamination. DTSC and the nine RWQCBs coordinate regulatory oversight of groundwater remediation. To ensure site-specific groundwater quality objectives are met, DTSC consults with RWQCB staff and appropriate groundwater basin plans.

Box M: Improving Coordination of Groundwater Information

California's groundwater resources are addressed by an array of different State and federal agencies. Each agency approaches groundwater from a unique perspective, based on its individual statutory mandate. As a result, each agency collects different types of groundwater data and information. To facilitate the effective and efficient exchange of groundwater resource information, the State Water Resources Control Board (SWRCB) is coordinating the Groundwater Resources Information Sharing Team (GRIST), which is composed of representatives from various groundwater agencies. Agencies currently participating in GRIST are:

- State Water Resources Control Board
- Department of Health Services
- Department of Water Resources
- Department of Pesticide Regulation
- Lawrence Livermore National Laboratory
- U.S. Geological Survey

One of the tasks of the GRIST is to identify data relevant to California groundwater resources. A listing of the data, along with the appropriate agency contacts and Internet links, will be maintained by SWRCB on the Groundwater Resources Information Database. In addition, to facilitate effective information sharing and communication among stakeholders, groundwater data will be made available on the SWRCB GeoTracker system. GeoTracker is a geographic information system that provides Internet access to environmental data. The centralization of environmental data through GeoTracker will enable more in-depth geospatial and statistical analyses of groundwater data in the future. For more information about GeoTracker, visit the GeoTracker Internet site at http://geotracker.arsenault.egy.com.

California Bay-Delta Authority

http://calwater.ca.gov The California Bay-Delta program was initiated in 1994 to develop and implement a long-term comprehensive plan that will restore ecological health and improve water management for beneficial uses of the Sacramento-San Joaquin Bay-Delta System. The partnership currently consists of more than 20 State and federal agencies. An important element of the program is to increase storage by developing an additional 500,000 acre-feet to 1.0 million acre-feet of groundwater storage capacity by the year 2020 (CALFED 2000).

Effective January 1, 2003, a newly formed State agency assumed responsibility for overseeing implementation of the Bay-Delta program. The California Bay-Delta Authority provides a permanent governance structure for the collaborative state-federal effort. The authority was established by enactment of Senate Bill 1653 in 2002. The legislation calls for the authority to sunset on January 1, 2006, unless federal legislation has been enacted authorizing the participation of appropriate federal agencies in the authority.

U.S. Environmental Protection Agency

http://www.epa.gov/safewater The U.S. Environmental Protection Agency (EPA) Office of Ground Water and Drinking Water, together with states, tribes, and many partners, protects public health by ensuring safe drinking water and protecting groundwater. The EPA's role in California groundwater is primarily related to protection of the resource and comes in the form of administering several federal programs in close coordination with State agencies such as SWRCB, DHS, and DTSC.

U.S. Geological Survey

http://ca.water.usgs.gov USGS has published results of many studies of California groundwater basins. USGS maintains an extensive groundwater level and groundwater quality monitoring network and has compiled this data in a database. The California District is working on cooperative programs with local, State, and other federal agencies. The most notable programs include three regional studies of the San Joaquin-Tulare Basin, the Sacramento River Basin, and the Santa Ana River Basin under the National Water Quality Assessment Program. Results were published for the San Joaquin-Tulare Basin in 1995 and the Sacramento River Basin in 2000. The Santa Ana River basin study is in progress.

U.S. Bureau of Reclamation

http://www.usbr.gov The U.S. Bureau of Reclamation (USBR) operates the Central Valley Project (CVP), an extensive network of dams, canals, and related facilities that delivers about 7 mat during normal years for agricultural, urban, and wildlife use. USBR's role with respect to groundwater is generally limited to monitoring for impacts to the groundwater systems adjacent to its CVP facilities. Through the cooperative efforts of USBR, DWR, irrigation districts, farmers, and other local entities, groundwater level data have been collected continuously since project conception in the 1930s and 1940s.

In addition to CVP monitoring, USBR monitors groundwater levels to identify potential impacts as a result of two other projects in California. That monitoring includes the Santa Ynez basin as part of the Cachuma Project on the central coast, and the Butte Creek Cone as part of the Sutter Project in the southwest Sacramento Valley. Both monitoring efforts are required as part of permitting for the projects.

USBR is planning to implement a groundwater information system to collect and distribute to the public the large volume of historical groundwater level data associated with its projects.

Chapter 6

Basic Groundwater Concepts

Chapter 6
Basic Groundwater Concepts

This chapter presents general concepts relating to the origin, occurrence, movement, quantity, and quality of groundwater. The concepts will be useful in providing the nontechnical reader with a basic understanding of groundwater. For more experienced readers, many topics are discussed specifically as they apply to California or as the terms are used in this report. A glossary of terms is included at the end of this report. For additional reading on basic groundwater concepts see *Basic Ground-Water Hydrology* (Heath 1983).

Origin of Groundwater

Groundwater is a component of the hydrologic cycle (Figure 1), which describes locations where water may occur and the processes by which it moves or is transformed to a different phase. In simple terms, water or one of its forms—water vapor and ice—can be found at the earth's surface, in the atmosphere, or beneath the earth's surface. The hydrologic cycle is a continuum, with no beginning or end, however, it is often thought of as beginning in the oceans. Water evaporates from a surface water source such as an ocean, lake, or through transpiration from plants. The water vapor may move over the land and condense to form clouds, allowing the water to return to the earth's surface as precipitation (rain or snow). Some of the snow will end up in polar ice caps or in glaciers. Most of the rain and snowmelt will either become overland flow in channels or will infiltrate into the subsurface. Some of the infiltrated water will be transpired by plants and returned to the atmosphere, while some will cling to particles surrounding the pore spaces in the subsurface, remaining in the vadose (unsaturated) zone. The rest of the infiltrated water will move gradually under the influence of gravity into the saturated zone of the subsurface, becoming groundwater. From here, groundwater will flow toward points of discharge such as rivers, lakes, or the ocean to begin the cycle anew. This flow from recharge areas to discharge areas describes the groundwater portion of the hydrologic cycle.

The importance of groundwater in the hydrologic cycle is illustrated by considering the distribution of the world's water supply. More than 97 percent of all earth's water occurs as saline water in the oceans (Lattet 1988). Of the world's fresh water, almost 75 percent is in polar ice caps and glaciers, which leaves a very small amount of fresh water readily available for use. Groundwater accounts for nearly all of the remaining fresh water (Alley and others 1999). All of the fresh water stored in the world's rivers and lakes accounts for less than 1 percent of the world's fresh water.

Occurrence of Groundwater

Groundwater is the water occurring beneath the earth's surface that completely fills (saturates) the void space of rocks or sediment. Given that all rock has some open space (voids), groundwater can be found underlying nearly any location in the State. Several key properties help determine whether the subsurface environment will provide a significant, usable groundwater resource. Most of California's groundwater occurs in material deposited by streams, called alluvium. Alluvium consists of coarse deposits, such as sand and gravel, and finer-grained deposits such as clay and silt. The coarse and fine materials are usually coalesced in thin lenses and beds in an alluvial environment. In this environment, coarse materials such as sand and gravel deposits usually provide the best source of water and are termed aquifers; whereas, the finer-grained clay and silt deposits are relatively poor sources of water and are referred to as aquitards. California's groundwater basins usually include one or a series of alluvial aquifers with interfingered aquitards. Less frequently, groundwater basins include aquifers composed of unconsolidated marine sediments that have been flushed by fresh water. We include the marine-deposited aquifers in the discussion of alluvial aquifers in this bulletin.

AR0069702

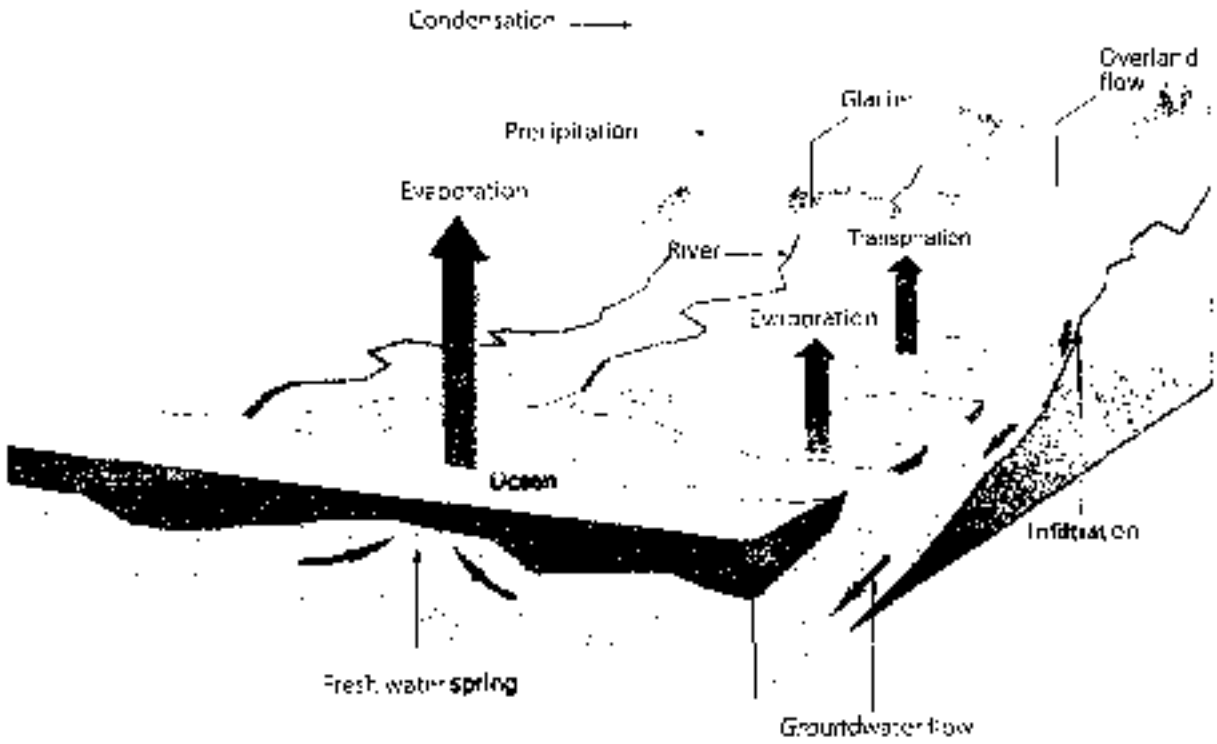

Figure 11 The Hydrologic Cycle

Although alluvial aquifers are most common in California, other groundwater development occurs in fractured crystalline rocks, fractured volcanics, and limestones. For this report, these non-alluvial areas that provide groundwater are referred to as "groundwater source areas," while the alluvial aquifers are called groundwater basins. Each of these concepts is discussed more fully below.

Groundwater and Surface Water Interconnection

Groundwater and surface water bodies are connected physically in the hydrologic cycle. For example, at some locations or at certain times of the year, water will infiltrate the bed of a stream to recharge groundwater. At other times or places, groundwater may discharge, contributing to the base flow of a stream. Changes in either the surface water or groundwater system will affect the other, so effective management requires consideration of both resources. Although this physical interconnection is well understood in general terms, details of the physical and chemical relationships are the topic of considerable research.

These details are the subject of significant recent investigations into the hyporheic zone, the zone of sand and gravel that forms the channel of a stream. As surface water flows downstream it may enter the gravels in the

AR0069703

Box M One Resource, Two Systems of Law

In California, two distinct legal regimes govern the appropriation of surface water and subterranean streams, and percolating groundwater. The California Water Code requires that water users taking water for beneficial use from surface watercourses and "subterranean streams flowing through known and definite channels" obtain water right permits or licenses from the State Water Resources Control Board (SWRCB) (Water Code § 1200 et seq.). Groundwater classified as percolating groundwater is not subject to the Water Code provisions concerning the appropriation of water, and a water user can take percolating groundwater without having a State-issued water right permit or license. Current Water Code section 1200 is derived from a provision in the Water Commission Act of 1913, which became effective on December 19, 1914.

The SWRCB developed a test to identify groundwater that is in a subterranean stream flowing through a known and definite channel and is therefore subject to the SWRCB's permitting authority. The physical conditions that must be present in a subterranean stream flowing in a known and definite channel are: (1) a subsurface channel must be present; (2) the channel must have relatively impermeable bed and banks; (3) the course of the channel must be known or capable of being determined by reasonable diligence; and (4) groundwater must be flowing in the channel. Whether groundwater is subject to the SWRCB's permitting authority under this test is a factual determination. Water that does not fit this test is "percolating groundwater" and is not subject to the SWRCB's permitting authority.

The SWRCB has issued decisions that find that groundwater under the following streams constitutes a "subterranean stream flowing through known and definite channels" and is therefore subject to the SWRCB's permitting authority (Murphey 2003 pers. com.):

Los Angeles River in Los Angeles County
Sheep Creek in San Bernardino County
Mission Basin of the San Luis Rey River in San Diego County
Bonsall Basin of the San Luis Rey River in San Diego County
Pala Basin of the San Luis Rey River in San Diego County
Carmel River in Monterey County
Carmelita Creek in Monterey County
Big Sur River in Monterey County
Russian River
Chorro Creek in San Luis Obispo County
Morro Creek in San Luis Obispo County
North Fork Cuyama River in Mendocino County

Contact the SWRCB, Division of Water Rights for specific stream regimes and other details of these decisions.

AR0069704

hyporheic zone, mix with groundwater, and re-enter the surface water in the stream channel. The effects of this interchange between surface water and groundwater can change the dissolved oxygen content, temperature, and mineral concentrations of the water. These changes may have a significant effect on aquatic and riparian biota.

Significantly, the physical and chemical interconnection of groundwater and surface water is not well represented in California's water rights system (see Box N "One Resource, Two Systems of Law").

Physical Properties That Affect Groundwater

The degree to which a body of rock or sediments will function as a groundwater resource depends on many properties, some of which are discussed here. Two of the more important physical properties to consider are porosity and hydraulic conductivity. Transmissivity is another important concept to understand when considering an aquifer's overall ability to yield significant groundwater. Throughout the discussion of these properties, keep in mind that sediment size in alluvial environments can change significantly over short distances, with a corresponding change in physical properties. Thus, while these properties are often presented as average values for a large area, one might encounter different conditions on a more localized level. Determination of these properties for a given aquifer may be based on lithologic or geophysical observations, laboratory testing, or aquifer tests with varying degrees of accuracy.

Porosity

The ratio of voids in a rock or sediment to the total volume of material is referred to as porosity and is a measure of the amount of groundwater that may be stored in the material. Figure 12 gives several examples of the types of porosity encountered in sediments and rocks. Porosity is usually expressed as a percentage and can be classified as either primary or secondary. Primary porosity refers to the voids present when the sediment or rock was originally formed. Secondary porosity refers to voids formed through fracturing or weathering of a rock or sediment after it was formed. In sediments, porosity is a function of the uniformity of grain size (sorting) and shape. Finer-grained sediments tend to have a higher porosity than coarser sediments because the finer-grained sediments generally have greater uniformity of size and because of the tabular shape and surface chemistry properties of clay particles. In crystalline rocks, porosity becomes greater with a higher degree of fracturing or weathering. As alluvial sediments become consolidated, primary porosity generally decreases due to compaction and cementation, and secondary porosity may increase as the consolidated rock is subjected to stresses that cause fracturing.

Porosity does not tell the entire story about the availability of groundwater in the subsurface. The pore spaces must also be interconnected and be large enough so that water can move through the ground to be extracted from a well or discharged to a water body. The term "effective porosity" refers to the degree of interconnectedness of pore spaces. For coarse sediments, such as the sand and gravel often stored in California's alluvial groundwater basins, the effective porosity is often nearly equal to the overall porosity. In finer-sediments, effective porosity may be low due to water that is tightly held in small pores. Effective porosity is generally very low in crystalline rocks that are not highly fractured or weathered.

While porosity measures the total amount of water that may be contained in void spaces, there are two related properties that are important to consider: specific yield and specific retention. Specific yield is the fractional amount of water that would drain freely from rocks or sediments due to gravity and describes the portion of the groundwater that could actually be available for extraction. The portion of groundwater that is retained either as a film on grains or in small pore spaces is called specific retention. Specific yield and specific retention of the aquifer material together equal porosity. Specific retention increases with decreasing

AR0069705

grain size. Table 7 shows that clays, while having among the highest porosities, make poor sources of groundwater because they yield very little water. Sand and gravel, having much lower porosity than clay, make excellent sources of groundwater because of the high specific yield, which allows the groundwater to flow to wells. Rocks such as limestone and basalt yield significant quantities of groundwater if they are well-weathered and highly fractured.

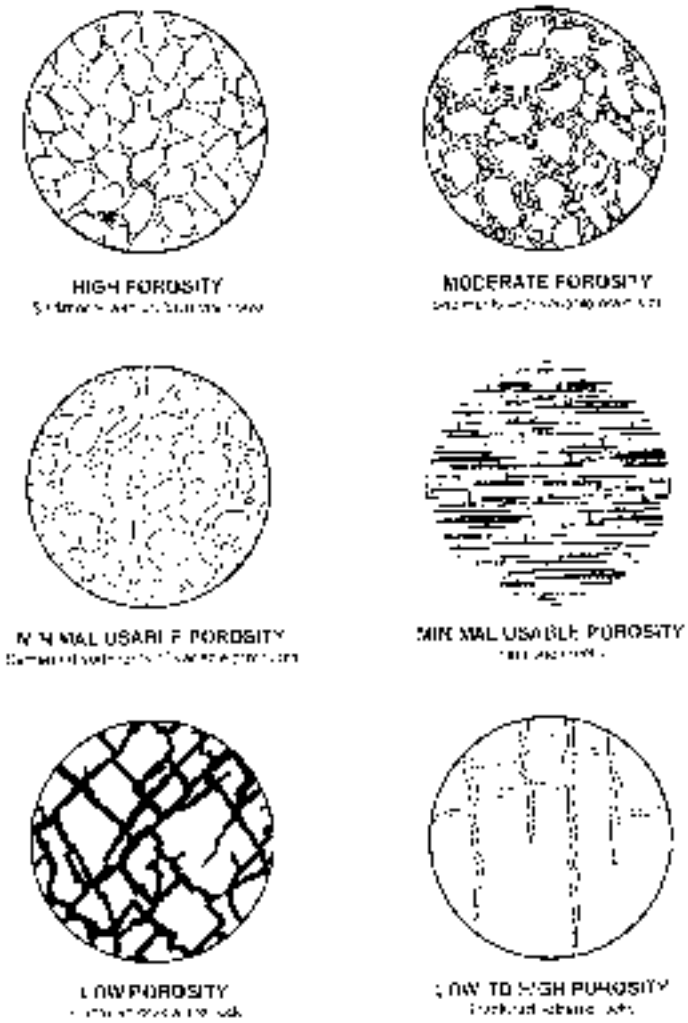

Figure 12 Examples of porosity in sediments and rocks

AR0069706

Table 7 Porosity (in percent) of soil and rock types

Material	Porosity	Specific yield	Specific retention
Clay	50	2	48
Sand	25	23	2
Gravel	20	19	1
Limestone	20	18	2
Sandstone (unconsolidated)	21	6	5
Granite	0.1	0.09	0.01
Basalt (young)	11	8	3

Modified from Heath (1983)

Hydraulic Conductivity

Another major property related to understanding water movement in the subsurface is hydraulic conductivity. Hydraulic conductivity is a measure of a rock or sediment's ability to transmit water and is often used interchangeably with the term permeability. The size, shape, and interconnectedness of pore spaces affect hydraulic conductivity (Driscoll, 1986).

Hydraulic conductivity is usually expressed in units of length/time: feet/day, meters/day, or gallons/day/square-foot. Hydraulic conductivity values in rocks range over many orders of magnitude from a low permeability unfractured crystalline rock at about 10^{-6} feet/day to a highly permeable well-sorted gravel at greater than 10^{5} feet/day (Heath 1983). Clays have low permeability, ranging from about 10^{-7} to 10^{-3} feet/day (Heath 1983). Figure 13 shows hydraulic conductivity ranges of selected rocks and sediments.

Transmissivity

Transmissivity is a measure of the aquifer's ability to transmit groundwater through its entire saturated thickness and relates closely to the potential yield of wells. Transmissivity is defined as the product of the hydraulic conductivity and the saturated thickness of the aquifer. It is an important property to understand because a given area could have a high value of hydraulic conductivity but a small saturated thickness, resulting in limited overall yield of groundwater.

Aquifer

An aquifer is a body of rock or sediment that yields significant amounts of groundwater to wells or springs. In many definitions, the word "significant" is replaced by "economic." Of course, either term is a matter of perspective, which has led to disagreement about what constitutes an aquifer. As discussed previously, coarse-grained sediments such as sands and gravels deposited in alluvial or marine environments tend to function as the primary aquifers in California. These alluvial aquifers are the focus of this report. Other aquifers, such as those found in volcanics, igneous intrusive rocks, and carbonate rocks are described briefly in the section Groundwater Source Areas.

Aquitard

An aquitard is a body of rock or sediment that is typically capable of storing groundwater but does not yield it in significant or economic quantities. Fine-grained sediments with low hydraulic conductivity, such as clays and silts, often function as aquitards. Aquitards are often referred to as confining layers because they retard the vertical movement of groundwater and under the right hydrogeologic conditions confine groundwater that is under pressure. Aquitards are capable of transmitting enough water to allow some flow between adjacent aquifers, and depending on the magnitude of this transfer of water, may be referred to as leaky aquitards.

AR0069707

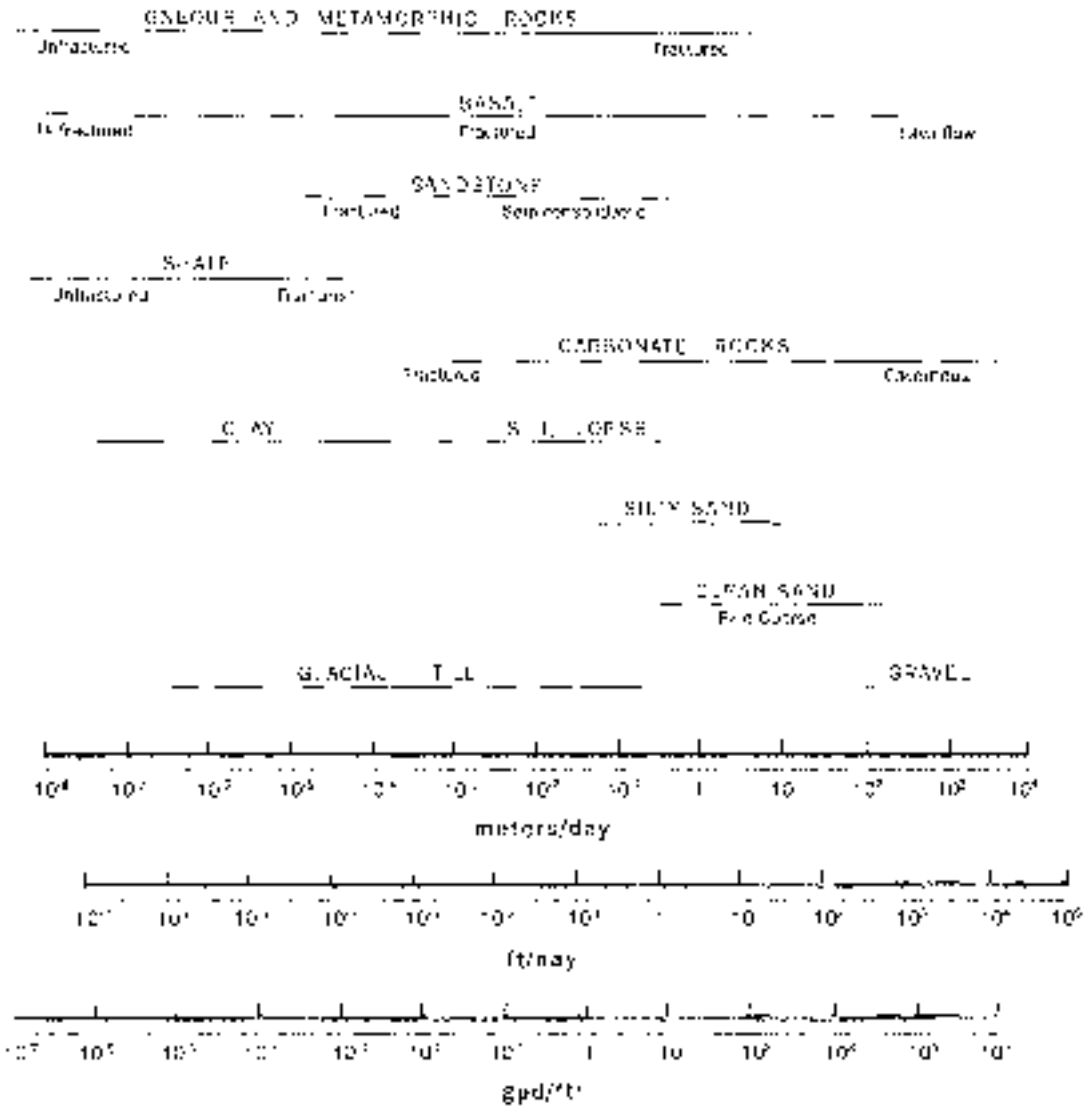

Figure 13 Hydraulic conductivity ranges of selected rocks and sediments

AR0069708

Unconfined and Confined Aquifers

In most depositional environments, coarser-grained deposits are interbedded with finer-grained deposits creating a series of aquifers and aquitards. When a saturated aquifer is bounded on top by an aquitard (also known as a confining layer), the aquifer is called a confined aquifer (Figure 14). Under these conditions, the water is under pressure so that it will rise above the top of the aquifer if the aquitard is penetrated by a well. The elevation to which the water rises is known as the potentiometric surface. Where an aquifer is not bounded on top by an aquitard, the aquifer is said to be unconfined. In an unconfined aquifer, the pressure on the top surface of the groundwater is equal to that of the atmosphere. This surface is known as the water table, so unconfined aquifers are often referred to as water table aquifers. The arrangement of aquifers and aquitards in the subsurface is referred to as hydrostratigraphy.

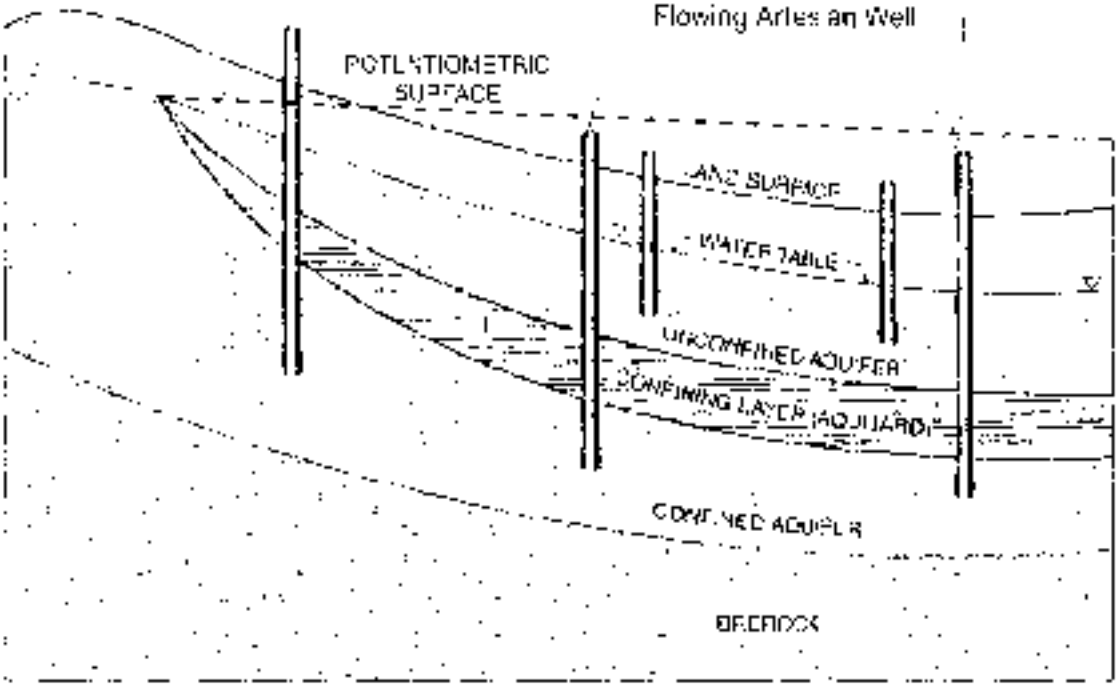

Figure 14 Interbedded aquifers with confined and unconfined conditions

With the notable exception of the Corcoran Clay of the Tulare Formation in the San Joaquin Valley and the equivalent in West Coast Basin in Los Angeles County, there are no clearly recognizable regional aquitards in California alluvial basins. Instead, due to the complexity of alluvial environments, it is the cumulative effect of multiple thin lenses of fine-grained sediments that causes increasing confinement of groundwater with increasing depth, creating what is often referred to as a semiconfined aquifer.

In some confined aquifers groundwater appears to defy gravity, but that is not the case. When a well penetrates a confined aquifer with a potentiometric surface that is higher than land surface, water will flow naturally to the surface. This is known as artesian flow, and results from pressure within the aquifer. The pressure results when the recharge area for the aquifer is at a higher elevation than the point at which discharge is occurring (Figure 14). The confining layer prevents the groundwater from returning to the surface until the confining layer is penetrated by a well. Artesian flow will discontinue as pressure in the aquifer is reduced and the potentiometric surface drops below the land surface elevation.

AR0069709

Groundwater Basin

A groundwater basin is defined as an alluvial aquifer or a stacked series of alluvial aquifers with reasonably well-defined boundaries in a lateral direction and a definable bottom. Lateral boundaries are features that significantly impede groundwater flow such as rock or sediments with very low permeability or a geologic structure such as a fault. Bottom boundaries would include rock or sediments of very low permeability if no aquifers occur below those sediments within the basin. In some cases, such as in the San Joaquin and Sacramento Valleys, the base of fresh water is considered the bottom of the groundwater basin. Table 8 is a generalized list of basin types and the features that define the basin boundaries.

Table 8 Types and boundary characteristics of groundwater basins

Characteristics of groundwater basins	
Groundwater basin	An aquifer or an aquifer system that is bounded laterally and at depth by one or more of the following features that affect groundwater flow: • Rock or sediments of lower permeability • A geologic structure, such as a fault • Hydrologic boundaries, such as a stream, lake, ocean, or groundwater divide
Types of basins and their boundaries	
Single alluvial basin	Basin surrounded, laterally overlain by less permeable rock Higher permeability near the periphery. Clays near the center. Unconfined around the periphery. Confined near the center. May have artesian flow near the center
Basin open to one or more places by other basins	May depict basins Merged alluvial fans. Topographic boundaries only. Includes some hydrologic boundaries.
Basin open to Pacific Ocean	Extends along the coast Water-bearing materials extend offshore May have contact with salt water Vulnerable to seawater intrusion.
Single complex basin	Basin rocks are surrounded by older water bearing materials and water bearing volcanics. Quantification is difficult because of lack knowledge between different rock types within the basin.
Groundwater in consolidated volcanic rocks	Basin concepts rarely applicable in volcanic rocks Volcanic rocks are highly variable in permeability.
Groundwater in weathered crystalline rocks (fractured rock) and unconsolidated deposits	Small quantities of groundwater Low-yielding wells Most wells are completed in the crystalline rock and rely on fractures to obtain groundwater
Potential hydraulic or management boundaries	Usually not selected as hydrologic boundaries for water-budget purposes, usually for managing surface water storage and delivery

AR0069710

Although only the upper surface of a groundwater basin can be shown on a map, the basin is three-dimensional and includes all subsurface fresh water-bearing material. These boundaries often do not extend straight down, but are dependent on the spatial distribution of geologic materials in the subsurface. In fact, in a few areas near California's coastal areas, aquifers in the subsurface are known to extend beyond the mapped surface of the basin and may actually be exposed under the ocean. Under natural conditions, fresh water flows from these aquifers into the ocean. If groundwater levels are lowered, sea water may flow into the aquifer. This has occurred in Los Angeles, Orange, Ventura, Santa Cruz and Monterey Counties, and some areas around San Francisco Bay. Depiction of a groundwater basin in three dimensions requires extensive subsurface investigation and data evaluation to delineate the basin geometry. Figure 15 is a cross section showing how a coastal basin might appear in the subsurface.

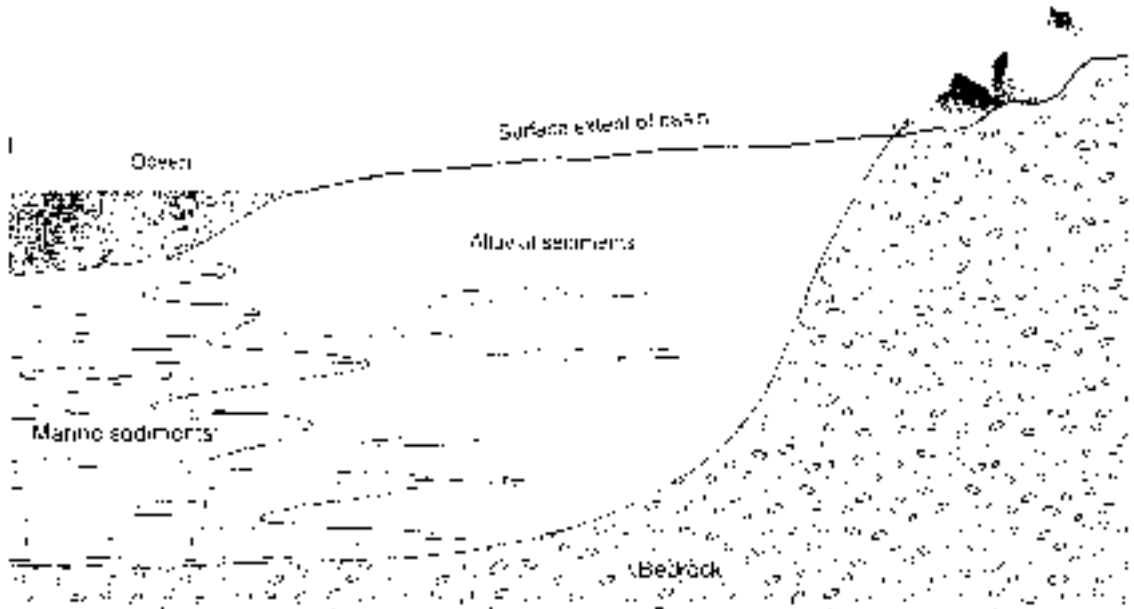

Figure 15 Groundwater basin near the coast with the aquifer extending beyond the surface basin boundary

Groundwater basin and subbasin boundaries shown on the map included with this bulletin are based on evaluation of the best available information. In basins where many studies have been completed and the basin has been operated for a number of years, the basin response is fairly well understood and the boundaries are fairly well defined. Even in these basins, however, there are many unknowns and changes in boundaries may result as more information about the basin is collected and evaluated. In many other basins where much less is known and understood about the basin, boundaries will probably change as a better understanding of the basin is developed. A procedure for collecting information from all the stakeholders should be developed for use statewide so that agreement on basin boundaries can be achieved.

AR0069711

Groundwater Subbasin

A subbasin is created by dividing a groundwater basin into smaller units using geologic and hydrologic barriers or, more commonly, institutional boundaries (see Table 8). These subbasins are created for the purpose of collecting and analyzing data, managing water resources, and managing adjudicated basins. As the definition implies, the designation of a subbasin boundary is flexible and could change in the future. The limiting rule for a subbasin is that it should not cross over a groundwater basin boundary.

An example of a hydrologic subbasin boundary would be a river or stream that creates a groundwater divide. While hydrologic boundaries may limit groundwater flow in the shallow subsurface, data indicate significant groundwater flow may occur across the boundary at greater depths. In addition, the location of the boundary may change over time if pumping or recharge patterns change. Institutional subbasin boundaries could be based on a political boundary, such as a county line or a water agency service area, or a legally mandated boundary, such as a court adjudication basin.

Groundwater Source Areas

Groundwater in California is also found outside of alluvial groundwater basins. Igneous extrusive (volcanic), igneous intrusive, metamorphic, and sedimentary rocks are all potential sources of groundwater. These rocks often supply enough water for domestic use, but in some cases can also yield substantial quantities. In this report the term groundwater source area is used for rocks that are significant in terms of being a local groundwater source, but do not fit the category of basin or subbasin. The term is not intended to imply that groundwater actually originates in these rocks, but that it is withdrawn from rocks underlying a generally definable area. Because of the increased difficulty in defining and understanding the hydrogeologic properties of these rocks, the limited data available for the areas in which these rocks occur, and the relatively small, though rapidly growing, segment of the population served by these water supplies, they are discussed separately from groundwater basins.

Volcanics

Groundwater in volcanics can occur in fractures that result from cooling or changes in stress in the crust of the Earth, lava tubes, tree molds, weathering surfaces, and porous tuff beds. Additionally, the volcanics could overlie other deposits from an alluvial environment. Flow in the fractures may approach the same velocities as that of surface water, but there is often very limited storage potential for groundwater. The tuff beds can act similarly to alluvial aquifers.

Some of the most productive volcanic rocks in the State include the Modoc Plateau volcanics in the northeast and the Napa-Sonoma volcanics northeast of San Francisco Bay (Figure 16). Wells in Modoc Plateau volcanics are commonly reported to yield between 100 and 1,000 gallons per minute, with some yields of 4,000 gpm (Planert and Williams 1995). Bulletin 118-75 assigned identification numbers to these volcanic rocks throughout the State (for example, Modoc Plateau Recent Volcanic Areas, 1-23). The numbers led some to misinterpret them as being groundwater basins. In this update, the numbers corresponding to the volcanics are being retired to eliminate this confusion.

AR0069712

Figure 16 Significant volcanic groundwater source areas

AR0069713

Igneous Intrusive, Metamorphic, and Sedimentary Rocks

Groundwater in igneous intrusive, metamorphic, and consolidated sedimentary rocks occurs in fractures resulting from tectonism and expansion of the rock as overburden pressures are relieved. Groundwater is extracted from fractured rock in many of the mountainous areas of the State, such as the Sierra Nevada, the Peninsular Range, and the Coast Ranges. Rocks in these areas often yield only enough supply for individual domestic wells, stock water wells, or small community water systems. Availability of groundwater in such formations can vary widely, even over a distance of a few yards. Areas of groundwater production from consolidated rocks were not defined in previous versions of Bulletin 118 and are not included in this update.

As population grows in areas underlain by these rocks, such as the foothills of the Sierra Nevada and southern California mountains, many new wells are being bored in fractured rock. However, groundwater data are often insufficient to accurately estimate the long-term reliability of groundwater supplies in these areas. Additional investigation, data evaluation, and management will be needed to ensure future sustainable supplies. The Legislature recognized both the complexity of these areas and the need for management in SB 1938 (2002), which amended the Water Code to require groundwater management plans with specific components be adopted for agencies to be eligible for certain funding administered by DWR for construction of groundwater projects. Water Code section 10753.7(a)(5) states:

> Local agencies that are located in areas outside the groundwater basins delineated on the latest edition of the department's groundwater basin and subbasin map shall prepare groundwater management plans incorporating the components in this subdivision, and shall use geologic and hydrologic principles appropriate to those areas.

In carbonate sedimentary rocks such as limestone, groundwater occurs in fractures and cavities formed as a result of dissolution of the rock. Flow in the largest fractures may approach the velocities of surface water, but where these rocks occur in California there is limited storage potential for groundwater. Carbonate rocks occur mostly in Inyo County near the Nevada border (USGS 1995), in the Sierra Nevada foothills, and in some parts of the Sacramento River drainage north of Redding. The carbonates near the Nevada state border in Inyo County are part of a regional aquifer that extends northeastward into Nevada. Springs in Nevada and in the Death Valley region in California are dependent on groundwater flow in this regional aquifer. In other parts of the country, such as Florida, carbonate rocks constitute significant sources of groundwater.

Movement of Groundwater

The movement of groundwater in the subsurface is quite complex, but in simple terms it can be described as being driven by potential energy. At any point in the saturated subsurface, groundwater has a hydraulic head value that describes its potential energy, which is the combination of its elevation and pressure. In an unconfined aquifer, the water table elevation represents the hydraulic head, while in a confined aquifer the potentiometric surface represents the hydraulic head (Figure 14). Water moves in response to the difference in hydraulic head from the point of highest energy toward the lowest. On a regional scale this results in flow of groundwater from recharge areas or discharge areas. In California, pumping depressions around extraction wells often create the discharge points to which groundwater flows. Groundwater may naturally exit the subsurface by flowing into a stream, lake, or ocean, by flowing to the surface as a spring or seep, or by being transpired by plants.

The rate at which groundwater flows is dependent on the hydraulic conductivity and the rate of change of hydraulic head over some distance. In the mid-19th century, Henry Darcy found through his experiments on sand filters that the amount of flow through a porous medium is directly proportional to the difference

AR0069714

between hydraulic head values and inversely proportional to the horizontal distance between them (Fetter 1988). His conclusions extend to flow through aquifer materials. The difference between hydraulic heads divided by the distance between them is referred to as the hydraulic gradient. When combined with the hydraulic conductivity of the porous medium and the cross-sectional area through which the groundwater flows, Darcy's law states:

$$Q = KA(dh/dl) \quad \text{(volume/time)}$$

Where:

Q = flow discharging through a porous medium
K = hydraulic conductivity (length/time)
A = cross-sectional area (length^2)
dh = change in hydraulic head between two points (length)
dl = distance between two points (length)

This version of Darcy's law provides a volumetric flow rate. To calculate the average linear velocity at which the water flows, the result is divided by the effective porosity. The rate of movement of groundwater is very slow, usually less than 1,000 feet per year because of the great amount of friction resulting from movement through the spaces between grains of sand and gravel.

Quantity of Groundwater

Because groundwater is a precious resource, the questions of how much there is and how more can be made available are important. There are many terms and concepts associated with the quantity of groundwater available in a basin, and some controversy surrounding their definition. Some of these include groundwater storage capacity, usable storage capacity, groundwater budget, change in storage, overdraft, and safe yield. This section discusses some of the more common terms used to represent groundwater quantity in California.

Groundwater Storage Capacity

The groundwater storage capacity of an individual basin or within the entire State is one of the questions most frequently asked by private citizens, water resource planners, and politicians alike. Total storage capacity seems easy to understand. It can be seen as how much physical space is available for storing groundwater. The computation of groundwater storage capacity is quite simple if data are available: capacity is determined by multiplying the total volume of a basin by the average specific yield. The total storage capacity is constant and is dependent on the geometry and hydrogeologic characteristics of the aquifer(s) (Figure 17).

Estimates of total groundwater storage capacity in California are staggering. Previous estimates of total storage range from 850 million acre-feet (maf) to 1.3 billion acre-feet (DWR 1975, DWR 1994). However, due to incomplete information about many of the groundwater basins, there has never been an accurately quantified calculation of total storage capacity statewide. Even if such a calculation were possible, the utility of such a number is questionable because total storage capacity might lead to overly optimistic estimates of how much additional groundwater development can contribute to meeting future demands.

Total groundwater storage capacity is misleading because it only takes into account one aspect of the physical character of the basin. Many other factors limit the ultimate development potential of a groundwater basin. These limiting factors may be physical, chemical, economic, environmental, legal, and institutional (Table 9). Some of these factors, such as the economic and institutional ones, can change with time. However, there may remain significant physical and chemical constraints that will limit groundwater development.

AR0069715

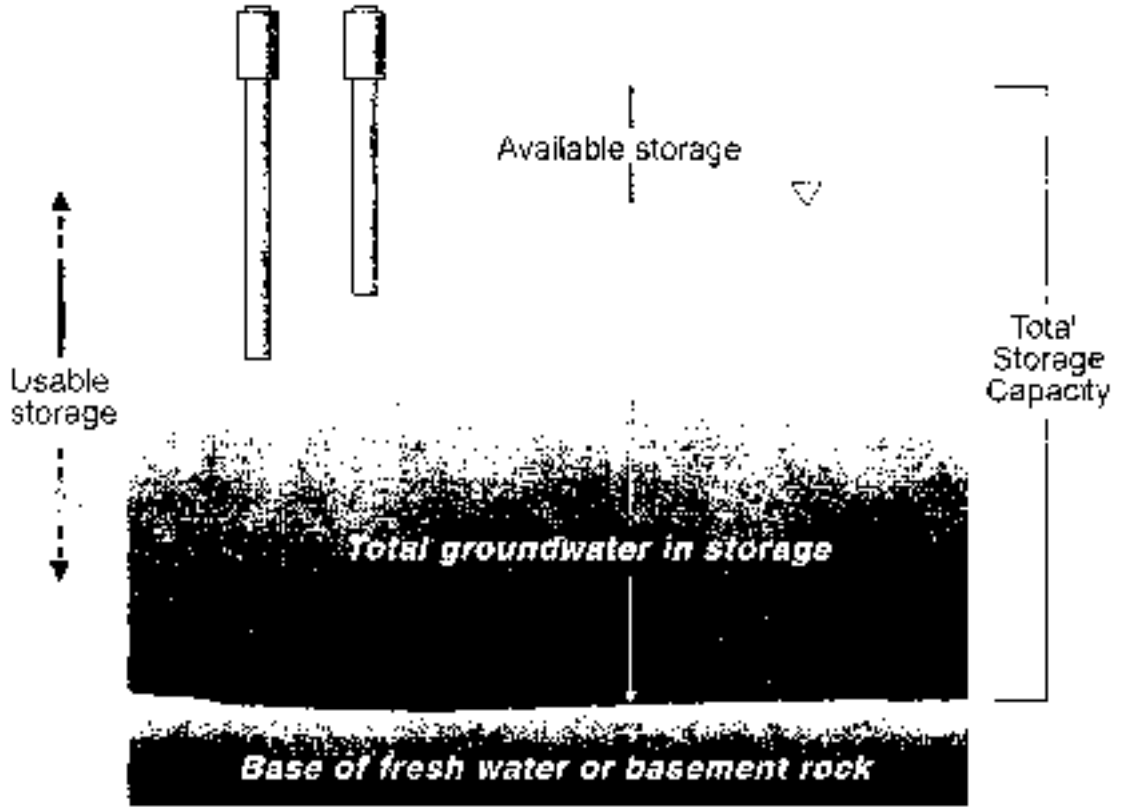

Figure 17 Schematic of total, usable, and available groundwater storage capacity

Table 9 Examples of factors that limit development of a groundwater basin

Limiting factor	Examples
Physical	Basin recharge area not adequate to sustain development; pumping too concentrated in a portion of basin; well yields too low for intended use.
Quality	Water quality not suitable for intended use; increased potential for seawater intrusion in coastal areas; upconing of poorer quality water in deeper parts of basin
Economic	Excessive costs associated with increased pump lifts and deepening of wells; cost of treating water if it does not meet requirements for intended use
Environmental	Need to maintain groundwater levels for wetlands, stream base flow, or other habitat.
Institutional	Court groundwater management plans or ordinances restrictions (e.g., basin adjudication); impacts on surface water rights of others.

AR0069716

Usable Groundwater Storage Capacity

Usable storage capacity is defined as the amount of groundwater of suitable quality that can be economically withdrawn from storage. It is typically computed as the product of the volume of the basin to some basin-specific depth that is considered economically available and the average specific yield of the basin (see Figure 17).

As more groundwater is extracted, groundwater levels may fall below some existing wells, which may then require replacement or deepening. This may be a consideration in management of the basin and will depend on the cost of replacement, the cost of pumping the water from deeper zones, and whether managers are willing to pay that cost. Other impacts that may increase the cost include subsidence and groundwater quality degradation. The usable storage may change because of changes in economic conditions.

Estimates of usable storage represent only the total volume of groundwater assumed to be usable in storage, not what would be available for sustained use on an annual basis. Previous estimates of usable groundwater storage capacity range from 143 to 450 maf (DWR 1975, DWR 1994). Unfortunately, the term "usable storage" is often used to indicate the amount of water that can be used from a basin as a source of long-term annual supply. However, the many limitations associated with total groundwater storage capacity discussed above may also apply to usable storage.

Available Groundwater Storage Capacity

Available storage capacity is defined as the volume of a basin that is unsaturated and capable of storing additional groundwater. It is typically computed as the product of the empty volume of the basin and the average specific yield of the unsaturated part of the basin (see Figure 17). The available storage capacity does not include the uppermost portion of the unsaturated zone in which saturation could cause problems such as crop root damage or increased liquefaction potential. The available storage will vary depending on the amount of groundwater taken out of storage and the recharge. The total groundwater in storage will change inversely as the available storage changes.

Available storage has often been used as a number to represent the potential for additional yield from a particular basin. Unfortunately, many of the limitations that exist in developing existing supply discussed above also limit taking advantage of available storage. Although limitations exist, looking only at available groundwater storage capacity may underestimate the potential for groundwater development. Opportunities to use groundwater already in storage and create additional storage space would be overlooked by this approach.

Groundwater Budget

A groundwater budget is an analysis of a groundwater basin's inflows and outflows to determine the change in groundwater storage. Alternatively, if the change in storage is known, the value of one of the inflows or outflows could be determined. The basic equation can be expressed as:

INFLOWS − OUTFLOWS = CHANGE IN STORAGE

Typical inflows include:

- natural recharge from precipitation;
- seepage from surface water channels;
- intentional recharge via ponds, ditches, and injection wells;
- net recharge of applied water for agricultural and other irrigation uses;
- unintentional recharge from leaky conveyance pipelines; and
- subsurface inflows from outside basin boundaries.

AR0069717

Outflows include:

- groundwater extraction by wells;
- groundwater discharge to surface water bodies and springs;
- evapotranspiration; and
- subsurface outflow across basin or subbasin boundaries.

Groundwater budgets can be useful tools to understand a basin, but detailed budgets are not available for most groundwater basins in California. A detailed knowledge of each budget component is necessary to obtain a good approximation of the change in storage. Absence or inaccuracy of one or more parameters can lead to an analysis that varies widely from a positive to a negative change in storage or vice versa. Since much of the data needed requires subsurface exploration and monitoring over a series of years, the collection of detailed field data is time-consuming and expensive. A management plan should develop a monitoring program as soon as possible.

Change in Groundwater Storage

As stated above, a groundwater budget is one potential way of estimating the change in storage in a basin, although it is limited by the accuracy and availability of data. There is a simpler way – by determining the average change in groundwater elevation over the basin, multiplied by the area overlying the basin and the average specific yield (or storativity in the case of a confined aquifer). The time interval over which the groundwater elevation change is determined is study specific, but annual spring-to-spring changes are commonly used. A change in storage calculation does not attempt to determine the volume of water in storage at any time interval, but rather the change from a previous period or baseline condition.

A change in storage calculation is a relatively quick way to represent trends in a basin over time. If change in storage is negligible over a representative period, the basin is in equilibrium under current use. Changes in storage calculations are more often available for a groundwater basin than groundwater budgets because water level measurements are available in many basins. Specific yield and storativity are readily estimated based on knowledge of the hydrogeologic setting and geologic materials or through aquifer pumping tests. Although simple, change in storage calculations have potential sources of error, so it is important to treat change in storage as just one of many tools in determining conditions in a groundwater basin. Well data sets must be carefully evaluated before use in these calculations. Mixing of wells constructed in confined and unconfined portions of the basin and measurement of different well sets over time can result in significant errors.

Although the change in storage calculation is a relatively quick and inexpensive method of measuring changes in the groundwater system, the full groundwater budget is preferable. A detailed budget describes an understanding of the physical processes affecting storage in the basin, which the simple change in storage calculation does not. For example, the budget takes into account the relationship between the surface water and the groundwater system. If additional groundwater extraction induced additional infiltration of surface water, the calculated change in storage could be minimal. However, if the surface water is used as a source of supply downstream, the impact of reduced flows could be significant.

Overdraft

Groundwater overdraft is defined as the condition of a groundwater basin or subbasin in which the amount of water withdrawn by pumping exceeds the amount of water that recharges the basin over a period of years, during which the water supply conditions approximate average conditions (DWR 1998). Overdraft can be characterized by groundwater levels that decline over a period of years and never fully recover, even in wet years. If overdraft continues for a number of years, significant adverse impacts may occur, including increased extraction costs, costs of well deepening or replacement, land subsidence, water quality degradation, and environmental impacts.

AR0069718

Despite its common usage, the term overdraft has been the subject of debate for many years. Groundwater management is a local responsibility; therefore, the decision whether a basin is in a condition of overdraft is the responsibility of the local groundwater or water management agency. In some cases local agencies may choose to deliberately extract groundwater in excess of recharge in a basin (known as "groundwater mining") as part of an overall management strategy. An independent analysis of water levels in such a basin might conclude that the basin is in overdraft. In other cases, where basin management is less active or nonexistent, declining groundwater levels are not considered a problem until levels drop below the depth of many wells in the basin. As a result, overdraft may not be reported for many years after the condition began.

Water quality changes and subsidence may also indicate that a basin has been overdrafted. For example, when groundwater levels decline in coastal aquifers, seawater fills the pore spaces in the aquifer that are vacated by the groundwater, indicating that the basin is being overdrafted. Overdraft has historically led to as much as 30 feet of land subsidence in some areas of the State and lesser amounts in other areas.

The word "overdraft" has been used to designate two unrelated types of water shortages. The first is "historical overdraft" similar to the type illustrated in Figure 18, which shows that ground water levels began to decline in the mid 1950s and then leveled off in the mid 1980s, indicating less groundwater extraction or more recharge. The second type of shortage is "projected overdraft" as used in the *California Water Plan Update* (DWR 1998). In reality, this is an estimate of future water shortages based on an assumed management program within the basin, including projected supply and projected demand. If water management practices change in those basins in which a water shortage is projected, the amount of projected shortage will change.

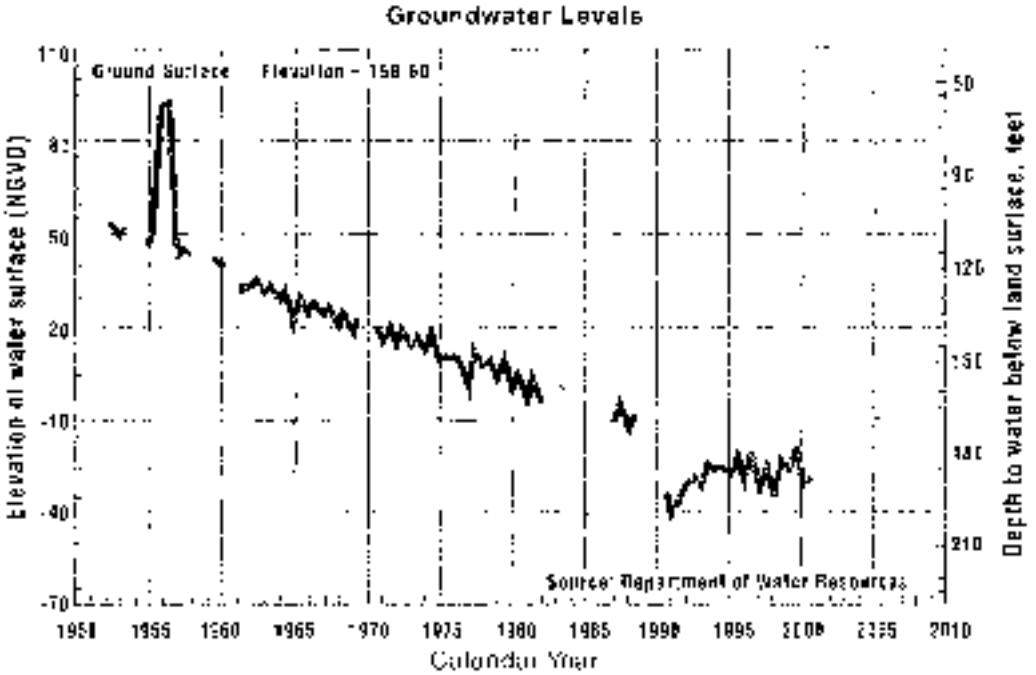

Figure 18 Hydrograph Indicating Overdraft

AR0069719

In some basins or subbasins, groundwater levels declined steadily over a number of years as agricultural or urban use of groundwater increased. In response, managing agencies developed surface water import projects to provide expanded water supplies to alleviate the declining groundwater levels. Increasing groundwater levels or refilling of the aquifer demonstrate the effectiveness of this approach in long-term water supply planning. In some areas of the State, the past overdraft is now being used to advantage. When the groundwater storage capacity that is created through historical overdraft is used in coordination with surface water supplies in a conjunctive management program, local and regional water supplies can be augmented.

In 1978 DWR was directed by the legislature to develop a definition of critical overdraft and to identify basins that were in a condition of critical overdraft (Water Code § 12924). The process that was followed and the basins that were deemed to be in a condition of critical overdraft are discussed in Box O, "Critical Conditions of Overdraft." This update to Bulletin 118 did not include similar direction from the legislature, nor funding to undertake evaluation of the State's groundwater basins to determine whether they are in a state of overdraft.

Box O Critical Conditions of Overdraft

In 1978 DWR was directed by the legislature to develop a definition of critical overdraft and to identify those basins in a critical condition of overdraft (Water Code § 12924). DWR held public workshops around the State to obtain public and water managers' input on what the definition should include, and which basins were critically overdrafted. Bulletin 118-80, *Ground Water Basins in California* was published in 1980 with the results of that local input. The definition of critical overdraft is:

> *A basin is subject to critical conditions of overdraft when continuation of present water management practices would probably result in significant adverse overdraft-related environmental, social, or economic impacts.*

No time is specified in the definition. Definition of the time frame is the responsibility of the local water managers, as is the definition of significant adverse impacts, which would be related to the local agency's management objectives.

Eleven basins were identified as being in a critical condition of overdraft. They are:

Pajaro Basin	Cuyama Valley Basin
Ventura Central Basin	Eastern San Joaquin County Basin
Chowchilla Basin	Madera Basin
Kings Basin	Kaweah Basin
Tulare Lake Basin	Tule Basin
Kern County Basin	

The task was not identified by the legislature, nor was the funding for this update (2003) sufficient to consult with local water managers and fully re-evaluate the conditions of the 11 critically overdrafted basins. Funding and duration were not sufficient to evaluate additional basins with respect to conditions of critical overdraft.

AR0069720

If a basin lacks existing information, the cost of a thorough evaluation of overdraft conditions in a single basin could exceed $1 million. In this update of Bulletin 118, DWR has included groundwater budget information for each basin description, where available. In most cases, however, sufficient quantitative information is not available, so conditions of overdraft or critical overdraft were not reported.

While this bulletin does not specifically identify overdrafted basins (other than the 11 basins from Bulletin 118-80), the negative effects of overdraft are occurring or may occur in the future in many basins throughout the State. Declining water levels, diminishing water quality, and subsidence threaten the availability of groundwater to meet current and future demands. A thorough understanding of overdraft can help local groundwater managers minimize the impacts and take advantage of the opportunity created by available groundwater storage capacity. Local groundwater managers and DWR should seek funding and work cooperatively to evaluate the groundwater basins of the State with respect to overdraft and its potential impacts. Beginning with the most heavily used basins and relying to the extent possible on available data collected by DWR and through local groundwater management programs, current or projected conditions of critical overdraft should be identified. If local agencies take the lead in collecting and analyzing data to fully understand groundwater basin conditions, DWR can use the information to update the designations of critically overdrafted basins. This can be a cost effective approach since much of the data needed to update the overdraft designations are the same data that agencies need to effectively manage groundwater.

Safe Yield

Safe yield is defined as the amount of groundwater that can be continuously withdrawn from a basin without adverse impact. Safe yield is commonly expressed in terms of acre-feet per year. Depending on how it is applied, safe yield may be an annual average value, or may be calculated based on changed conditions each year. Although safe yield may be indicated by stable groundwater levels measured over a period of years, a detailed groundwater budget is needed to accurately estimate safe yield. Safe yield has commonly been determined in groundwater basin adjudications.

Proper application of the safe yield concept requires that the value be modified through time to reflect changing practices within the basin. One of the common misconceptions is that safe yield is a static number. That is, once it has been calculated, the amount of water can be extracted annually from the basin without any adverse impacts. An example of a situation in which this assumption could be problematic is when land use changes. In some areas, where urban development has replaced agriculture, surface pavement, storm drains, and sewers have increased runoff and dramatically reduced recharge into the basin. If extraction continues at the predetermined safe yield of the basin, water level decline and other negative impacts could occur.

AR0069721

Figure 19 Photograph of extensometer

An extensometer is a well with a concrete foundation and a steel wire suspended from the bottom of the well. A pipe extends from the concrete base to the land surface. As subsidence of the fine-grained sediments occurs, leading to land surface subsidence, the pipe in the well will appear to extend out of the well casing, while the wire remains in contact with the stationary bottom of the well. The land surface has moved down with the land surface has moved.

Subsidence

When groundwater is extracted from some aquifers in sufficient quantity, compaction of the fine-grained sediments can cause subsidence of the land surface. As the groundwater level is lowered, water pressure decreases and many of the weight of the overlying sediments is supported by the sediment grains within the aquifer. If these sediments have not previously been surcharged with an equivalent load, the overlying load will compact them. Compaction decreases the porosity of the sediments and decreases the overall volume of the finer grain sediments, leading to subsidence at the land surface. While the finer sediments within the aquifer system are compacted, the usable storage capacity of the aquifer is not greatly decreased.

Data from extensometers (Figure 19) show that as groundwater levels decline in an aquifer, the land surface falls slightly. As groundwater levels rise, the land surface also rises to its original position. This component of subsidence is called elastic subsidence because it recovers. Inelastic subsidence, the second component of subsidence, is what occurs when groundwater levels decline to the point that the finer sediments are compacted. This compaction is not recoverable.

Conjunctive Management

Conjunctive management in its broadest definition is the coordinated and combined use of surface water and groundwater to increase the overall water supply of a region and improve the reliability of that supply. Conjunctive management may be implemented to meet other objectives as well, including reducing groundwater overdraft and land subsidence, protecting water quality, and improving environmental conditions. Although surface water and groundwater are sometimes considered to be separate resources, they are connected in the hydrologic cycle. By using or storing additional surface water when it is plentiful, and relying more heavily on groundwater during dry periods, conjunctive management can change the timing and location of water so it can be used more efficiently.

Although a specific project or program may be extremely complex, there are several components common to conjunctive management projects. The first is to recharge surplus surface water when it is available to increase groundwater in storage. Recharge may occur through surface spreading, by injection wells, or by reducing groundwater use by substituting surface water. The surplus surface water used for recharge may be local runoff, imported water, stored surface water, or recycled water. The second component is to reduce surface water use in dry years or dry seasons by switching to groundwater. This use of the stored groundwater may take place through direct extraction and use, pumping back to a conveyance facility, or through exchange of another water supply. A final component that should be included is an ongoing monitoring program to evaluate conditions and allow water managers to respond to changes in groundwater, surface water, or environmental conditions that could violate management objectives or impact other water users.

AR0069722

Quality of Groundwater

All water contains dissolved constituents. Even rainwater, often described as being naturally pure, contains measurable dissolved minerals and gases. As it moves through the hydrologic cycle, water dissolves and incorporates many constituents. These include naturally occurring and man-made constituents.

Most natural minerals are harmless up to certain levels. In some cases, higher mineral content is preferable to consumers for taste. For example, minerals are added to many bottled drinking waters after going through a filtration process. At some level, however, most naturally occurring constituents, along with those introduced by human activities, are considered contaminants. The point at which a given constituent is considered a contaminant varies depending on the intended use of the groundwater and the toxicity level of the constituents.

Beneficial Uses

For this report, water quality is a measure of the suitability of water for its intended use, with respect to dissolved solids and gases and suspended material. An assessment of water quality should include the investigation of the presence and concentration of any individual constituent that may limit the water's suitability for an intended use.

The SWRCB has identified 23 categories of water uses, referred to as beneficial uses. The beneficial use categories and a brief description of each are presented in Appendix C. The actual criteria that are used to evaluate water quality for each of the beneficial uses are determined by the nine Regional Water Quality Control Boards, resulting in a range of criteria for some of the uses. These criteria are published in each of the Regional Boards' Water Quality Control Plans (Basin Plans).[1]

A summary of water quality for all of the beneficial uses of groundwater is beyond the scope of this report. Instead, water quality criteria for two of the most common uses—municipal supply (referred to as public drinking water supply in this report) and agricultural supply—are described below.

Public Drinking Water Supply

Standards for maximum contaminant levels (MCLs) of constituents in drinking water are required under the federal Safe Drinking Water Act of 1974 and its updates. There are primary and secondary standards. Primary standards are developed to protect public health and are legally enforceable. Secondary standards are generally for the protection of aesthetic qualities such as taste, odor, and appearance, and cosmetic qualities, such as skin or tooth discoloration, and are generally nonenforceable guidelines. However, in California secondary standards are legally enforceable for all new drinking water systems and new sources developed by existing public water suppliers (DWR 1997). Under these primary and secondary standards, the U.S. Environmental Protection Agency regulates more than 90 contaminants, and the California Department of Health Services regulates about 120. Federal and State primary MCLs are listed in Appendix F.

Agricultural Supply

An assessment of the suitability of groundwater as a source of agricultural supply is much less straightforward than that for public water supply. An evaluation of water supply suitability for use in agriculture is difficult because the impact of an individual constituent can vary depending on many factors, including soil chemical and physical properties, crop type, drainage, and irrigation method. Elevated levels of constituents usually do not result in an area being taken entirely out of production, but may lower crop yields. Management decisions will determine appropriate land use and irrigation methods.

[1] Digital versions of these plans are available online at http://www.swrcb.ca.gov/plnspls/index.html

AR0069723

There are no regulatory standards for water applied on agriculture. Criteria for crop water have been provided as guidelines. Many constituents have the potential to negatively impact agriculture, including more than a dozen trace elements (Ayers and Westcot 1985). Two constituents that are commonly considered with respect to agricultural water quality are salinity -- expressed as total dissolved solids (TDS) -- and boron concentrations.

Increasing salinity in irrigation water inhibits plant growth by reducing a plant's ability to absorb water through its roots (Pratt and Suarez 1996). While the impact will depend on crop type and soil conditions, it is useful to look at the TDS of the applied water as a general assessment tool. A range of values for TDS with their estimated suitability for agricultural uses is presented in Table 10. These ranges are modified from criteria developed for use in the San Joaquin Valley by the San Joaquin Valley Drainage Program. However, they are similar to values presented in Ayers and Westcot (1985).

Table 10 Range of TDS values with estimated suitability for agricultural uses

Range of TDS (mg/L)	Suitability
<500	Generally no restrictions on use
500 – 1,500	Generally slight restrictions on use
1,500 – 2,500	Generally moderate restrictions on use
>2,500	Generally severe restrictions on use

Modified from SJVDP (1990)
TDS = total dissolved solids

High levels of boron can present toxicity problems in plants by damaging leaves. The boron is absorbed through the root system and transported to the leaves. Boron then accumulates during plant transpiration, resulting in leaf burn (Ayers and Westcot 1985). Boron toxicity is highly dependent on a crop's sensitivity to the constituent. A range of values of dissolved boron in irrigation water, with their estimated suitability on various crops is presented in Table 11. These ranges are modified from Ayers and Westcot (1985).

Table 11 Range of boron concentrations with estimated suitability on various crops

Range of dissolved boron (mg/L)	Suitability
<0.5	Suitable for all but most highly boron sensitive crops
0.5 – 1.0	Suitable for most boron sensitive crops
1.0 – 2.0	Suitable for most moderately boron sensitive crops
>2.0	Suitable for only moderately to highly boron tolerant crops

Source: Modified from Ayers and Westcot 1985

AR0069724

Contaminant Groups

Because there are so many potential individual constituents to evaluate, researchers have often summarized contaminants into groups depending on the purpose of the study. Recognizing that there are exceptions to any classification scheme, this update considered groups according to their common sources of contamination—those naturally occurring and those caused by human activities (anthropogenic). Each of these sources includes more than one contaminant group. A listing of the contaminant groups and the individual constituents belonging to those groups, summarized in this report, is included in Appendix B.

Naturally Occurring Sources

In this report, naturally occurring sources include three primary groups: (1) inorganic constituents with primary MCLs, (2) inorganic constituents with secondary MCLs, and (3) radiological constituents. Inorganics primarily include naturally occurring minerals such as arsenic or mercury, although human activities may certainly contribute to observed concentrations. Radiological constituents include primarily naturally occurring constituents such as radon, gross alpha, and uranium. Although radioactivity is not considered a significant contaminant statewide, it can be locally important, particularly in communities in the Sierra Nevada.

Anthropogenic Sources

Anthropogenic contaminants include pesticides, volatile organic compounds (VOCs), and nitrates. Pesticides and VOCs are often grouped together into an organic contaminant group. However, separating the two gives a general idea of which contaminants are primarily from agricultural activities (pesticides) and which are primarily from industrial activities (VOCs). One notable exception to the groupings is dibromochloropropane (DBCP). Even though this compound is a VOC, DBCP is a soil fumigant and is included with pesticides. Nitrates are a surprising anthropogenic class to some observers. Nitrogen is certainly a naturally occurring inorganic constituent. However, because most nitrates are associated with agriculture (see Box F, "Focused on Nitrates: Detailed Study of a Contaminant") and nitrates are among California's leading contaminants, it is appropriate to consider them separately from inorganics.

Box F: Focused on Nitrates: Detailed Study of a Contaminant

Because water has so many potential uses, the study of water quality means different things to different people. Thomas Harter, a professor at the University of California at Davis, has chosen to focus on nitrates as one of his research interests. Harter's monitoring network consists of 70 wells on 8 dairies in the San Joaquin Valley.

A common result of dairy activities is the release of nitrogen into the surroundings, which changes to nitrate in groundwater. Nitrates are notorious for their role in interfering with oxygen transport in babies, a condition commonly referred to as "blue baby syndrome." Nitrates are also of interest because more public supply wells have been closed due to nitrate contamination than from any other contaminant (Bachman and others 1997).

Harter's study has focused on two primary activities. The first is a meticulous examination of nitrogen at the surface and nitrates in the uppermost 25 feet of the subsurface. This monitoring has been ongoing since 1993, and has shown that a significant amount of nitrate can reach shallow groundwater. The second focus of the study has been to change management practices to reduce the amount of nitrogen available to reach groundwater, along with continued monitoring. This has occurred since 1996. Results of the study use better management practices that significantly reduce the amount of nitrogen available to groundwater. This will help minimize the potential adverse impacts to groundwater quality from nitrates.

Chapter 7

Inventory of California's Groundwater Information

Chapter 7
Inventory of California's Groundwater Information

The groundwater information in this chapter summarizes the available information on statewide and regional groundwater issues. For more detailed information on specific groundwater basins see the supplement to this report that is available on the California Department of Water Resources (DWR) website, http://www.waterplan.water.ca.gov/groundwater/index.htm. See Appendix A for information on accessing individual basin descriptions and the map delineating California's groundwater basins.

Statewide Groundwater Information

There is a large amount of data available for many of the State's most heavily developed groundwater basins. Conversely, there is relatively little data available on groundwater in the undeveloped areas. The information in this report is primarily limited to a compilation of the information readily available to DWR staff and may not include the most up-to-date data generated by studies that have been completed recently by water management agencies. For this reason, the collection of additional, more recent data on groundwater basins should be continued and integrated into the basin descriptions. Statewide summaries are included below.

Groundwater Basins

There are currently 431 groundwater basins delineated, underlying about 40 percent of the surface area of the State. Of these, 24 basins are subdivided into a total of 268 subbasins, giving a total of 515 distinct groundwater systems described in this report (Figure 20). Basin delineation methods are described in Appendix C. Additionally, many of the subbasin boundaries were developed or modified with public input, but little physical data. These boundaries should not be considered as precisely defining a groundwater basin boundary; the determination of whether any particular area lies within a groundwater basin boundary should be determined only after detailed local study.

Groundwater basin and subbasin boundaries shown on the map included with this bulletin are based on evaluation of the best available information. In basins where many studies have been completed and the basin has been operated for a number of years, the basin response is fairly well understood and the boundaries are fairly well defined. Even in these basins, however, there are many unknowns and changes in boundaries may result as more information about the basin is collected and evaluated.

Groundwater Budgets

Rather than simply providing all groundwater budget data collected during this update, the budget information was classified into one of three categories indicating the relative level of detail of information available. These categories, types A, B, and C, are discussed in Box B, "Explanation of Groundwater Data Tables." A type A budget indicates that much of the information needed to characterize the groundwater budget for the basin or subbasin was available. DWR staff did not verify these type A budgets, so DWR cannot address the accuracy of the data provided by them. Type B indicates that enough data are available to estimate the groundwater extraction to meet local water use needs. This is useful in understanding the reliance of a particular area on groundwater. Type C indicates a low level of knowledge of any of the budget components for the area.

Figure 21 depicts where these type A, B, and C budgets occur. In general, there is a greater level of understanding (type A or B) in the more heavily developed areas in terms of groundwater use. These include the Central Valley and South Coast. The lowest level of knowledge of groundwater budget data is in the southeast desert area. A discussion of groundwater use in each region is included below.

AR0069728

Box Q How Does the Information in This Report Relate to the Recently Enacted Laws Senate Bill 221 and Senate Bill 610 (2002)?

Recently enacted legislation requires developers of certain new housing projects to demonstrate an adequate water supply for that development. If a part of that proposed water supply is groundwater, urban water suppliers must provide additional information on the availability of an adequate supply of groundwater to meet the projected demand and show that they have the legal right to extract that amount of groundwater. SB 610 (2002) amended the Water Code to require, among other things, the following information (Section 10631 (b)(2)):

> *For basins that have not been adjudicated, information as to whether the department has identified the basin or basins as overdrafted or has projected that the basin will become overdrafted if present management conditions continue, in the most current official departmental bulletin that characterizes the condition of the groundwater basin, and a detailed description of the efforts being undertaken by the urban water supplier to eliminate the long-term overdraft condition.*

The hydrogeologic information contained in the basin descriptions that supplement this update of Bulletin 118 includes only the information that was available in California's recent past of Water Resources (DWR) files through reference searches and through limited contact with local agencies. Local agencies may have conducted more recent studies that have generated additional information about water budgets and aquifer characteristics. Unless the agency notifies DWR, or provided a copy of the recent reports to DWR staff, that recent information has not been included in the basin descriptions. Therefore, although SB 610 refers to groundwater basins identified as overdrafted in Bulletin 118, it would be prudent for local water suppliers to evaluate the potential for overdraft of any basin included as a part of a water supply assessment.

Persons interested in collecting groundwater information in accordance with the Water Code as amended by SB 221 and SB 610 may start with the information in Bulletin 118, but should follow up by consulting the references listed for each basin and contacting local water agencies to obtain any new information that is available. Otherwise, evaluation of available groundwater resources as mandated by SB 221 and SB 610 may not be using the most complete and recent information about water budgets and aquifer characteristics.

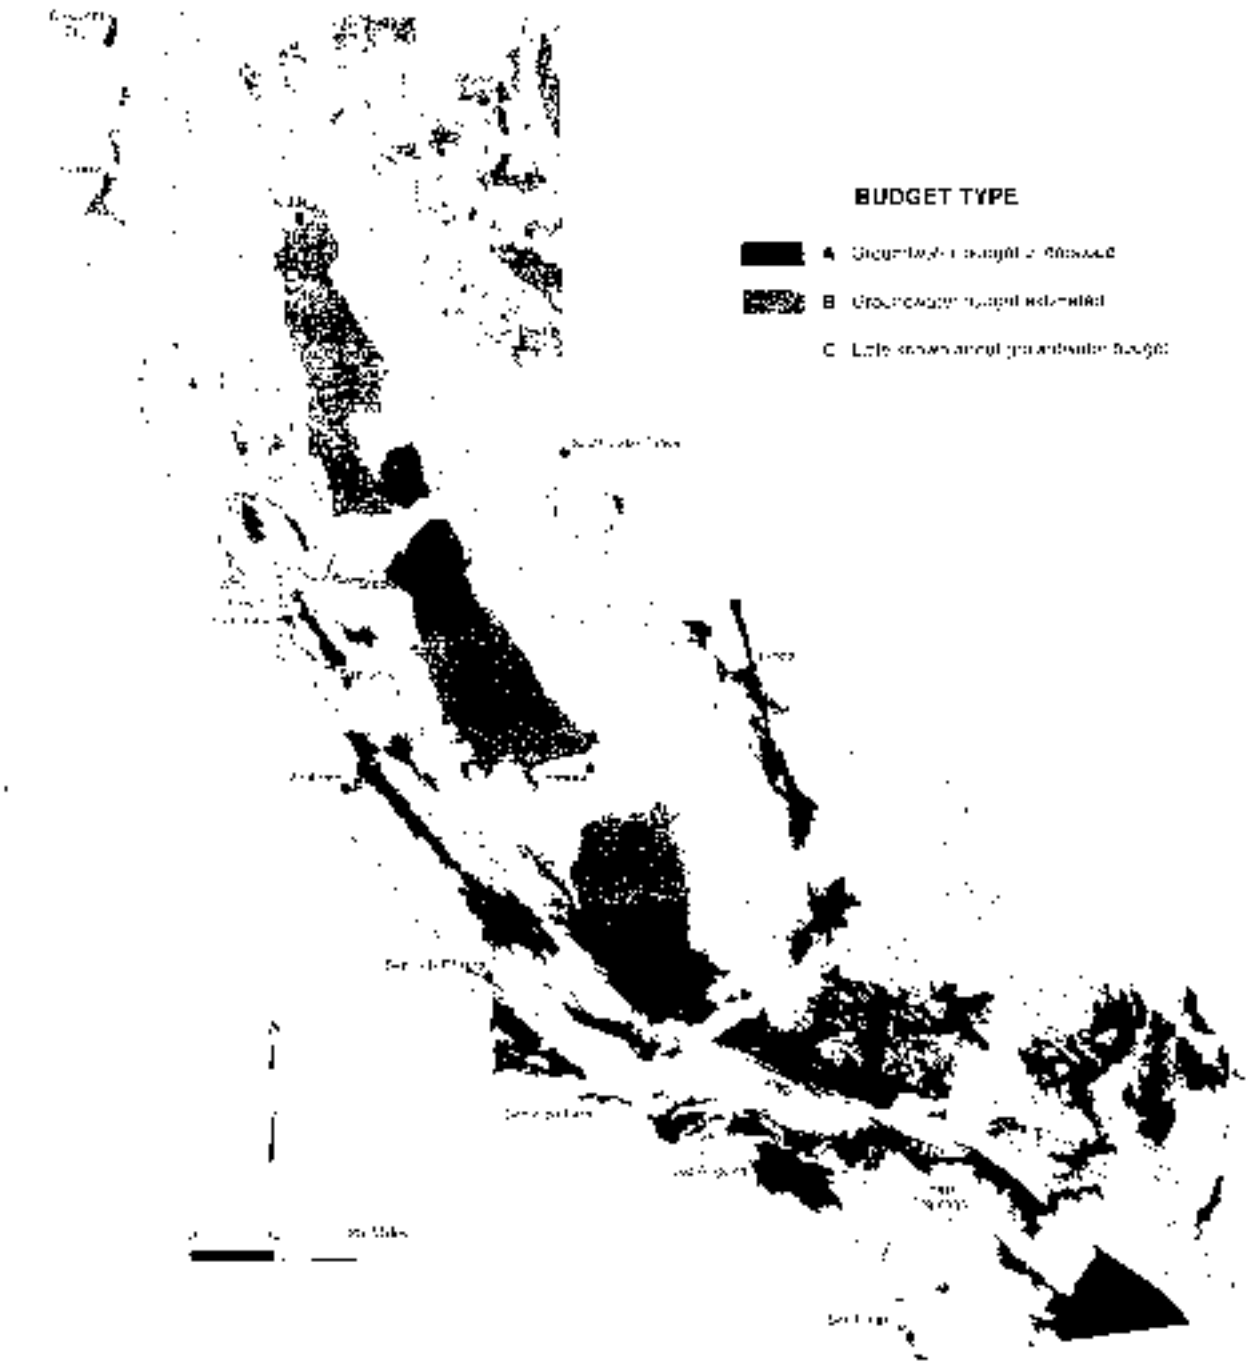

Figure 2. Basin and subbasin groundwater budget types

AR0069731

Box B Explanation of Groundwater Data Tables

A groundwater data table for each hydrologic region is included at the end of each hydrologic region section in Chapter 7. The tables include the following information:

Basin/Subbasin Number. The basin numbering format is x-xxx.xx. The first number in the sequence assigns the basin to one of the nine Regional Water Quality Control Board boundaries. The second number is the groundwater basin number. Any number following the decimal identifies that the groundwater basin has been further divided into subbasins. Reinterpretation of available hydrogeologic information resulted in the deletion of some basins and subbasins as compiled in Bulletins 118-75 and 118-80. Because of this, there are some gaps in the sequence of basin numbers in this report. The methods used for developing the current groundwater basin maps are discussed in Appendix H. The names and numbers of the basins deleted, along with any comments related to their elimination are included in the appropriate region in Chapter 7. Previously unidentified groundwater basins or subbasins that were delineated during this update are assigned new identification numbers that sequentially follow the last number used in Bulletin 118-80 for groundwater basins or subbasins.

Basin or Subbasin Name. Basin names are based on published and unpublished reports, topographic maps, and local terminology. Names of newly delineated basins or subbasins are based on the principal geographic feature, which in most cases corresponds to the name of a valley. In the case of a subbasin, its formal name should include the name of the basin (for example, Sacramento Valley Groundwater Basin, North American Subbasin). However, both informally and informally, the term subbasin is used interchangeably with basin (for example, North American Basin).

Area. The area for each basin or subbasin is presented in acres rounded to three significant figures (for example, 147,148 acres was rounded to 147,000 acres). The area data box only the upper surface or map view of a basin. The basin underlies the area and may extend beyond the surface expression (discussed in Chapter 3).

Groundwater Budget Type. The type of groundwater budget information available was classified as Type A, B, or C based on the following criteria:

Type A - indicates one of the following: (1) a groundwater budget exists for the basin or enough components from separate studies could be combined to give a general indication of the basin's groundwater budget, (2) a groundwater model exists for the basin that can be used to calculate a groundwater budget, or (3) actual groundwater extraction data exist for the basin.

Type B - indicates that a use-based estimate of groundwater extraction is calculated for the basin. The use-based estimate is determined by calculating the overall use from California Department of Water Resources land use and urban water use surveys. Known surface water supplies are then subtracted from the total demand, leaving the rest of the use to be met by groundwater extraction.

Type C - indicates that there are not enough data to provide either an estimate of the basin's groundwater budget or groundwater extraction from the basin.

Well Yields. Maximum and average well yields in gallons per minute (gpm) are reported for municipal supply and agricultural wells where available. Most of the values reported are from initial tests reported during construction of the well, which may not be an accurate indication of the long-term production capacity of the wells.

Box B continued on next page

AR0069732

Box B Explanation of Groundwater Data Tables (continued)

Types of Monitoring. This includes monitoring of both groundwater levels and quality. "Levels" indicate the number of wells actively monitored without consideration of frequency. Most wells are monitored semi-annually, but many are monitored monthly. "Quality" indicates the number of wells monitored for various constituents; these could range from a grab sample taken for a field specific conductance measurement to a full analysis of organic and inorganic constituents. "Title 22" indicates the number of public water system wells that are actively sampled and monitored under the direction of California Department of Health Services (DHS) Title 22 Program.

Total Dissolved Solids. This category includes range and average values of total dissolved solids (TDS). This data primarily represents data from published reports. In some cases, a range of average TDS values is presented.

Active Monitoring

The summary of active monitoring includes wells that are monitored for groundwater elevation or groundwater quality within the delineated groundwater basins as of 1999. Groundwater elevation data collected by DWR and cooperators are available online at http://wdl.water.ca.gov. Most of the water quality data are for public supply wells and were provided by the California Department of Health Services (DHS). Other groundwater level and water quality monitoring activities were reported by local agencies during this update. The summary indicates that there are nearly 14,000 wells monitored for groundwater levels, 10,700[1] wells monitored under DHS water quality monitoring program, and 4,700 wells monitored for miscellaneous water quality by other agencies.

[1] Some counties include wells in both DHS and local quality; through joint data exchange, DHS has responsibility for more than 10,000 public supply wells.

AR0069733

Box 5: What Happens When an MCL Exceedance Occurs?

All suppliers of domestic water to the public are subject to regulations adopted by the U.S. Environmental Protection Agency under the Safe Drinking Water Act (42 U.S.C. 300f et seq.) as well as by the California Department of Health Services under the California Safe Drinking Water Act (Health and Safety Code §§ 116270-116760).

These regulations include primary drinking water standards that establish maximum contaminant levels (MCLs) for inorganic and organic chemicals and radioactivity. MCLs are based on public protection, technical feasibility and economic factors.

California requires public water systems to sample their drinking water sources, analyze for regulated contaminants, and determine compliance with the MCLs on a regular basis. Sampling frequency depends on the contaminant, type of water source, and previous sampling results. Frequency can range from monthly to once every nine years, or none at all if sampling is waived because the source is not vulnerable to the contaminant.

Primary MCLs are enforceable standards. In California, compliance is usually determined at the wellhead or the surface water intake. To meet water quality standards and comply with regulations, a water system with a contaminant exceeding an MCL must notify the public and remove the source from service or initiate a process and schedule to install treatment for removing the contaminant.

Notification requirements reflect the severity of the regulated health risks. Immediate health concerns prompt immediate notice to consumers. Violations that do not pose a significant health concern may use a less immediate notification process. In addition to consumer notification, a water system is required by statute to notify the local governing body (for example, city council or county board of supervisors) whenever a drinking water well exceeds an MCL, even if the well is taken out of service.

Detections of regulated contaminants (and certain unregulated contaminants) must also be reported to consumers in the water system's annual Consumer Confidence Report.

Groundwater Quality

This summary of water quality relied heavily on data from the DHS Title 22 water quality monitoring program. The assessment consisted of querying the DHS database for active wells that have constituents exceeding the maximum contaminant level (MCL) for drinking water. Summaries of this assessment for each of the State's hydrologic regions (HRs) are discussed in this chapter.

DHS data are the most comprehensive statewide water quality data set available, but this data set should not be used as a sole indicator of the groundwater quality in California. Data from these wells are not necessarily representative of any given basin; it only represents the quality of groundwater where a public water supply is extracted.

AR0069734

The Natural Resources Defense Council (NRDC 2001) issued a report that concludes California's groundwater resources face a serious long-term threat from contamination. Despite heavy reliance on groundwater, no comprehensive statewide assessments of groundwater quality were available. In response to the NRDC report, the State Water Resources Control Board (SWRCB) is planning a comprehensive assessment of the State's groundwater quality. This program is discussed in Chapter 4, in the section titled "Groundwater Quality Monitoring Act of 2001 (AB 599)."

Regional Groundwater Use

The importance of groundwater as a resource varies regionally throughout the State. For planning purposes, DWR divides California into 10 hydrologic regions (HRs), which correspond to the State's major drainage areas. HR boundaries are shown in Figure 22. A review of average water year supplies from the California Water Plan (DWR 1998) shows the importance of groundwater as a local supply for agricultural and municipal use throughout the State and in each of California's 10 HRs (Table 12 and Figure 23).

Table 12 Annual agricultural and municipal water demands met by groundwater

Hydrologic region	Total Demand Volume (TAF)	Demand met by Groundwater (TAF)	Demand met by Groundwater (%)
North Coast	960	265	25
San Francisco Bay	1353	68	5
Central Coast	1263	1045	83
South Coast	5124	1177	23
Sacramento River	8720	2692	31
San Joaquin River	7301	2146	30
Tulare Lake	10536	4348	41
North Lahontan	569	157	28
South Lahontan	480	269	56
Colorado River	4467	357	8

Source: DWR 1998

With more than 80 percent of demand met by groundwater, the Central Coast HR is heavily reliant on groundwater to meet its local needs. The Tulare Lake and South Lahontan HRs meet more than 40 percent of their local demand from groundwater. The South Coast, North Coast, North Lahontan, San Joaquin River, and Sacramento River HRs take between 20 and 40 percent of their supply from groundwater. Groundwater is a relatively minor source of supply in the San Francisco Bay and Colorado River HRs.

Of all the groundwater extracted annually in the state, an estimated 35 percent is produced from the Tulare Lake HR. More than 70 percent of groundwater extraction occurs in the Central Valley (Tulare Lake, San Joaquin River, and Sacramento River HRs combined). Nearly 20 percent is extracted in the highly urbanized South Coast and Central Coast HRs, while less than 10 percent is extracted in the remaining five HRs combined.

AR0069735

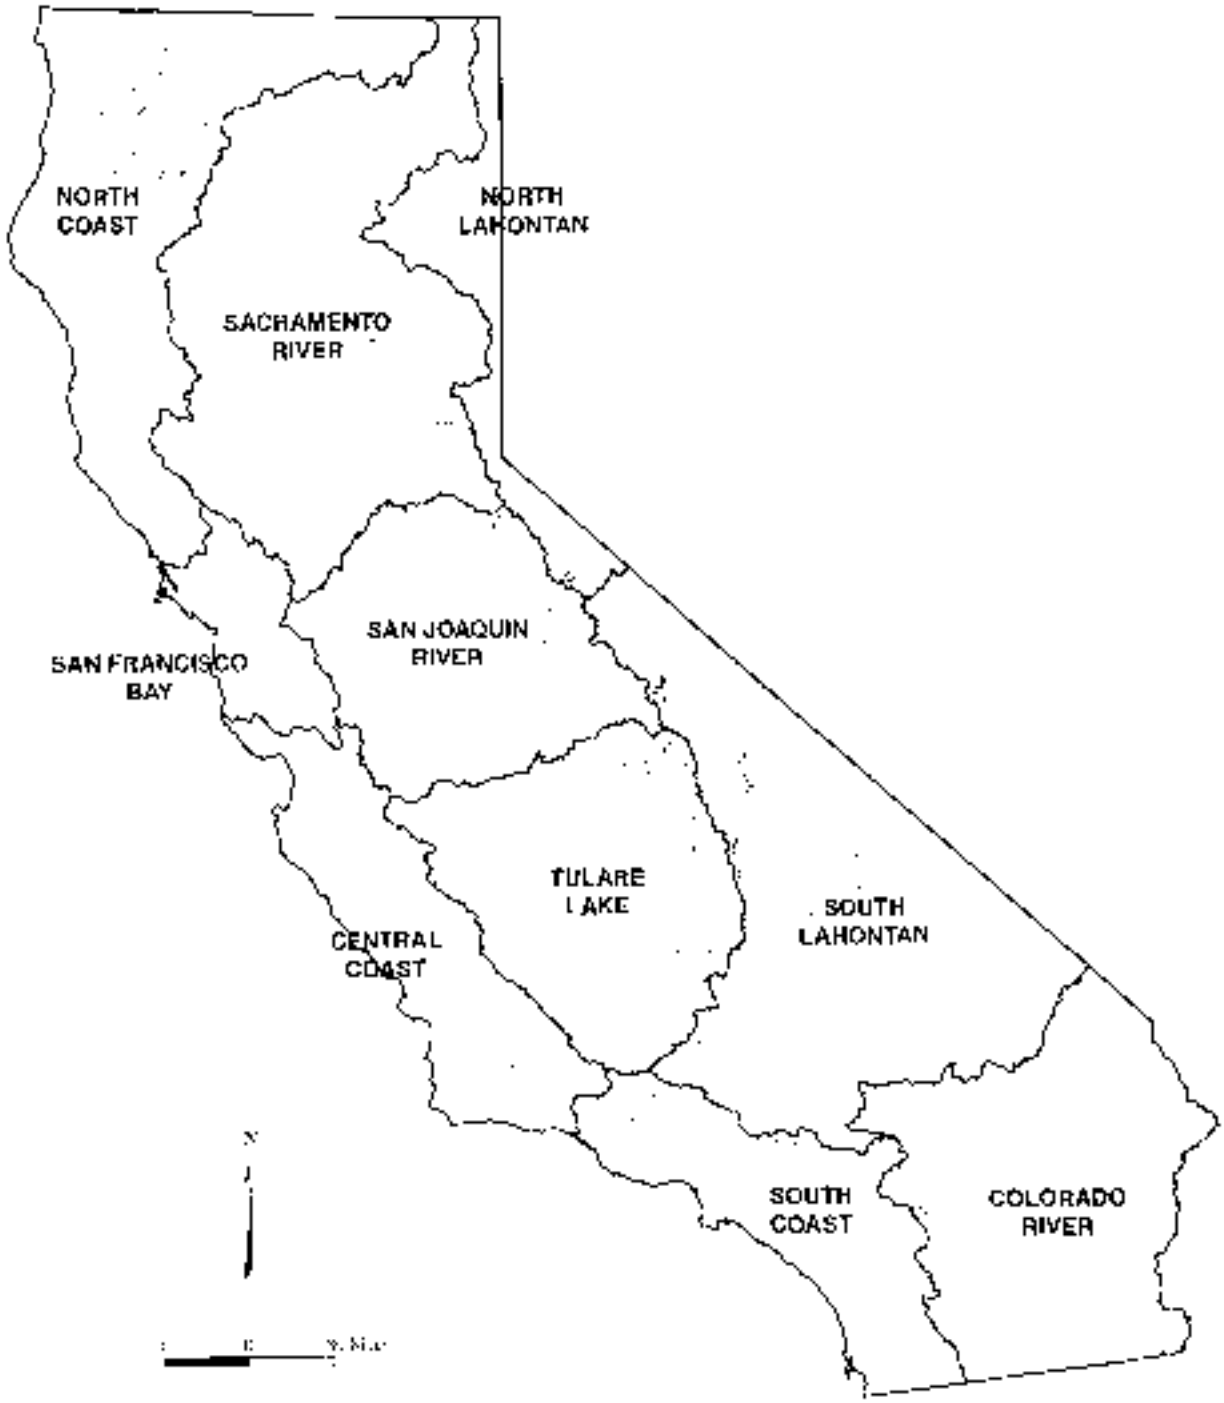

Figure 22 California's 10 hydrologic regions

AR0069736

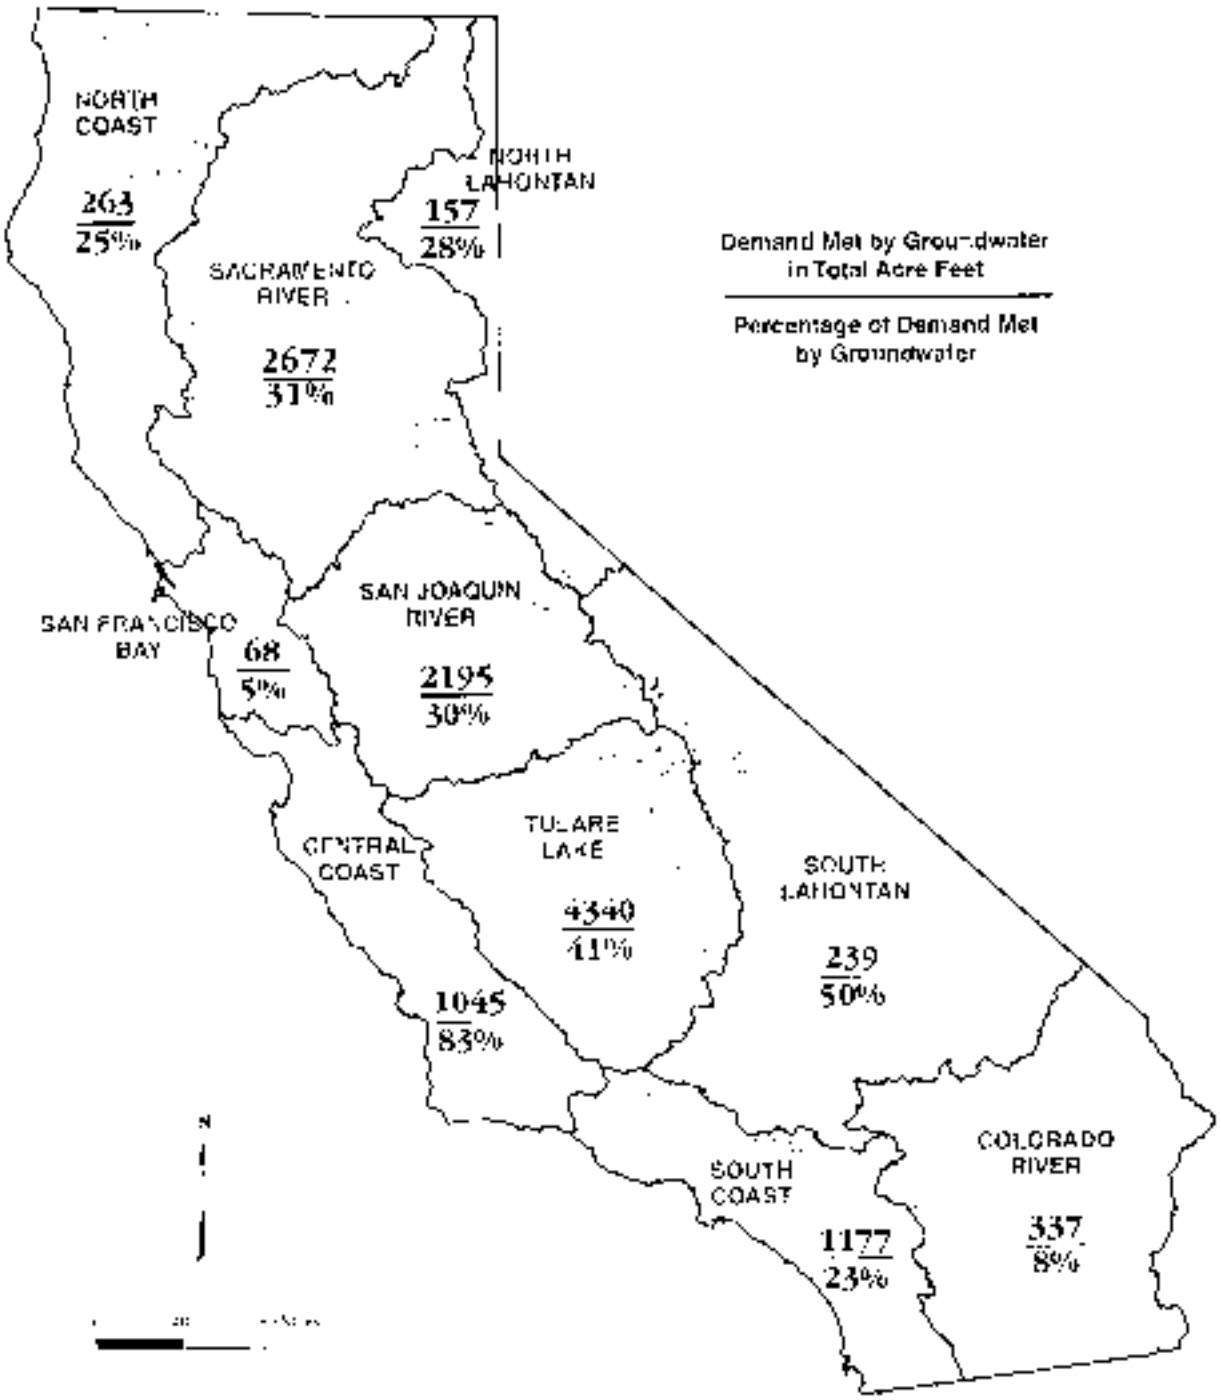

Figure 23 Agricultural and urban demand supplied by groundwater in each hydrologic region

AR0069737

The remainder of this chapter provides a summary of each of the 10 HRs. A basin location map for each HR is followed by a brief discussion of groundwater occurrence and groundwater conditions. A summary tabulation of groundwater information for each groundwater basin within the HR is provided. Greater detail for the data presented in these tables, including a bibliography, is provided in the individual basin/subbasin descriptions in the supplemental report (see Appendix A). Because the groundwater basin numbers are based on the boundaries of the State's nine Regional Water Quality Control Boards (RWQCB), Figure 24 shows the relationship between the Regional Board boundaries and DWR's HR boundaries.

The groundwater basin tabulations give an overview of available data. Where a basin is divided into subbasins, only the information for the subbasins is provided. The data for each subbasin generally come from different sources, so it is inappropriate to sum the data into a larger basin summary. An explanation of each of the data items presented in the summary table is provided in Box B.

AR0069743

Description of the Region

The North Coast HR covers approximately 12.46 million acres (19,479 square miles) and includes all or portions of Modoc, Siskiyou, Del Norte, Trinity, Humboldt, Mendocino, Lake, and Sonoma counties (Figure 25). Small areas of Shasta, Tehama, Glenn, Colusa, and Marin counties are also within the region. Extending from the Oregon border south to Tomales Bay, the region includes portions of four geomorphic provinces. The northern Coast Range forms the portion of the region extending from the southern boundary north to the Mad River drainage and the fault contact with the metamorphic rocks of the Klamath Mountains, which continue north into Oregon. East of the Klamath terrane along the State border are the volcanic terranes of the Cascades and the Modoc Plateau. In the coastal mountains, most of the basins are along the narrow coastal strip between the Pacific Ocean and the rugged Coast Range and Klamath Mountains and along inland river valleys; alluviated basin areas are very sparse in the steep Klamath Mountains. In the volcanic terrane to the east, most of the basins are in block faulted valleys that once held Pleistocene-age lakes. The North Coast HR corresponds to the boundary of RWQCB 1. Significant geographic features include basin areas such as the Klamath River Basin, the Eureka/Arcata area, Hoopa Valley, Anderson Valley, and the Santa Rosa Plain. Other significant features include Mount Shasta, forming the southern border of Shasta Valley, and the rugged north coastal shoreline. The 1995 population of the entire region was about 606,000, with most being centered along the Pacific Coast and in the inland valleys north of the San Francisco Bay Area.

The northern mountainous portion of the region is rural and sparsely populated, primarily because of the rugged terrain. Most of the area is heavily forested. Some irrigated agriculture occurs in the narrow river valleys, but most occurs in the broader valleys on the Modoc Plateau where pasture, grain, and alfalfa predominate. In the southern portion of the region, closer to urban centers, crops like wine grapes, nursery stock, orchards, and truck crops are common.

A majority of the surface water in the North Coast HR goes to environmental uses because of the "wild and scenic" designation of most of the region's rivers. Average annual precipitation ranges from 100 inches in the Smith River drainage to 29 inches in the Santa Rosa area and about 10 inches in the Klamath drainage; as a result, drought is likely to affect the Klamath Basin more than other portions of the region. Communities that are not served by the area's surface water projects also tend to experience shortages. Surface water development in the region includes the U.S. Bureau of Reclamation (USBR) Klamath Project, Humboldt Bay Municipal Water District's Ruth Lake, and U.S. Army Corps of Engineer's Russian River Project. An important factor concerning water demand in the Klamath Project area is water allocation for endangered fish species in the upper and lower basin. Surface water deliveries for agriculture in 2001, a severe drought year, were only about 20 percent of normal.

Groundwater Development

Groundwater development in the North Coast HR occurs along the coast, near the mouths of some of the region's major rivers, on the adjacent narrow marine terraces, or in the inland river valleys and basins. Reliability of these supplies varies significantly from area to area. There are 63 groundwater basins/subbasins delineated in the region, two of which are shared with Oregon. These basins underlie approximately 1.023 million acres (1,600 square miles).

Along the coast, most groundwater is developed from shallow wells installed in the sand and gravel beds of several of the region's rivers. Under California law, the water produced in these areas is considered surface water underflow. Water from Ranney collectors installed in the Klamath River, Rowdy Creek, the Smith

AR0069744

River, and the Mad River supply the towns of Klamath, Smith River and Crescent City in Del Norte County and most of the Humboldt Bay area in Humboldt County. Except on the Mad River, which has continuous supply via releases from Ruth Reservoir, these supplies are dependent on adequate precipitation and flows throughout the season. In drought years when streamflows are low, seawater intrusion can occur causing brackish or saline water to enter these systems. This has been a problem in the town of Klamath, which in 1995 had to obtain community water from a private well source. Toward the southern portion of the region, along the Mendocino coast, the Town of Mendocino typifies the problems related to groundwater development in the shallow marine terrace aquifers. Groundwater supply is limited by the aquifer storage capacity, and surveys done in the Town of Mendocino in the mid-1980s indicate that about 10 percent of wells go dry every year and up to 40 percent go dry during drought years.

Groundwater development in the inland coastal valleys north of the divide between the Russian and Eel Rivers is generally of limited extent. Most problems stemming from reliance on groundwater in these areas is a lack of alluvial aquifer storage capacity. Many groundwater wells rely on hydrologic connection to the rivers and streams of the valleys. The City of Rio Dell has experienced water supply problems in community wells and, as a result, recently developed plans to install a Ranney collector near the Eel River. South of the divide, in the Russian River drainage, a significant amount of groundwater development has occurred in the Santa Rosa Plain and surrounding areas. The groundwater supplies augment surface supplies from the Russian River Project.

In the north-central part of the North Coast HR, the major groundwater basins include the Klamath River Valley, Shasta Valley, Scott River Valley, and Butte Valley. The Klamath River Valley is shared with Oregon. Of these groundwater basins, Butte Valley has the most stable water supply conditions. The historical annual agricultural surface water supply has been about 20,000 acre-feet. As farming in the valley expanded from the early 1950s to the early 1990s, bringing nearly all the arable land in the valley into production, groundwater was developed to farm the additional acres. It has been estimated that current, fully developed demands are only about 80 percent of the available groundwater supply. By contrast, water supply issues in the other three basins are contingent upon pending management decisions regarding restoration of fish populations in the Klamath River and the Upper Klamath Basin system. The Endangered Species Act (ESA) fishery issues include lake level requirements for two sucker fish species and in-stream flow requirements for coho salmon and steelhead trout. Since about 1905, the Klamath Project has provided surface water to the agricultural community, which in turn has provided water to the wildlife refuges. Since the early 1990s, it has been recognized that surface water in the Klamath Project is over-allocated, but very little groundwater development had occurred. In 2001, which was a severe drought year, USBR delivered a total of about 25,000 acre-feet of water to agriculture in California, about 20 percent of normal. In the Klamath River Groundwater Basin this translated to a drought disaster, both for agriculture and the wildlife refuges. In addition, there were significant impacts for both coho salmon and sucker fisheries in the Klamath River watershed. As a result of the reduced surface water deliveries, significant groundwater development occurred, and groundwater extraction increased from an estimated 6,000 acre-feet in 1997 to roughly 60,000 acre-feet in 2001. Because of the complexity of the basin's water issues, a long-term Klamath Project Operations plan has not yet been finalized. Since 1995, USBR has issued an annual operation plan based on estimates of available supply. The Scott River Valley and Shasta Valley rely to a significant extent on surface water diversions. In most years, surface water supplies the majority of demand, and groundwater extraction supplements supply as needed depending on wet or dry conditions. Discussions are under way to develop strategies to conjunctively use surface water and groundwater to meet environmental, agricultural, and other demands.

AR0069745

Groundwater Quality

Groundwater quality characteristics and specific local impairments vary with regional setting within the North Coast HR. In general, seawater intrusion and nitrates in shallow aquifers are problems in the coastal groundwater basins; high total dissolved solids (TDS) content and general alkalinity are problems in the lake sediments of the Modoc Plateau basins; and iron, boron, and manganese can be problems in the inland basins of Mendocino and Sonoma counties.

Water Quality in Public Supply Wells

From 2004 through 2009, 584 public supply water wells were sampled in 32 of the 63 basins and subbasins in the North Coast HR. Analyzed samples indicate that 553 wells, or 95%, met the state primary Maximum Contaminant Levels (MCL) for drinking water. Thirty-one wells, or 5%, sampled have constituents that exceed one or more MCL. Figure 26 shows the percentage of each contaminant group that exceeded MCLs in the 31 wells.

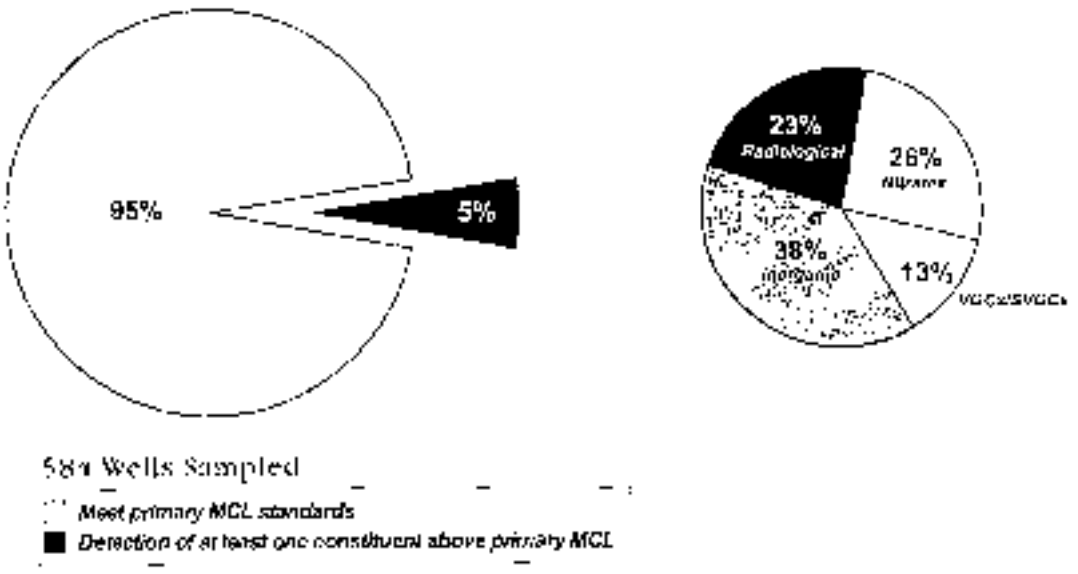

Figure 26 MCL exceedances in public supply wells in the North Coast Hydrologic Region

Table 13 lists the three most frequently occurring individual contaminants in each of the five contaminant groups and shows the number of wells in the HR that exceeded the MCL for these contaminants.

AR0069746

Table 13 Most frequently occurring contaminants by contaminant group in the North Coast Hydrologic Region

Contaminant group with health significance – Primary exceedance	Contaminant – # of wells Aluminum – 4	Contaminant – # of wells Arsenic – 4	Contaminant – # of wells Fluoride – 4
Inorganics – Secondary	Manganese – 150	Iron – 108	Copper – 2
Radiological	Radium-228 – 3	Combined RA226 + RA228 – 4	Radium-226 – 1
Nitrates	Nitrate (as NO3) – 7	Nitrate (as N) – 1	
VOCs/SVOCs	TCE – 2	2 total exceedances	

TCE = Trichloroethylene
VOC = Volatile Organic Compound
SVOC = Semi-Volatile Organic Compound

Changes from Bulletin 118-80

Since Bulletin 118-80 was published, RWQCB 2 boundary has been modified. This resulted in several basins being reassigned to RWQCB 1. These are listed in Table 14, along with other modifications to North Coast HR.

Table 14 Modifications since Bulletin 118-80 of groundwater basins in North Coast Hydrologic Region

Basin name	New number	Old number
Wildwood Valley	1-56	2-12
Knights Valley	1-56	2-13
Potter Valley	1-5	2-14
Ukiah Valley	1-52	2-15
Sanel Valley	1-53	2-16
Alexander Valley	1-54	2-17
Santa Rosa Valley	1-55	2-18
Lower Russian River Valley	1-60	2-20
Sonoma Bay Area	1-57	2-21
Modern Pleistocene Recent Volcanic Area	deleted	2-3
Modern Pleistocene Pliocene Volcanic Area	deleted	2-24
Glenelda River Valley	deleted	2-17
Wilson Grove Formation Highlands	1-59	2-25
Petaluma River Tidal Deposits	2-61	
Wilson Point Area	1-62	

AR0069747

Fort Ross Terrace Deposits (1-61) and Wilson Point Area (1-62) have been defined since B118-80 and are included in this update. Mad River Valley Groundwater Basin (1-8) has been subdivided into two subbasins. Sebastopol Merced Formation (2-25) merged into Basin 2-59 and was renamed Wilson Grove Formation Highlands.

There are a couple of deletions of groundwater basins from Bulletin 118-80. The Modoc Plateau Recent Volcanic Area (1-22) and the Modoc Plateau Pleistocene Volcanic Area (1-24) are volcanic aquifers and were not assigned basin numbers in this bulletin. These are considered to be groundwater source areas as discussed in Chapter 6. Cicalala River Valley (1-47) was deleted because the State Water Resources Control Board determined the water being extracted in this area as surface water within a subterranean stream.

Description of the Region

The San Francisco Bay HR covers approximately 2.88 million acres (4,500 square miles) and includes all of San Francisco and portions of Marin, Sonoma, Napa, Solano, San Mateo, Santa Clara, Contra Costa, and Alameda counties (Figure 27). The region corresponds to the boundary of RWQCB 2. Significant geographic features include the Santa Clara, Napa, Sonoma, Petaluma, Suisun-Fairfield, and Livermore valleys; the Marin and San Francisco peninsulas; San Francisco, Suisun, and San Pablo bays; and the Santa Cruz Mountains, Diablo Range, Bolinas Ridge, and Coast Mountains of the Coast Range. While being the smallest in size of the 10 HRs, the region has the second largest population in the State at about 5.8 million in 1995 (DWR 1998). Major population centers include the cities of San Francisco, San Jose and Oakland.

Groundwater Development

The region has 28 identified groundwater basins. Two of those, the Napa-Sonoma Valley and Santa Clara Valley groundwater basins, are further divided into three and four subbasins, respectively. The groundwater basins underlie approximately 896,000 acres (1,400 square miles) or about 30 percent of the entire HR.

Despite the tremendous urban development in the region, groundwater use accounts for only about 5 percent (68,000 acre-feet) of the region's estimated average water supply for agricultural and urban uses, and accounts for less than one percent of statewide groundwater uses.

In general, the freshwater-bearing aquifers are relatively thin in the smaller basins and moderately thick in the more heavily utilized basins. The more heavily utilized basins in this region include the Santa Clara Valley, Napa-Sonoma Valley, and Petaluma Valley groundwater basins. In these basins, the municipal and irrigation wells have average depths ranging from about 200 to 500 feet. Well yields in these basins range from less than 50 gallons per minute (gpm) to approximately 3,000 gpm. In the smaller basins, most municipal and irrigation wells have average well depths in the 100- to 200-foot range. Well yields in the smaller and less utilized basins are typically less than 500 gpm.

AR0069753

Land subsidence has been a significant problem in the Santa Clara Valley Groundwater Basin in the past. An extensive annual monitoring program has been set up within the basin to evaluate changes in an effort to maintain land subsidence at less than 0.01 feet per year (SCVWD 2001). Additionally, groundwater recharge projects have been implemented in the Santa Clara Valley to ensure that groundwater will continue to be a viable water supply in the future.

Groundwater Quality

In general, groundwater quality throughout most of the region is suitable for most urban and agricultural uses with only local impairments. The primary constituents of concern are high TDS, nitrate, boron, and organic compounds.

The areas of high TDS (and chloride) concentrations are typically found in the region's groundwater basins that are situated closest to the San Francisco Bay, such as the northern Santa Clara, southern Sonoma, Petaluma, and Napa valleys. Elevated levels of nitrate have been detected in a large percentage of private wells tested within the Coyote Subbasin and Llagas Subbasin of the Gilroy Hollister Valley Groundwater Basin (in the Central Coast HR) located to the south of the Santa Clara Valley (SCVWD 2007). The shallow aquifer zone within the Petaluma Valley also shows persistent nitrate contamination. Groundwater with high TDS, iron, and boron levels is present in the Calistoga area of Napa Valley, and elevated boron levels in other parts of Napa Valley make the water unfit for agricultural uses. Releases of fuel hydrocarbons from leaking underground storage tanks and spills/leaks of organic solvents at industrial sites have caused minor to significant groundwater impacts in many basins throughout the region. Methyl tertiary-butyl ether (MTBE) and chlorinated solvent releases to soil and groundwater continue to be problematic. Environmental oversight for many of these sites is performed either by local city and county enforcement agencies, the RWQCB, the Department of Toxic Substances Control, and/or the U.S. Environmental Protection Agency.

Water Quality in Public Supply Wells

From 1994 through 2006, 485 public supply water wells were sampled in 18 of the 33 basins and subbasins in the San Francisco Bay HR. Analyzed samples indicate that 410 wells, or 85 percent, met the state primary MCLs for drinking water standards. Seventy-five wells, or 15 percent, have constituents that exceed one or more MCL. Figure 28 shows the percentages of each contaminant group that exceeded MCLs in the 75 wells.

Table 16 lists the three most frequently occurring contaminants in each contaminant group and the number of wells in the HR that exceeded the MCL for those contaminants.

AR0069754

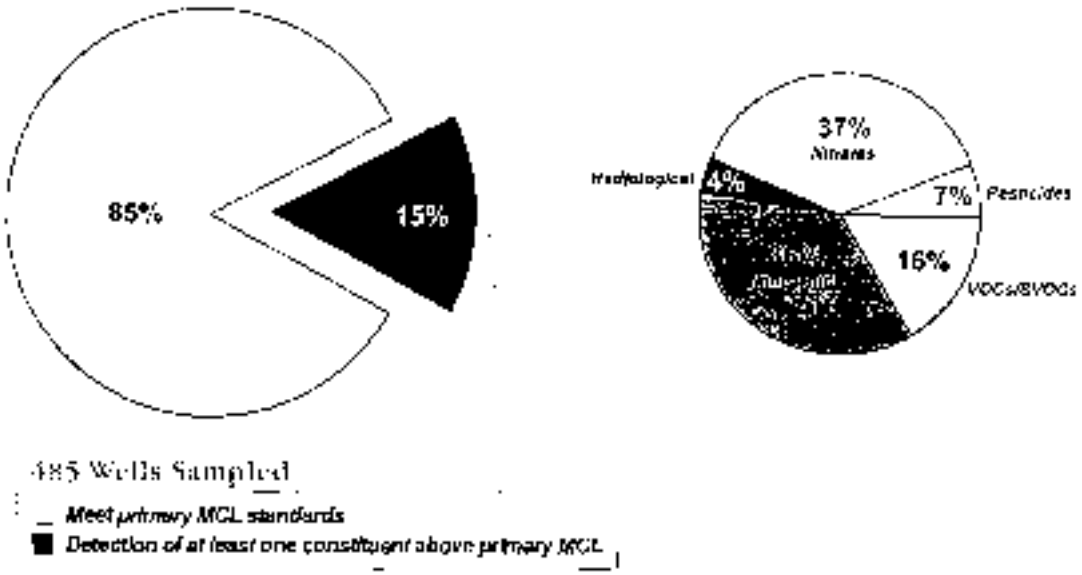

Figure 23 MCL exceedances in public supply wells in the San Francisco Bay Hydrologic Region

Table 16 Most frequently occurring contaminants by contaminant group in the San Francisco Bay Hydrologic Region

Contaminant group	Contaminant - # of wells	Contaminant - # of wells	Contaminant - # of wells
Inorganics	Iron - 37	Manganese - 27	Chloride - 7
Radiological	Gross Alpha - 2	Radium 226 - 1

Pesticides	DCPA - 4	Simazine - 1	
VOCs/SVOCs	PCE - 4	Dichloroethane - 3	TCE - 2 Vinyl Chloride - 2

TCE = Trichloroethylene
PCE = Tetrachloroethylene
VOC = Volatile Organic Compounds
SVOC = Semi-volatile Organic Compounds

AR0069755

Changes from Bulletin 118-80

Since Bulletin 118-80 was published, RWQCB 2 boundary has been modified. This resulted in several basins being reassigned to RWQCB 1. These are listed in Table 17.

Table 17 Modifications since Bulletin 118-80 of groundwater basins in San Francisco Bay Hydrologic Region

Basin name	New number	Old number
Mcdowell Valley	1-56	2-17
Knights Valley	1-58	2-13
Petrta Valley	1-51	2-14
Wilson Valley	1-52	2-15
Sonoi Valley	1-53	2-16
Alexander Valley	1-54	2-17
Santa Rosa Valley	1-55	2-18
Lower Russian River Valley	1-60	2-20
Bodega Bay Area	1-57	2-21

No additional basins were assigned to the San Francisco Bay HR in this revision. However, the Santa Clara Valley Groundwater Basin (2-9) has been subdivided into four subbasins instead of two, and the Napa Sonoma Valley Groundwater Basin is now three subbasins instead of two.

There are several deletions of groundwater basins from Bulletin 118-80. The San Francisco Sand Dune Area (2-34) was deleted when the San Francisco groundwater basins were redefined in a USGS report in the early 1990s. The Napa-Sonoma Volcanic Highlands (2-23) is a volcanic aquifer and was not assigned a basin number in this bulletin. This is considered to be a groundwater source area as discussed in Chapter 6. Bulletin 118-80 identified seven groundwater basins that were stated to differ from 118-75: Sonoma County Basin, Napa County Basin, Santa Clara County Basin, San Mateo Basin, Alameda Bay Plain Basin, Niles Cone Basin, and Livermore Basin. They were created primarily by combining several smaller basins and subbasins within individual counties. This report does not consider these seven as basins. There is no change in numbering because the basins were never assigned a basin number.

AR0069761

Description of the Region

The Central Coast HR covers approximately 7.22 million acres (11,200 square miles) in central California (Figure 29). This HR includes all of Santa Cruz, Monterey, San Luis Obispo, and Santa Barbara counties, most of San Benito County, and parts of San Mateo, Santa Clara, and Ventura counties. Significant geographic features include the Pajaro, Salinas, Carmel, Santa Maria, Santa Ynez, and Cuyama valleys, the coastal plain of Santa Barbara, and the Coast Range. Major drainages in the region include the Salinas, Cuyama, Santa Ynez, Santa Maria, San Antonio, San Lorenzo, San Benito, Pajaro, Nacimiento, Carmel, and Big Sur Rivers.

Population data from the 2000 Census suggest that about 1.4 million people or about 4 percent of the population of the State live in this HR. Major population centers include Santa Barbara, Santa Maria, San Luis Obispo, Gilroy, Hollister, Morgan Hill, Salinas, and Monterey.

The Central Coast HR has 50 delineated groundwater basins. Within this region, the Gilroy-Hollister Valley and Salinas Valley groundwater basins are divided into four and eight subbasins, respectively. Groundwater basins in this HR underlie about 2,290 million acres (3,740 square miles) or about one-third of the HR.

Groundwater Development

Locally, groundwater is an extremely important source of water supply. Within the region, groundwater accounted for 83 percent of the annual supply used for agricultural and urban purposes in 1995. For an average year, groundwater in the region accounts for about 8.4 percent of the statewide groundwater supply and about 1.3 percent of the total state water supply for agricultural and urban needs. In drought years, groundwater in this region is expected to account for about 9.7 percent of the statewide groundwater supply and about 1.9 percent of the total State water supply for agricultural and prison needs (DWR 1998).

Aquifers are varied and range from large extensive alluvial valleys with thick multilayered aquifers and aquifers in small inland valleys and coastal terraces. Several of the larger basins provide a dependable and drought-resistant water supply to coastal cities and farms.

Conjunctive use of surface water and groundwater is a long-standing practice in the region. Several reservoirs including Hernandez, Twitchell, Lake San Antonio, and Lake Nacimiento are operated primarily for the purpose of groundwater recharge. The concept is to maintain streamflow over a longer period than would occur without surface water storage and thus provide for increased recharge of groundwater. Seawater intrusion is a major problem throughout much of the region. In the Salinas Valley Groundwater Basin, seawater intrusion was first documented in the 1930s and has been observed more than 5 miles inland.

Groundwater Quality

Much of the groundwater in the region is characterized by calcium sulfate to calcium sodium bicarbonate sulfate water types because of marine sedimentary rock in the watersheds. Aquifers intruded by seawater are typically characterized by sodium chloride to calcium chloride, and have chloride concentrations greater than 500 mg/L. In several areas, groundwater exceeds the MCL for nitrate.

Water Quality in Public Supply Wells

From 1994 through 2000, 711 public supply water wells were sampled in 38 of the 50 basins and subbasins in the Central Coast HR. Analyzed samples indicate that 587 wells, or 83 percent, met the state primary MCLs for drinking water. One hundred-twenty-four wells, or 17 percent, have constituents that exceed one or more MCL. Figure 30 shows the percentages of each contaminant group that exceeded MCLs in the 124 wells.

AR0069762

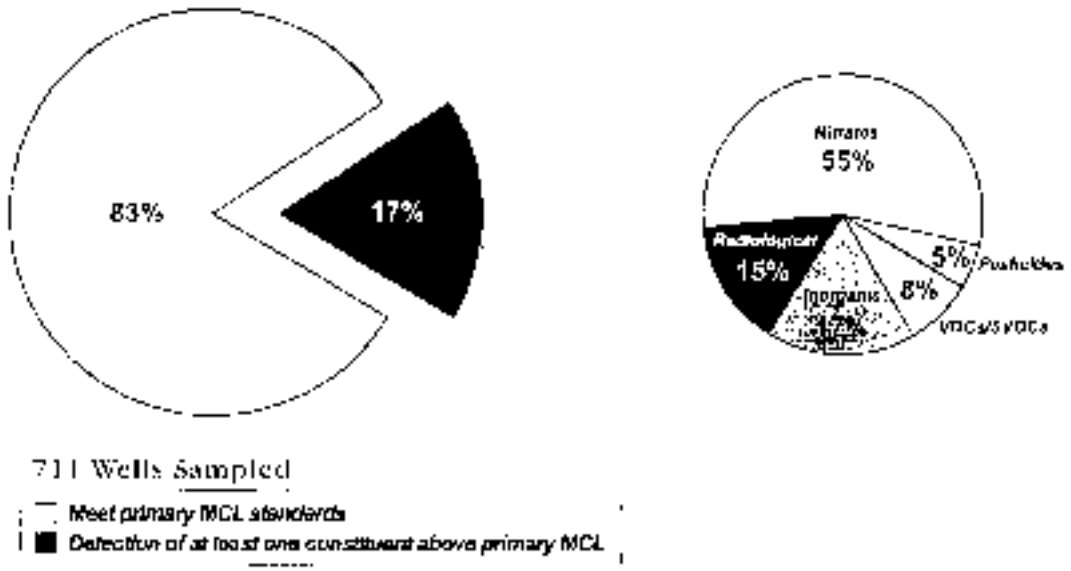

Figure 30 MCL exceedances in public supply wells in the Central Coast Hydrologic Region

Table 19 lists the three most frequently occurring contaminants in each of the six contaminant groups and shows the number of wells in the HR that exceeded the MCL for these contaminants.

Table 19 Most frequently occurring contaminants by contaminant group in the Central Coast Hydrologic Region

Contaminant group	Contaminant	# of wells	Contaminant	# of wells	Contaminant	# of
Inorganics – Primary	Arsenic	6	Aluminum	4	Chromium (Total)	4
Inorganics – Secondary	Iron	145	Manganese	135	TDS	11
Radiological	Gross Alpha	15	Radium 226	3	Uranium	3
Nitrates	Nitrate (as NO_3)	59	Nitrate – Nitrite	24		
Pesticides	Heptachlor	4	Di(2-Ethylhexyl)phthalate	2		
VOCs/SVOCs	TCE	3	3 others tied at 2 exceedances			

TCE = Trichloroethylene
VOC = Volatile Organic Compound
SVOC = Semivolatile Organic Compound

AR0069763

Changes from Bulletin 118-80

Four new basins have been defined since Bulletin 118-80. They are Felton Area, Majors Creek, Needle Rock Point, and Foster Groundwater basins. Additionally, new subbasins have been broken out in both the Gilroy-Hollister Valley Groundwater Basin (3-9) and the Salinas Valley Groundwater Basin (3-4) (Table 20)

Table 20 Modifications since Bulletin 118-80 of groundwater basins and subbasins in Central Coast Hydrologic Region

Subbasin name	New number	Old number
Llagas Area	3-3.01	3-3
Bolsa Area	3-3.02	3-3
Hollister Area	3-3.03	3-3
San Juan Bautista Area	3-3.04	3-3
[illegible] Fort Aquifer	3-4.01	3-4
East Side Aquifer	3-4.02	3-4
Upper Forebay Aquifer	3-4.04	3-4
Upper Valley Aquifer	3-4.05	3-4
Pismo Creek Valley Basin	3-12	3-10
Arroyo Grande Creek Basin	3-12	3-11
Cuyama Sand Highlands Basin	3-12 and 3-14	3-18
Felton Area	3-50	
Majors Creek	3-51	
Needle Rock Point	3-52	
Foster	3-53	

Pismo Creek Valley Basin (3-10) and Arroyo Grande Creek Basin (3-11) have been merged into the Santa Maria River Valley Basin (3-12). Cuyama Sand Highlands Basin (3-18) has been merged into the Santa Maria River Valley Basin (3-12) and San Antonio Creek Valley Basin (3-14).

AR0069769

Description of the Region

The South Coast HR covers approximately 6.78 million acres (10,600 square miles) of the southern California watershed that drains to the Pacific Ocean (Figure 3-1). The HR is bounded on the west by the Pacific Ocean and the watershed divide near the Ventura-Santa Barbara County line. The northern boundary corresponds to the crest of the Transverse Ranges through the San Gabriel and San Bernardino mountains. The eastern boundary lies along the crest of the San Jacinto Mountains and low-lying hills of the Peninsular Range that form a drainage boundary with the Colorado River HR. The southern boundary is the international boundary with the Republic of Mexico. Significant geographic features include the coastal plain, the central Transverse Ranges, the Peninsular Ranges, and the San Fernando, San Gabriel, Santa Ana River, and Santa Clara River valleys.

The South Coast HR includes all of Orange County, most of San Diego and Los Angeles Counties, parts of Riverside, San Bernardino, and Ventura counties, and a small amount of Kern and Santa Barbara Counties. This HR is divided into Los Angeles, Santa Ana and San Diego subregions, RWQCBs 4, 8, and 9 respectively. Groundwater basins are numbered according to these subregions. Basin numbers in the Los Angeles subregion are preceded by a 4, in Santa Ana by an 8, and in San Diego by a 9. The Los Angeles subregion contains the Ventura, Santa Clara, Los Angeles, and San Gabriel River drainages, Santa Ana encompasses the Santa Ana River drainage, and San Diego includes the Santa Maria River, San Luis Rey River, and the San Diego River and other drainage systems.

According to 2000 census data, about 17 million people live within the boundaries of the South Coast HR, approximately 50 percent of the population of California. Because this HR amounts to only about 7 percent of the surface area of the State, this has the highest population density of any HR in California (DWR 1998). Major population centers include the metropolitan areas surrounding Ventura, Los Angeles, San Diego, San Bernardino, and Riverside.

The South Coast HR has 56 delineated groundwater basins. Twenty-one basins are in subregion 4 (Los Angeles), eight basins in subregion 8 (Santa Ana), and 27 basins in subregion 9 (San Diego).

The Los Angeles subregion overlies 21 groundwater basins and encompasses most of Ventura and Los Angeles counties. Within this subregion, the Ventura River Valley, Santa Clara River Valley, and Coastal Plain of Los Angeles basins are divided into subbasins. The basins in the Los Angeles subregion underlie 1,01 million acres (1,580 square miles) or about 40 percent of the total surface area of the subregion.

The Santa Ana subregion overlies eight groundwater basins and encompasses most of Orange County and parts of Los Angeles, San Bernardino, and Riverside counties. The Upper Santa Ana Valley Groundwater Basin is divided into nine subbasins. Groundwater basins underlie 979,000 acres (1,520 square miles) or about 34 percent of the Santa Ana subregion.

The San Diego subregion overlies 27 groundwater basins, encompasses most of San Diego County, and includes parts of Orange and Riverside counties. Groundwater basins underlie about 277,000 acres (433 square miles) or about 12 percent of the surface of the San Diego subregion.

Overall, groundwater basins underlie about 2.27 million acres (3,530 square miles) or about 33 percent of the South Coast HR.

AR0069770

Groundwater Development

Groundwater has been used in the South Coast HR for well over 100 years. High demand and use of groundwater in Southern California has given rise to many disputes over management and pumping rights, with the resolution of most cases playing a large role in the establishment and clarification of water rights law in California. Raymond Groundwater Basin, located in this HR, was the first adjudicated basin in the state. Of the 16 adjudicated basins in California, 11 are in the South Coast HR. Groundwater provides about 23 percent of water demand in normal years and about 29 percent in drought years (DWR 1998).

Groundwater is found in unconfined alluvial aquifers in most of the basins of the San Diego subregion and the inland basins of the Santa Ana and Los Angeles subregions. In some larger basins, typified by those underlying the coastal plain, groundwater occurs in multiple aquifers separated by aquitards that create confined groundwater conditions. Basins range in depth from tens or hundreds of feet in smaller basins, to thousands of feet in larger basins. The thickness of aquifers varies from tens to hundreds of feet. Well yields vary in this HR depending on aquifer characteristics and well location, size, and use. Some aquifers are capable of yielding thousands of gallons per minute to municipal wells.

Conjunctive Use

Conjunctive use of surface water and groundwater is a long-standing practice in the region. At present, much of the potable water used in Southern California is imported from the Colorado River and from sources in the eastern Sierra and Northern California. Several reservoirs are operated primarily for the purpose of storing surface water for domestic and irrigation use, but groundwater basins are also recharged from the outflow of some reservoirs. The concept is to maintain streamflow over a longer period of time than would occur without regulated flow and thus provide for increased recharge of groundwater basins. Most of the larger basins in this HR are highly managed, with many conjunctive use projects being developed to optimize water supply.

Coastal basins in this HR are prone to intrusion of seawater. Seawater intrusion barriers are maintained along the Los Angeles and Orange County sections of the coastal plain. In Orange County, recycled water is injected into the ground to form a mound of groundwater between the coast and the main groundwater basin. In Los Angeles County, imported and recycled water is injected to maintain a seawater intrusion barrier.

Groundwater Quality

Groundwater in basins of the Los Angeles subregion is mainly calcium sulfate and calcium bicarbonate in character. Nitrate content is elevated in some parts of the subregion. Volatile organic compounds (VOCs) have created groundwater impairments in some of the industrialized portions of the region. The San Gabriel Valley and San Fernando Valley groundwater basins both have multiple sites of contamination from VOCs. The main constituents in the contamination plumes are trichloroethylene (TCE) and tetrachloroethylene (PCE). Some of the locations have been declared federal Superfund sites. Contamination plumes containing high concentrations of TCE and PCE also occur in the Bunker Hill Subbasin of the Upper Santa Ana Valley Groundwater Basin. Some of these plumes are also designated as Superfund sites. Perchlorate is emerging as an important contaminant in several areas in the South Coast HR.

Groundwater in basins of the Santa Ana subregion is primarily calcium and sodium bicarbonate in character. Local impairments from excess nitrate or VOCs have been recognized. Groundwater and surface water in the Chino Subbasin of the Santa Ana River Valley Groundwater Basin have elevated nitrate concentrations, partly derived from a large dairy industry in that area. In Orange County, water from the Santa Ana River provides a large part of the groundwater replenishment. Wetlands maintained along the Santa Ana River near the boundary of the Upper Santa Ana River and Orange County Groundwater Basins provide effective removal of nitrate from surface water, while maintaining critical habitat for endangered species.

AR0069771

Groundwater in basins of the San Diego subregion has mainly calcium and sodium cations and bicarbonate and sulfate anions. Local impairments by nitrate, sulfate, and TDS are found. Camp Pendleton Marine Base, in the northwestern part of this subregion, is on the EPA National Priorities List for soil and groundwater contamination by many constituents.

Water Quality in Public Supply Wells

From 1998 through 2000, 2,342 public supply water wells were sampled in 47 of the 73 basins and subbasins in the South Coast HR. Analyzed samples indicate that 1,360 wells, or 58 percent, met the state primary MCLs for drinking water. Nine-hundred-eighty-two wells, or 42 percent, have constituents that exceed one or more MCL. Figure 32 shows the percentages of each contaminant group that exceeded MCLs in the 982 wells.

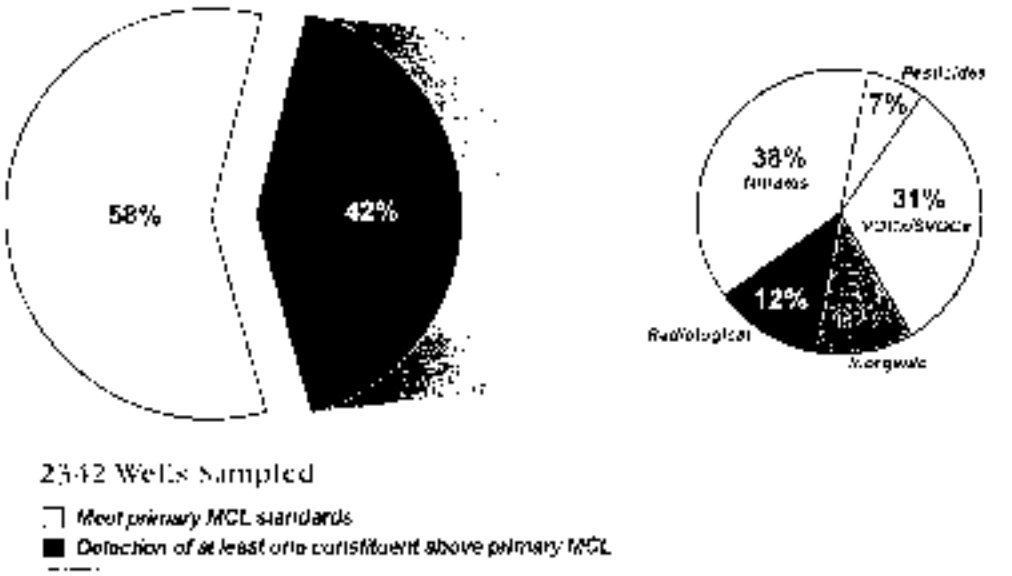

Figure 32 MCL exceedances in public supply wells in the South Coast Hydrologic Region

Table 22 lists the three most frequently occurring contaminants in each of the six contaminant groups and shows the number of wells in the HR that exceeded the MCL for those contaminants.

Changes from Bulletin 118-80

Several modifications from the groundwater basins presented in Bulletin 118-80 are incorporated in this report (Table 23). The Cajalco Valley (8-31), Jurupa Valley (9-20), Las Pulgas Valley (9-21), Pine Valley (9-26), and Tecate Valley (9-30) Groundwater Basins have been deleted in this report because they have thin deposits of alluvium and well completion reports indicate that groundwater production is from underlying fractured bedrock. The Cuyamaca-Laguna Mountains Area (8-32) is a mountainous area and was not assigned a basin number in this bulletin. This is considered to be groundwater source area as discussed in Chapter 6.

AR0069772

Table 22 Most frequently occurring contaminants by contaminant group in the South Coast Hydrologic Region

Contaminant group	Contaminant - # of wells	Contaminant - # of wells	Contaminant - # of wells
Inorganics - Primary	Fluoride - 56	Thallium - 15	Arsenic - 12
Inorganics - Secondary	Iron - 337	Manganese - 335	TDS - 56
Radiological	Gross Alpha - 204	Uranium - 90	Radium 226 + Radium 228 - 7
Nitrates	Nitrate (as NO3) - 564	Nitrate + Nitrite - 179	Nitrate Nitrogen (NO3-N) - 4
Pesticides	DBCP - 61	Di(2-ethylhexyl)phthalate - 5	Heptachlor - 2 2,3,8 - 2
VOCs/SVOCs	TCE - 196	PCE - 152	1,2-Dichloroethane - 43

DBCP = Dibromochloropropane
EDB = Ethylene Dibromide
VOCs = Volatile Organic Compounds
SVOCs = Semi-volatile Organic Compounds

The Ventura River Valley (4-3), Santa Clara River Valley (4-4), Coastal Plain of Los Angeles (4-11), and Upper Santa Ana Valley (8-2) Groundwater Basins have been divided into subbasins in this report. The extent of the San Jacinto Groundwater Basin (8-5) has been decreased because completion of Diamond Valley Reservoir has inundated the valley. Paloma Valley has been removed because well logs indicate groundwater production is solely from fractured bedrock. The Rayanond Groundwater Basin (4-23) is presented as an individual basin instead of being incorporated into the San Gabriel Valley Groundwater Basin (4-13) because it is bounded by physical barriers and has been managed as a separate and individual groundwater basin for many decades. In Bulletin 118-75, groundwater basins in two different subregions were designated the Upper Santa Ana Valley Groundwater Basin (4-14 and 8-2). To alleviate this confusion, basin 4-14 has been divided, with parts of the basin incorporated into the neighboring San Gabriel Valley Groundwater Basin (4-13) and the Chino subbasin of the Upper Santa Ana Valley Groundwater Basin (8-2.01). The San Marcos Area Groundwater Basin (9-32) in central San Diego County is presented as a new basin in this report.

AR0069779

Description of the Region

The Sacramento River HR covers approximately 17.4 million acres (27,200 square miles). The region includes all or large portions of Modoc, Siskiyou, Lassen, Shasta, Tehama, Glenn, Plumas, Butte, Colusa, Sutter, Yuba, Sierra, Nevada, Placer, Sacramento, El Dorado, Yolo, Solano, Lake, and Napa counties (Figure 33). Small areas of Alpine and Amador counties are also within the region. Geographically, the region extends south from the Modoc Plateau and Cascade Range at the Oregon border, to the Sacramento-San Joaquin Delta. The Sacramento Valley, which forms the core of the region, is bounded to the east by the crest of the Sierra Nevada and southern Cascades and to the west by the crest of the Coast Range and Klamath Mountains. Other significant features include Mount Shasta and Lassen Peak in the southern Cascades, Sutter Buttes in the south central portion of the valley, and the Sacramento River, which is the longest river system in the State of California with major tributaries the Pit, Feather, Yuba, Bear and American rivers. The region corresponds approximately to the northern half of RWQCB 5. The Sacramento metropolitan area and surrounding communities form the major population center of the region. With the exception of Redding, cities and towns to the north, while steadily increasing in size, are more rural than urban in nature, being based on major agricultural areas. The 1995 population of the entire region was 2.372 million.

The climate in the northern, high desert plateau area of the region is characterized by cold snowy winters with only moderate precipitation and hot dry summers. This area depends on adequate snowpack to provide runoff for summer supply. Annual precipitation ranges from 10 to 20 inches. Other mountainous areas in the northern and eastern portions of the region have cold wet winters with large amounts of snow, which typically provide abundant runoff for summer supplies. Annual precipitation ranges from 40 to more than 80 inches. Summers are generally mild in these areas. The Coast Range and southern Klamath Mountains receive copious amounts of precipitation, but most of the runoff flows to the coast in the North Coastal drainage. Sacramento Valley comprises the remainder of the region. At a much lower elevation than the rest of the region, the valley has mild winters with moderate precipitation. Annual precipitation varies from about 35 inches in Redding to about 18 inches in Sacramento. Summers in the valley are hot and dry.

Most of the mountainous portions of the region are heavily forested and sparsely populated. Three major national forests (Mendocino, Trinity, and Shasta) make up the majority of lands in the Coast Range, southern Klamath Mountains, and the southern Cascades; these forests and the region's rivers and lakes provide abundant recreational opportunities. In the few mountain valleys with arable land, alfalfa, grain and pasture are the predominant crops. In the foothill areas of the region, particularly adjacent to urban centers, suburban to rural housing development is occurring along major highway corridors. This development is leading to urban sprawl and is replacing the former agricultural production on those lands. In the Sacramento Valley, agriculture is the largest industry. Truck, field, orchard, and rice crops are grown on approximately 2.1 million acres. Rice represents about 25 percent of the total irrigated acreage.

The Sacramento River HR is the main water supply for much of California's urban and agricultural areas. Annual runoff in the HR averages about 22.4 maf, which is nearly one-third of the State's total natural runoff. Major water supplies in the region are provided through surface storage reservoirs. The two largest surface water projects in the region are USBR's Shasta Lake (Central Valley Project) on the upper Sacramento River and Lake Oroville (DWR's State Water Project) on the Feather River. In all, there are more than 40 major surface water reservoirs in the region. Municipal, industrial, and agricultural supplies in the region are about 8 maf, with groundwater providing about 2.5 maf of that total. Much of the remainder of the runoff goes to dedicated natural flows, which support various environmental requirements, including in-stream fishery flows and flushing flows in the Delta.

AR0069780

Groundwater Development

Groundwater provides about 31 percent of the water supply for urban and agricultural uses in the region, and has been developed in both the alluvial basins and the hard rock uplands and mountains. There are 88 basin/subbasins delineated in the region. These basins underlie 5,053 million acres (7,900 square miles), about 29 percent of the entire region. The reliability of the groundwater supply varies greatly. The Sacramento Valley is recognized as one of the foremost groundwater basins in the State, and wells developed in the sediments of the valley provide excellent supply to irrigation, municipal, and domestic uses. Many of the mountain valleys of the region also provide significant groundwater supplies to multiple uses.

Geologically, the Sacramento Valley is a large trough filled with sediments having variable permeabilities; as a result, wells developed in areas with coarser aquifer materials will produce larger amounts of water than wells developed in fine aquifer materials. In general, well yields are good and range from one-hundred to several thousand gallons per minute. Because surface water supplies have been so abundant in the valley, groundwater development for agriculture primarily supplemented the surface supply. With the changing environmental laws and requirements, this balance is shifting to a greater reliance on groundwater, and conjunctive use of both supplies is occurring to a greater extent throughout the valley, particularly in dry/critical years. Groundwater provides all or a portion of municipal supply in many valley towns and cities. Redding, Anderson, Cline, Marysville, Sacramento, Olivehurst, Wheatland, Willows, and Williams rely to differing degrees on groundwater. Red Bluff, Corning, Woodland, Davis, and Dixon are completely dependent on groundwater. Domestic use of groundwater varies, but in general, rural unincorporated areas rely completely on groundwater.

In the mountain valleys and basins with arable land, groundwater has been developed to supplement surface water supplies. Most of the rivers and streams of the area have adjudicated water rights that go back to the early 1900s, and diversion of surface water has historically supported agriculture. Droughts and increased competition for supply have led to significant development of groundwater for irrigation. In some basins, the fractured volcanic rock underlying the alluvial fill is the major aquifer for the area. In the rural mountain areas of the region, domestic supplies come almost entirely from groundwater. Although a few mountain communities are supplied in part by surface water, most rely on groundwater. These groundwater supplies are generally quite reliable in areas that have sufficient aquifer storage or where surface water supplies supply throughout the year. In areas that depend on seasonal runoff, water levels can be significantly depleted in drought years and many old, shallow wells can be dewatered. During 2001, an extreme drought year on the Modoc Plateau, many well owners experienced problems with water supply.

Groundwater development in the fractured rocks of the foothills of the southern Cascades and Sierra Nevada is fraught with uncertainty. Groundwater supplies from fractured rock sources are highly variable in terms of water quantity and water quality and are an uncertain source for large-scale residential development. Originally, foothill development relied on water supply from springs and river diversions with flumes and ditches for conveyance that date back to gold mining era operations. Current development is primarily based on individual private wells, and as pressures for larger scale development increase, questions about the reliability of supply need to be addressed. Many existing foothill communities have considerable experience with dry or drought year shortages. In Butte County residents in Cohasset, Forest Ranch, and Magalia have had to rely on water brought up the ridges in tanker trucks. The suggested answer has been the development of regional water supply projects. Unfortunately, the area's development pattern of small, geographically dispersed population centers does not lend itself to the kind of financial base necessary to support such projects.

AR0069781

Groundwater Quality

Groundwater quality in the Sacramento River HR is generally excellent. However, there are areas with local groundwater problems. Natural water quality impairments occur at the north end of the Sacramento Valley in the Redding subbasin, and along the margins of the valley and around the Sutter Buttes, where Cretaceous-age marine sedimentary rocks containing brackish to saline water are near the surface. Water from the older underlying sediments mixes with the fresh water in the younger alluvial aquifer and degrades the quality. Wells constructed in these areas typically have high TDS. Other local natural impairments are moderate levels of hydrogen sulfide in groundwater in the volcanic and geothermal areas in the western portion of the region. In the Sierra foothills, there is potential for encountering uranium and radon bearing rock or sulfide mineral deposits containing heavy metals. Human induced impairments are generally associated with individual septic system development in shallow unconfined portions of aquifers or in fractured hard rock areas where insufficient soil depths are available to properly leach effluent before it reaches the local groundwater supply.

Water Quality in Public Supply Wells

From 1994 through 2000, 1,356 public supply water wells were sampled in 51 of the 88 basins and subbasins in the Sacramento River HR. Samples analyzed indicate that 1,282 wells, or 95 percent, met the state primary MCLs for drinking water. Seventy-four wells, or 5 percent, have constituents that exceed one or more MCL. Figure 34 shows the percentages of each contaminant group that exceeded MCL's in the 74 wells.

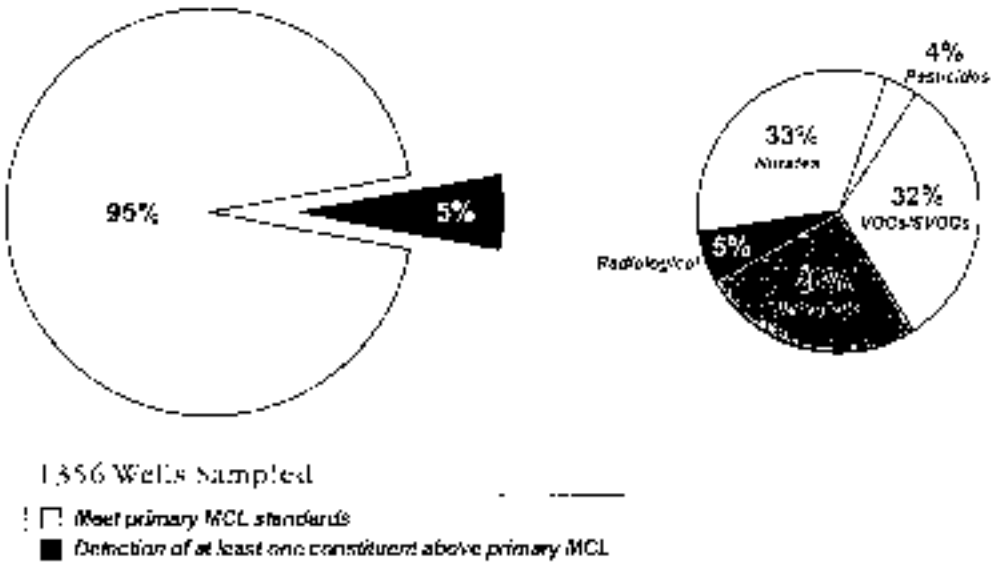

Figure 34 MCL exceedances in public supply wells in the Sacramento River Hydrologic Region

AR0069782

Table 25 lists the three most frequently occurring contaminants in each of the six contaminant groups and shows the number of wells in the HR that exceeded the MCL for those contaminants.

Table 25 Most frequently occurring contaminants by contaminant group in the Sacramento River Hydrologic Region

Contaminant group	Contaminant - # of wells	Contaminant - # of wells	Contaminant - # of wells
Inorganics - Primary	Cadmium - 4	Chromium (Total) - 3	3 tied at 2
Inorganics - Secondary	Manganese - 221	Iron - 166	Specific Conductance - 3
Radionuclides	Gross Alpha - 4		
Nitrates	Nitrate (as NO_3) - 22	Nitrate + Nitrite - 5	Nitrate Nitrogen (NO_3)-N) - 2
Pesticides	1,2,3-Trichloropropane - 4		
VOCs/SVOCs	PCE - 11	TCE - 7	Benzene - 4

PCE - Tetrachloroethylene
TCE - Trichloroethylene
VOC - Volatile Organic Compounds
SVOC - Semivolatile Organic Compound

Changes from Bulletin 118-80

Some modifications from the groundwater basins presented in Bulletin 118-80 are incorporated in this report. These are listed in Table 26.

Table 26 Modifications since Bulletin 118-80 of groundwater basins and subbasins in Sacramento River Hydrologic Region

Basin name	New number	Old number
Fandango Valley	5-110	5-39
Homer Swamp Valley	deleted	5-42
Modoc Plateau Recent Volcanic Areas	deleted	5-52
Modoc Plateau Pleistocene Volcanic Areas	deleted	5-53
Mount Shasta Area	deleted	5-51
Sacramento Valley eastside Tuscan Formation/Highlands	deleted	5-55
Clear Lake Pleistocene Volcanics	deleted	5-67

AR0069783

No additional basins were assigned to the Sacramento River HR in this revision. However, four basins have been divided into subbasins. Goose Lake Valley Groundwater Basin (5-1) has been subdivided into two subbasins, Fandango Valley (5-39) was modified to be a subbasin of Goose Lake Valley. Redding Area Groundwater Basin has been subdivided into six subbasins. Sierra Valley Groundwater Basin has been subdivided into two subbasins, and the Sacramento Valley Groundwater Basin has been subdivided into 18 subbasins.

There are several deletions of groundwater basins from Bulletin 118-80. Butcher Swamp Valley Basin (5-42) was deleted due to a thin veneer of alluvium over rock. Modoc Plateau Recent Volcanic Areas (5-32), Modoc Plateau Pleistocene Volcanic Areas (5-33), Mount Shasta Area (5-34), Sacramento Valley Eastside Tuscan Formation Highlands (5-55), and Clear Lake Pleistocene Volcanics (5-69) are no same aquifers and were not assigned basin numbers in this bulletin. These are considered to be groundwater source areas as discussed in Chapter 6.

Description of the Region

The San Joaquin River HR covers approximately 9.7 million acres (15,200 square miles) and includes all of Calaveras, Tuolumne, Mariposa, Madera, San Joaquin, and Stanislaus counties, most of Merced and Amador counties, and parts of Alpine, Fresno, Alameda, Contra Costa, Sacramento, El Dorado, and San Benito counties (Figure 15). The region corresponds to a portion near the middle of RWQCB 5. Significant geographic features include the northern half of the San Joaquin Valley, the southern part of the Sacramento-San Joaquin Delta, the Sierra Nevada and Diablo Range. The region is home to about 1.6 million people (DWR 1998). Major population centers include Merced, Modesto, and Stockton. The Merced area is entirely dependent on groundwater for its supply, as will be the new University of California at Merced campus.

Groundwater Development

The region contains two entire groundwater basins and part of the San Joaquin Valley Groundwater Basin, which continues south into the Tulare Lake HR. The San Joaquin Valley Groundwater Basin is divided into nine subbasins in this region. The basins underlie 3.73 million acres (5,830 square miles) or about 38 percent of the entire HR area.

The region is heavily groundwater reliant. Within the region groundwater accounts for about 30 percent of the annual supply used for agricultural and urban purposes. Groundwater use in the region accounts for about 18 percent of statewide groundwater use for agricultural and urban needs. Groundwater use in the region accounts for 5 percent of the State's overall supply from all sources for agricultural and urban uses (DWR 1998).

The aquifers are generally quite thick in the San Joaquin Valley subbasins, with groundwater wells commonly extending to depths of up to 800 feet. Aquifers include unconsolidated alluvium and consolidated rocks with unconfined and confined groundwater conditions. Typical well yields in the San Joaquin Valley range from 300 to 2,000 gpm with yields of 5,000 gpm possible. The region's only significant basin located outside of San Joaquin Valley is Yosemite Valley. Yosemite Valley Basin supplies water to Yosemite National Park and has substantial well yields.

AR0069791

Conjunctive Use

Since near the beginning of the region's agricultural development, groundwater has been used conjunctively with surface water to meet water needs. Groundwater was and is used when and where surface water is unable to fully meet demands either in time or area. For several decades, this situation was more of an incidental conjunctive use than a formal one. Historical groundwater use has resulted in some land subsidence in the southwest portion of the region.

Groundwater Quality

In general, groundwater quality throughout the region is suitable for most urban and agricultural uses with only local impairment. The primary constituents of concern are TDS, nitrate, boron, chloride, and organic compounds. The Yosemite Valley Groundwater Basin has exceptionally high quality groundwater.

Areas of high TDS content are primarily along the west side of the San Joaquin Valley and in the trough of the valley. The high TDS content of west-side groundwater is due to recharge of streamflow originating from marine sediments in the Coast Ranges. High TDS content in the trough of the valley is the result of concentration of salts due to evaporation and poor drainage. Nitrates may occur naturally or as a result of disposal of human and animal waste products and fertilizer. Boron and chloride are likely a result of concentration from evaporation near the valley trough. Organic contaminants can be broken into two categories, agricultural and industrial. Agricultural pesticides and herbicides have been detected in groundwater throughout the region, but primarily along the east side of the San Joaquin Valley where soil permeability is higher and depth to groundwater is shallower. The most notable agricultural contaminant is dibromochloropropane (DBCP), a now-banned soil fumigant and known carcinogen once used extensively on grapes and cotton. Industrial organic contaminants include TCE, dichloroethylene (DCE), and other solvents. They are found in groundwater near airports, industrial areas, and landfills.

Water Quality in Public Supply Wells

From 1994 through 2009, 689 public supply water wells were sampled in 30 of the 31 basins and subbasins in the San Joaquin River HR. Samples analyzed indicate that 523 wells, or 76 percent, met the state primary MCLs for drinking water. One-hundred-sixty-six wells, or 24 percent, have constituents that exceed one or more MCL. Figure 26 shows the percentages of each contaminant group that exceeded MCLs in the 166 wells.

Table 28 lists the three most frequently occurring contaminants in each of the six contaminant groups and shows the number of wells in the HR that exceeded the MCL for those contaminants.

Changes from Bulletin 118-80

The subbasins of the San Joaquin Valley, which were delineated as part of the 118-80 update, are given their first numeric designation in this report. Additionally, the Cosumnes Subbasin has been added to the subbasins within the San Joaquin River HR. It is worth noting that the southern portion of the South American Subbasin of the Sacramento Valley Groundwater Basin is also included as part of this HR. The subbasin names and numbers within the region are listed in Table 29.

Description of the Region

The Tulare Lake HR covers approximately 19,0 [illegible] square miles) and includes all of Kings and Tulare counties and most of Fresno and Kern counties (Figure 37). The region corresponds to approximately the southern one-third of RWQCB 5. Significant geographic features include the southern half of the San Joaquin Valley, the Temblor Range to the west, the Tehachapi Mountains to the south, and the southern Sierra Nevada to the east. The region is home to more than 3.7 million people as of 1995 (DWR, 1998). Major population centers include Fresno, Bakersfield, and Visalia. The cities of Fresno and Visalia are entirely dependent on groundwater for their supply, with Fresno being the second largest city in the United States reliant solely on groundwater.

Groundwater Development

The region has 12 distinct groundwater basins and 7 subbasins of the San Joaquin Valley Groundwater Basin, which crosses north into the San Joaquin River HR. These basins underlie approximately 5.35 million acres (8,330 square miles) or 49 percent of the entire HR area.

Groundwater has historically been important to both urban and agricultural uses, accounting for 41 percent of the region's total annual supply and 35 percent of all groundwater use in the State. Groundwater use in the region represents about 10 percent of the State's overall supply for agricultural and urban uses (DWR 1998).

The aquifers are generally quite thick in the San Joaquin Valley subbasins with groundwater wells commonly exceeding 1,000 feet in depth. The maximum thickness of freshwater-bearing deposits (4,000 feet) occurs at the southern end of the San Joaquin Valley. Typical well yields in the San Joaquin Valley range from 300 gpm to 2,000 gpm with yields of 4,000 gpm possible. The smaller basins in the mountains surrounding the San Joaquin Valley have thinner aquifers and generally lower well yields averaging less than 500 gpm.

AR0069799

The cities of Fresno, Bakersfield, and Visalia have groundwater recharge programs to ensure that groundwater will continue to be a viable water supply in the future. Extensive groundwater recharge programs are also in place in the south valley where water districts have recharged several million acre-feet for future use and transfer through water banking programs.

The extensive use of groundwater in the San Joaquin Valley has historically caused subsidence of the land surface primarily along the west side and south end of the valley.

Groundwater Quality

In general, groundwater quality throughout the region is suitable for most urban and agricultural uses with only local impairments. The primary constituents of concern are high TDS, nitrate, arsenic, and organic compounds.

The areas of high TDS content are primarily along the west side of the San Joaquin Valley and in the trough of the valley. High TDS content of west-side water is due to recharge of stream flow originating from marine sediments in the Coast Range. High TDS content in the trough of the valley is the result of concentration of salts because of evaporation and poor drainage. In the central and west-side portions of the valley, where the Corcoran Clay confining layer exists, water quality is generally better beneath the clay than above it. Nitrates may occur naturally or as a result of disposal of human and animal waste products and fertilizer. Areas of high nitrate concentrations are known to exist near the town of Shafter and other isolated areas in the San Joaquin Valley. High levels of arsenic occur locally and appear to be associated with lakebed areas. Elevated arsenic levels have been reported in the Tulare Lake, Kern Lake and Buena Vista Lake bed areas. Organic contaminants can be broken into two categories, agricultural and industrial. Agricultural pesticides and herbicides have been detected throughout the valley, but primarily along the east side where soil permeability is higher and depth to groundwater is shallower. The most notable agricultural contaminant is DBCP, a now-banned soil fumigant and known carcinogen once used extensively on grapes. Industrial organic contaminants include TCEs, DCEs, and other solvents. They are found in groundwater near airports, industrial areas, and landfills.

Water Quality in Public Supply Wells

From 1994 through 2000, 1,476 public supply water wells were sampled in 11 of the 19 groundwater basins and subbasins in the Tulare Lake HR. Evaluation of analyzed samples shows that 1,019 of the wells, or 71 percent, met the state primary MCLs for drinking water. Four-hundred-twenty-seven wells, or 29 percent, exceeded one or more MCLs. Figure 38 shows the percentages of each contaminant group that exceeded MCLs in the 127 wells.

AR0069800

AR0069801

Changes from Bulletin 118-80

There are no newly defined basins since Bulletin 118-80. However, the subbasins of the San Joaquin Valley, which were delineated as part of the 118-80 update, are given their first numeric designation in this report (Table 32).

Table 32 Modifications since Bulletin 118-80 of groundwater basins and subbasins in Tulare Lake Hydrologic Region

Subbasin name	New number	Old number
Kings	5-22.08	5-22
Westside	5-22.09	5-22
Pleasant Valley	5-22.10	5-22
Kaweah	5-22.11	5-22
Tulare Lake	5-22.12	5-22
Tule	5-22.13	5-22
Kern County	5-22.14	5-22
Squaw Valley	deleted	5-34
Cedar Grove Area	deleted	5-72
Three Rivers Area	deleted	5-73
Springville Area	deleted	5-74
Templeton Mountain Area	deleted	5-75
Monache Meadow Area	deleted	5-76
Sacate Canyon Valley	deleted	5-77
Rockhouse Meadows Valley	deleted	5-78
Iron Valley	deleted	5-79
Bear Valley	deleted	5-81

Several basins have been deleted from the Bulletin 118-80 report. In Squaw Valley (5-34) all 118 wells are completed in hard rock. Cedar Grove Area (5-72) is a narrow river valley in Kings Canyon National Park with no wells. Three Rivers Area (5-73) has a thin alluvial terrace deposit but 128 of 130 wells are completed in hard rock. Springville Area (5-74) is a thin strip of alluvium adjacent to Tule River and all wells are completed in hard rock. Templeton Mountain Area (5-75), Monache Meadow Area (5-76), and Sacate Canyon Valley (5-77) are all at the crest of mountains with no wells. Rockhouse Meadows Valley (5-78) is in wilderness with no wells. Iron Valley (5-79) and Bear Valley (5-81) both have all wells completed in hard rock.

Description of the Region

The North Lahontan HR covers approximately 3.91 million acres (6,110 square miles) and includes portions of Modoc, Lassen, Sierra, Nevada, Placer, El Dorado, Alpine, Mono, and Tuolumne counties (Figure 39). Reaching south from the Oregon border almost to Mono Lake on the east side of the Sierra, this region encompasses portions of two geomorphic provinces. From Long Valley north, most of the groundwater basins of the region were formed by basin and range block faulting near the western extent of the province. South from Long Valley, most of the basins are in the alpine valleys of the Sierra Nevada or are at the foot of the Sierra along the California-Nevada border where streams and rivers draining the eastern Sierran slopes terminate in desert sinks or lakes. The region corresponds to approximately the northern half of RWQCB 6. Significant geographic features include the Sierra Nevada, the volcanic terrain of the Modoc Plateau, Honey Lake Valley, and Lake Tahoe. The latter two areas are the major population centers in the region. The 1995 population of the entire region was about 84,000 people (DWR, 1998).

The northern portion of the region is rural and sparsely populated. Cattle ranching and associated hay cropping are the predominant land uses in addition to some pasture irrigation. Less than 4 percent of the entire region is irrigated. About 75 percent of the irrigated lands are in Modoc and Lassen counties, and most of the remainder is in Alpine and Mono counties. Much of the southern portion of the region is federally owned and managed as national forest lands where tourism and recreation constitute much of the economic base.

Much of the North Lahontan HR is chronically short of water due to the arid, high desert climate, which predominates in the region. Throughout the northern portion of the region where annual precipitation can be as low as 4 inches, runoff is typically scant and streamflows decrease rapidly during the irrigation season as the snowpack in the higher elevations melts. In the southern portion of the region, annual precipitation ranges from more than 70 inches (mostly snow in the higher elevations of the mountains) to as little as 8 inches in the low elevation valleys. In wet years, surface water can meet much of the agricultural demand, but in dry years, most of the region relies heavily on groundwater to meet water supply needs.

AR0069807

Groundwater Development

There are 24 groundwater basins in the region, one of which is divided into three subbasins. Thirteen of these basins are shared with Nevada and one with Oregon. These basins underlie approximately 1.03 million acres (1,610 square miles) or about 26 percent of the entire region. Although the groundwater basins were delineated based on mapped alluvial fill, much of the groundwater produced in many of them actually comes from underlying fractured rock aquifers. This is particularly true in the volcanic areas of Modoc and Lassen counties where, in many basins, volcanic flows are interstratified with lake sediments and alluvium. Wells constructed in the volcanics commonly produce large amounts of groundwater, whereas wells constructed in fine-grained lake deposits produce less. Because the thickness and lateral extent of the hard rocks outside of the defined basin are generally not known, actual groundwater in storage in these areas is unknown.

Locally, groundwater is an important resource accounting for about 28 percent of the annual supply for agricultural and urban uses. Groundwater use in the region represents less than 1 percent of the State's overall supply for agricultural and urban uses (DWR 1998).

In the northern portion of the region, a sizable quantity of groundwater (nearly 30,000 acre-feet) is extracted annually for agricultural and municipal purposes. Groundwater extracted from the Honey Lake Valley Basin accounts for 41,900 acre-feet of the agricultural supply and 12,000 acre-feet of the municipal supply (based on normalized data from 1990). An additional 5,100 acre-feet is extracted to meet the demands of the Honey Lake Wildlife Area, which provides habitat for several threatened species (Bald Eagle, Sandhill Crane, Bank Swallow, and Peregrine Falcon).

Well yields in the Honey Lake Valley Basin are greatest in alluvial and volcanic deposits. Wells drawing from these deposits may have yields that vary from 10 gpm to more than 2,000 gpm, but drawdown in these cases is generally high. Eight wells in the Honey Lake Wildlife Area have an average yield of between 1,200 and 2,100 gpm. Depths of completed wells in the region range from 20 to 720 feet.

The Honey Lake Valley Basin is very close to exceeding prudent perennial yield, and future development could come at the expense of water for agriculture. A 1987 agreement between DWR, the state of Nevada, and the U.S. Geological Survey resulted in a study of the groundwater flow system in eastern Honey Lake Valley. Upon conclusion of the study in September 1990, a Nevada state engineer ruled that only about 13,000 acre-feet could be safely transferred from the basin.

No major changes in water use are anticipated in the near future in the northern portion of the region. Irrigated agriculture is already constrained by economically available water supplies. A small amount of agricultural expansion is expected but only in areas that can support minor additional groundwater development. Likewise, the modest need for additional municipal and irrigation supplies can be met by minor expansion of present surface systems or by increased use of groundwater.

The principal drainages in the southern portion of the region are the Truckee, Walker and Carson rivers. Water rights in these drainages historically have been heavily contested, and allocations are limited by interstate agreements with Nevada, in-stream environmental requirements, and miscellaneous private rights holders. In the Lake Tahoe Basin, further development is strictly limited because of concerns regarding water quality in the lake. Surface water storage developed in the region's drainages provides urban and agricultural supply to the Reno/Sparks area and to the many smaller communities in the eastern Sierra and at the foot of the mountain slopes. Most communities rely on a combination of surface water and groundwater supply.

AR0069808

In the upper Truckee drainage, the primary groundwater basins underlie the areas around Lake Tahoe and Martis Valley, where the Town of Truckee is located. Both areas use surface water and groundwater for urban and surrounding, rural domestic supplies.

Little is known about the small groundwater basins developed along the foot of the eastern Sierra. Most communities overlying these basins are along the streams and rivers flowing down the mountains, and groundwater is extracted from the underlying alluvium. Groundwater augments surface supplies for agricultural purposes and supports municipal and rural domestic supplies.

Groundwater Quality

In basins in the northern portion of the region, groundwater quality ranges widely from excellent to poor. Wells that obtain their water supply from lake deposits can have high concentrations of boron, arsenic, fluoride, nitrate, and TDS. TDS content generally increases toward the central portions of these basins where concentrations have accumulated over time. The groundwater quality along the margins of most of these basins tends to be of much better quality. There is a potential for future groundwater pollution occurring in urban/suburban areas where single-family septic systems have been installed, especially in hard rock areas. Groundwater quality in the alpine basins is good to excellent. And, as in any area where single-family septic systems have been installed, there is potential for degradation of groundwater quality.

Water Quality in Public Supply Wells

From 1994 through 2000, 169 public supply water wells were sampled in 8 of the 26 basins and subbasins in the North Lahontan HR. Evaluation of the analyzed samples indicates that 147 wells, or 87 percent, met the state primary MCLs for drinking water. Twenty-two wells, or 13 percent, have constituents that exceed one or more MCL. Figure 40 shows the percentages of each contaminant group that exceeded MCLs in the 22 wells.

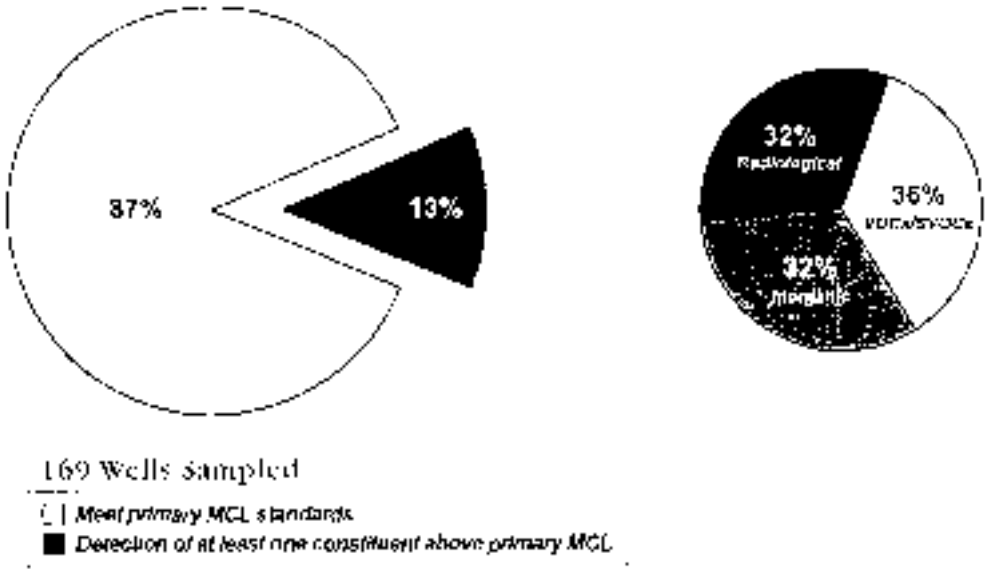

Figure 40 MCL exceedances in public supply wells in the North Lahontan Hydrologic Region

AR0069809

Table 34 lists the three most frequently occurring contaminants in each contaminant group and shows the number of wells in the HR that exceeded the MCL for those contaminants.

Table 34 Most frequently occurring contaminants by contaminant group in the North Lahontan Hydrologic Region

Contaminant group	Contaminant - # of wells	Contaminant - # of wells	Contaminant - # of wells
Inorganics - Primary	Nitrate - 11	Sulfate - 7	Chloride - 2
Inorganics - Secondary	Iron - 14	Manganese - 10	TDS - 1
Radiologicals	Gross Alpha - 7	Uranium - 5	Radium 226 - 1
VOCs/SVOCs	1,2 Dichloroethane - 8	TCE - 2	MTBE - 1

TCE = trichloroethylene
MTBE = Methyl tert-butyl ether
VOC = Volatile Organic Compound
SVOC = Semi-volatile Organic Compound

Changes from Bulletin 118-80

There are no newly defined basins since Bulletin 118-80. The only delineated areas removed from the list of region basins are the Recent and Pleistocene volcanic areas of the Modoc Plateau, previously numbered 6-102 and 6-103, respectively.

AR0069810

AR0069815

Description of the Region

The South Lahontan HR covers approximately 21.2 million acres (33,100 square miles) in eastern California. This region includes about 21 percent of the surface area of California and both the highest (Mount Whitney) and lowest (Death Valley) surface elevations of the contiguous United States. The HR is bounded on the west by the crest of the Sierra Nevada and on the north by the watershed divide between Mono Lake and East Walker River drainages; on the east by Nevada and the south by the crest of the San Gabriel and San Bernardino mountains and the divide between watersheds draining south toward the Colorado River and those draining northward. This HR includes the Owens, Mojave, and Amargosa River systems, the Mono Lake drainage system, and many other internally drained basins. Average annual precipitation is about 7.9 inches, and runoff is about 1.3 maf per year (DWR 1994).

The South Lahontan HR includes Inyo County, much of Mono and San Bernardino counties, and parts of Kern and Los Angeles counties (Figure 21). National forests, national and state parks, military bases and other public lands comprise most of the land in this region. The Los Angeles Department of Water and Power is also a major landowner in the northern part of the HR and controls rights to much of the water draining the eastern Sierra Nevada.

According to 2000 census data, the South Lahontan HR is home to about 530,000 people, or 1.6 percent of the state's population. The major population centers are in the southern part of the HR and include Palmdale, Lancaster, Victorville, Apple Valley, and Hesperia.

Groundwater Development

In this report, 79 groundwater basins are delineated in the South Lahontan HR, and the Longford Valley Groundwater Basin (6-36) is divided into two subbasins. The groundwater basins underlie about 11.60 million acres (18,100 square miles) or about 55 percent of the HR.

Most of the groundwater production is concentrated, along with the population, in basins in the southern part of this region. Groundwater provides 41 percent of water supply for agriculture and urban uses (DWR 1998). Much of this HR is public land with very low population density; within these areas there has been little groundwater development and little is known about the basins.

In most smaller basins, groundwater is found in unconfined alluvial aquifers; however, in some of the larger basins, or near dry lakes, aquifers may be separated by aquitards that cause confined groundwater conditions. Depths of the basins range from tens or hundreds of feet in smaller basins to thousands of feet in larger basins. The thickness of aquifers varies from tens to hundreds of feet. Well yields vary in this region depending on aquifer characteristics and well location, size, and use.

Conjunctive use of surface water and groundwater is practiced in the more heavily pumped basins. Some water used in the southern part of the HR is imported from Northern California by the State Water Project. Some of this imported water is used to recharge groundwater in the Mojave River Valley basins (6-40, 6-41, and 6-42). Surface water and groundwater are exported from the South Lahontan HR to the South Coast HR by the Los Angeles Department of Water and Power.

Groundwater Quality

The chemical character of the groundwater varies throughout the region, but most often is calcium or sodium bicarbonate. Near and beneath dry lakes, sodium chloride and sodium sulfate-chloride water is common. In general, groundwater near the edges of valleys contains lower TDS content than water beneath the central part of the valleys or near dry lakes.

AR0069816

Drinking water standards are most often exceeded for TDS, fluoride, and boron content. The EPA lists 15 sites of contamination in this HR. Of these, three military installations in the Antelope Valley and Mojave River Valley groundwater basins are federal Superfund sites because of VOCs and other hazardous contaminants.

Water Quality in Public Supply Wells

From 1994 through 2000, 605 public supply water wells were sampled in 19 of the 77 basins and subbasins in the South Lahontan HR. Analyzed samples indicate that 506 wells, or 84 percent, met the state primary MCLs for drinking water. Ninety-nine wells, or 16 percent, have constituents that exceed one or more MCL. Figure 42 shows the percentages of each contaminant group that exceeded MCLs in the 99 wells.

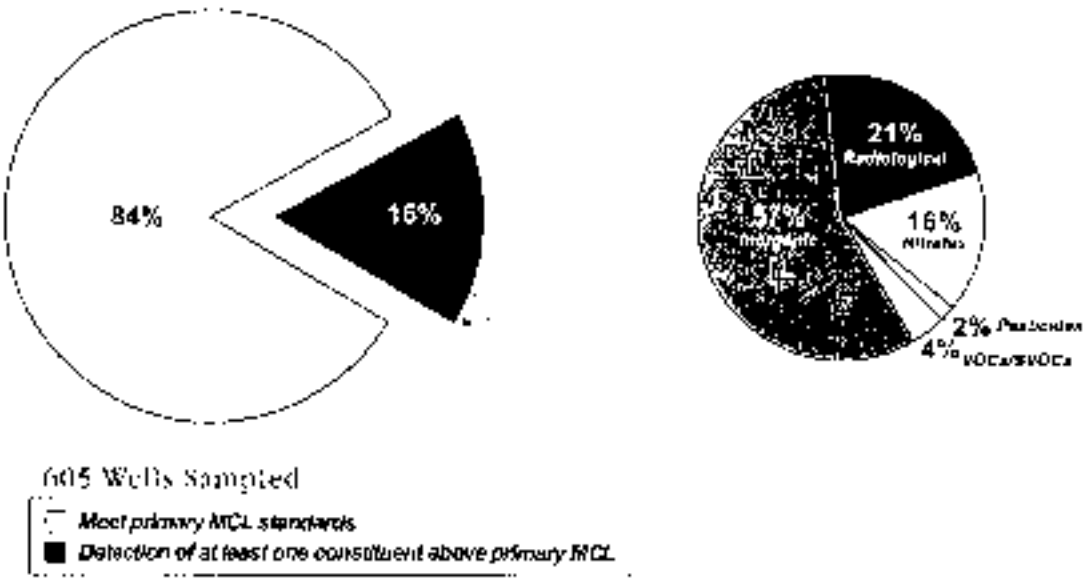

Figure 42 MCL exceedances in public supply wells in the South Lahontan Hydrologic Region

AR0069817

Table 36 lists the three most frequently occurring contaminants in each of the six contaminant groups and shows the number of wells in the HR that exceeded the MCL for those contaminants.

Table 36 Most frequently occurring contaminants by contaminant group in the South Lahontan Hydrologic Region

Contaminant group	Contaminant (# of wells)	Contaminant (# of wells)	Contaminant (# of wells)
Inorganics - Primary	Fluoride (6)	Arsenic (19)	Antimony (5)
Inorganics - Secondary	Iron (83)	Manganese (36)	Specific Conductance (5) TDS (5)
Radiological	Gross Alpha (15)	Uranium (7)	Radium 228 (3)
Dissolved Nitrogen	Nitrate (as NO3) (17)	Nitrate + Nitrite (6)	Nitrate (as N) (4)
Pesticides	Di(2-Ethylhexyl)phthalate (2)		
VOCs/SVOCs	MCBF (2)	TCE (2)	Carbon Tetrachloride (2)

TCE = Trichloroethylene
MCBF = Monochlorobenzotrifluoride
VOC = Volatile Organic Compound
SVOC = Semivolatile Organic Compound

Changes from Bulletin 118-80

Several modifications from the groundwater basins presented in Bulletin 118-80 are incorporated in this report (Table 37). Long Valley Groundwater Basin (6-35) has been divided into two subbasins. Granite Mountain Area (6-59) and Fish Slough Valley (6-60) groundwater basins have been deleted because no information was found concerning wells or groundwater in these basins or because well completion reports indicate that groundwater production is derived from fractured rocks beneath the basins. Furnace Creek Area Groundwater Basin (6-83) has been incorporated into Death Valley Groundwater Basin (6-18), and Butterbread Canyon Valley Groundwater Basin (6-87) has been incorporated into Lost Lake Valley Groundwater Basin (6-71).

Table 37 Modifications since Bulletin 118-80 of groundwater basins and subbasins in South Lahontan Hydrologic Region

Basin/subbasin name	New number	Old number

Butterbread Canyon Valley	Deleted - incorporated into 6-71	6-87

AR0069818

Troy Valley Groundwater Basin (6-39) has been split at the Pisgah fault, which is a groundwater barrier, and has been incorporated into Lower Mojave River Valley (6-40) and Lavic Valley (7-14) groundwater basins. This change incorporates part of the South Lahontan HR into a basin in the Colorado River HR[1]. The Middle Mojave River Valley Groundwater Basin (6-41) has changed boundaries along the north (Harper Valley, 6-42) and east sides (Lower Mojave River Valley, 6-40). The new boundaries are along the Camp Rock-Harper Lake fault zone, Waterman fault, and Helendale fault. Groundwater level elevations indicate that these faults are likely strong barriers to groundwater movement.

The boundary between the Upper Mojave River Valley Groundwater Basin (6-42) and the Lucerne Valley Groundwater Basin (7-19) was changed from the regional surface divide to the southern part of the Helendale fault, which is a groundwater barrier. This change incorporates part of the Colorado Desert HR into a basin in the South Lahontan HR[1].

[1] The boundaries of the hydrologic regions are defined by surface drainage patterns. In this case, faults impede groundwater flow causing it to flow beneath the surface drainage divide into the adjacent hydrologic region.
[2] See previous note.

AR0069825

Description of the Region

The Colorado River HR covers approximately 13 million acres (20,000 square miles) in southeastern California. It is bounded on the east by Nevada and Arizona, the south by the Republic of Mexico, the west by the Laguna, San Jacinto, and San Bernardino mountains, and the north by the New York, Providence, Granite, Old Dad, Bristol, Rodman, and Ord Mountain ranges. An average annual precipitation of 5.5 inches and average annual runoff of only 200,000 acre-feet makes this the most arid HR of California (DWR 1994). Surface runoff drains to many closed basins or to the Colorado River.

This HR includes all of Imperial, most of Riverside, much of San Bernardino, and part of San Diego counties (Figure 43). Many of the alluvial valleys in the region are underlain by groundwater aquifers that are the sole source of water for local communities.

About 533,000 people live within the Colorado River HR (DWR 1998). The largest population centers are Palm Springs, Palm Desert, Indio, Coachella, and El Centro.

Groundwater Development

The earliest groundwater development in California may have been prehistoric water wells dug by the Cahuilla Indians in Coachella Valley of the Colorado River HR. In this report, 64 groundwater basins/subbasins are delineated in this HR. The Deadman Valley, Johnson Valley Area, and Coachella Valley groundwater basins have been divided into subbasins. Groundwater basins underlie about 8,68 million acres or about 26 percent of this HR.

In the Colorado River HR, groundwater provides about 8 percent of the water supply in normal years for agricultural and urban uses (DWR 1998). In most smaller basins, groundwater is found in unconfined alluvial aquifers. In some of the larger basins, particularly near dry lakes, aquifers may be separated by aquitards that create confined groundwater conditions. Depths of basins range from tens or hundreds of feet in smaller basins and along arms of ephemeral rivers to thousands of feet in larger basins. The thickness of aquifers varies from tens to hundreds of feet. Well yields vary in this region depending on aquifer characteristics and well location, size, and use. Some aquifers are capable of yielding thousands of gallons per minute to municipal wells.

Conjunctive use of surface water and groundwater is a long-standing practice in the region. Water is imported from the Colorado River for irrigation in Imperial, Coachella, and Palo Verde Valleys and from groundwater recharge in Coachella Valley. Water imported from Northern California is used to replenish Warren and Joshua Tree groundwater basins. Many agencies have erected systems of barriers to allow more efficient percolation of ephemeral runoff from surrounding mountains. The concept of utilizing groundwater basins in this sparsely populated HR for storing water that would be pumped during drought years is getting much attention.

Groundwater Quality

The chemical character of groundwater in the Colorado River HR is variable. Cation concentration is dominated by sodium with calcium common and magnesium appearing less often. Bicarbonate is usually the dominant anion, although sulfate and chloride waters are also common. In basins with closed drainages, water character often changes from calcium-sodium bicarbonate near the margins to sodium chloride or chloride sulfate beneath a dry lake. It is not uncommon for concentrations of dissolved constituents to rise dramatically toward a dry lake where saturation of mineral salts is reached. An example of this is found at Bristol Valley Groundwater Basin, where the mineral halite (sodium chloride) is formed and then mined by

AR0069826

evaporation of groundwater in trenches in Bristol (dry) Lake. The TDS content of groundwater is high in many of the basins in this region. High fluoride content is common; sulfate content occasionally exceeds drinking water standards; and high nitrate content is common, especially in agricultural areas.

Two of the primary challenges in the Colorado River HR are overdraft in the Coachella Valley and leaking underground storage tanks. The EPA has not yet placed any contamination sites in this HR on the Superfund National Priorities List; however, one site is under consideration because of high pesticide levels.

Water Quality in Public Supply Wells

From 1994 through 2000, 214 public supply water wells were sampled in 23 of the 64 basins and subbasins in the Colorado River HR. Analyzed samples indicate that 270 wells, or 86 percent, met the state primary MCLs for drinking water standards. Forty-four wells, or 14 percent, have constituents that exceed one or more MCL. Figure 44 shows the percentages of each contaminant group that exceeded MCLs in the 44 wells.

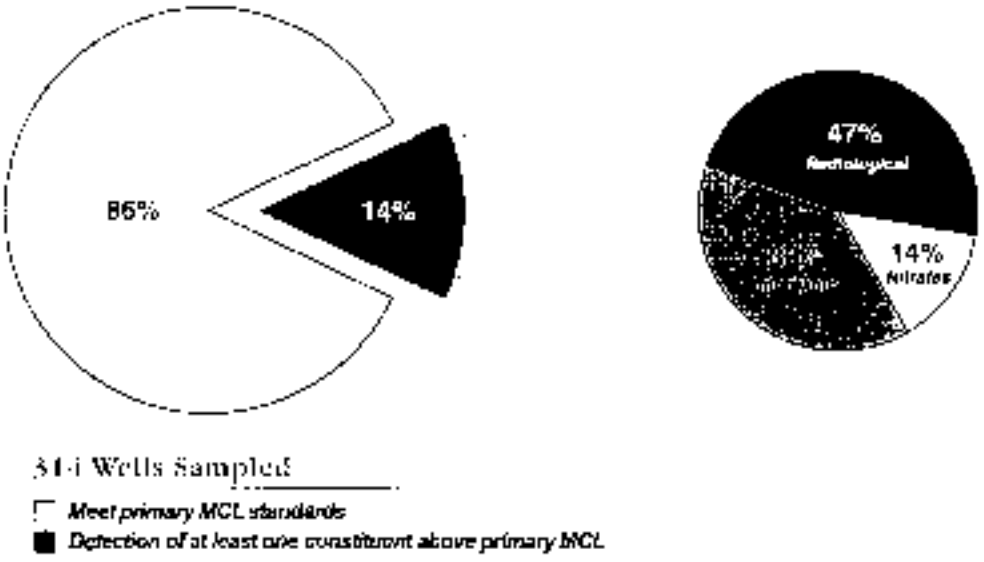

Figure 44 MCL exceedances in public supply wells in the Colorado River Hydrologic Region

Table 39 lists the three most frequently occurring contaminants in each contaminant group and shows the number of wells in the HR that exceeded the MCL for those contaminants.

Table 39 Most frequently occurring contaminants by contaminant group in the Colorado River Hydrologic Region

Contaminant group	Contaminant - # of wells	Contaminant - # of wells	Contaminant - # of wells
Inorganics - Primary	Fluoride - 17		
Inorganics - Secondary	Iron - 38	Manganese - 35	TDS - 5
Radiological	Radium 228 - 5	Combined RA226 + RA228 - 3	Radium 226 - 1
Nutrients	Nitrate as NO3 - 6	Nitrate + Nitrite - 1	

AR0069827

Changes from Bulletin 118-80

Several modifications from the groundwater basins presented in Bulletin 118-80 are incorporated in this report (Table 40). Lucerne Valley East Groundwater Basin (7-60) has been deleted because of lack of information about groundwater in this basin. The Pinyon Wash Area (7-57) and Whale Peak Area (7-58) groundwater basin names have been deleted because they are now incorporated into other larger basins. Similarly, Clark Valley (7-22) and Ocotillo Valley (7-23) groundwater basins are now the combined Ocotillo-Clark Valley Groundwater Basin (7-25). The Deadman Valley (7-13), Johnson Valley Area (7-18), and Coachella Valley (7-21) groundwater basins have been subdivided into subbasins in this report. The western boundary of Lucerne Valley Groundwater Basin (7-19) has been moved eastward from the HR boundary to the Helendale Fault. Groundwater level elevations indicate that this fault is a groundwater barrier and that groundwater flows westward back under the surface divide into the Upper Mojave River Groundwater Basin (6-42). The boundary between Lucerne Valley (7-19) and Johnson Valley Area (7-18) groundwater basins is delineated in this report.

The boundaries of Twentynine Palms Valley (7-10), Copper Mountain Valley (7-11), Warren Valley (7-12), Deadman Lake (7-13), and Ames Valley (7-16) groundwater basins have been redrawn in light of newer groundwater level data. These data indicate that the Pinto Mountain fault is a groundwater barrier. Joshua Tree Groundwater Basin (7-62) is a new basin that has been delineated from parts of Copper Mountain Valley and Twentynine Palms Valley Groundwater Basins because the Pinto Mountain fault is such a strong barrier. Buck Ridge Fault Valley Groundwater Basin (7-64) was presented in Bulletin 118-80 as two unconnected deposits of water-bearing alluvium separated by outcrop of nonwater-bearing rocks. These water-bearing deposits have been designated as separate groundwater basins in this report, with the Buck Ridge Fault Valley Groundwater Basin (7-64) as the northern basin and Vandeventer Flat Groundwater Basin (7-63) presented as the southern basin.

Table 40 Modifications since Bulletin 118-80 of Groundwater Basins in Colorado River Hydrologic Region

Basin name	New number	Old number
Clark Valley	Deleted - combined with 7-25	7-22
Ocotillo-Clark Valley	7-25 (now combined)	7-25
Pinyon Wash Area	Incorporated into 7-56	7-57
Whale Peak Area	Incorporated into 7-28	7-58
Lucerne Valley East	Deleted	7-60
Joshua Tree	7-62 (new)	
Vandeventer Flat	7-63 (new)

Glossary

Glossary

A

acre-foot (af) The volume of water necessary to cover one acre to a depth of one foot, equal to 43,560 cubic feet or 325,851 gallons.

adjudication A case that has been heard and decided by a judge. In the context of an adjudicated groundwater basin, landowners or other parties have turned to the courts to settle disputes over how much groundwater can be extracted by each party to the decision.

alluvial Of or containing to or composed of alluvium.

alluvium A general term for clay, silt, sand, gravel or similar unconsolidated detrital material, deposited during comparatively recent geologic time by a stream or other body of running water, as a sorted or semi-sorted sediment in the bed of the stream or on its floodplain or delta, as a cone or fan at the base of a mountain slope.

anthropogenic Of human origin or resulting from human activity.

appropriative right The right to use water that is diverted or extracted by a nonriparian or nonoverlying party for nonriparian or nonoverlying uses. In California, surface water appropriative rights are subject to a statutory permitting process while groundwater appropriation is not.

aquitard A confining bed and/or formation composed of rock or sediment that retards but does not prevent the flow of water to or from an adjacent aquifer. It does not readily yield water to wells or springs, but stores ground water.

aquifer A body of rock or sediment that is sufficiently porous and permeable to store, transmit, and yield significant or economic quantities of groundwater to wells and springs.

aridity A term describing a climate or region in which precipitation is so deficient in quantity or occurs so infrequently that intensive agricultural production is not possible without irrigation.

artesian aquifer A body of rock or sediment containing groundwater that is under greater than hydrostatic pressure; that is, a confined aquifer. When an artesian aquifer is penetrated by a well, the water level will rise above the top of the aquifer.

artesian pressure Hydrostatic pressure of artesian water, often expressed in terms of pounds per square inch or the height, in feet above the land surface, of a column of water that would be supported by the pressure.

artificial recharge The addition of water to a groundwater reservoir by human activity, such as putting surface water into dug or constructed spreading basins or injecting water through wells.

available groundwater storage capacity The volume of a groundwater basin that is unsaturated and capable of storing groundwater.

average annual runoff The average value of total annual runoff volume calculated for a selected period of record, at a specified location, such as a dam or stream gage.

average year water demand Demand for water under average hydrologic conditions for a defined level of development.

AR0069836

B

basin management objectives (BMOs) See management objectives

beneficial use One of many ways that water can be used either directly by people or for their overall benefit. The State Water Resources Control Board recognizes 23 types of beneficial use with water quality criteria for those uses established by the Regional Water Quality Control Boards.

borehole geophysics The general field of geophysics developed around the lowering of a variety of probes into a boring or well. Borehole logging provides additional information concerning physical, electrical, acoustic, nuclear and chemical aspects of the soils and rock encountered during drilling.

C

community water system A public water system that serves at least 15 service connections used by year-long residents or regularly serves at least 25 year-long residents (DDS 2000).

confined aquifer An aquifer that is bounded above and below by formations of distinctly lower permeability than that of the aquifer itself. An aquifer containing confined ground water. See artesian aquifer.

conjunctive use The coordinated and planned management of both surface and groundwater resources in order to maximize the efficient use of the resources; that is, the planned and managed operation of a groundwater basin and a surface water storage system, combined through a coordinated conveyance infrastructure. Water is stored in the groundwater basin for later and planned use by intentionally recharging the basin during years of above-average surface water supply.

contaminant Any substance or property present in the use or reducing the usability of the water for ordinary purposes such as drinking, preparing food, bathing, washing, recreation, and cooling. Any solute or cause of change in physical properties that renders water unfit for a given use. (Generally considered synonymous with pollutant).

critical conditions of overdraft A groundwater basin in which continuation of present practices would probably result in significant adverse overdraft-related environmental, social, or economic impacts. The definition was created after an extensive public input process during the development of the Bulletin 118-80 report.

D

deep percolation Percolation of water through the ground and beyond the lower limit of the root zone of plants into groundwater.

desalination A process that converts seawater or brackish water to fresh water or an otherwise more usable condition through removal of dissolved solids.

domestic well A water well used to supply water for the domestic needs of an individual residence or systems of four or fewer service connections.

drinking water system See public water system.

drought condition Hydrologic conditions during a defined period when rainfall and runoff are much less than average.

drought year supply The average annual supply of a water development system during a defined drought period.

AR0069837

E

electrical conductivity (EC) The measure of the ability of water to conduct an electrical current, the magnitude of which depends on the dissolved mineral content of the water.

effective porosity The volume of voids or open spaces in alluvium and rocks that is interconnected and can transmit fluids.

environmental water Water serving environmental purposes, including instream fishery flow needs, wild and scenic river flows, water needs of fresh-water wetlands, and Bay Delta requirements.

evapotranspiration (ET) The quantity of water transpired (given off), retained in plant tissues, and evaporated from plant tissues and surrounding soil surfaces.

G

groundwater basin An alluvial aquifer or interlocked series of alluvial aquifers with reasonably well defined boundaries in a lateral direction and having a definable bottom.

groundwater budget A numerical accounting, the *groundwater equation*, of the recharge, discharge and changes in storage of an aquifer, part of an aquifer, or a system of aquifers.

groundwater in storage The quantity of water in the zone of saturation.

groundwater management The planned and coordinated management of a groundwater basin or portion of a groundwater basin with a goal of long-term sustainability of the resource.

groundwater management plan A comprehensive written document developed for the purpose of groundwater management and adopted by an agency having appropriate legal or statutory authority.

groundwater mining The process, deliberate or inadvertent, of extracting groundwater from a source at a rate in excess of the replenishment rate such that the groundwater level declines persistently, threatening exhaustion of the supply or at least a decline of pumping levels to uneconomic depths.

groundwater monitoring network A series of monitoring wells at appropriate locations and depths to effectively cover the area of interest. Scale and density of monitoring wells is dependent on the size and complexity of the area of interest, and the objective of monitoring.

groundwater overdraft The condition of a groundwater basin in which the amount of water withdrawn by pumping exceeds the amount of water that recharges the basin over a period of years during which water supply conditions approximate average conditions.

groundwater quality See water quality.

groundwater recharge facility A structure that serves to conduct surface water into the ground for the purpose of replenishing groundwater. The facility may consist of dug or constructed spreading basins, pits, ditches, furrows, streambed modifications, or injection wells.

groundwater recharge The natural or intentional infiltration of surface water into the zone of saturation.

groundwater source area An area where groundwater may be found in economically retrievable quantities outside of normally defined groundwater basins, generally referring to areas of fractured bedrock in foothill and mountainous terrain where groundwater development is based on successful well penetration through interconnecting fracture systems. Well yields are generally lower in fractured bedrock than wells within groundwater basins.

AR0069838

groundwater storage capacity Volume of void space that can be occupied by water in a given volume of a formation, aquifer, or groundwater basin.

groundwater subbasin A subdivision of a groundwater basin created by dividing the basin using geologic and hydrologic conditions or institutional boundaries.

groundwater table The upper surface of the zone of saturation in an unconfined aquifer.

groundwater Water that occurs beneath the land surface and fills the pore spaces of the alluvium, soil, or rock formation in which it is situated. It excludes soil moisture, which refers to water held by capillary action in the upper unsaturated zones of soil or rock.

H

hazardous waste Waste that poses a present or potential danger to human beings or other organisms because it is toxic, flammable, radioactive, explosive or has some other property that produces substantial risk to life.

hydraulic barrier A barrier created by injecting fresh water to control seawater intrusion in an aquifer, or created by water injection to control migration of contaminants in an aquifer.

hydraulic conductivity A measure of the capacity for a rock or soil to transmit water; generally has the units of feet/day or cm/sec.

hydrograph A graph that shows some property of groundwater or surface water as a function of time.

hydrologic cycle The circulation of water from the ocean through the atmosphere to the land and ultimately back to the ocean.

hydrologic region A study area consisting of multiple planning subareas. California is divided into 10 hydrologic regions.

hydrostratigraphy A geologic framework consisting of a body of rock having considerable lateral extent and composing a reasonably distinct hydrologic system.

hyporheic zone The region of saturated sediments beneath and beside the active channel and that contains some proportion of surface water that was part of the flow in the surface channel and went back underground and is mixing with groundwater.

I

infiltration The flow of water downward from the land surface into and through the upper soil layers.

infiltration capacity The maximum rate at which infiltration can occur under specific conditions of soil moisture.

in-lieu recharge The practice of providing surplus surface water to historic groundwater users, thereby leaving groundwater in storage for later use.

ISI Integrated Storage Investigations Program, an element of the CALFED Bay Delta Program.

J

joint powers agreement (JPA) An agreement entered into by two or more public agencies that allows them to jointly exercise any power common to the contracting parties. The JPA is defined in Chapter 5 (commencing with Section 6500) of Division 7 of Title 1 of the California Government Code.

L

land subsidence The lowering of the natural land surface due to groundwater (or oil and gas) extraction.

AR0069839

leaky confining layer A low-permeability layer that can transmit water at sufficient rates to furnish some recharge from an adjacent aquifer to a well.

lithologic log A record of the lithology of the soils, sediments and/or rocks encountered in a borehole from the surface to the bottom.

lithology The description of rocks, especially in hand specimen and in outcrop, on the basis of such characteristics as color, mineralogic composition, and grain size.

losing stream A stream or reach of a stream that is losing water by seepage into the ground.

M

management objectives Objectives that set forth the priorities and measurable criteria of local groundwater basin management. For example, one management objective could be to minimize degradation of groundwater quality with a criteria set that groundwater will not be degraded by more than 100 mg/l in terms of TDS.

maximum contaminant level (MCL) The highest drinking water contaminant concentration allowed under federal and State Safe Drinking Water Act regulations.

N

natural recharge Natural replenishment of an aquifer generally from snowmelt and runoff through seepage from the surface.

nonpoint source Pollution discharged over a wide land area, not from one specific location. These are forms of diffuse pollution caused by sediment, nutrients, etc., carried to lakes and streams by surface runoff.

O

operational yield An optimal amount of groundwater that should be withdrawn from an aquifer system or a groundwater basin each year. It is a dynamic quantity that must be determined from a set of alternative groundwater management decisions subject to goals, objectives, and constraints of the management plan.

ordinance A law set forth by a governmental authority.

overdraft See groundwater overdraft.

overlying right Property owners above a common aquifer possess a mutual right to the reasonable and beneficial use of a groundwater resource on land overlying the aquifer from which the water is taken. Overlying rights are correlative (related to each other) and overlying users of a common water source must share the resource on a pro rata basis in times of shortage. A proper overlying use takes precedence over all non-overlying uses.

P

perched groundwater Groundwater supported by a zone of material of low permeability located above an underlying main body of groundwater.

perennial yield The maximum quantity of water that can be annually withdrawn from a groundwater basin over a long period of time (during which water supply conditions approximate average conditions) without developing an overdraft condition.

perforated interval The depth interval where slotted casing or screen is placed in a well to allow entry of water from the aquifer formation.

AR0069840

permeability The capability of soil or other geologic formations to transmit water. See hydraulic conductivity.

pesticide Any of a class of chemicals used for killing insects, weeds or other undesirable entities. Most commonly associated with agricultural activities, but has significant domestic use in California.

point source A specific site from which wastewater or polluted water is discharged into a water body.

pollution (of water) The alteration of the physical, chemical, or biological properties of water by the introduction of any substance into water that adversely affects any beneficial use of water.

porosity The ratio of the voids or open spaces in alluvium and rocks to the total volume of the alluvium or rock mass.

possible contaminating activity (PCA) Human activities that are actual or potential origins of contamination for a drinking water source. PCAs include sources of both microbiological and chemical contaminants that could have an adverse effect upon human health (DHS 2000).

potentiometric surface The surface to which the water in a confined aquifer will rise in a tightly cased well.

prescriptive right rights obtained through the open and notorious adverse use of another's water rights. By definition, adverse use is not use of a surplus, but the use of some surplus water to the direct detriment of the original rights holder.

primary porosity Voids or open spaces that were present when alluvium and rocks were originally deposited or formed.

public supply well A well used as a part of a public water system.

public water system A system for the provision of water for human consumption through pipes or other constructed conveyances that has 15 or more service connections or regularly serves at least 25 individuals daily at least 60 days out of the year. (DHS 2000)

pueblo right A water right possessed by a municipality which, as a successor of a Spanish or Mexican pueblo, entitled to the beneficial use of all needed, naturally-occurring surface and groundwater of the original pueblo watershed. Pueblo rights are paramount to all other claims.

R

recharge Water added to an aquifer or the process of adding water to an aquifer. Ground water recharge occurs either naturally as the net gain from precipitation, or artificially as the result of human influence. See artificial recharge.

recharge basin A surface facility constructed to infiltrate surface water into a groundwater basin.

riparian right A right to use surface water, such right derived from the fact that the land in question abuts upon the banks of streams.

runoff The volume of surface flow from an area.

S

safe yield The maximum quantity of water that can be continuously withdrawn from a groundwater basin without adverse effect.

salinity Generally, the concentration of mineral salts dissolved in water. Salinity may be expressed in terms of a concentration or as electrical conductivity. When describing salinity influenced by seawater, salinity often refers to the concentration of chlorides in the water. See also total dissolved solids.

AR0069841

saline intrusion The movement of salt water into a body of fresh water. It can occur in either surface water or groundwater bodies.

saturated zone The zone in which all interconnected openings are filled with water, usually underlying the unsaturated zone.

seawater intrusion barrier A system designed to retard, cease or repel the advancement of seawater intrusion into potable groundwater supplies along coastal portions of California. The system may be a series of specifically placed injection wells where water is injected to form a hydraulic barrier.

secondary porosity Voids in a rock formed after the rock has been deposited; not formed with the genesis of the rock, but later due to other processes. Fractures in granite and caverns in limestone are examples of secondary openings.

seepage The gradual movement of water into, through or from a porous medium. Also the loss of water by infiltration into the soil from a canal, ditches, laterals, watercourse, reservoir, storage facilities, or other body of water, or from a field.

semi-confined aquifer A semi-confined aquifer or leaky confined aquifer is an aquifer that has aquitards either above or below that allow water to leak into or out of the aquifer depending on the direction of the hydraulic gradient.

service area The geographic area served by a water agency.

specific conductance See electrical conductivity.

specific retention The ratio of the volume of water a rock or sediment will retain against the pull of gravity to the total volume of the rock or sediment.

specific yield The ratio of the volume of water a rock or soil will yield by gravity drainage to the total volume of the rock or soil.

spring A location where groundwater flows naturally to the land surface or a surface water body.

stakeholders Any individual or organization that has an interest in water management activities. In the broadest sense, everyone is a stakeholder, because water sustains life. Water resources stakeholders are typically those involved in protecting, supplying, or using water for any purpose, including environmental uses, who have a vested interest in a water-related decision.

stratigraphy The science of rocks. It is concerned with the original succession and age relations of rock strata and their form, distribution, lithologic composition, fossil content, geophysical and geochemical properties—all characters and attributes of rocks as strata—and their interpretation in terms of environment and mode of origin and geologic history.

subsidence See land subsidence.

subterranean stream Subterranean streams flowing through known and definite channels are regulated by California's surface water rights system.

surface supply Water supply obtained from streams, lakes, and reservoirs.

sustainability Of, relating to, or being a method of using a resource so that the resource is not depleted or permanently damaged.

T

total dissolved solids (TDS) A quantitative measure of the residual minerals dissolved in water that remain after evaporation of a solution. Usually expressed in milligrams per liter. See also salinity.

AR0069842

toxic Poisonous, relating to or caused by a poison. Toxicity is determined for individual contaminants or for mixtures of contaminants as found in waste discharges.

transmissivity The product of hydraulic conductivity and aquifer thickness; a measure of a volume of water to move through an aquifer. Transmissivity generally has the units of ft²/day or gallons per day/foot. Transmissivity is a measure of the subsurface's ability to transmit groundwater horizontally through its entire saturated thickness and affects the potential yield of wells.

transpiration An essential physiological process in which plant tissues give off water vapor to the atmosphere.

U

unconfined aquifer An aquifer which is not bounded on top by an aquitard. The upper surface of an unconfined aquifer is the water table.

underground stream Body of water flowing as a definite current in a distinct channel below the surface of the ground, usually in an area characterized by joints or fissures. Application of the term to ordinary aquifers is incorrect.

unsaturated zone The zone below the land surface in which pore space contains both water and air.

urban water management plan (UWMP) An UWMP is required for all urban water suppliers having more than 3,000 connections or supplying more than 3,000 acre-feet of water. The plans include discussions on water supply, supply reliability, water use, water conservation, and water shortage contingency and serve to assist urban water suppliers with their long-term water resources planning to ensure adequate water supplies for existing and future demands.

usable storage capacity The quantity of groundwater of acceptable quality that can be economically withdrawn from storage.

V

vadose zone See unsaturated zone.

volatile organic compound (VOC) A manmade organic compound that readily vaporizes in the atmosphere. These compounds are often highly mobile in the groundwater system and are generally associated with industrial activities.

W

water quality Description of the chemical, physical, and biological characteristics of water, usually in regard to its suitability for a particular purpose or use.

water table See groundwater table.

water year A continuous 12-month period for which hydrologic records are compiled and summarized. Different agencies may use different calendar periods for their water years.

watershed The land area from which water drains into a stream, river, or reservoir.

well completion report A required, confidential report detailing the construction, alteration, abandonment, or destruction of any water well, cathodic protection well, groundwater monitoring well, or geothermal heat exchange well. The reports were called *Water Well Drillers' Report* prior to 1991 and are often referred to as "driller's logs." The report requirements are described in the California Water Code commencing with Section 13750.

WQCP Water Quality Control Plan for the San Francisco Bay/Sacramento San Joaquin Delta Estuary.

Appendix A
Obtaining Copies of Supplemental Material

Bulletin 118 Update 2003 includes this report and supplemental material consisting of individual basin descriptions and a GIS-compatible map of each of the delineated groundwater basins in California. The supplemental material will be updated as new information becomes available and can be viewed or downloaded at http://www.waterplan.water.ca.gov/groundwater/118index.htm

AR0069846

Appendix B
The Right to Use Groundwater in California

California does not have a statewide management program or statutory permitting system for groundwater. Some local agencies have adopted groundwater ordinances under their police powers, or have adopted groundwater management programs under a variety of statutory authorities.

Prior to a discussion of groundwater management, it is helpful to understand some of the laws governing the right to use groundwater in California. When the Water Commission Act of 1913 (Stats. 1913, Ch. 586) became effective in 1914, appropriative surface water rights became subject to a statutory permitting process. This appropriation procedure can be found in Water Code Section 1200 *et seq.* Groundwater classified as underflow of a surface stream, a "subterranean stream flowing through a known and definite channel," was made subject to the State permit system. However, most groundwater in California is presumed to be "percolating water," that is, water in underground basins and groundwater which has escaped from streams. This percolating water is not subject to a permitting process. As a result, most of the body of law governing groundwater use in California today has evolved through a series of court decisions beginning in the early 20th century. Key cases are listed in Table B-1, and some of the most significant are discussed below.

AR0069847

Table B-1 Significant court cases related to the right to use groundwater in California

Case	Issues addressed
Katz v. Walkinshaw, 141 Cal. 116 (1903)	Established California's Correlative Rights Doctrine. Correlative rights of overlying users, and surplus supply available for appropriation after needs of overlying users.
Peabody v. City of Vallejo, 2 Cal. 2d 351 (1935)	Limited riparian rights under the reasonable and beneficial use requirement of the 1928 constitutional amendment requirement of reasonable and beneficial use.
Pasadena v. Alhambra, 33 Cal. 2d 908 (1949)	First case to apply definition of California's established Doctrine of Mutual Prescription.
Mojave Sand and Gravel Co. v. Antelope Valley Water District, 69 Cal. App. 3d 924 (1977)	Established right to store water in underground basins.
Tehachapi-Cummings County Water District v. Armstrong, 49 Cal. App. 3d 692 (1976)	Modified the Water Prescription Doctrine as articulated in Pasadena v. Alhambra. Overlying owners' water rights must be quantified on the basis of current reasonable and beneficial use of the water. Appropriative rights must be subordinated to overlying rights, including the amount of water available, the extent of overdraft in the basin, and the nature of the water use.
Los Angeles v. San Fernando, 14 Cal. 3d 199 (1975)	Significantly modified Mutual Prescription Doctrine by establishing "safe yield" as the criterion for quantifying rights. Established that the right to store imported water in a basin and recapture water needed to serve the rights of overlying landowners.
Wright v. Goleta Water District, 174 Cal. App. 3d 74 (1985)	The unexercised water rights of overlying owners are protected from appropriators, notice and opportunity must be given to overlying owners before any interference with their rights.
Tri-Desert County Water District v. Blue Skies Country Club,	Reference of overlying rights to adjudication of prescriptive rights by Tri-Desert, 23 Cal. App. 4th 1723 (1994). Overlying rights
Baldwin v. Tehama County, 31 Cal. App. 4th 166 (1994)	City and County regulation of groundwater through police power authority in the Sacramento Valley.
City of Barstow v. Mojave Water Agency,	Held that correlative rights quantified by physical solution. 23 Cal. 4th 1224 (2000), involving adjudicated appropriators, court must consider correlative rights of parties that did not join the stipulation.

This table was modified from Bach, et al. (2002).

AR0069848

Katz v. Walkinshaw (141 Cal. 116)

In the 1903 decision, *Katz v. Walkinshaw*, the California Supreme Court rejected the English Common Law doctrine of groundwater rights and established the Doctrine of Correlative Rights. Prior to the *Katz* decision, California had followed the doctrine articulated in the 1843 English decision of *Acton v. Blundell* (12 M. & W. 324, 152 Eng. Rep. 1223), which established that landowners enjoyed absolute ownership of groundwater underneath their property. The 1903 decision rejected the English Common Law approach as inapplicable for the "natural conditions" in California, and instead established the Correlative Rights Doctrine and ingrafted to a riparian right. Each overlying landowner was entitled to make reasonable beneficial use of groundwater with a priority equal to all other overlying users. Water in excess of the needs of the overlying owners could be pumped and used on nonoverlying lands on a first-in-time, first-in-right basis under what is known as an appropriative right. An appropriative groundwater right, unlike its surface water counterpart, is not subject to a permitting process. Where overlying owners made full use of available supplies, appropriative rights were extinguished. Where there was insufficient water to meet even the needs of the overlying owners, the court applied the Correlative Rights Doctrine to apportion the available groundwater among the overlying landowners. Figure B-1 depicts the rights to use groundwater established in *Katz v. Walkinshaw*.

City of Pasadena v. City of Alhambra (33 Cal. 2d 908)

The 1949 decision, *Pasadena v. Alhambra*, added significant complexity to the right to use groundwater in California. This decision, involving the adjudication of the Raymond Basin, established the doctrine of mutual prescription. Groundwater levels in the basin had been declining for many years by the time court action was initiated. Most substantial pumpers, both overlying and appropriators, were joined in the action. Previously, appropriators only had a right to water surplus to the needs of overlying users. However, based upon a stipulation by most of the parties, the court in *Pasadena* adopted a program of proportionate reductions. These appropriators had each effectively gained a prescriptive right, similar to that of surface water rights, in which they had taken the water in an open, notorious, and hostile manner for at least five years. Mutual prescription provided groundwater rights to both overlying users and appropriators in depleted groundwater basins by prorating their rights based on the highest continuous amount of pumping during the five years following commencement of the overdraft. All of the users in the Raymond Basin were thus entitled to extract their portion of the court-approved safe yield of the basin.

City of Los Angeles v. City of San Fernando (14 Cal. 3d 199)

In 1975, in *Los Angeles v. San Fernando*, the California Supreme Court significantly limited the Mutual Prescription Doctrine introduced in Pasadena v. Alhambra. This opinion has far-reaching impacts on both the right to use groundwater and the practice of conjunctive use of groundwater and surface water to manage a basin. The case began in 1955, when the City of Los Angeles sued the cities of San Fernando, Glendale, Burbank and other pumpers, asserting a prior right to the San Fernando Valley groundwater basins in the northern part of the City of Los Angeles. The court, relying on Civil Code Section 1007, held that public agencies and public utilities cannot lose their groundwater rights by prescription. This holding effectively ruled out any future "mutual prescription" settlements or judgements involving rights held by public entities.

With respect to the native water supply of the San Fernando Basin, the court found that the City of Los Angeles had prior rights to all of this supply pursuant to its "pueblo right." Pueblo rights are traceable to rights recognized by the Spanish crown and the Mexican government. Under the Spanish/Mexican system, water rights were held in trust by pueblos for the benefit of all of its inhabitants. Under the Treaty of Guadalupe Hidalgo executed by Mexico and the United States in 1848, the municipal successors to Spanish/Mexican pueblos retained their pueblo rights upon the cession of California. In the San Fernando decision, the court confirmed Los Angeles' pueblo right, finding it superior to the rights of all overlying landowners. While a pueblo right is rare, it is an example of the complexity of the rights to use groundwater in California.

AR0069849

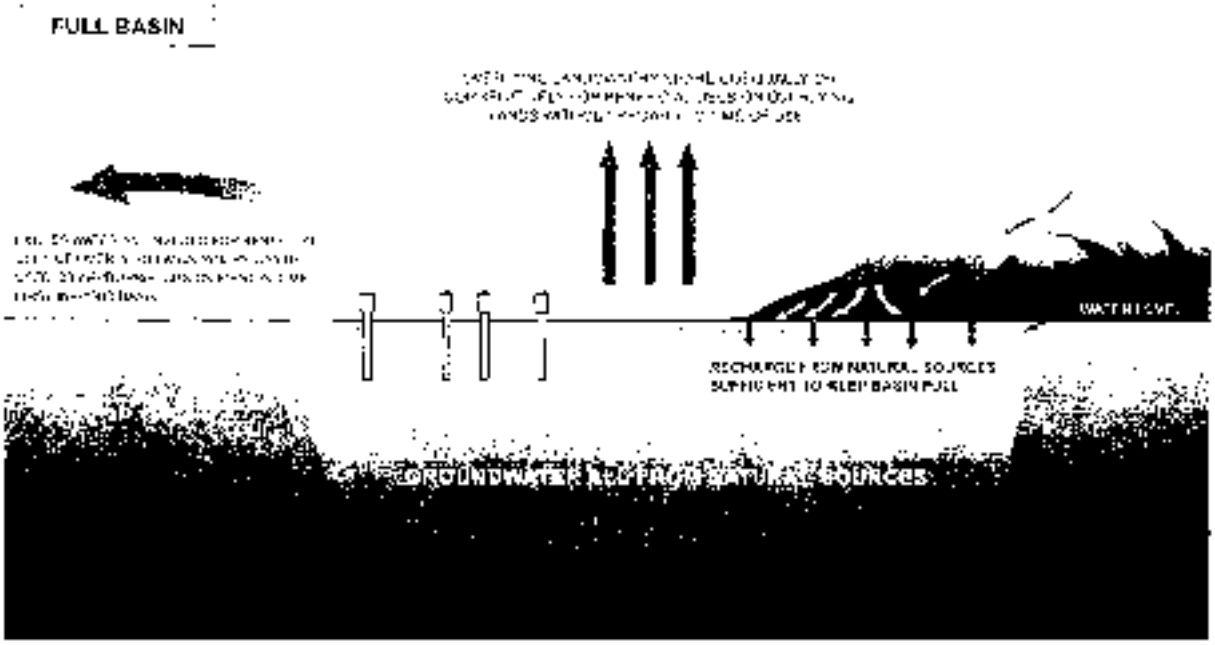

Figure B-1 Rights to groundwater use in full basin established in Katz v. Walkinshaw

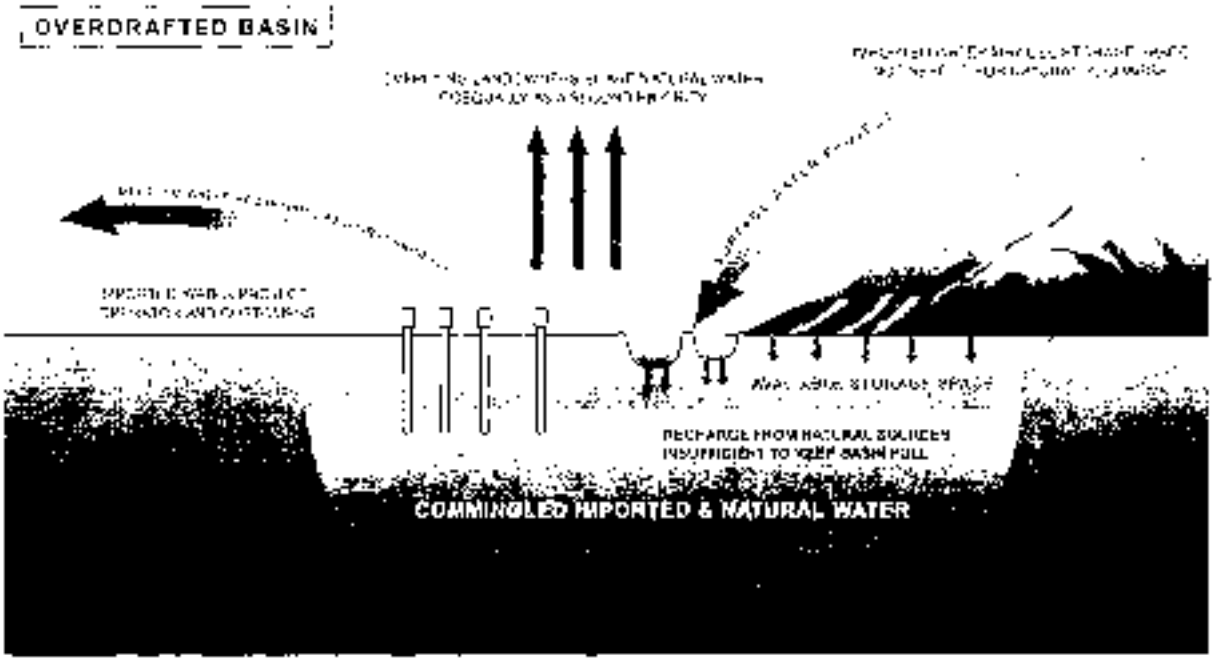

Figure B-2 Rights to groundwater use in overdrafted basin established in Los Angeles v. San Fernando

AR0069850

For the future of conjunctive use of groundwater basins, the court's holding with respect to the rights to available storage space in the Basin is significant. The court upheld the right of public agencies – namely the cities of San Fernando, Los Angeles, Burbank, and Glendale – to recapture the imported water they added to the Basin. The court held that the rights of the respective public agencies to recover such imported water are of equal priority to the City of Los Angeles' pueblo right, and that all such public agency rights are "prior to the rights dependent on ownership of overlying land or based solely upon appropriation of groundwater from the basin." The court remanded the case, directing the trial court to apportion the safe yield of the Basin accordingly.

The court noted that there did not appear to be any shortage of underground storage space in relation to the demand and, hence, the court did not find it necessary to determine priorities as to the future use of such space. The Judgment issued by the trial court on remand, however, provided: "To the extent of any future spreading or in lieu storage of import water or reclaimed water by Los Angeles, Glendale, Burbank or San Fernando, the party causing said water to be so stored shall have a right to extract an equivalent amount of ground water from the San Fernando Basin." Pursuant to the Judgment, a court-appointed Watermaster now manages the groundwater extraction and storage rights within the SFVARA. Figure 8-2 depicts the rights to use groundwater established in Los Angeles v. San Fernando in an overdrafted basin where water has been stored.

City of Barstow v. Mojave Water Agency (23 Cal. 4th 1224)

In 2000, the California Supreme Court partially overturned the 1995 adjudication of the Mojave River Basin. The trial court had approved a negotiated settlement (or stipulated agreement) that failed to include a well-by-well determination of water rights. The trial court held the negotiated settlement to be binding on all users in the basin, including some pumpers who had not agreed to the settlement. The lower court decision was based on the doctrine of "equitable apportionment," in which the available water is shared based on concepts of equity and fairness. The Court of Appeal had partially reversed the lower court, and held that the trial court did not have the authority to ignore California's traditional water rights doctrine giving overlying users a priority right to beneficial and reasonable use of the groundwater. The Court of Appeal affirmed the trial court's negotiated settlement except as it applied to two of the parties. First, the Court of Appeal reversed the holding against a non-negotiating party since the trial court had ignored that party's existing overlying water rights. Secondly, the Court of Appeal reversed the trial court's judgment as it applied to a company, where the negotiated agreement did not give the company a water allowance equal to its actual water use. The Supreme Court affirmed the Court of Appeal decision, but reversed the judgment applying to the company's water allowance. The Supreme Court also affirmed that the trial court could not apply the doctrine of equitable apportionment when overlying water users had already established a prior water right. The Court stated that, while the trial court could impose a physical solution (such as the negotiated settlement), the court could not simply ignore affected owners' legal water rights. Equitable apportionment, thus, remains a tool for adjudicating basin groundwater rights, but only if all parties stipulate to its use.

AR0069851

Appendix C
Required and Recommended Components of Local Groundwater Management Plans

Section 10750 et seq. of the Water Code, commonly referred to as Assembly Bill 3030, stipulates certain procedures that must be followed in adopting a groundwater management plan under this section.

Amendments to Section 10750 et seq. added the requirement that new groundwater management plans prepared under Section 10750 et seq. must include component 1 below (SBX7 98 (Stats. 2002, Ch 603)).

In addition, the amendments mandate that if the agency preparing the groundwater management plan intends to apply for funding administered by the California Department of Water Resources (DWR) for groundwater or groundwater quality projects, the agency must prepare and implement a groundwater management plan that includes components 2, 3, 6, 7 and 9 below. DWR recommends that all the components below be included in any groundwater management plan to be adopted and implemented by a local managing entity.

Consideration and development of these components for the specific conditions of the basin to be managed under the plan will help to ensure effective groundwater management. In developing these criteria, DWR recognizes that the goal of a groundwater management plan and the goal of an ordinance to manage groundwater should be the same—assurance of a long-term, sustainable, reliable, good quality groundwater supply. Such efforts can benefit greatly from cooperative management within the basin or region.

None of the suggested data reporting in the components below should be construed as recommending disclosure of information that is confidential under State law.

1. Include documentation that a written statement was provided to the public "describing the manner in which interested parties may participate in developing the groundwater management plan," which may include appointing a technical advisory committee (Water Code § 10753.4 (b)).
2. Include a plan by the managing entity to "involve other agencies that enables the local agency to work cooperatively with other public entities whose service area or boundary overlies the groundwater basin." (Water Code § 10753.7 (a)(2)). A local agency includes "any local public agency that provides water service to all or a portion of its service area" (Water Code § 10752 (g)).
3. Provide a map showing the area of the groundwater basin, as defined by DWR Bulletin 118, with the area of the local agency subject to the plan as well as the boundaries of other local agencies that overlie the basin in which the agency is developing a groundwater management plan (Water Code § 10753.7 (a)(3));
4. Establish an advisory committee of stakeholders (interested parties) within the plan area that will help guide the development and implementation of the plan and provide a forum for resolution of controversial issues.
5. Describe the area to be managed under the plan, including:
   a. The physical structure and characteristics of the aquifer system underlying the plan area in the context of the overall basin.,

AR0069852

b. A summary of the availability of historical data including, but not limited to, the components in Section 7 below.

c. Issues of concern including, but not limited to, issues related to the components in Section 7 below.

d. A general discussion of historical and projected water demands and supplies.

6. Establish management objectives (MOs) for the groundwater basin that is subject to the plan. (Water Code § 10753.7 (a)(1)).

7. Include components relating to the monitoring and management of groundwater levels, groundwater quality, inelastic land surface subsidence, and changes in surface flow and surface water quality that directly affect groundwater levels or quality or are caused by groundwater pumping. (Water Code § 10753.7 (a)(1)). Consider additional components listed in Water Code § 10753.8 (a) through (f).

8. For each MO, describe how meeting the MO will contribute to a more reliable supply for long-term beneficial uses of groundwater in the plan area, and describe existing or planned management actions to achieve MOs.

9. Adopt monitoring protocols for the components in Section 7 (Water Code § 10753.7 (a)(4)) Monitoring protocols are not defined in the Water Code, but the section is interpreted to mean developing a monitoring program capable of tracking changes in conditions for the purpose of meeting MOs.

10. Describe the monitoring program, including:

a. A map indicating the general locations of any applicable monitoring sites for groundwater levels, groundwater quality, subsidence stations, or stream gages.

b. A summary of monitoring sites indicating the type (groundwater level, groundwater quality, subsidence, stream gage) and frequency of monitoring. For groundwater level and groundwater quality wells, indicate the depth interval(s) or aquifer zone monitored and the type of well (public, irrigation, domestic, industrial, monitoring).

11. Describe any current or planned actions by the local managing entity to coordinate with other land use, zoning, or water management planning agencies or activities. (Water Code § 10753.8 (a), (1))

12. Provide for periodic report(s) summarizing groundwater basin conditions and groundwater management activities. The report(s), prepared annually or at other frequencies as determined by the local management agency, should include:

a. Summary of monitoring results, including a discussion of historical trends.

b. Summary of management actions during the period covered by the report.

c. A discussion, supported by monitoring results, of whether management actions are achieving progress in meeting MOs.

d. Summary of proposed management actions for the future.

e. Summary of any plan component changes, including addition or modification of MOs, during the period covered by the report.

f. Summary of actions taken to coordinate with other water management and land use agencies, and other government agencies.

13. Provide for the periodic re-evaluation of the entire plan by the managing entity.

14. For local agencies not overlying groundwater basins, plans should be prepared including the above listed components and using geologic and hydrologic principles appropriate to those areas (Water Code § 10753.7 (a)(5)).

AR0069853

Appendix D
Groundwater Management Model Ordinance

In developing this model ordinance, the California Department of Water Resources recognizes that the goal of a groundwater management plan and the goal of an ordinance to manage groundwater should be the same – assurance of a long term, sustainable, reliable, good quality groundwater supply. Such efforts require cooperative management within the region or sub-region.

Chapter X

Groundwater Management Ordinance

Sections:

X.01 Declaration of Findings
X.02 Purpose
X.03 Declaration of Intent
X.04 Definitions
X.05 Groundwater Management Program
X.06 Management Objectives
X.07 Monitoring Program Network
X.08 Monitoring Frequency
X.09 Changes in Monitoring
X.10 Review of Technical Data
X.11 Data Dissemination
X.12 Actions when MO Noncompliance is Reported
X.13 Regional Coordination
X.14 Integrated Resource Management
X.15 Data Relating to Export and Substitution of Groundwater

X.01 Declaration of Findings - The Board finds that:

A. The protection of the groundwater resource for its use within the County is of major concern to the residents of the County for the protection of their health, welfare, and safety.

B. The reliability and sustainability of the groundwater supply for all beneficial uses are of critical importance to the economic, social, and environmental well-being of the County.

C. A lack of effective groundwater management may have significant negative impacts, including, but not limited to:

1. Lower groundwater levels leading to additional expenses for:
   a) Increased energy consumption.
   b) The need to deepen existing wells.
   c) The need to build new wells.
   d) The need to destroy non-functioning wells.
2. Costly damage to public roads, bridges, canals, and other structures caused by land subsidence.
3. Reduction of surface and subsurface flows leading to the potential loss of critical riparian and wetland habitat.
4. Degradation of groundwater quality.

AR0069854

D. It is essential for management purposes to adopt a monitoring program addressing groundwater levels, groundwater quality, land subsidence, and surface water flow and quality where it directly impacts or is impacted by groundwater.

X.02 Purpose – In support of the findings above, the County has determined that this groundwater management ordinance is necessary to ensure that:

A. Groundwater continues to be a reliable and sustainable resource.
B. The extraction of groundwater does not result in significant adverse economic, environmental or social impacts.
C. Groundwater quality is protected.
D. Excessive land surface subsidence from groundwater extraction is prevented.

X.03 Declaration of Intent

A. The County intends to foster prudent groundwater management practices by establishing a policy that encourages appropriate management of the resource based on recommendations by a committee of stakeholders.
B. The County intends that its groundwater management activities occur as an open and public process that considers input from all stakeholders in the County.
C. The County intends to work cooperatively with interested local agencies to further develop and implement joint groundwater management activities.
D. The County does not intend to regulate, in any manner, the use of groundwater, except as a last resort to protect the groundwater resource.
E. The County intends to act as an enforcing agency should the local resource become threatened.
F. The County does not intend to infringe upon the rights of surface water users in the managed area.
G. The County does not intend to limit other authorized means of managing groundwater within the County.

X.04 Definitions

A. "Aquifer" means a geologic formation that stores groundwater and transmits and yields significant quantities of water to wells and springs. Significant quantity is an amount that that satisfies local needs and may range from thousands of gallons per minute to less than 5 gpm, depending on rock type and intended use.
B. "Board" means the Board of Supervisors of the County.
C. "District" means a district or municipality, located wholly or partially within the boundaries of the County, that is a purveyor of water for agricultural, domestic, or municipal use.
D. "Enforcement Agency" means the Board as the enforcement agency under this chapter.
E. "Groundwater" means all water beneath the surface of the earth below the zone of saturation, but does not include subterranean streams flowing in known and definite channels.
F. "Groundwater Basin" means an aquifer or series of aquifers with a reasonably defined lateral and vertical extent, as defined in Bulletin 118 by Department of Water Resources. "Non-basin areas" are outside defined groundwater basins and contain smaller amounts of groundwater in unconsolidated sediments or fractured hard rock.
G. "Groundwater export" means the conveyance of groundwater outside of the boundaries of the County and outside of the boundaries of any district that is partially within the County.
H. "Groundwater substitution" means the voluntary use of an available groundwater supply instead of surface water for the purposes of using the surface water outside the County and outside the boundaries of any district that is partially within the County.

AR0069855

L. "Land Subsidence" means the lowering of the ground surface caused by the inelastic consolidation of clay beds in the aquifer system.

I. "Management Objective" (MO) means a condition identified for each subunit to ensure that the groundwater supply is reliable and sustainable. The MOs set acceptable conditions with respect to groundwater levels, groundwater quality, inelastic land surface subsidence, and surface water flows and quality. Compliance with the MOs is tracked by a monitoring program and threshold values that are adopted for each Management Objective.

K. "Recharge" means flow to groundwater storage from precipitation, and infiltration from streams, irrigation, spreading basins, injection wells, and other sources of water.

L. "Reliability" means having an available, predictable, and usable groundwater supply at any given point in time.

M. "Stakeholder" means an individual or an entity, such as a water supplier or a county resident, with a permanent interest in the availability of the groundwater resource.

N. "Subunit" means any subdivision of a groundwater basin or non-basin area in the County created for the purposes of representation of stakeholders and the establishment of local area management objectives.

O. "Sustainable" means the groundwater resource is maintained for use by residents in the basin over a prolonged period of time.

P. "Technical Advisory Committee" means a committee of persons knowledgeable in groundwater management, hydrology, and hydrogeology established for the purpose of providing technical guidance to the Water Advisory Committee.

Q. "Threshold values" mean the limits established by the WAC for groundwater levels, groundwater quality, land surface subsidence, and surface water flow and quality that are not to be exceeded if the MOs are to be met.

R. "Water Advisory Committee" (WAC) means a multiparty advisory body established for the purpose of aiding the Board in providing effective management of the groundwater resources in the County, and representing all of the subunits that are identified.

S. "Water Management Entities" means any local agency, or group of agencies, authorized to manage groundwater.

X.05 Groundwater Management Program

A. The County recognizes that effective groundwater management is key to maintaining a reliable and sustainable resource. For the purposes of establishing an effective groundwater management program, the Board shall appoint a WAC to establish MOs and make recommendations to the Board to ensure that MOs are met.

B. For purposes of establishing a WAC, the groundwater basins and non-basin areas of the County will be divided into subunits based on hydrogeologic principles and institutional boundaries. These subunits shall be established by the Board based on public input to address the groundwater management needs of the County. The WAC shall consist of members that represent each subunit. Upon establishment of the subunits, the Board shall appoint a member to represent each subunit on the WAC.

C. The WAC shall have the following responsibilities to the Board:
   1. Recommend MOs for each groundwater management subunit.
   2. Recommend a groundwater monitoring network for purposes of tracking MOs.
   3. Recommend the frequency of monitoring.
   4. Propose changes in monitoring.
   5. Ensure monitoring data receive technical review.
   6. Ensure that monitoring data are made available to the public.

AR0069856

7. Recommend actions to resolve noncompliance with MOs.

D. For the purposes of providing technical advice to the WAC in carrying out its responsibilities, a technical advisory committee (TAC) shall be established. The TAC shall consist of local experts or a combination of local expertise and technical consultants from private and public organizations that are nominated by the WAC and approved by the Board. Individuals appointed to the TAC should be highly knowledgeable in groundwater management, hydrology, and hydrogeology. The TAC shall review technical data collected by monitoring programs within the County and advise the WAC.

X.06 Management Objectives

A. To ensure that the County maintains a reliable and sustainable groundwater supply, MOs for groundwater levels, groundwater quality, land subsidence, and surface water flow and quality shall be adopted for each subunit. Threshold values that are not to be exceeded shall be defined for each MO.

B. Compliance with the MOs will be determined by evaluation of data collected from groundwater level, groundwater quality, land subsidence, and surface water flow and quality monitoring networks. Evaluation of these data with respect to threshold values shall be the basis for determining compliance with the MOs.

C. Each WAC member shall recommend MOs for their subunit. The WAC shall develop a comprehensive set of recommendations for all subunits, and the Board shall adopt these MOs for the County. MOs may differ from subunit to subunit, but the established MOs shall be consistent with the overall goal of supply reliability for the County.

D. Groundwater management practices based on the established MOs for one subunit of the County shall not adversely impact adjacent subunits.

X.07 Monitoring Program Network

The WAC shall develop County-wide monitoring programs to collect representative data on groundwater levels, groundwater and surface water quality, land surface subsidence, and stream flow and quality. Each subunit shall propose its own monitoring program, and the WAC shall adopt a comprehensive monitoring program for the County. The data collected, showing current conditions and changes over time as a result of groundwater extraction, shall be evaluated by the WAC in consultation with the TAC. The WAC will recommend policies and actions to ensure that MOs for each subunit are met. The collection and evaluation of the data shall be based on scientifically sound principles, and shall incorporate appropriate quality assurance and quality control protocols.

A. Groundwater levels: The groundwater level monitoring network shall be proposed by the WAC and approved by the Board. The intent of the groundwater level monitoring network is to measure water levels in selected wells that can adequately determine representative conditions in the aquifer system for determination of compliance with the MOs. The network will include selected municipal, domestic, and irrigation wells owned by water districts, private parties, and municipal and industrial water suppliers. Where needed, dedicated monitoring wells may be installed. Participation by well owners will be voluntary.

B. Water Quality: The groundwater quality monitoring network shall be proposed by the WAC and approved by the Board. The intent of the groundwater quality monitoring network is to monitor selected wells that can adequately determine representative groundwater quality conditions in the aquifer system for identification of compliance with the MOs. The network will include selected municipal, domestic, and irrigation wells owned by water districts, private parties, and municipal

AR0069857

and industrial water suppliers. Where needed, dedicated monitoring wells may be installed. Participation by well owners will be voluntary.

C. Land Subsidence: The land subsidence program and network shall be proposed by the WAC and approved by the Board. The intent of the land subsidence monitoring is to detect land subsidence for determination of compliance with the MOs. The network may include benchmarks that are surveyed for changes in elevation throughout the County, based on the judgment of the WAC of the need for such a program.

D. Surface Water Flow and Quality: The surface water flow and quality network shall be proposed by the WAC and approved by the Board. The intent of this network is to detect changes in surface water flow or surface water quality that directly affect groundwater levels or quality or are caused by groundwater pumping for evaluation of compliance with MOs.

X.08 Monitoring Frequency

The recommended frequency of collection of data for each of the parameters listed above shall be determined by the WAC. Initially, each parameter should be measured at the frequencies outlined below, unless the WAC notes upon evaluation of existing data that more frequent monitoring or additional analyses are called for.

A. Groundwater levels should be measured at least three times during the year: one measurement prior to the period of highest groundwater use, one measurement during peak groundwater use, and one measurement following the period of highest groundwater use (approximately the months of _____, _____, and _____).

B. Groundwater quality measurements of electrical conductivity, temperature, and pH should be obtained at least twice annually during the periods of highest and lowest groundwater use (approximately the months of __ and ___). Upon evaluation of the data, the WAC may propose analyses for other constituents.

C. Selected benchmarks in the County land subsidence monitoring network should be surveyed every five years at a minimum. These surveys should be conducted following aquifer recovery and prior to the period of highest groundwater extraction (approximately the month of).

D. Measurement of surface water flow and quality in areas determined to directly affect groundwater levels or quality or that are affected by groundwater pumping shall be obtained at least ___ times per month as long as there are flows in the channel.

X.09 Changes in Monitoring

If evaluation of the groundwater level, groundwater quality, land subsidence, surface water flow, or surface water quality data indicates a need for more or less frequent measurements or analyses, the WAC may propose a change in the monitoring frequency. Similarly, if evaluation of the data indicates that additional monitoring sites are necessary, the WAC may propose an additional or a reduced number of sites for data collection. The Board shall adopt these changes when supported by available evidence.

X.10 Review of Technical Data

A. The TAC shall purpose and the WAC shall adopt standard methods using scientifically sound principles for review and analysis of the collected data. The TAC will meet, as needed and requested by the WAC, to evaluate the technical data and shall report their findings at appropriate meetings of the WAC. The WAC shall meet at least ___ times per month during the period of maximum groundwater use (months of ___ through ____) and quarterly during the off season (months of _____ through ____), or as necessary.

B. During the period of highest groundwater use, the WAC meetings will focus on data review and analysis with respect to compliance with the current MOs. During the period of low

AR0069858

groundwater use, the WAC meetings will focus on a review of compliance with MOs for the previous period of high groundwater use and consideration of the need for changes to the MOs.

X.11 Data Dissemination

The WAC, in addition to establishing methods for data collection and evaluation, shall establish methods for data storage and dissemination. The WAC shall disseminate the monitoring data and evaluation reports through public presentations and through a County-maintained groundwater Internet site. At a minimum, the WAC shall publicly present findings from the monitoring program to the Board twice annually.

X.12 Actions when MO Noncompliance is Reported

A. Action by Technical Advisory Committee. In the event that the TAC identifies an area that is not in compliance with the MOs, or if noncompliance is reported by any other means, the TAC shall report to the WAC on the regional extent and magnitude of the noncompliance. This information shall also be released to the public no later than _ _ days from the time that noncompliance with MOs was identified. The TAC shall then collect all available pertinent hydrologic data, investigate possible causes for noncompliance with MOs, and recommend actions to the WAC to bring the area into compliance. These recommendations shall be made no later than days after the report of noncompliance is released to the public. The TAC shall first make recommendations that focus on correcting the noncompliance through negotiations with all parties in the affected area.

B. Action by Water Advisory Committee. The WAC shall act as lead negotiator in re-establishing compliance with the MO. If negotiations with parties in the affected area do not result in timely and positive action to re-establish compliance with MOs for the basin, the WAC may recommend a plan to the Board to modify, reduce or terminate groundwater extraction in the affected area or take other necessary actions. Such a plan will be recommended to the Board only after the WAC has thoroughly reviewed the recommendations of the TAC at a public meeting. The modification, reduction, or termination of groundwater extraction in the affected area shall first be applied to wells involved in any export or substitution programs, and then to other wells if necessary. Domestic wells shall not be considered for any modification, reductions, or termination of groundwater extraction.

C. Action by Board of Supervisors. The Board of Supervisors, using its police powers, shall act as the enforcement agency for this ordinance. Any recommendation of the WAC may be appealed to the Board within _ working days.

X.13 Regional Coordination

Management decisions recommended by the WAC and adopted by the Board shall not deleteriously affect groundwater resources in any portions of groundwater basins or non-basin areas that share a common groundwater resource in adjacent counties. To accomplish this goal, the WAC shall meet and coordinate with water management entities outside the County that overlie a common groundwater basin at least twice per year, once prior to the period of highest groundwater use and once following the period of highest groundwater use.

X.14 Integrated Resource Management

A. To ensure integration of planning activities within the County, the WAC shall inform County departments involved with groundwater related activities, including but not limited to Land Use or Zoning, Planning, Public Works, Utilities, and Environmental Health, of all WAC meetings and actions regarding MOs. In turn, these County departments shall take into consideration the

AR0069859

adopted MOs when approving development or zoning changes or construction projects that may rely on or affect groundwater quantity or quality.

B. To the greatest extent practicable, the WAC should also integrate resource management planning with other agencies within the basin. Resource activities that could benefit from integrated planning with groundwater management include, but are not limited to:
   - Stormwater management planning by other agencies—agricultural, municipal, industrial, local government
   - Watershed management plans
   - Urban water management plans
   - Management and disposal of municipal solid waste and municipal sewage
   - Drinking water source assessment and protection programs
   - Public water system emergency and disaster response plans
   - Surface water and groundwater conjunctive management programs
   - Expansion of surface and groundwater facilities
   - Water efficiency programs
   - Water recycling programs
   - Environmental habitat construction or restoration programs
   - Water quality protection programs
   - Recharge programs
   - Transportation infrastructure planning

X.15 Data Relating to Export and Substitution of Groundwater

A. Districts, persons, or contractors intending to operate a groundwater export or groundwater substitution program shall submit the following data to the WAC ___ working days prior to commencing the program:
   1. A description of the project with the total amount of groundwater to be exchanged or substituted.
   2. The dates over which the project will take place.
   3. A statement of the anticipated impacts of the project relative to adopted MOs.
   4. A discussion of possible contingencies in the event of MO noncompliance.
   5. A map showing the location of the wells to be used by the program.
   6. A summary of any monitoring program proposed.
   7. All required environmental documentation.

B. While the program is in operation, the following information shall be provided to the WAC at least ___ times per month.
   1. All static and pumping groundwater level measurements made in the pumping well during the period of extraction for the export or substitution program.
   2. The amount of groundwater extracted from each well per week.
   3. Static groundwater level measurements in at least ___ of the most proximal wells to the project pumping wells that can be practicably monitored.

C. All costs for providing such information to the WAC shall be borne by the project participants.

Note: Although the terms "County" and "Board" are used throughout the model ordinance for clarity, the model could be used by any local government or agency with appropriate authority or powers.

AR0069860

Appendix E
SWRCB Beneficial Use Designations[1]

Agricultural Supply (AGR) – Uses of water for farming, horticulture, or ranching including, but not limited to, irrigation, stock watering, or support of vegetation for range grazing.

Aquaculture (AQUA) – Uses of water for aquaculture or mariculture operations including, but not limited to, propagation, cultivation, maintenance, or harvesting of aquatic plants and animals for human consumption or bait purposes.

Cold Freshwater Habitat (COLD) – Uses of water that support cold water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

Estuarine Habitat (EST) – Uses of water that support estuarine ecosystems including, but not limited to, preservation or enhancement of estuarine habitats, vegetation, fish, shellfish, or wildlife (e.g., estuarine mammals, waterfowl, shorebirds).

Freshwater Replenishment (FRSH) – Uses of water for natural or artificial maintenance of surface water quantity or quality (e.g., salinity).

Groundwater Recharge (GWR) – Uses of water for natural or artificial recharge of groundwater for purposes of future extraction, maintenance of water quality, or halting of saltwater intrusion into freshwater aquifers.

Hydropower Generation (POW) – Uses of water for hydropower generation.

Industrial Process Supply (PRO) – Uses of water for industrial activities that depend primarily on water quality.

Industrial Service Supply (IND) – Uses of water for industrial activities that do not depend primarily on water quality including, but not limited to, mining, cooling water supply, hydraulic conveyance, gravel washing, fire protection, or oil well repressurization.

Inland Saline Water Habitat (SAL) – Uses of water that support inland saline water ecosystems including, but not limited to, preservation or enhancement of aquatic saline habitats, vegetation, fish, or wildlife, including invertebrates.

Marine Habitat (MAR) – Uses of water that support marine ecosystems including, but not limited to, preservation or enhancement of marine habitats, vegetation such as kelp, fish and fish, or wildlife (e.g., marine mammals, shorebirds).

Migration of Aquatic Organisms (MIGR) – Uses of water that support habitats necessary for migration or other temporary activities by aquatic organisms, such as anadromous fish.

Municipal and Domestic Supply (MUN) – Uses of water for community, military, or individual water supply systems including, but not limited to, drinking water supply.

Navigation (NAV) – Uses of water for shipping, travel, or other transportation by private, military, or commercial vessels.

Noncontact Water Recreation (REC-2) – Uses of water for recreational activities involving proximity to water, but not normally involving body contact with water where ingestion of water is reasonably possible. These uses include, but are not limited to, picnicking, sunbathing, hiking, beachcombing, camping, boating, tidepool and marine life study, hunting, sightseeing, or aesthetic enjoyment in conjunction with the above activities.

Ocean Commercial and Sport Fishing (COMM) – Uses of water for commercial or recreational collection of fish, shellfish, or other organisms including, but not limited to, uses involving organisms intended for human consumption or bait purposes.

[1] From SWRCB 2000

AR0069861

Preservation of Biological Habitats of Special Significance (BIOL) – Uses of water that support designated areas or habitats, such as established refuges, parks, sanctuaries, ecological reserves, or Areas of Special Biological Significance (ASBS), where the preservation or enhancement of natural resources requires special protection.

Rare, Threatened, or Endangered Species (RARE) – Uses of water that support habitats necessary, at least in part, for the survival and successful maintenance of plant or animal species established under State or federal law as rare, threatened or endangered.

Shellfish Harvesting (SHEL) – Uses of water that support habitats suitable for the collection of filter-feeding shellfish (e.g., clams, oysters, and mussels) for human consumption, commercial, or sports purposes.

Spawning, Reproduction, and/or Early Development (SPWN) – Uses of water that support high quality aquatic habitats suitable for reproduction and early development of fish.

Warm Freshwater Habitat (WARM) – Uses of water that support warmwater ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

Water Contact Recreation (REC-1) – Uses of water for recreational activities involving body contact with water, where ingestion of water is reasonably possible. These uses include, but are not limited to, swimming, wading, water skiing, skin and scuba diving, surfing, white water activities, fishing, or use of natural hot springs.

Wildlife Habitat (WILD) – Uses of water that support terrestrial ecosystems including, but not limited to, preservation and enhancement of terrestrial habitats, vegetation, wildlife (e.g., mammals, birds, reptiles, amphibians, invertebrates), or wildlife water and food sources.

a "eff" denotes the date the MCL was effective unless data prevented indication when EPA established that it promulgated the MCL.

b Secondary MCL.

c MFL = million fibers per liter with fiber length > 10 microns.

d Regulatory Action Level = treatment technique. If more than 10% of the customer taps sampled exceed the action level, monitoring, corrosion control, source water treatment and public education programs may be required.

e The MCLG = 0 but was converted with the adoption of the regulation to an enforceable standard.

f. MCL is for nitrate + nitrite, 10 mg/L as nitrogen; 1 mg/L for nitrite, 10 mg/L as nitrogen.

g. Effective for surface water systems serving more than 10,000 people; effective 1/2001 for all others.

h. TT = treatment technique, because no MCL was established.

i. Federal and State MCL is 4 mrem/yr. (5/2006)

AR0069866

Appendix G
Development of Current Groundwater Basin/Subbasin Map

This Bulletin 118 update represents the first time that groundwater basin boundaries have been released as a digital coverage. The basin boundaries for the revised groundwater basin map were primarily defined using geologic contacts and hydrogeologic barriers. Specifically the identification of the groundwater basins was initially based on the presence and areal extent of unconsolidated alluvial sediments identified on 1:250,000 scale, geologic maps published by the California Department of Conservation, Division of Mines and Geology. The identified groundwater basin areas were then further evaluated through review of relevant geologic and hydrogeologic reports and well completion reports, and using the basin definition criteria listed in Table 8. Basin boundaries that are specified in each of the court decisions has been used for the boundaries of adjudicated basins.

Well completion reports for wells present in basin areas that were identified from the geologic map were reviewed to identify the depth to the top of the water table and the top of impermeable bedrock. If there was less than 25 feet of permeable material present or if there was no groundwater present within the permeable material, the area was eliminated from the map. The well completion reports were also reviewed to determine if water supply wells located within the delineated basin areas were extracting groundwater from the permeable materials underlying the area or from the bedrock beneath the permeable material. If the wells only extracted groundwater from the bedrock, the area was eliminated from the map. This resulted in the elimination of some areas identified as basins in previous Bulletin 118 publications. If there were no wells present in basin areas identified from the geologic map and no other information on the geology underlying these areas, the areas were retained in the current version of the map. Additional hydrogeologic information might or might not verify that these areas should be retained as groundwater basins.

Groundwater basins were delineated and separated from each other by the following restrictions on groundwater flow. For more detail on the types of basins and the flow boundaries of those basins, see Table 8.

Impermeable Bedrock. Impermeable bedrock with lower water yielding capacity. These include consolidated rocks of continental and marine origin and crystalline or metamorphic rock.

Constrictions in Permeable Materials. A lower permeability material, even with openings that are filled with more permeable stream channel materials, generally forms a basin boundary for practical purposes. While groundwater may flow through the sediment filled gaps, the flow is restricted to those gaps.

Fault. A fault that crosses permeable materials may form a barrier to groundwater movement if movement along the fault plane has created fine material that impedes groundwater movement or juxtaposed low permeability material adjacent to an aquifer. This is usually indicated by noticeable difference in water levels in wells and/or flow patterns on either side of the fault. Not all faults act as barriers to groundwater flow.

Low Permeability Zone. Areas of clay or other fine-grained material that have significant areal or vertical extent generally form a barrier to groundwater movement within the basin but do not form basin boundaries.

AR0069867

Groundwater Divide. A groundwater divide is generally considered a barrier to groundwater movement from one basin to another for practical purposes. Groundwater divides have noticeably divergent groundwater flow directions on either side of the divide with the water table sloping away from the divide. The location of the divide may change as water levels in either one of the basins change, making such a "divide" less useful. Such a boundary is often used for subbasins.

Adjudicated Basin Boundaries. The basin boundaries established by court order were used for all adjudicated basins. These court-decided boundaries affect the location of natural boundaries of adjoining basins. Some adjudicated basins are represented as subbasins in this bulletin.

Available reports on the geologic and hydrogeologic conditions in the delineated basin areas were also reviewed to determine if there was information that would further define the boundaries of the basin areas. This review resulted in changes to some of the basin boundaries identified in previous versions of Bulletin 118.

Several of the larger groundwater basins were further subdivided into groundwater subbasins in Bulletin 118-80 and additional large groundwater basins were subdivided during this 2003 revision. The subbasin boundaries were also primarily defined using geologic structures and hydrogeologic divides where possible. If this was not possible, political or institutional boundaries were used.

The hydrogeologic information contained in the basin descriptions that supplement this update of Bulletin 118 includes only the information that was available in California Department of Water Resources (DWR) files through reference searches and through limited contact with local agencies. Local agencies may have conducted more recent studies that have generated additional information about water budgets and aquifer characteristics. Unless the agency notifies DWR or provides a copy of the recent reports to DWR staff that recent information has not been included in the basin descriptions. Therefore, although Senate Bill 610 refers to groundwater basins identified as overdrafted in Bulletin 118, it would be prudent for local water suppliers to evaluate the potential for overdraft of any basin included as a part of a water supply assessment.

Persons interested in collecting groundwater information in accordance with the Water Code as amended by SB 221 and SB 610 may start with the information in Bulletin 118, but should follow up by consulting the references listed for each basin and contacting local water agencies to obtain any new information that is available. Otherwise, evaluation of available groundwater resources as mandated by SB 221 and SB 610 may not be using the most complete and recent information about water budgets and aquifer characteristics.

Groundwater basin and subbasin boundaries shown on the map included with this bulletin are based on evaluation of the best available information. In basins where many studies have been completed and the basin has been operated for a number of years, the basin response is fairly well understood and the boundaries are fairly well defined. Even in these basins, however, there are many unknowns and changes in boundaries may result as more information about the basin is collected and evaluated.

In many other basins where much less is known and understood about the basin, boundaries will probably change as a better understanding of the basin is developed. A procedure for collecting information from all the stakeholders should be developed for use statewide so that agreement on basin boundaries can be achieved.

Preface

This 2012 Integrated Resource Plan (IRP) document revises and builds upon last year's 2011 IRP. Major changes from 2011 include expanded discussion regarding the Power Reliability Program, more detailed information on transmission planning and projects, a new subsection on the impacts of climate change on power system operations, and new case options that analyze higher levels of energy efficiency and solar distributed generation.

The current load forecast used in this IRP is lower than the one used in 2011. Compared to the prior forecast, electricity sales for year 2020 decreased by approximately 5.3 percent mostly due to increasing levels of energy efficiency.

Early coal replacement continues to be a key strategy to reduce greenhouse gas emissions. As with last year's IRP, this 2012 IRP recommends divestiture of the Navajo coal plant by 2015, four years ahead of the scheduled 2019 end date. LADWP will replace the loss of Navajo with energy efficiency, renewable energy, and natural gas generation. LADWP's other coal source – the Intermountain Power Project—is undergoing discussions which could enable a future conversion to lower emitting resources. Because LADWP is one of thirty-six purchasers of IPP energy, any future plans must be agreed to by all project participants. Proposed amendments to the existing contracts are being considered by the purchasers which would require IPP to switch fuel from coal to natural gas no later than July 1, 2025 (two-years before the legal deadline). These amendments require unanimous approval and final purchaser decisions are expected by the end of 2013. Since the results of these discussions are not available for this 2012 IRP, we are hopeful that the plan will be in place for inclusion into next year's IRP process.

This 2012 IRP process included public outreach. Stakeholder meetings were held early in the year to solicit input towards the development of strategic case options. After the case options were analyzed, preliminary results were presented to the public for comment at meetings and through the LADWP website. This 2012 IRP documents the public outreach effort, and addresses the major themes that emerged from that process.

This IRP also includes a general assessment of the revenue requirements and rate effects that support the recommended resource plan through 2032. While this assessment was not as detailed and exhaustive as the financial analysis within the just completed rate case, it does show clearly the general requirements.

The recently concluded rate process confirmed LADWP's revenue requirements, over the next two years, to meet its mandated obligations and responsibilities. As a long-term planning process, the IRP looks at a 20-year horizon to secure adequate supplies of electricity. In that respect, it is our desire that the IRP contribute towards future rate processes by presenting and discussing the programs and projects required to fulfill our City Charter mandate to delivery reliable electric power to the City of Los Angeles.

1. Introduction and Purpose

This document represents the Los Angeles Department of Water and Power (LADWP) Integrated Resource Plan (IRP) for 2012. The goal of this IRP is to identify a portfolio of generation resources and Power System assets that meets the city's future energy needs at the lowest cost and risk consistent with LADWP's environmental priorities and reliability standards. The IRP is an important planning document for electric utilities, and many states and regulatory agencies require development of an IRP prior to approval of procurement programs or electric rate increases.

This document goes beyond traditional integrated resource planning and incorporates additional Power System planning elements to form a comprehensive Power System plan. It is intended that this Power System plan will drive the priorities, financial planning, and budgeting effort for the Power System.

This IRP considers a 20-year planning horizon to guide LADWP as it executes major new and replacement projects and programs. The overriding purpose is to provide a framework to assure the future energy needs of LADWP customers are met in a manner that balances the following key objectives:

- Superior reliability and supply of electric service
- Competitive electric rates consistent with sound business principles
- Responsible environmental stewardship exceeding all regulatory obligations

In balancing these objectives, LADWP's strategic planning efforts must ensure a high level of system reliability, consider impacts to the local and regional economy, mitigate the volatility in fuel and other cost factors, comply with federal, state, and local regulations, and guarantee fiscal responsibility.

LADWP is the largest municipal utility in the nation, and the third largest utility in California. While numerous recent accomplishments have been made – including achieving 20% of renewable energy sales in 2010 – significant challenges lie ahead. Increasing renewable energy to 33% by 2020, the continued rebuilding of coastal generation units, replacement of coal, infrastructure reliability investments, and ramping up energy efficiency and other demand side programs are all critical and concurrent strategic actions that LADWP will have to carry out over the coming decade.

The 2012 integrated resource planning process developed alternative strategic cases that assess different replacement options for coal-fired generation, as well as different projected levels of energy efficiency and distributed generation. The cases are modeled to determine their respective operational and fiscal impacts, as well as their effects on greenhouse gas emission levels. This document presents the results of this analysis, recommended near-term actions, and a recommended strategy to best meet the future electrical needs of Los Angeles.

AR0069880

LADWP Power System Vision

The transformation that this utility will undergo in the next 20 years will be unprecedented as the use of electricity broadens to new applications and as customer expectations of clean affordable energy continues to take root. Increases in electric vehicle use, expanded electrification of processes to reduce emissions and greenhouse gases, and growing wide-spread use of information technology equipment will require a stable, resilient power grid that delivers affordable power. By adopting energy efficiency, promoting solar rooftop and supporting other clean technologies that mitigate the need to build new fossil-fueled power plants, our customers are embracing the vision of a greener resource portfolio that sustains the environment for future generations.

LADWP and its City Leaders have traditionally taken a leadership position, particularly among public power utilities, to ensure a sustainable, diverse supply of generation and transmission resources to provide electricity to our customers. This utility has also been very progressive in adopting aggressive clean energy goals and programs well before many of today's laws and regulations were in place, and participated in the development of many of the laws and regulations that we see today. In 2000, this utility set out to reduce load growth by 50 percent through the use of renewables, energy efficiency, and distributed generation. Today we have the same electricity consumption as we had in 2000 largely due to these earlier efforts. In 2005, we adopted a renewable target of 20 percent renewable by 2010, and we succeeded to be the largest California utility to achieve 20 percent renewable generation in 2010. Since 1990, we have divested of 2 coal plants and repowered several natural gas in-basin generating stations using cleaner and more efficient new combustion technology, resulting in 21 percent lower greenhouse gas emissions and over 80 percent lower NOx emissions. Reducing ocean water use and reducing the impact on marine life has also been an on-going effort and by next year we will use 42% less ocean water from 1990 levels, with total elimination targeted by 2029.

The world today is not the same as it was 20 years ago, and the world 20 years from now will not be the same as it is today. And while LADWP's mission of providing reliable, affordable electricity in an environmentally responsible manner remains the same, the planning and execution of that mission requires continued diligence to account for, adopt, and even influence, the changing public concerns and priorities related to electricity generation and use.

AR0069881

1.1 Major Changes from Last Year's IRP

Major changes from last year's 2011 IRP include expanded discussion on the Power Reliability Program, more detailed information on transmission planning and projects, a new sub-section on the future impacts of climate change on power generation and operations, and new case options that analyze higher levels of Energy Efficiency (EE) and Distributed Solar Generation (Solar DG).

This 2012 IRP incorporates updates to reflect the latest load forecast, fuel price and projected renewable price forecasts, and other numerous modeling assumptions. Compared to the prior forecast, projected electricity sales in calendar year 2020 decreased by 5.3 percent, mostly due to increased levels of energy efficiency. The new forecast reduces the overall need for renewable energy (assuming 33% RPS) by approximately 461 GWh in 2020 and 745 GWh in 2030.

Long term natural gas price forecasts have been revised downwards from last year with recent prices reaching very low levels over the last year. Compared to last year's 2011 IRP, Opal and SoCal expected gas prices are 16% lower on average in the short term (2011-2020) and 8-9% lower on average in the long term (2021-2030). Coal price forecasts are also lower; with IPP coal at 4% lower for the period 2012-2027, and Navajo coal at 14% lower for the period 2012-2019.

Other changes include lower cost assumptions for solar and geothermal, reflecting price competition for both resources, and updates regarding legislative and regulatory issues. See Section 3 and Appendix N for more details.

AR0069882

2. Recent Accomplishments

A summary of recent LADWP accomplishments consistent with the objectives of this IRP are presented below in Table ES-1. These accomplishments promote the goals of maintaining high reliability and exercising environmental stewardship, while keeping rates competitive. See Section 1.5 for more details.

Table ES-1. LADWP RECENT ACCOMPLISHED PROJECTS/PROGRAMS

Project/Program	Time Period	Accomplishment
Renewable Portfolio Standard	2003 to 2010	Increased renewable energy percentage from 3% to 20%
Adelanto Solar	2012	10 MW solar project built, put in-service
Energy Efficiency Program	2012	Recommitment goals adopted: 10% by 2020, with target of 15%
Solar Incentive Program	1999 to Present	Provided funding that has enabled the installation of 55 MW of solar to date
Solar Feed-in-Tariff	2012	Pilot program conducted, followed by full scale re-launch for up to 150 MW
Milford II Wind Project	2011	Supply over 100 MW of wind energy
CO_2 Emissions Reduction	1990 to 2010	CO_2 emission 22% lower than 1990 level
Once-through Cooling	1990 to Present	OTC reduced by 17% from 1990 level
Haynes 5&6	2011-12	Repowering project initiated, new turbines installed. In-service scheduled for 2013
Castaic Upgrade	2004 to 2014	Project adds up to 80 MW of renewable capacity
Power Reliability Program	Ongoing	In 2011-12, replaced 1,813 poles, 2,054 transformers, and 51 miles of UG cable
Navajo Generation Station Replacement	Ongoing	Process to divest initiated. RFP for replacement capacity issued.
Southern Transmission System Upgrade	2011	Increased capacity of 480 MW was added to the existing transmission line
Green Power Program	1999 to 2011	Participants receive 104 GWh of renewable energy annually
Electric Vehicles Incentive	2011	Provide a $2000 rebate for home EV charging systems
Demand Response Program	1999 to Present	Signed up 60 MW of load shifting and interruptible load
Alternative Marine Power Program	Through 2012	Signed up 13.8 MW of load to offset diesel motor emissions at the Port of LA

AR0069883

3. 2012 IRP Development Process

The IRP is prepared by a group of engineers dedicated to LADWP resource planning and preparation of the IRP document. While this group performs the production model and report preparation for the IRP, the bulk of the work is collaborative across the numerous work groups and functional areas of the Power System, including wholesale marketing, grid operations, renewable procurement, environmental and legislative affairs, and financial services.

The following general sequence represents the process to develop this IRP document:

1. Gather stakeholder input
2. Establish clear goals and objectives
3. Identify and approve key assumptions
4. Establish strategic case alternatives
5. Conduct computer modeling of Power System operations
6. Present preliminary findings and gather internal and public comments
7. Recommend and approve a preferred resource case

Stakeholder input was considered in the establishment of the goals and objectives for the IRP analysis. Modeling assumptions and case alternatives were identified and approved by an internal IRP Steering Committee consisting of Power System Division and Section heads. Preliminary results were analyzed and presented to the public for review and input. Final recommendations incorporating public feedback were then forwarded to the General Manager and Board of Water and Power Commissioners.

The IRP development process includes coordination among multiple LADWP organizations responsible for different aspects of Power System operations. Recommended positions at the various stages were presented to LADWP's leadership team, including Division and Section Heads. The approval process for recommendations was based on consensus from the managers of each area of responsibility.

AR0069884

4. Public Outreach

The 2012 IRP process includes a public outreach effort to provide information and gather public input.

Public outreach began with two stakeholder meetings held in early 2012. LADWP staff met with key major customers and business representatives in February; and in March with key environmental organization representatives. Comments received during these stakeholder meetings were considered in the development of the preliminary cases that were analyzed.

The preliminary results were documented in the 2012 Draft IRP that was made available at www.ladwp.com/lapowerplan on October 5, 2012. The draft IRP was presented at three stakeholder meetings and one public workshop held on October 11, 2012. Comments were accepted through November 5, 2012.

Comments received were synthesized into the following major themes. Each theme is considered of equal importance. The following list is not presented in any order of importance

Eliminate Coal from LADWP's Energy Portfolio

Incorporate More Renewables

Incorporate More Local Solar

Incorporate More Distributed Generation

Incorporate More Energy Efficiency

Reduce Greenhouse Gas Emissions

Look at New Case Scenarios

Financial and Rate Concerns

Maintain Power Reliability

LADWP Should Take a Leadership Role

Public comment and input received was considered prior to finalizing this 2012 IRP.

A summary of the public comments received is included in Section 5 and Appendix O.

AR0069885

5. Challenges and Critical Issues

LADWP faces a number of concurrent issues and challenges that require careful assessment. Long term strategies must focus on these issues so they can be addressed in the most cost effective manner without compromising reliability compliance and environmental stewardship. The major issues around which the strategies of this IRP are centered include: adequate funding to support programs; ensuring reliability; greenhouse gas emissions reduction; increasing the amounts of renewable generation resources; and addressing once-through cooling.

5.1 Adequate Funding to Support Programs

To support the recommended projects and programs, adequate funding is necessary. Due to the delay of the rate action that was previously anticipated in 2011, many of the programs were scaled down, delayed or deferred. The rate process that concluded on October 5, 2012 is a positive step towards LADWP's fulfillment of its responsibilities and regulatory obligations that are discussed throughout this 2012 IRP.

Properly funded programs will enable LADWP to achieve the following objectives:

- Modernize its coastal generation units to replace aging equipment and to satisfy once-through cooling and local emissions regulatory requirements.
- Implement early coal divestiture and replacement to accelerate the reduction of greenhouse gas emissions and to enhance integration of renewable energy and energy efficiency measures.
- Secure the state-mandated amounts of renewable energy.
- Increase use of local distributed solar generation and combined heat and power to support State goals.
- Through the Power Reliability Program, reduce the number and duration of distribution outages and improve system reliability.
- Implement necessary transmission improvements to maintain reliability and support new resources, including renewables.
- Provide energy efficiency and customer solar programs for participation by our customers through the Customer Opportunities Program.
- Achieve energy efficiency and other demand-side-resource target levels.
- Implement Smart Grid initiatives.
- Comply with FERC-approved reliability and Cyber-security standards.

Securing adequate multi-year funding is crucial to ensure LADWP's ability to stay on track towards meeting its future long term goals and obligations.

AR0069886

5.2 Ensuring Reliability

Challenges to ensuring continued reliable electric service include the replacement of aging generation facilities, maintaining grid reliability, the integration of intermittent renewable energy resources, and the replacement of poles, power cables, transformers and other elements of the local distribution system.

LADWP's Repowering Program, which began in 1994, is a long term program to upgrade LADWP's in-basin generating units. The program is a sequence of projects that extends to 2029 that will eliminate the use of once through cooling and provide modern units that are more reliable, efficient, and community-friendly than the units they are replacing.

To maintain grid reliability, LADWP's Ten-Year Transmission Assessment Plan has identified a number of necessary improvements that are needed to avoid potential overloads on key segments of the Basin transmission system. These overload conditions, if encountered, could lead to load shedding events (intentional power outages) to minimize the overall impact on the Power System.

The integration of renewable energy into the grid poses major reliability challenges. Because renewable resources like wind and solar produce electricity variably and intermittently (i.e., only when the wind is blowing or when the sun is shining), integration of these resources requires additional supplemental generator units to compensate for significant and often rapid swings in energy production. These swings present operational challenges and must be leveled by controllable generation capable of equally rapid changes of generation in the opposite direction.

Between 2003 and 2005, LADWP experienced a growing number of distribution outages due to, among other things, aging infrastructure (poles, lines, transformers, etc.), deferred maintenance and asset replacement.[1] In response, LADWP established a comprehensive Power Reliability Program (PRP) in 2006 which provided increased funding to address the growing maintenance and replacement backlog. The PRP experienced initial success as the number of outages decreased from 6,323 in 2006 to 4,523 in 2009. Since then, however, funding constraints have prevented any measurable improvement.

5.3 Greenhouse Gas Emissions Reduction

While LADWP has multiple and concurrent GHG emissions reduction strategies, the primary focus is early replacement of coal-fired generation. Because coal-fired energy production emits relatively high levels of CO_2, switching to energy efficiency, renewables and other cleaner fuels will significantly lower the overall emission levels. Early coal replacement facilitates LADWP's compliance with AB 32's upcoming cap and trade program.

During calendar year 2011, 41 percent of the energy delivered to LADWP customers was

[1] To illustrate the age of the distribution system, over 25 percent of the City's 321,780 distribution poles have already exceeded their 60-year life expectancy.

AR0069887

generated from two coal-fired generating stations: the Intermountain Power Project (IPP), located in Utah, and the Navajo Generating Station (NGS), located in Arizona. The NGS's operating agreement and land lease expires in December 2019 and IPP's Power Purchase Agreement (PPA) contract is in effect until June 2027. Although these stations provide dependable, low cost base load generation to Los Angeles, they emit about twice as much CO_2 as energy generated with natural gas. Accordingly, this 2012 IRP focuses on early coal replacement options as a means to lower LADWP's CO_2 emission levels. Sections 3 and 4 discuss the coal replacement options in detail.

LADWP's CO_2 emissions reduction strategy must comply with state regulations:

- SB 1368, the California Greenhouse Gas Emissions Performance Standard Act, enacted in 2006, prohibits LADWP and other California utilities from entering into long-term financial commitments for base load generation unless it complies with the CO_2 emissions performance standard. The CO_2 emissions level must be equal, or below the emissions performance standard of 1,100 lbs. per MWh that can be achieved by gas-fired combined cycle units. This standard also applies to existing power plants for any long-term investments or contractual extensions, effectively prohibiting LADWP from continued acceptance of coal-fired generation beyond the current contractual expiration dates for NGS (2019) and IPP (2027).
- Assembly Bill (AB) 32, the California Global Warming Solutions Act of 2006, calls for reducing the state's CO_2 emissions to 1990 levels by 2020. The regulations for implementing a greenhouse gas emissions Cap and Trade program under AB 32 were finalized and adopted on October 20, 2011 by the California Air Resources Board (ARB). Enforcement and compliance with the trading program will begin January 1, 2013. LADWP has been granted an administrative allocation of emission allowances that reflects its resource projections through 2020. At this time, it is uncertain if the program will extend beyond 2020.

5.4 Increasing Renewable Resources

LADWP's policy for renewables was initiated in the early 2000's, and has guided the adoption of increasing levels of renewable energy, including the milestone achievement of 20 percent of energy sales in 2010. Major legislation affecting LADWP's renewable policy are SB 1, SB 32, and SB 2 (1X).

Senate Bill 1 (SB 1)

Former Governor Schwarzenegger signed the California Solar Initiative (CSI), outlined in SB 1, on August 21, 2006. The CSI mandated that all California electric utilities, including municipals, implement a solar incentive program by January 1, 2008. The goal of the CSI is 3,000 MW of net-metered solar energy systems over 10 years with expenditures not to exceed $3.35 Billion. Expenditures for local publicly owned electric utilities shall not exceed $784 Million. The LADWP cap amount is $313 Million, based on its serving 39.9% of the municipal load in the state.

AR0069888

SB 32

SB 32, signed into law on October 11, 2009, requires LADWP to make a tariff available to eligible renewable electric generation facilities within its service territory until LADWP meets its 75 MW share of the statewide target. Through this program, owners or operators of eligible renewable energy systems may sell their energy directly to LADWP. The purchase of SB 32 qualifying energy includes all environmental attributes, capacity rights, and renewable energy credits. This energy is just one of the many renewable energy sources that will apply towards LADWP's 33 percent renewable requirement.

SB 2 (1X)

Following the passage of SB 2 (1X) in 2011, LADWP's renewable energy policy is now largely driven by those requirements of SB 2 (1X).

SB 2 (1X), which was passed in April 2011 and became effective on December 10, 2011, subjects all utilities to procurement of eligible renewable energy resources of 33 percent by 2020, including the following interim targets:

- Maintain at least an average of 20 percent renewables between 2011 and 2013
- Achieve 25 percent renewables by 2016

In December 2011, LADWP amended its Renewable Portfolio Standard Policy and Enforcement Program to comply with the requirements of SB 2 (1X). However, LADWP's policy continues to include some requirements that are not a part of SB 2 (1X) but were in place prior to enactment of the State legislation. These additional requirements include the provision for LADWP to own at least 50 percent of its renewable energy resources, and to give preference to projects located within the City.

As LADWP expands its renewable resource portfolio, it is important that it do so in a cost effective manner to minimize the impact on ratepayers. Some of the considerations in selecting these resources are as follows:

- Cost differences for different renewable technologies
- Cost trends that reflect decreasing prices
- Variable integration costs and operational impacts
- Technologies that deliver more energy during peak hours
- Preference for local projects
- Proximity of projects to transmission
- For PPA resources, tax credits that can be passed along as cost savings
- PPA proposals that provide future ownership opportunities
- Overall diversity of resource mix and geography
- Qualification as "Bucket 1" energy according to CEC RPS regulation and guidelines
- Assessing projects on the basis of value to maximize benefits and minimize risks

AR0069889

In this 2012 IRP, the overall base renewable portfolio levelized cost is $98/MWh, which represents an $11/MWh decrease from last year. This cost reduction was achieved by selecting a more optimized and diverse portfolio that accounts for changing price trends and market developments. By maintaining flexibility in the selection of cost-effective renewable resources, LADWP is able to secure the best pricing as market conditions evolve.

5.5 Once Through Cooling

Once-through cooling (OTC) is the process of drawing water from a river, lake, or ocean, pumping it through a generating station's cooling system, and discharging it back to the original body of water. OTC is a utility regulatory issue, stemming from the Federal Clean Water Act Section 316(b) and administered locally by the State Water Resources Control Board (SWRCB).

OTC regulations affect LADWP's three coastal generating stations – Scattergood, Haynes, and Harbor. To comply with OTC regulations, generation units at those stations that utilize ocean water for cooling will be repowered with new units that do not use ocean water. The amount of generation capacity affected by OTC is significant – approximately 2,600 MW of LADWP's total in-basin plant capacity of 3415 MW. The total expenditures required are also significant, on the order of $2.2 billion. Because of the size and scope of the effort required, the work to comply with OTC regulation is a long term program, extending to 2029. Figure ES-1 is a timeline of the program target dates. More information regarding OTC is provided in Section 1.6.6.

Figure ES-1. Timeline for OTC compliance.

5.6 Workforce Development

To effectively implement the programs and projects recommended in this IRP, an effective human resources strategy is required. The Power System is challenged to develop a sustainable workforce development plan that addresses the following human resource elements:

AR0069890

Staffing
Adequate staffing is needed to meet mandated deadlines and regulatory obligations, to execute new and expanded work functions, and to manage the volume of retirements expected over the next 3-5 years.

Proper Skill Sets
New work areas such as renewable energy facility operations, solar distributed generation, and smart grid deployment will require analysis to identify the skills, knowledge and abilities required to perform these functions in a safe, effective and efficient manner.

Training/Professional Development and New Technologies
LADWP supports employee development by providing various computer-based training programs, and offers tuition reimbursement for those who return to school to enroll in work-related courses and advanced degree programs. Across the Power System, different work groups are encouraged to develop training specific to their particular functions and needs. This is especially important as new and emerging technologies become applicable to various work functions. Applied correctly, technology increases employee productivity, enhances safety, and enables new and expanded customer services.

Recruitment
Recruiting the best qualified employees assures an effective workforce capable of meeting the near term and long term challenges identified in this IRP. Continued use of LADWP's website and social media to promote career opportunities will help ensure that the best qualified individuals consider joining the LADWP workforce.

5.7 Other Challenges

Additional challenges that LADWP must address in the coming years include:

- Managing potential natural gas price volatility
- Incorporating higher levels of Distributed Generation (DG) that advance renewable resource and local solar objectives, and support the State's promotion for more DG
- A heightened demand for transmission planning to support new and intermittent resources that has introduced greater complexity
- Cyber security regulations
- The relicensing of the Castaic Pumped Storage facility with the Federal Energy Regulatory Commission
- Accounting for the effects of climate change on power generation, operations, and markets
- Load factor improvement
- Acquisition of replacement resources for coal-fired generation

AR0069891

6. Strategic Case Alternatives

The 2012 IRP strategic cases incorporate the latest developments in legislation and regulation, and tactical plans developed by the Power System. This 2012 IRP also includes updated assumptions that have influenced the composition of potential resource portfolios that can fulfill LADWP's goals of reliability, competitive rates, and environmental stewardship.

The coal cases analyzed in this 2012 IRP consider different replacement dates for LADWP's two coal resources – the Navajo Generating Station (NGS), and the Intermountain Power Project (IPP). The coal replacement dates for Cases 1, 2 and 3 are similar to the cases analyzed in last year's 2011 IRP. The replacement date of December 2023 for IPP (Case 4) is new for this year.

In addition to the coal cases, this 2012 IRP also analyzes four additional cases to consider higher levels of energy efficiency and solar distributed generation.

The assumptions used in the development of all cases have been updated to reflect recent changes in fuel pricing, renewable project cost estimates and renewable resource mix, and updated energy efficiency goals including 10 percent by 2020.

Section 3 of this IRP provides more information surrounding the development of the cases, including resource adequacy and net-short considerations. Table ES-2 provides a detailed description of each strategic case. For comparison purposes, the recommended case from last year's IRP is included in the table.

More detailed description of the assumptions used in developing these cases can be found in Appendix N.

AR0069892

Table ES-2. CANDIDATE RESOURCE PORTFOLIOS FOR 2012 IRP

COAL CASES

		GHG or SB1368 Compliance Date		2020	2010 thru 2020	2010 thru 2032	New Renewables Installed Capacity (MW) 2012 - 2020					New Renewables Installed Capacity (MW) 2012-2032

ENERGY EFFICIENCY AND DISTRIBUTED GENERATION CASES

		2020	2010 thru 2020	2010 thru 2032	New Renewables Installed Capacity (MW) 2012 - 2020					New Renewables Installed Capacity (MW) 2012-2032				
Case ID	Resource Strategy[1]	RPS Target	EE (Net GWh)	EE (Net GWh)	Geo / Biomass	Wind	Non-DG Solar	Dist. Solar	Generic	Geo / Biomass	Wind	Non-DG Solar	Dist. Solar	Generic
5 (Base Case)	Base EE , Base Solar DG	33%	2300	3500	242	0	887	337	39	283	54	915	496	114
6	Advanced EE, Base Solar DG	33%	2300	4000	242	0	887	337	39	283	0	915	496	114
7	Base EE, High Solar DG	33%	2300	3500	242	0	847	485	39	258	0	876	852	95
8	Advanced EE, High Solar DG	33%	2300	4000	242	0	847	485	39	258	0	876	852	0

[1]EE percentages are as follows:

	By 2020	By 2032
Base EE	10%	15.2%
Advanced EE	10%	17.4%

The feasibility of attaining EE levels greater than 10% are uncertain at this time, but will be addressed in the upcoming EE Potential Study to be completed in 2013.

AR0069893

7. Evaluation of Strategic Case Options

Key results for each model run were tabulated and compared against each other. Each strategy was compared on average incremental dollars per megawatt hour generation cost and the total million metric tons of CO_2 emissions. The selection of the best case for LADWP ratepayers hinges mainly upon the load forecast, price of fuel, and CO_2 emission levels. All cases meet the mandated RPS percentage targets and reliability standards. The analytics performed for this IRP examined the associated costs of each strategic case.

The key modeling results are summarized below:

7.1 CO_2 Emissions Considerations

Current GHG emissions levels are approximately 14.1 MMT which is 21 percent below 1990 levels due to the prior elimination of power from the Mojave and Colstrip coal plants, completed repowering of units at Haynes and Valley generating stations with cleaner gas-fired replacements, and increased renewable generation from 3% in 2003 to 20% of overall sales in 2010. Using Case 1 (Navajo divestiture in 2019, IPP replacement in 2027) as a baseline, early divestiture of Navajo in Cases 2, 3 and 4 results in approximately 7.2 MMT less GHG emissions between 2016 and 2019. For Case 3 (IPP replaced in 2020) there is an additional post-2020 cumulative reduction of 19.5 MMT. For Case 4, the post-2020 reduction is 9.3 MMT. These GHG emission reductions are shown below in Table ES-3 and Figure ES-2.

Table ES-3 GHG EMISSIONS REDUCTION LEVELS IN MMT

Case	Reduction 2016-19	Reduction 2020-27	Total Reduction 2016-27
1	Baseline	Baseline	Baseline
2	7.2	0.0	7.2
3	7.2	19.5	26.7
4	7.2	9.3	16.3

AR0069894

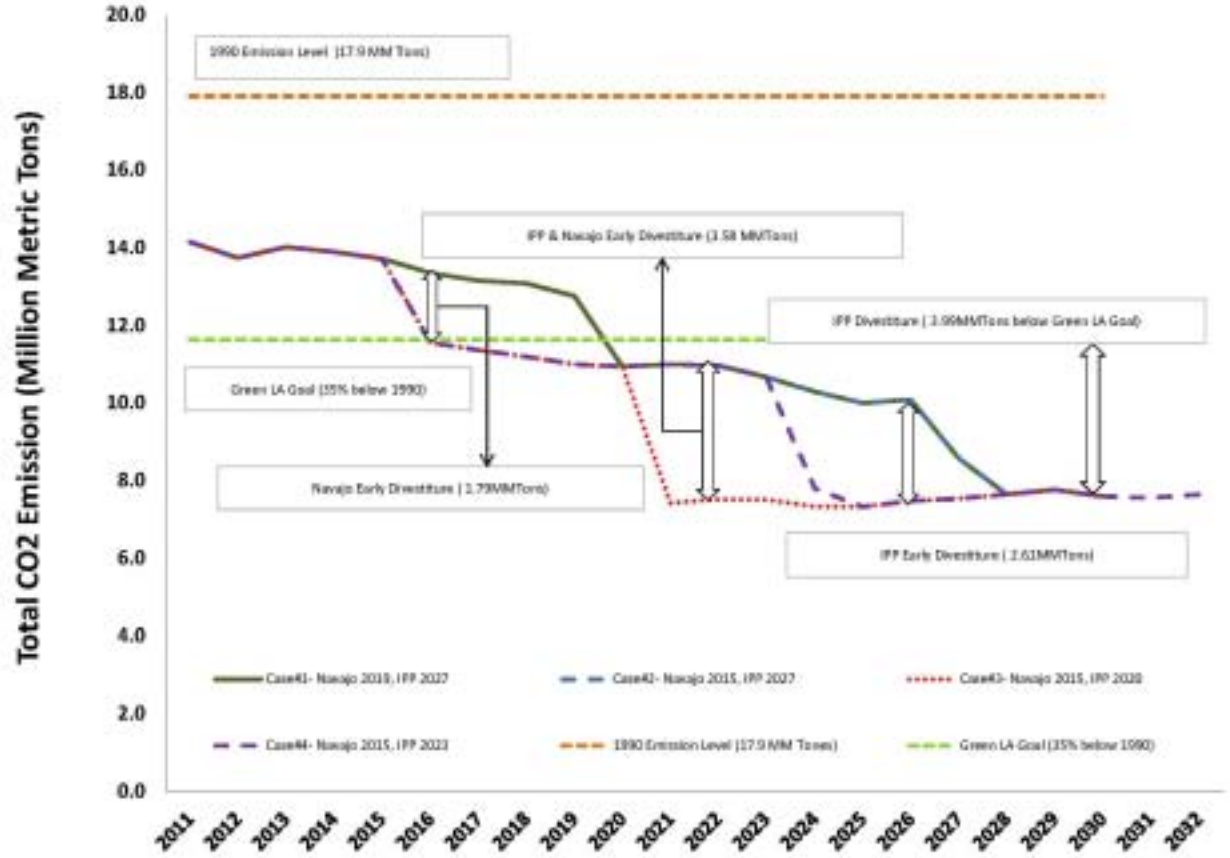

Figure ES-2. GHG emissions comparison by calendar year.

Emissions levels for energy efficiency and solar distributed generation, Cases 5 thru 8, were also evaluated and are shown in Figure ES-3. Advanced levels of EE were found to result in slightly lower emissions of CO_2 as compared to the Base EE cases. Higher levels of Solar DG were found to have little effect on reducing CO_2 emissions since Solar DG would have been replaced with other zero emissions resources. Although these higher levels of EE and distributed generation have a small impact on emissions compared to the base EE, it is important to note that the base level of energy efficiency in itself has a very significant impact on reducing overall CO_2 levels as shown by the "No More EE" curve illustrated in Figure ES-2. If no additional EE were implemented, annual GHG emissions levels would be approximately 2.0 MMT higher by 2032. This is equivalent to removing 385,000 cars from the road. For reference purposes, the CARB emissions allocation for LADWP as part of the AB 32 Cap and Trade program being implemented in 2013 and ending in 2020 is included in Figure ES-3.

AR0069895

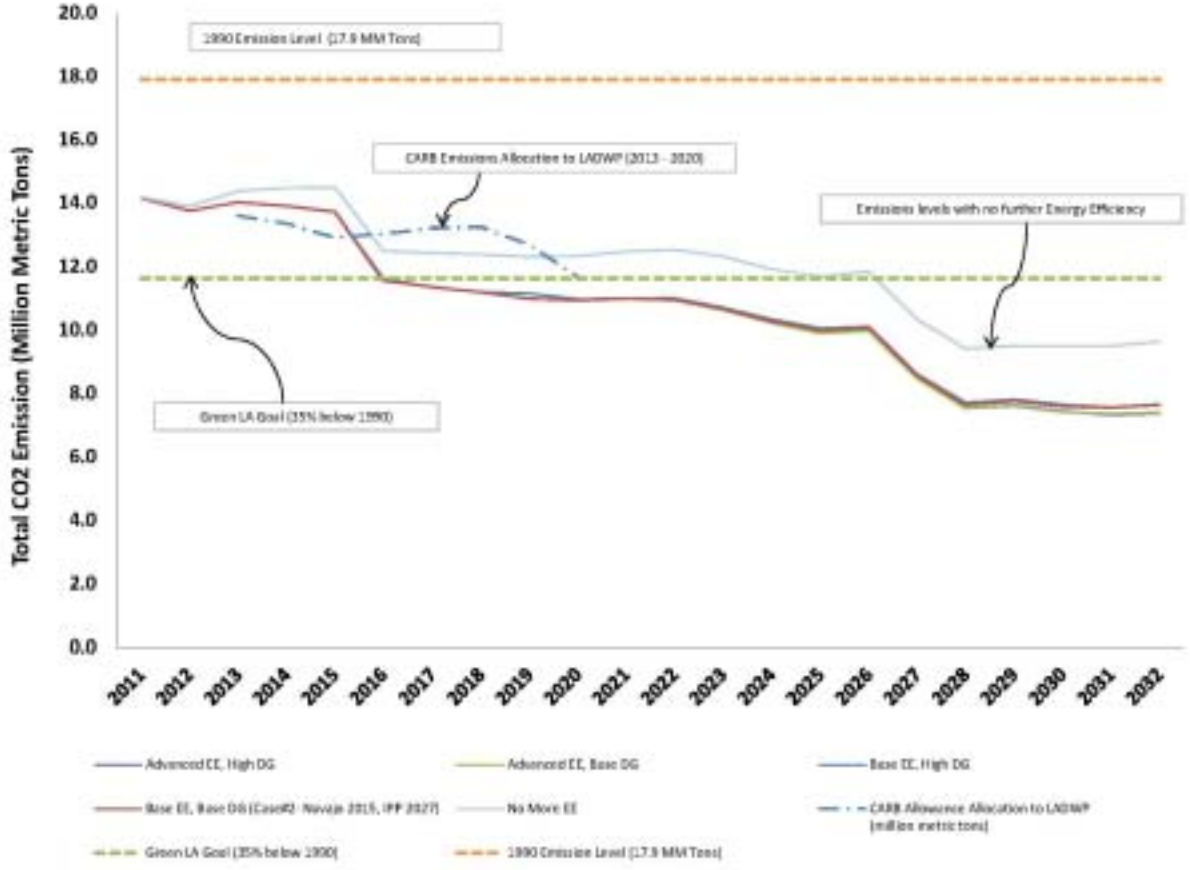

Figure ES-3. GHG emissions comparison for Energy Efficiency and Solar Distributed Generation cases by calendar year.

7.2 Total Power System Cost Comparisons

The total Power System cost for each case includes bulk power costs, depreciation costs related to transmission, distribution, and generation, bond debt-service, and city transfer costs[2]. These costs assume full funding of the Power System programs including the Power Reliability Program and Energy Efficiency programs among others. Total annual Power System costs are shown in Figure ES-4 and reflect short-term spending reductions through 2011-12 fiscal year with subsequent years reflecting a restoration of funding levels to ensure that the longer term IRP recommendations can be implemented. To the extent that energy efficiency costs are lower than the costs of generation it is replacing, its effect is to lower total costs. The costs shown in Figure ES-4 do not attempt to represent a thorough analysis of Power System finances, but they do illustrate the general trend of Power System costs relative to the 4 coal and 4 EE/DG cases analyzed.

[2] The city transfer payment is 8% of the previous year's operating revenue.

AR0069896

Note:
Unless otherwise stated, forecasted costs in all charts in this IRP are "nominal".

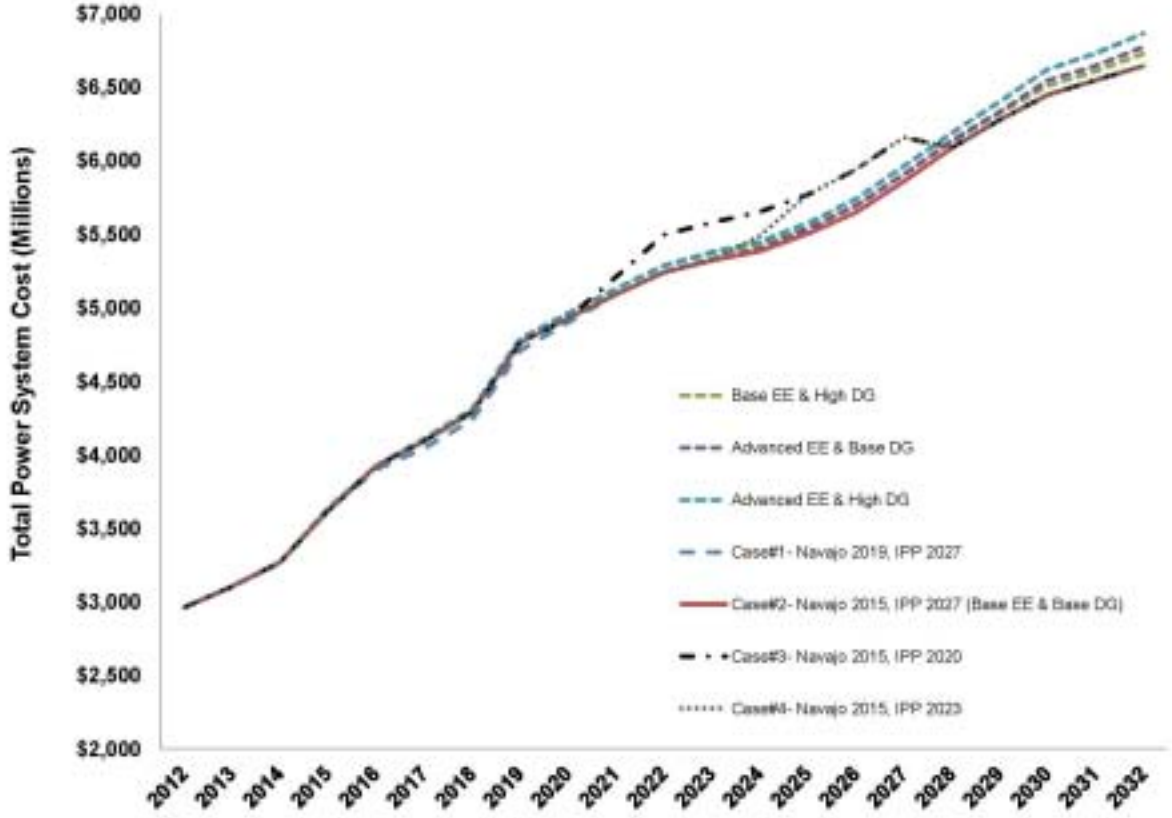

Figure ES-4. Comparison of annual Power System costs over the next 20 fiscal years.

The cost differences between the cases are highlighted in Table ES-4, which presents the incremental costs of the 4 coal cases and the 4 EE/DG cases. For the coal cases, the values listed under the Case 2 column represent the incremental costs between Cases 1 and 2 – i.e., the cost of early divestment of Navajo. The values listed under Case 3 and Case 4 represent the additional incremental costs of early IPP replacement in 2020 and 2023, respectively.

All EE & DG cases assume Navajo divestment in 2015 and IPP replaced in 2027. The values shown for Cases 6, 7, and 8 represent each case's incremental costs when compared to Case 5.

AR0069897

TABLE ES-4 INCREMENTAL COST COMPARISONS BETWEEN CASES

Coal Case Summary

	Case 1	Case 2	Case 3	Case 4
Case Description	Navajo 2019, IPP 2027	Navajo 2015	IPP 2020	IPP 2023
Total Incremental Revenue $M	$0	$205	$1,790	$980
Average Incremental Revenue ($M/yr)	$0	$51	$275	$280

EE & DG Case Summary

	Case 5 (Baseline) *	Case 6	Case 7	Case 8
Case Description	Base EE & Base DG	Base EE & High DG	Advanced EE & Base DG	Advanced EE & High DG
Total Incremental Revenue $M	$0	$669	$494	$1,247
Average Incremental Revenue ($M/yr)	$0	$32	$24	$59

7.3 Sensitivity Analyses

An analysis of the effects of fuel price volatility was performed for the four coal cases and is shown in Figure ES-5. With the early divestiture of Navajo in 2015 and the IPP coal contract ending in June 2027, increased bulk power costs are expected with the replacement of each of these resources.

Elimination of coal involves the switch to more natural gas generation, which has higher fuel price volatility compared to coal. The resulting decrease in fuel diversity, along with the higher volatility of natural gas, will increase the risk of fuel cost changes in the future and so warrants careful evaluation when comparing the different case scenarios.

It is important to note that bulk power costs shown in Figure ES-5 include fuel, renewable and other purchase power costs in addition to coal replacement costs. After applying high and low fuel prices to these bulk power costs, the replacement of these resources could result in large cost increases should fuel prices remain at higher than expected levels. Conversely, lower than expected fuel prices could have the opposite effect on bulk power costs.

To help manage natural gas fuel price volatility, LADWP employs financial hedges for up to ten years, and physical hedges for up to five years. LADWP is in the process of developing a revised hedging strategy based on the newly approved rate ordinance.

AR0069898

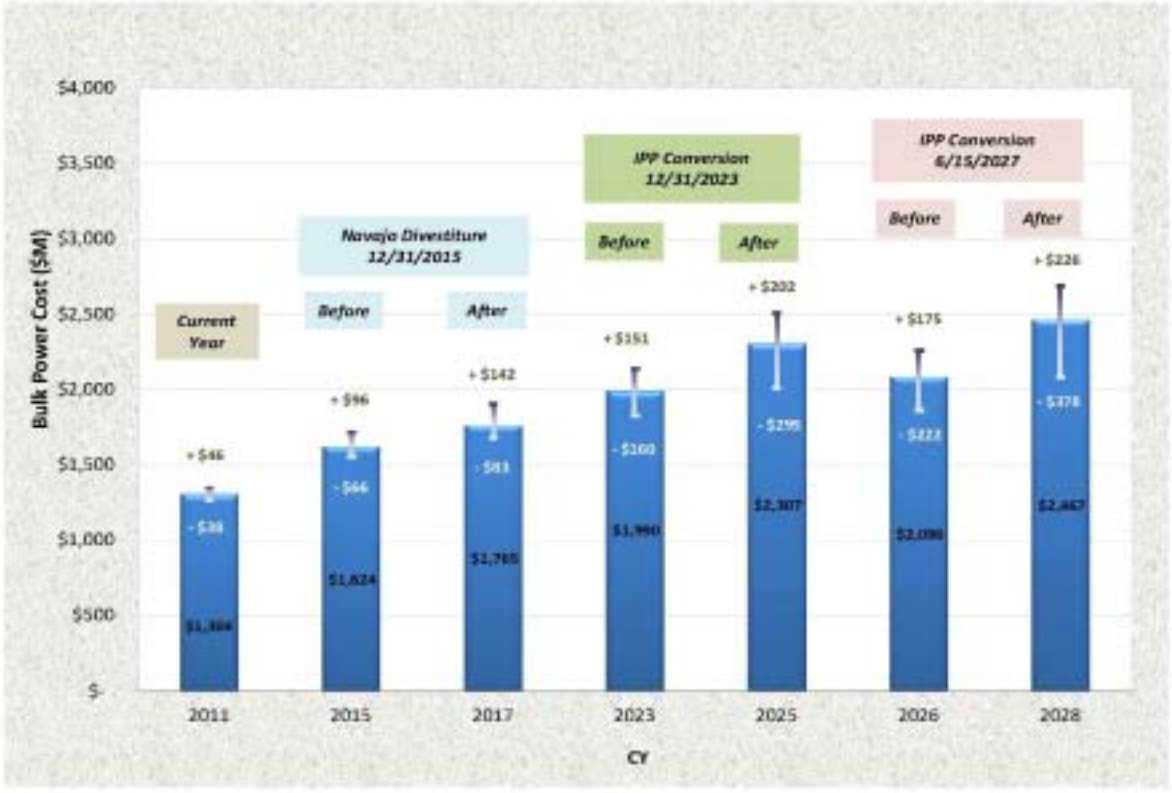

Figure ES-5. Bulk power cost before and after coal replacement with potential cost impacts from high (+$) and low (-$) fuel prices.

Increased risk exposure from high fuel costs may translate into higher customer electric rates. Figure ES-6 shows the potential rates that could be experienced under the 4 coal cases given high, expected, and low fuel ranges for both gas and coal fuel types. Today, overall coal costs represent approximately 65 percent of overall fuel expenditures. Once Navajo coal is replaced in 2015, this percentage will drop to 50 percent of overall fuel expenditures. From 2023 thru 2026, coal expenditures will gradually drop to 30 percent before reaching zero percent in 2027 when IPP coal is replaced, and future fuel price increases will be based solely on natural gas and nuclear.

AR0069899

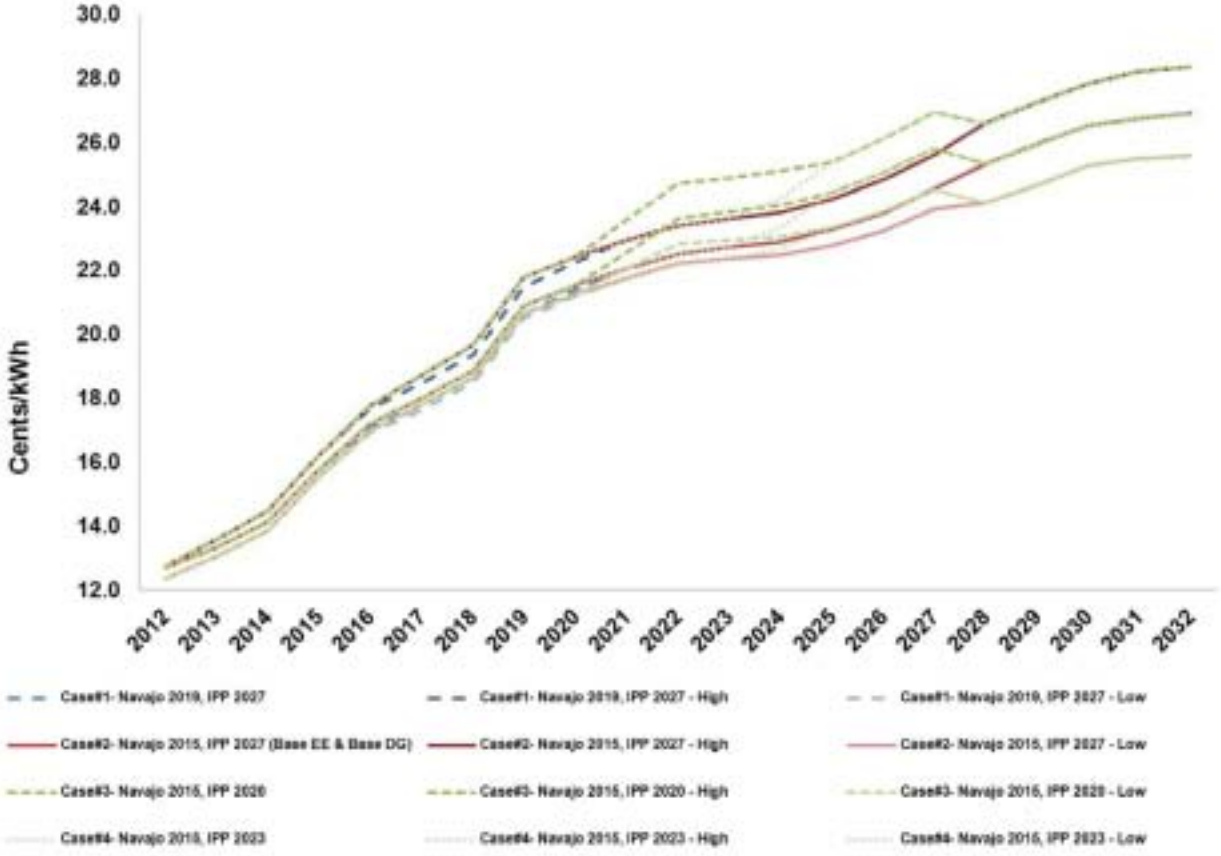

Figure ES-6. Estimated electric rate comparison with fuel price sensitivity over 20 years by fiscal year-ending

AR0069900

7.4 Rate Contributions Breakdown

Figure ES-7 presents the fiscal year breakdown for Case 5 comprising rate contributions from reliability, energy efficiency, renewable energy, reliability, coal replacement, OTC repowering, other Generation, Transmission and Distribution (GT&D), and fuel costs between 2012 and 2032. These individual contributions represent incremental adders to the rates. For analysis purposes, the Reliability Program has been segmented into the basic program and preferred program. The preferred program contribution shown is incremental to the basic program.

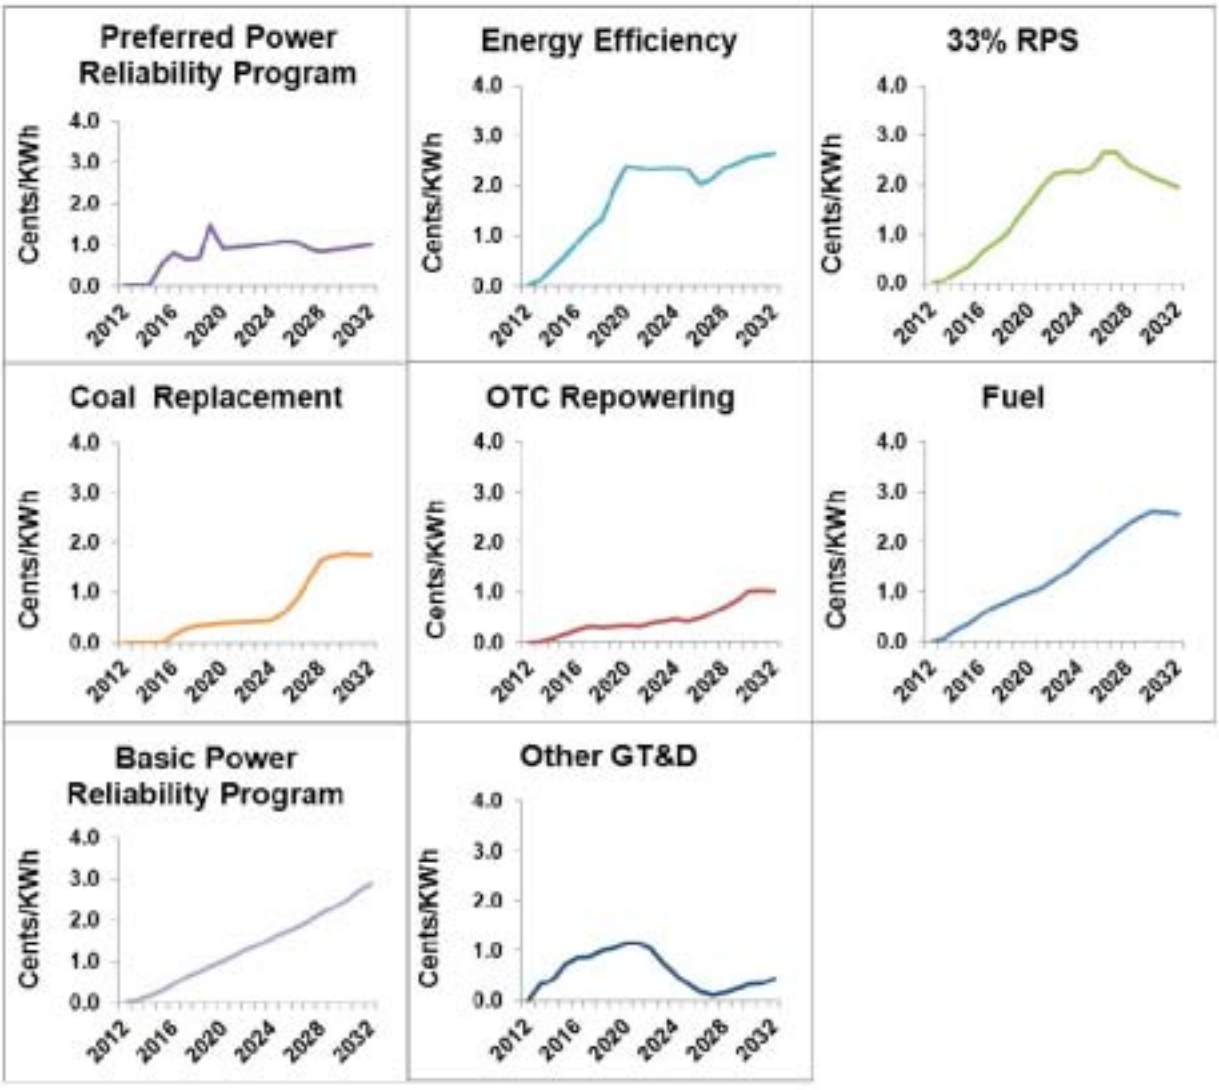

Figure ES-7. Retail electric rate contributions breakdown, based on the 2012-13 budget forecast (Case 5).

AR0069901

Figure ES-8 shows the total retail rate impact after combining all of the program components. One can draw the conclusion that rising fuel costs and complying with various regulatory requirements are the primary drivers of the growth in rates.

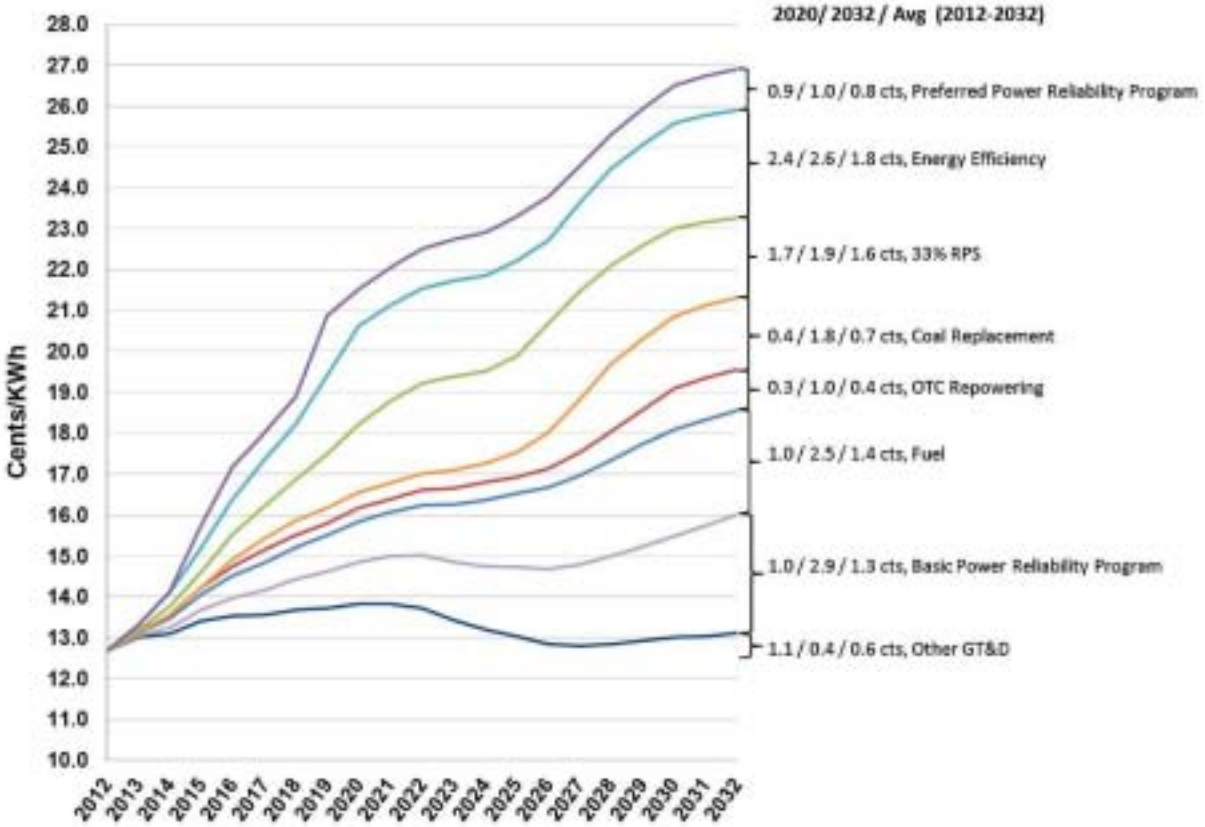

Figure ES-8. Total retail electric rate composite by fiscal year, based on the 2012-13 budget forecast (Case 5).

A few observations from Figures ES-7 and ES-8[3] can be made regarding the RPS and EE programs. Firstly, the influence of the RPS program on rates increases substantially through 2020 after the RPS percentage of sales reaches 33% and the RPS component of rates begins to decline as fuel savings increases over time with escalating fuel prices. In 2027, the RPS component of rates increases as new renewable projects are added to replace expiring PPA agreements and then the RPS component of rates resumes a downward trend due to fuel savings. Secondly, the EE program component of rates increases over time as program incentive payments and net revenue loss attributable to the EE program are recovered. Like RPS, EE has

[3] Figures ES-7 and ES-8 represent forecasted rate increases based on system averages, and do not account for rate structure variations across and within customer classes.

AR0069902

savings beyond 2020 due to fuel savings. Thirdly, general inflation in fuel costs and GT&D costs represents a significant growth in rates.

Preferred levels of funding for the Power Reliability Program (PRP) include capital and O&M expenditures to replace over age distribution and transmission system components that have exceeded their life expectancy and ensure levels of funding to reduce the backlog of "fix-it" tickets which are temporary repairs that need to be corrected. The spikes in the preferred PRP and EE curve occurs when capital borrowing limits are reached around 2019-20 and cash is needed to fund capital expenses. This quickly subsides as the capacity to borrow resumes shortly thereafter.

The GT&D component of rates rises in the early years because of general inflationary pressure. After 2023 when the IPP debt is fully paid, the GT&D component of rates lowers slightly and goes slightly negative until IPP is replaced with new gas-fired generation and then resumes the familiar inflationary path.

Figures ES-9 and ES-10[*] further illustrate the impact to average residential and commercial/industrial customer monthly bills from these environmental and reliability programs. To show the potential effect of energy efficiency on customer bills, the dashed lines on these figures represents what a total monthly bill would amount to after implementing energy efficiency measures that result in a 14% savings. While LADWP's overall energy efficiency program is evolving and much will depend on the new potential study to be conducted in 2013, these figures illustrate what may reasonably be achievable by customers who have not already implemented significant energy efficiency measures to reduce their electricity consumption.

[*] Figures ES-9 and ES-10 are general representations only and do not account for rate structure variations across and within customer classes such as the effect of tiered rates, minimum charges, time-of-use, etc. The figures provide an indication of the relative contributions of the individual program areas toward a typical monthly bill.

AR0069903

AR0069905

8. Recommendations

8.1 Strategic Overview

LADWP's recommended strategy set forth in this IRP for meeting its key objectives can be separated into two areas: (1) Regulatory and Reliability Initiatives, and (2) Strategic Initiatives. Regulatory and Reliability Initiatives are required actions to ensure system reliability and compliance with regulatory and legislative mandates. Strategic Initiatives are policy actions to achieve objectives established by the LADWP Board of Water and Power Commissioners and the Los Angeles City Council, and reflect their vision and leadership. These policies include, for example, energy efficiency targets, social and economic development goals, early compliance with SB 1368, and investing in local solar distributed generation.

Regulatory and Reliability Initiatives

- RPS

  LADWP must increase its percentage of renewable energy per recently enacted state law, from the current 20 percent, to 33 percent by the end of 2020. SB 2 (1X) also establishes interim targets to ensure progress towards the 33 percent goal. In addressing this mandate, it is important that LADWP expand its renewable portfolio in the most cost-effective manner as possible. As two subsets of the RPS program, SB 1 requires $313 Million of expenditures towards solar incentives (Customer Net Metered), and SB 32 mandates a Feed in Tariff program of 75 MW (although LADWP by choice will exceed this mandate and provide 150 MW by 2016).

- Power Reliability Program (PRP) and System Infrastructure Investment

  To ensure system reliability, LADWP must re-establish sustained funding to invest in replacing transmission and distribution infrastructure that are contributing to outages. Recent funding shortfalls have resulted in an increase in the frequency and duration of system outages. Section 1.6.3 of this IRP discusses the importance of fully funding the Power Reliability Program (PRP). As discussed in Section 2.4.6, the PRP will also increase the resiliency of the distribution infrastructure to better withstand the higher future wear-and-tear effects that are expected due to climate change.

- Re-powering for Reliability and to Address OTC

  LADWP will continue to re-power older, gas-fired generating units at its coastal generating station for the reasons discussed in Section 2.4.2. The repowering program is a long-term series of projects through 2029 that will increase generation reliability and efficiency, reduce NO_X emissions, and eliminate the need for once-through ocean water cooling.

AR0069906

- AB 32 – GHG Cap and Trade

  LADWP will participate in the mandated greenhouse cap-and-trade system which is scheduled to start January 1, 2013. LADWP has been granted an administrative allocation of emission allowances that reflects its resource projections through 2020. At this time, it is uncertain if the program will extend beyond 2020 and if so, what LADWP obligations would be.

- Energy Efficiency (EE)

  LADWP will continue to pursue and implement EE programs per AB 2021 standards and as directed by the Board of Water and Power Commissioners, who have adopted a goal of achieving 10 percent EE by 2020, with a target of up to 15% by 2030 pending the results of an upcoming new EE Potential Study. The Base EE cases evaluated in this 2012 IRP have all incorporated 10% EE by year 2020, with higher levels of up to 15% by 2032. Next year's IRP will incorporate the findings and recommendations of the potential study as they are finalized and approved.

- SB 1368 Compliance

  LADWP's two coal fired generation sources, the Navajo Generating Station (NGS), and the Intermountain Power Project (IPP), must be compliant with the mandates established in SB 1368 by 2019 and 2027, respectively. IRP modeling determined that these units will be replaced earlier with a combination of renewable energy, demand response, EE, short term market purchases, and conventional gas-fired generation.

- Energy Storage

  Per AB 2514, LADWP is investigating Energy Storage (ES) technologies and will establish targets for implementation by October 1, 2014. LADWP will look for programs and projects that support its unique electric grid, resource plan, and projects that will facilitate renewable integration, distributed generation and demand response. As these projects are identified and scoped, they will be incorporated into and analyzed in future IRPs. See Section 2.4.5 for more information.

- Castaic FERC Re-licensing Program

  On January 31, 2022, the Federal Energy Regulatory Commission's (FERC) license to operate Castaic Pumped-storage Hydroelectric Plant will expire. The license is a co-license between LADWP and the Department of Water Resources and includes a number of hydro power plants along the California Aqueduct. Both parties have initiated the joint re-licensing process that, on average, requires ten years to complete. Through 2015, LADWP expects to complete preliminary studies, contract negotiations, and prepare a new application strategy. In 2016, LADWP expects to file a notice-of-intent (NOI) and initiate the formal studies and applications.

AR0069907

- Transmission

  LADWP's Ten-Year Transmission Plan is prepared each year to ensure that LADWP remains compliant with NERC Transmission Planning Standards. The planning process involves complex modeling of the LADWP system, and concludes with findings and recommendations to maintain operational flexibility and avoid potential future overload conditions. LADWP will continue to implement the recommended projects, including construction of a new transmission line between Scattergood Generating Station and Receiving Station K, and upgrades at various other receiving and switching stations.

Strategic Initiatives

- Early Compliance with SB 1368

  Regarding the Navajo Generating Station (NGS), while power imports can legally continue until 2019, LADWP recommends divestiture from NGS four years earlier, in 2015. There are many strategic advantages to early divestiture, including:

  1. Better sales terms and conditions than waiting until the 2019 deadline.
  2. Avoiding the risk of pending federal regulations that could potentially encumber the plant with expensive mitigation requirements.
  3. Better availability and pricing for replacement generation (including existing plants), and lower fuel costs.
  4. Reduced CO_2 emissions, alleviating LADWP from subsequently having to purchase emission credits for native load.
  5. Transmission network for importing additional solar and geothermal resources becomes available.
  6. Low load growth and increased renewable energy place less reliance on the plant for energy.
  7. Provides time to handle contingencies, and to ensure that competition for replacement resources is going to benefit our ratepayers.

  Regarding the Intermountain Power Project (IPP), LADWP recommends modeling and planning to be compliant with SB 1368 by 2027. However, LADWP, the Intermountain Power Agency (IPA), and the other 36 participants are considering the conversion of IPP from coal to natural gas. A new contractual arrangement is in process, which will establish a firm conversion date that will be no later than, and possibly sooner, than 2027. Until a firm conversion date is established and for analysis purposes, Case 4 was developed for this IRP which has IPP coal replacement in 2023. Once a firm date is determined, it will be incorporated into the IRP base case model runs.

  Strategically, it is important for LADWP to remain a participant at IPP to retain geographic diversity in its resource mix, access the regional fuel supply, and retain the project's transmission lines to access renewable energy from the region.

AR0069908

- Local Solar

  Comments received at prior public workshops indicate local solar development should be a priority in LADWP's renewables procurement strategy. LADWP is recommending a policy action to allow 340 MW of its solar resources be sited locally by 2016, through initiatives including the Solar Incentive Program, feed-in tariffs, and installation of solar on City-owned properties.

- Demand Response

  LADWP should accelerate its evaluation and implementation of Demand Response programs that will initially provide 5 MW of new peak demand capacity beginning in 2013 and gradually build to 200 MW by 2020 and 500 MW by 2026. Ramping the program in this manner will promote the development of in-house expertise, and will also allow time to deploy the supporting information systems necessary to implement these systems successfully.

- Advanced Technologies/Research and Development

  LADWP is looking ahead to technologies that will enhance the reliability of its system including smart grid, energy storage, enhanced information and management systems, automation of system functions, advanced methods of outage management, and weather forecasting. These system enhancements will increase reliability, facilitate the integration of local solar generation and other variable renewable resources into the distribution network, enable smart charging of electric vehicles, and advanced demand-side management technologies. LADWP should continue to pursue grants, cost sharing opportunities, and joint projects that promote the use and deployment of new technologies that meet its strategic goals.

- Provide Sufficient Generation

  Provide sufficient generation, demand response, and limited short term purchases in peak season Q3 to cover operating and replacement reserves in accordance to applicable federal and regional reliability requirements.

- Control of Transmission Assets

  In addition to the regulatory requirement to remain compliant with NERC Transmission Planning Standards, LADWP will maintain its policy of maintaining control of its transmission assets and continue to augment those assets commensurate with load growth, reliability needs, and renewable energy opportunities.

AR0069909

- Collaborate with Water System

  The LADWP Power System will continue to work with the Water System to develop programs that reduce the usage of electricity and conserve water, as well as optimizing hydroelectric energy production.

- Financial Targets

  To preserve and maintain its credit rating, the following financial targets have been adopted:
  - Maintain debt service coverage at 2.25 times
  - Minimum operating cash target of $300 million
  - Debt-to-capitalization ratio less than 68 percent

8.2 Recommended Strategic Case

Achieving the goals of reliability and environmental stewardship, while maintaining competitive rates, requires that costs be closely managed. Considering these factors, Case 5 with early Navajo coal divestiture in 2015, Base EE and Base DG with additional local solar Feed in Tarrif (FiT) DG becomes the Recommended Case for the 2012 IRP. Whereas Case 5 has 75 MW of local solar FiT by 2016, the new recommendation is to adopt an additional 75 MW for a total of 150 MW by 2016 based on input that was received from the public outreach efforts. The increase in cost for the additional 75 MW of FiT is an average of 0.018 cents/kWh or a 9 cent increase in the typical residential monthly bill (500 kWh/month). Although Case 5 with the added FiT represents additional cost as compared to the 2011 Recommended Case, the additional costs to rate payers appears to be reasonable in light of the benefits of job growth and support of the local economy from adopting higher levels of DG solar. As described in the 2011 IRP, the environmental benefits of reducing GHG emissions by 7.2 MMT are still present with the early Navajo replacement. The cost to implement Navajo divestiture in terms of metric tons of GHG removed is $28/MMT. This represents a reasonable cost in line with the range of expected AB 32 cap and trade allowance prices. Other benefits of early Navajo divestiture include a better sales price than waiting until 2019, and better availability (lower costs) of replacement energy. With Case 5 and the noted addition of FiT and Navajo divestiture in place, LADWP can begin to focus its attention on early replacement of IPP coal generation, prior to 2027, by working with the other power purchasers and the IPP plant owner.

The 2011 IRP included the same recommendation to accelerate divestiture of Navajo and this 2012 IRP further clarifies and supports this prior recommendation. This 2012 IRP recommended case presents a reasonable approach to achieving environmental goals and promoting job growth in the local economy without excessive costs to our ratepayers while limiting potential exposure to possible fuel price volatility to within manageable limits.

AR0069910

Table ES-5. 2012 IRP RECOMMENDED CASE

	2020	SB 1368 Compliance Date		New Renewables Installed (MW) 2012-2020				New Renewables Installed (MW) 2012-2032				
Case ID	RPS Target	Navajo End Date	IPP End Date	Geo/ Biomass	Non-DG Solar	Dist. Solar	Generic	Geo/ Biomass	Wind	Non-DG Solar	Dist. Solar	Generic
Case 5	33%	12/31/2015	6/15/2027	242	842	382	39	283	54	915	496	114

Figure ES-11 illustrates the changing generation resource percentages for 2010, 2020, and 2030 based on the Recommended Case. Because energy efficiency forecasts are forward-looking, the savings of 1,256 GWh or 5.5 percent of sales that was implemented between 2000 and 2010 are embedded into the load forecast and are not included as part of the generation resource mix shown below.

AR0069911

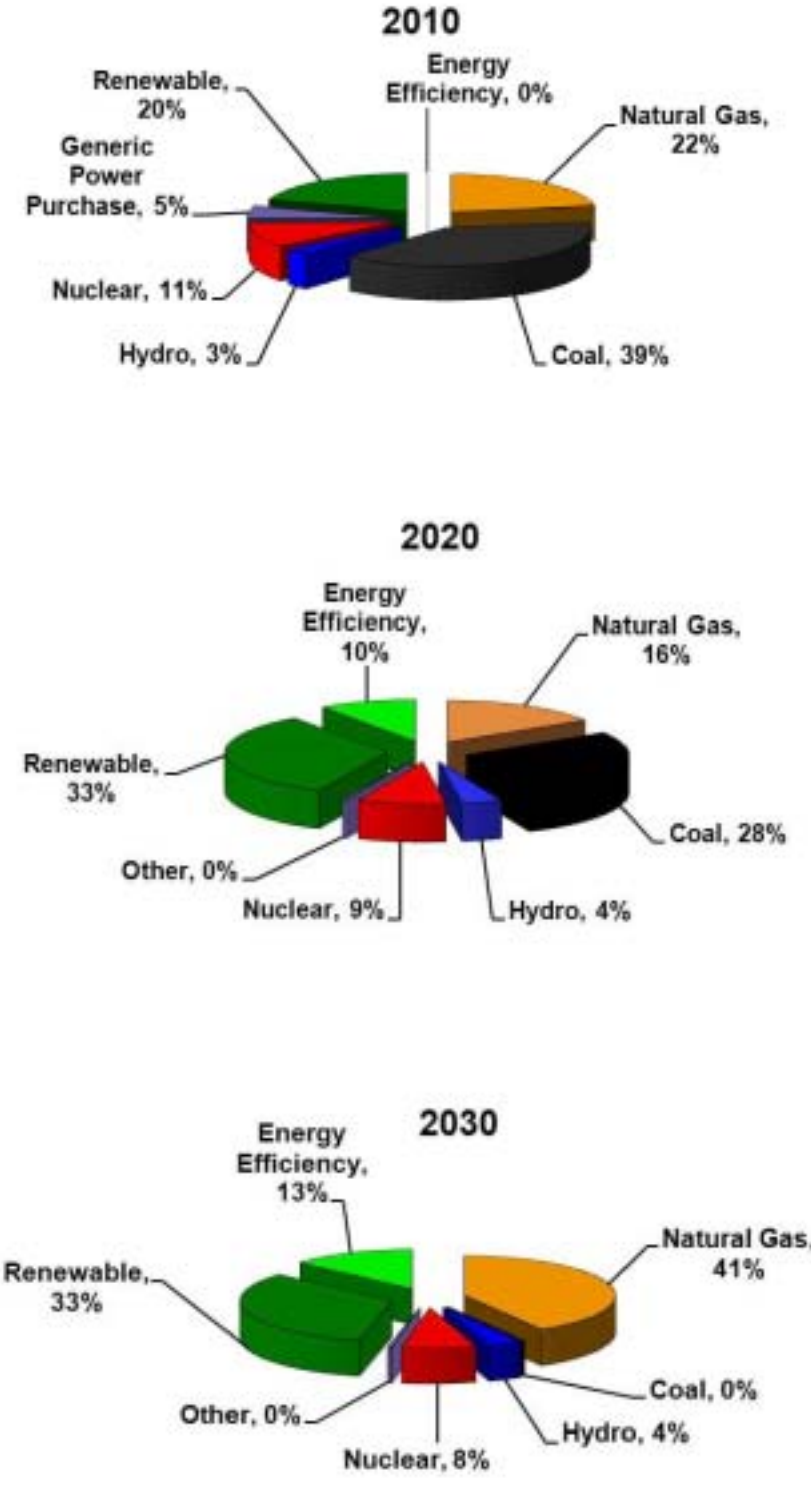

Figure ES-11. Recommended case generation resource percentages for 2010, 2020, and 2030.

AR0069912

Figure ES-12 shows the breakdown of renewable generation by technology, and Figure ES-13 illustrates the dependable capacity mix for the recommended case.

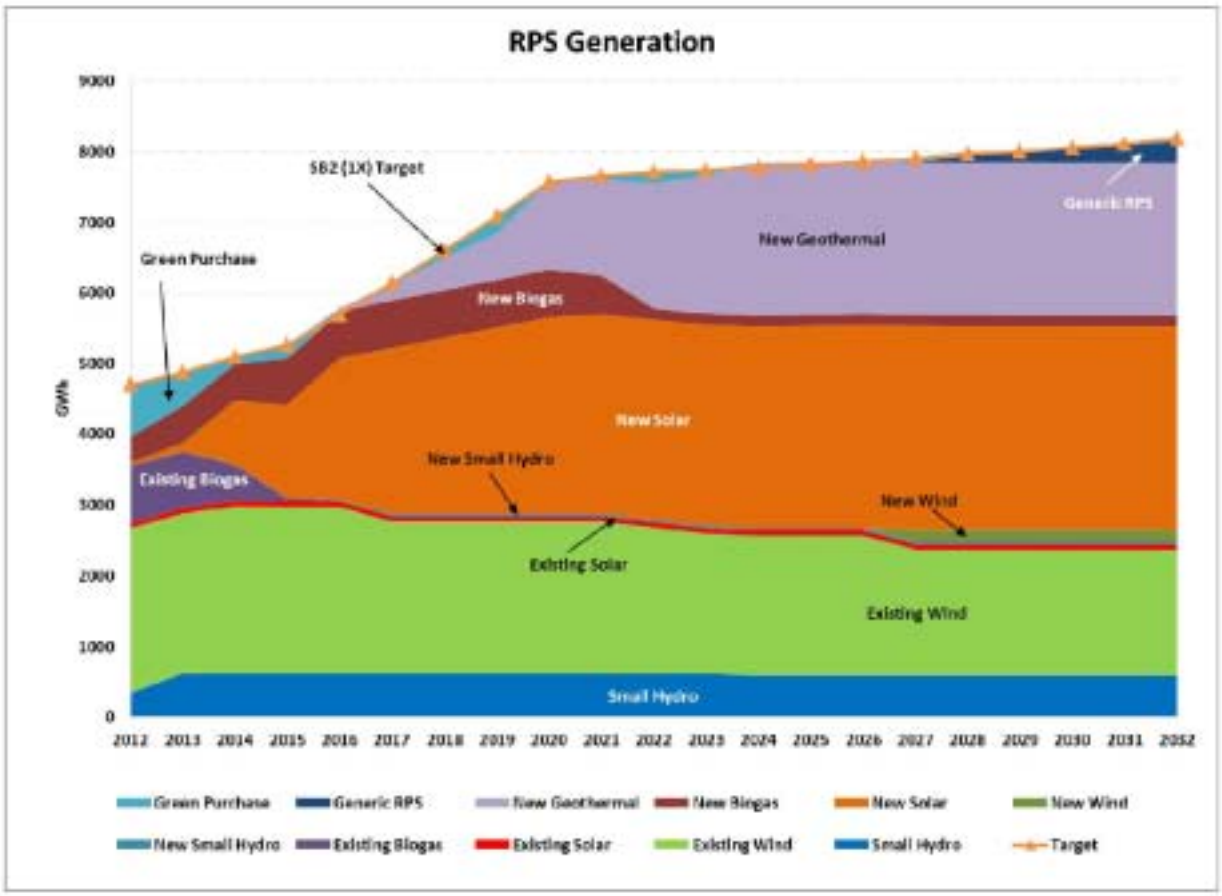

Figure ES-12. Recommended case renewable generation by technology.

AR0069913

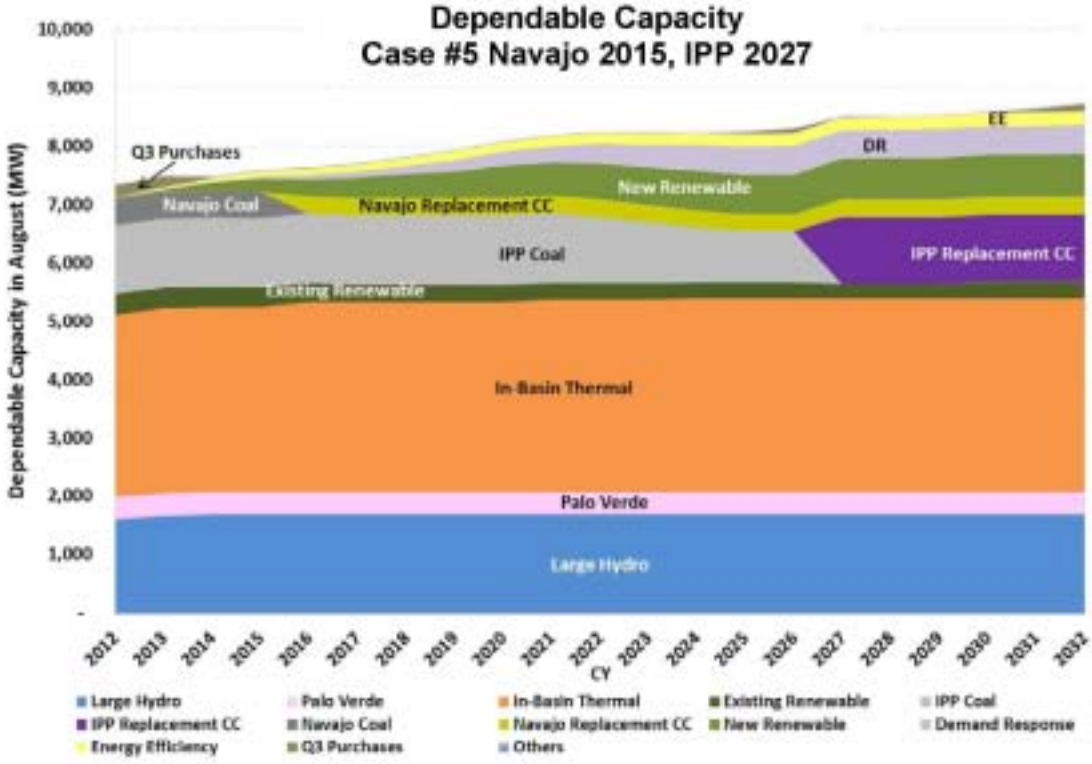

Figure ES-13. Dependable capacity profile, recommended case.

Because the analysis and conclusions are dependent on a number of assumptions, LADWP will constantly refresh its analysis as new IRPs are developed in future years.

8.3 Recommended Near Term Actions

Except for early Navajo divestiture, the actions needed to be taken by LADWP in the next two to four years are very similar no matter what resource strategy is chosen. Based on the strategic requirements presented earlier and projected resource procurement needs, the following actions are recommended to be taken in the near-term:

1. Proceed with re-powering plans for generation units at the Haynes and Scattergood Generating Stations, and pre-development plans for the Harbor Generating Station.
2. Continue to investigate the technical and contractual options for coal-fired generation to be compliant with SB 1368.
3. Divest from the Navajo Coal Plant by 2015.

AR0069914

4 Continue the implementation of existing energy efficiency efforts, in anticipation of an expanded program pending the results of a new energy efficiency potential study to be conducted in 2013

5 Continue to implement the Power Reliability Program (PRP) to replace aging infrastructure components. Develop electric modeling capability to better define the necessary investments and to prioritize the expenditures

6 Develop/update a sustainable workforce development plan that addresses staffing needs, skill set identification for new and evolving work areas, training/professional development, application of new technologies, and recruitment strategy

7 Implement recommendations contained in the Ten-Year Transmission Assessment Plan

8 Develop a Demand Response Program to initially provide 5 MW of new peak load reduction capability by 2013 which will ramp up incrementally to 200 MW by 2020 and 500 MW by 2026

9 Implement renewable strategies for geothermal, biogas, solar, and wind resources to ensure increasing levels of renewable procurement in accordance with SB 2 (1X). Sign Power Purchase Agreements for an additional 300-400 MW of cost effective renewable energy projects by 2014

10. Complete a comprehensive study of issues associated with integrating increasing amounts of variable energy resources such as wind and solar to reflect possible megawatt limits for the LADWP electric Power System

11 Develop and incorporate strategies to
   a Fully utilize existing transmission assets.
   b Locate renewables as close as practical to the load center to reduce transmission losses.
   c Preserve existing brown field sites to be repurposed for renewable or natural gas generation.
   d Incorporate the concept of O&M cluster zones[5] to maximize operational efficiencies.
   e Assess and develop necessary transmission facilities to deliver electricity generated from new facilities.

12 Develop a renewable energy feed-in tariff program to encourage 150 MW of renewable generation resources to be developed by 2016

13 Encourage the development of an additional 50 MW of customer net-metered solar projects before 2015

14. Develop up to 30 MW of solar capacity on existing properties under public/private partnership projects before 2015

15. Investigate the use of term physical gas supply arrangements, either with contracts for physical supplies or futures contracts to limit LADWP's exposure to volatile gas prices. Evaluate and potentially implement any recommendations in the Fuel Hedging Plan.

16 Investigate and develop energy storage targets by October 1, 2014, per AB 2514

[5] Clustering renewable projects in relative proximity with decrease O&M expenditures due to economies of scales and personnel efficiencies. This would need to be balanced with the need for geographic diversity.

AR0069915

17 Refine and implement a Smart Grid strategy that can assist in the procurement and development of advanced technologies to support areas such as weather forecasting/ energy scheduling, customer kWh metering, high speed communications and information systems, and energy storage systems. Deployment of these technologies will increase operational efficiency, help reduce system losses, improve outage response times, increase utilization of predictive/proactive maintenance techniques for improved grid reliability, enable better management of the Power System, and lower costs.

1.0 INTRODUCTION

1.1 Overview of the 2012 Integrated Resource Plan

This document represents the Los Angeles Department of Water and Power (LADWP) Integrated Resource Plan (IRP) for 2012. The goal of this IRP is to identify a portfolio of generation resources and Power System assets that meets the city's future energy needs at the lowest cost and risk consistent with LADWP's environmental priorities and reliability standards. The IRP is an important planning document for electric utilities, and many states and regulatory agencies require development of an IRP prior to approval of procurement programs or electric rate increases.

This document goes beyond traditional integrated resource planning and incorporates additional Power System planning elements to form a comprehensive Power System plan. It is intended that this Power System plan will drive the priorities, financial planning, and budgeting effort for the Power System.

This IRP considers a 20-year planning horizon to guide LADWP as it executes major new and replacement projects and programs. The overriding purpose is to provide a framework to assure the future energy needs of LADWP customers are met in a manner that balances the key objectives of:

- Superior reliability and supply of electric service
- Competitive electric rates consistent with sound business principles
- Responsible environmental stewardship exceeding all regulatory obligations

In balancing these key objectives, LADWP's strategic planning efforts must ensure a high level of system reliability, consider impacts to the local and regional economy, mitigate the volatility in fuel and other cost factors, comply with federal, state, and local regulations, and guarantee fiscal responsibility.

LADWP is the largest municipal utility in the nation, and the third largest utility in California. While numerous recent accomplishments have been made – including achieving 20% of renewable energy sales in 2010 – significant challenges lie ahead. Increasing renewable energy to 33% by 2020, the continued rebuilding of coastal generation units, replacement of coal, infrastructure reliability investments, and ramping up energy efficiency and other demand side programs are all critical and concurrent strategic actions that LADWP will have to carry out over the coming decade.

The 2012 integrated resource planning process developed alternative strategic cases that assess different replacement options for coal-fired generation, as well as different projected levels of energy efficiency and distributed generation. The cases are modeled to determine their respective operational and fiscal impacts, as well as their effects on greenhouse gas emission levels. This document presents the results of this analysis and recommends the appropriate near-term actions and long-term plan to best meet the future electrical needs of Los Angeles.

AR0069922

LADWP Power System Vision

The transformation that this utility will undergo in the next 20 years will be unprecedented as the use of electricity broadens to new applications and as customer expectations of clean affordable energy continues to take root. Increases in electric vehicle use, expanded electrification of processes to reduce emissions and greenhouse gases, and growing wide-spread use of information technology equipment will require a stable, resilient power grid that delivers affordable power. By adopting energy efficiency, promoting solar rooftop and supporting other clean technologies that mitigate the need to build new fossil-fueled power plants, our customers are embracing the vision of a greener resource portfolio that sustains the environment for future generations.

LADWP and its City Leaders have traditionally taken a leadership position, particularly among public power utilities, to ensure a sustainable, diverse supply of generation and transmission resources to provide electricity to our customers. This utility has also been very progressive in adopting aggressive clean energy goals and programs well before many of today's laws and regulations were in place, and participated in the development of many of the laws and regulations that we see today. In 2000, this utility set out to reduce load growth by 50 percent through the use of renewables, energy efficiency, and distributed generation. Today we have the same electricity consumption as we had in 2000 largely due to these earlier efforts. In 2005, we adopted a renewable target of 20 percent renewable by 2010, and we succeeded to be the largest California utility to achieve 20 percent renewable generation in 2010. Since 1990, we have divested of 2 coal plants and repowered several natural gas in-basin generating stations using cleaner and more efficient new combustion technology, resulting in 21 percent lower greenhouse gas emissions and over 80 percent lower NOx emissions. Reducing ocean water use and reducing the impact on marine life has also been an on-going effort and by next year we will use 42% less ocean water from 1990 levels, with total elimination targeted by 2029.

The world today is not the same as it was 20 years ago, and the world 20 years from now will not be the same as it is today. And while LADWP's mission of providing reliable, affordable electricity in an environmentally responsible manner remains the same, the planning and execution of that mission requires continued diligence to account for, adopt, and even influence, the changing public concerns and priorities related to electricity generation and use.

AR0069923

1.1.1 Major Changes from Last Year's IRP

Major changes from last year's 2011 IRP include expanded discussion on the Power Reliability Program, more detailed information on transmission planning and projects, a new sub-section on the future impacts of climate change on power generation and operations, and new case options that analyze higher levels of Energy Efficiency (EE) and Distributed Solar Generation (Solar DG).

This 2012 IRP incorporates updates to reflect the latest load forecast, fuel price and projected renewable price forecasts, and other numerous modeling assumptions. Compared to the prior forecast, projected electricity sales in calendar year 2020 decreased by 3.4 percent, mostly due to increased levels of energy efficiency. The new forecast reduces the overall need for renewable energy (assuming 33% RPS) by approximately 461 GWh in 2020 and 745 GWh in 2030.

Long term natural gas price forecasts have been revised downwards from last year with recent prices reaching very low levels over the last year. Compared to last year's 2011 IRP, Opal and SoCal expected gas prices are 16% lower on average in the short term (2011-2020) and 8-9% lower on average in the long term (2021-2030). Coal price forecasts are also lower, with IPP coal at 4% lower for the period 2012-2027, and Navajo coal at 14% lower for the period 2012-2018.

Other changes include lower cost assumptions for solar and geothermal, reflecting price competition for both resources, and updates regarding legislative and regulatory issues. See Section 3 and Appendix N for more details.

AR0069924

1.2 Organization of the IRP

This document is organized as follows:

- Section 1, "Introduction," presents an overview of the LADWP Power System, and the issues and challenges facing LADWP as it strives to secure a reliable supply of electricity for the next 20 years, at competitive rates, and in an environmentally responsible manner.
- Section 2, "Load Forecast and Resources," provides forecasts of electricity demand, discusses the resources available or needed to meet that demand, and addresses the issues associated with each resource and the Power System in general.
- Section 3, "Strategic Case Development," establishes potential alternatives (Cases) available to LADWP to meet its projected electricity demand, and considers varying levels of energy efficiency and solar distributed generation as well as different options for early replacement of coal fired generation.
- Section 4, "Strategic Case Analysis," addresses the operational modeling and the results used to assess the impact of each alternative on cost, energy rates, and levels of greenhouse gas emissions.
- Section 5, "Recommendations," provides the strategic overview, the recommended case including the revenue requirements to support it, and the near term actions required to keep LADWP on track towards meeting its obligations and responsibilities.

Detailed information is provided in the following Appendices:

Appendix A: Load Forecasting
Appendix B: Energy Efficiency and Demand side Management
Appendix C: Environmental Issues
Appendix D: Renewable Portfolio Standard
Appendix E: Power Reliability Program
Appendix F: Generation Resources
Appendix G: Distributed Generation
Appendix H: Fuel Procurement Issues
Appendix I: Transmission System
Appendix J: Integration of Intermittent Renewable Resources
Appendix K: Energy Storage
Appendix L: Smart Grid
Appendix M: Climate Change Effects on Power Generation
Appendix N: Model Description and Assumptions
Appendix O: Public Outreach
Appendix P: Abbreviations and Acronyms

AR0069925

1.3 Objectives of the IRP

This 2012 IRP documents the long term planning efforts for LADWP's Power System. It includes a review of the various issues and considerations that LADWP must address moving forward, and summarizes the planning process used to identify future energy resource requirements. The recommended long term plan is presented, as are the actions and initiatives LADWP must undertake over the next several years. The key objectives of LADWP's long term planning efforts are: (1) maintaining a high level of electric service reliability, (2) exercising environmental stewardship, and (3) keeping its energy rates competitive.

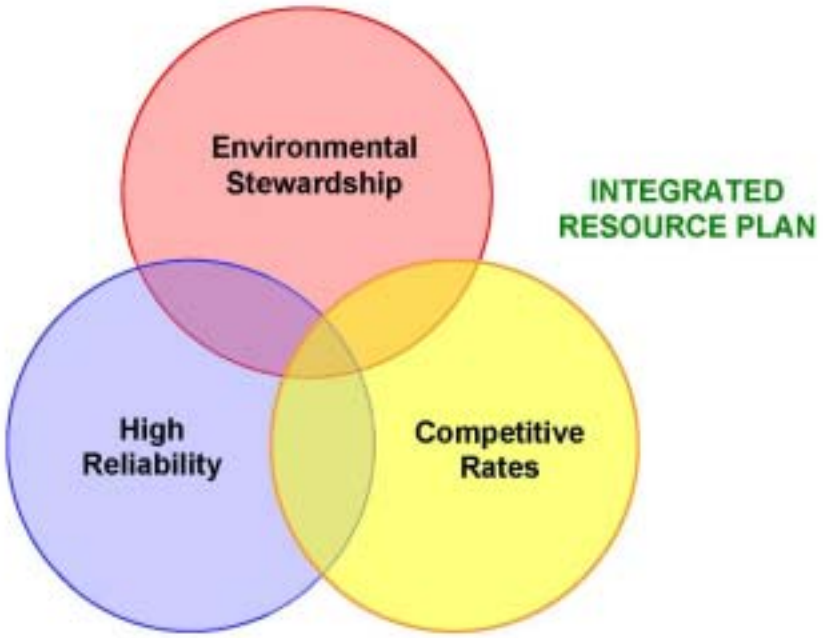

Figure 1-1. Objectives of this IRP.

1.3.1 Reliable Electric Service

Providing reliable electric service to the residents and businesses of Los Angeles has always been a cornerstone of LADWP. Some of the key principles, policies and program areas related to reliability are listed here:

- Reliability Standards

  LADWP continues to be in compliance with all applicable Federal Energy Regulatory Commission (FERC), North American Electric Reliability Corporation (NERC) and Western Electric Coordinating Council (WECC) standards regarding bulk power

AR0069926

system reliability. With the enactment of the Energy Policy Act of 2005, FERC granted NERC the legal authority to enforce reliability standards with all users, owners and operators of the bulk power system in the United States. WECC, under the delegated authority of NERC, is the regional entity responsible for coordinating and promoting bulk electric system reliability in the Western Interconnection. Both of these electric utility organizations enforce reliability standards on owners, operators and users of the bulk power system.

- CAISO

  The California Independent System Operator (CAISO) was established in 1998 as part of California's electric utility restructuring effort. CAISO was established as a non-profit public benefit corporation charged with operating the majority of California's high-voltage wholesale power grid and providing equal access to the grid for all qualified users. LADWP is not a member of CAISO but was certified by CAISO in 2012 to be a scheduling coordinator which authorizes LADWP to buy and sell energy and ancillary services directly with CAISO.

- Balancing Authority

  LADWP is a registered Balancing Authority with NERC and is responsible for coordinating and balancing the load, generation and delivery of electricity through its system. LADWP will continue to maintain its presence as a Balancing Authority.

- Self-Sufficiency

  LADWP maintains a policy of owning or controlling its transmission and generation resources to serve its native load customers. However, in consideration of economic and environmental factors involved with the coal replacement options (discussed in Section 3 and 4), a limited amount of firm energy is proposed to come from 3rd quarter purchases acquired from the electricity market.

- Coastal Power Plants

  LADWP operates three coastal natural gas-fired power plants that are critical to its operations. These plants were built from the 1940s up to the 1970s. One of these plants was modernized in the 1990s, resulting in increased efficiency and reliability while reducing emissions and maintenance costs. The modernization of the remaining generation units is a long term program targeted for completion in 2029. LADWP must modernize these plants to comply with environmental regulations, improve efficiency, better integrate renewable resources, and provide for transmission import capability. See Section 1.6.6 and Appendix C for more details.

- Power Reliability Program

  In response to an increase in power outages between 2003–2005, LADWP established the Power Reliability Program. The goals of the program include: (1) mitigating problem circuits and stations based on the types of outages specific to a given facility, (2) implementing proactive maintenance and capital improvements to prevent problems before they occur, and (3) establishing replacement cycles for facilities that are in alignment with the equipment's life cycle. See Section 1.6.3 and Appendix E for more details.

AR0069927

- Smart Grid

  Smart Grid refers to the application of advanced information-based technologies that will improve system operations in a variety of areas. Smart Grid technologies provide information that allows the implementation of real-time, self-monitoring communication networks that are predictive rather than reactive to system disruptions. These technologies will enable LADWP and its customers to make decisions to optimize the use of energy, improve reliability, and reduce the consumption of fossil fuels. See Appendix F for more information.

- Distributed Generation

  Distributed Generation (DG) refers to the installation and operation of small-scale electric generators that are located at or near the electrical load. Cogeneration, solar photovoltaic, and fuel cells are examples of DG applications. As more DG is added within the city of Los Angeles, it is important that these generation sources be managed in a manner that does not reduce grid reliability. More information on DG is provided in Section 2.3.3 and Appendix G.

1.3.2 Competitive Rates Consistent With Sound Business Principles

Historically, LADWP's electric rates have been consistently among the lowest in California. As utilities throughout the industry address renewable energy, greenhouse gas emissions, ocean water cooling and other issues, it can be expected that rates for most, if not all utilities, will rise. By continuing its strategic planning and implementation activities, LADWP hopes to maintain its rates as among the lowest in the region.

Energy rates

Based on a typical monthly residential bill for a customer consuming 500 kWh of electricity, the LADWP has the lowest monthly electric bill compared to five of its neighboring utilities in Southern California. See Figure 1-2 below.

AR0069928

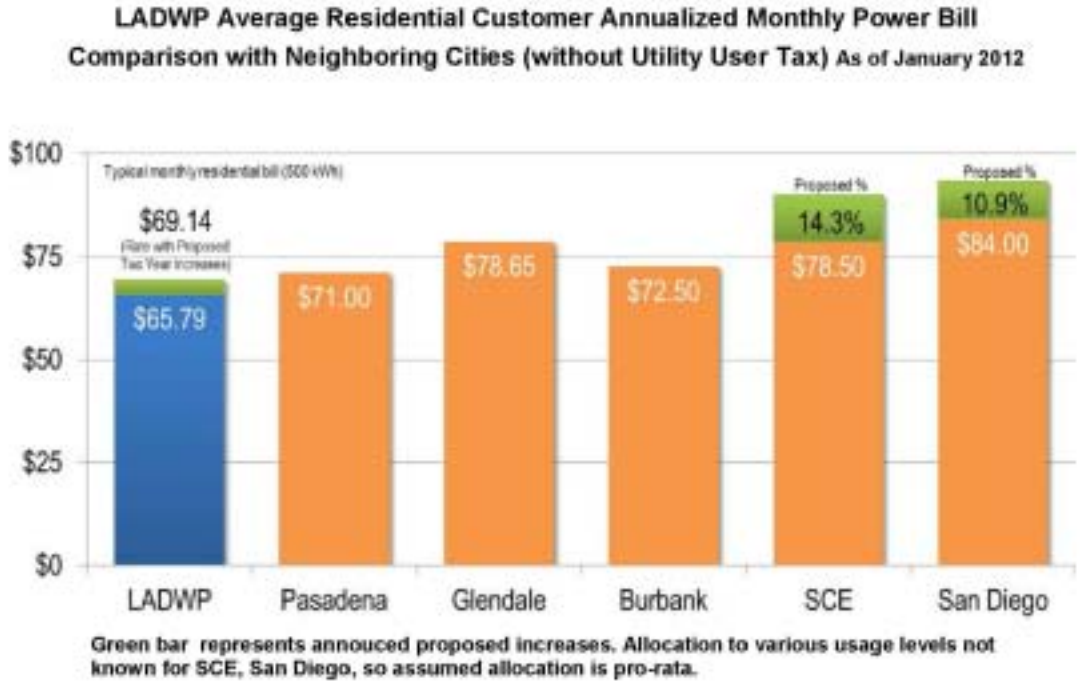

Figure 1-2. LADWP power bill comparison among other electric utilities.

While LADWP provides electricity at competitively low rates, several factors challenge the current rate structure. These factors include the costs to replace aging infrastructure, the potential volatility of natural gas and coal prices, and new regulatory requirements for renewable energy and the reduction of greenhouse gas emissions and use of ocean water for power plant cooling. Transmission capacity upgrades, energy efficiency and demand response programs, and projects to implement coal replacement will also exert upward pressure on energy rates. Because of these and other initiatives, it is expected that future structural rate adjustments and amendments to the Rate Ordinance will be necessary to maintain appropriate debt ratios and bond ratings.

Since LADWP sells substantial amounts of bonds to finance its capital expenditures, maintaining its high credit rating is essential to minimizing financial costs. To maintain its high credit rating, LADWP adheres to the following policies:

- Debt service coverage

  Maintain a debt service coverage ratio of at least 2.25
- Cash on hand

  Maintain a cash balance of $300 Million
- Capitalization ratio

  Maintain a debt-to-capitalization ratio of less than 68%

AR0069929

These financial parameters are used in the electric rates analysis discussed in Section 5.5.

1.3.3 Environmental Stewardship

LADWP's mission includes a role as an environmentally responsible public agency. Programs and subject areas related to improving the environment include:

- Renewable energy

  LADWP will continue its efforts to increase the use of renewable energy resources in a cost effective manner. LADWP will, at a minimum, comply with local, state and federal mandates for levels of renewable energy as a percentage of electricity sales. Senate Bill (SB) 2 (1X) sets renewable energy targets of 20% for years 2011-2013, 25% by 2016 and 33% by 2020 and thereafter. For more information, see Sections 1.5, 1.6.5, 2.4, 3.4.3, and Appendix D.

- Carbon dioxide (CO_2) emissions

  LADWP will continue its efforts to reduce CO_2 emissions. The potential early replacement of coal-fired generation, a key strategic focal point of this 2012 IRP, is one means of achieving reductions of CO_2 emissions. Additional recommended means of reducing CO_2 emissions include the continuation and expansion of energy efficiency programs and the transition towards increasing amounts of energy generated from renewable resources. For further information, see Section 3.6.4 and Appendix C.

- Once-Through Cooling (OTC)

  LADWP has embarked on a series of repowering projects that are eliminating the use of ocean water for cooling at its coastal generating stations. A series of repowering projects is planned through 2029. As each project is completed, the use of ocean water decreases. Within the 20-year planning horizon of this IRP, these projects will totally eliminate the use of ocean water. More information on OTC can be found in Sections 1.6.6.

- Energy Efficiency

  Energy efficiency programs has been ongoing for more than a decade, and will be serving a more prominent and strategic resource planning role as LADWP looks to the next 20 years and beyond. This IRP considers higher levels of energy efficiency than was previously considered in past IRPs. LADWP is committed to developing comprehensive programs with measurable, verifiable goals as well as implementing robust, cost-effective energy efficiency programs. Further information regarding LADWP's EE Program can be found in Section 2.3.1 and Appendix B.

AR0069930

- Solar Incentive Program and Feed-in Tariff

  LADWP's Solar Incentive Program (SIP) encourages the installation of solar PV capacity in Los Angeles. This program is a multi-year investment designed to expand solar power in the city to meet the goals of SB 1. This program provides a one-time incentive to customers who install a solar PV system on their property for their consumption. When a customer's SIP solar system produces more energy than they use for the billing cycle, the excess energy is calculated as a credit to be used on the customer's future bill.

  Additionally, LADWP is implementing a separate SB 32 Feed-in Tariff (FiT) program, whereby LADWP contracts to purchase ALL the power generated from an eligible renewable system under a standard power purchase contract. Although this program is open to all eligible renewable generators, most will likely be solar.

  The FiT and SIP programs are exclusive from each other; one renewable system cannot be enrolled in both. However, one property may have two separate renewable systems; one system feeding energy directly to LADWP's grid via a FiT meter and the other system feeding the customer's load via a Net-metering scheme.

  Solar energy will help LADWP achieve its environmental goals of increased energy generated from renewable resources and reduced levels of greenhouse gas emissions.

- Demand Response Program

  This IRP recommends the implementation of a Demand Response (DR) program, which will lessen environmental impacts by deferring the need to build additional generation facilities and infrastructure; as well as reducing energy usage and the associated greenhouse gas emissions. For a full discussion of DR and details regarding LADWP plans, see Section 2.3.2.

"Demand Response" is a mechanism utilities use to manage energy demand, especially during critical peak demand periods. When demand is at its highest (e.g., on a hot August afternoon), almost all of the generation supply is engaged, leaving little reserve available in case a generating unit falters or a transmission line trips. To reduce the risk of system failure that this condition imposes, demand response provides a means to lower the demand. Customers who sign up to participate are provided financial incentives and agree to lower their demand if and when called upon by the utility.

AR0069931

1.4 LADWP's Power System

LADWP's Power System serves approximately 4.1 million people and is the nation's largest municipal electric utility. LADWP experienced an all-time net energy-for-load peak demand of 6,142 megawatts (MW), which occurred on September 27, 2010, and has an installed net dependable generation capacity greater than 7,125 MW. Its service territory covers the City and many areas of the Owens Valley, with annual sales exceeding 23 million megawatt-hours (MWh). LADWP is the third largest California electric utility in terms of consumption, behind Southern California Edison and Pacific Gas & Electric—see Figure 1-3 below. Projected future demand growth for LADWP is less than one percent per year[1].

"Capacity" is a measure of the capability to produce power or the rate at which energy is transferred. The term is applied to the amount of electric power delivered or required to meet the power demand, and is expressed in Megawatts (MW) or Gigawatts (GW). "Energy" is a measure of the quantity of electricity used in a given time period and is expressed in Megawatt-hours (MWh) or Gigawatt-hours (GWh).

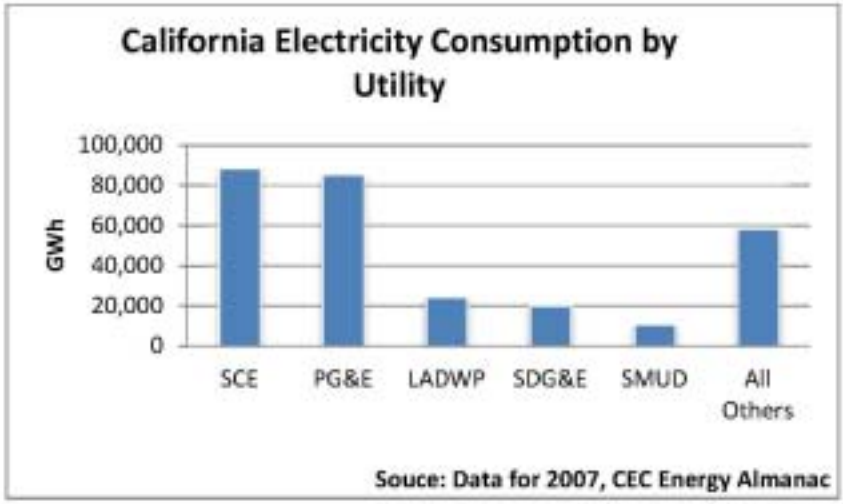

Figure 1-3. Comparison of California utilities by consumption.

LADWP is a "vertically integrated" utility—both owning and operating the majority of its generation, transmission, and distribution systems. LADWP is currently fully resourced to meet peak demand but maintains transmission and wholesale marketing operations to keep production costs low and increase system reliability.

While LADWP customers represent roughly 10 percent of California's electrical load, approximately 25 percent of the state's total transmission capacity is owned by LADWP. LADWP's transmission reach also extends beyond California, enabling the transport of power from a diversified set of generation resources from across the Western United States.

[1] Prior to energy efficiency and distributed generation, which will reduce load growth to an approximate yearly average of 0.3% between 2012 and 2032.

AR0069932

Additional information on the Power System's generation and transmission assets can be found in Section 2.4 and Appendices F and I.

AR0069933

1.5 Recent Accomplishments

A summary of recent LADWP accomplishments consistent with the objectives of this IRP are presented below. These accomplishments promote the goals of maintaining high reliability and exercising environmental stewardship, while keeping rates competitive.

- Renewable portfolio standard

  Through the active procurement of renewable resources, LADWP has increased the renewable energy component of its resource mix from 3% in 2003 to 20% in 2010. In 2011, the renewable percentage slightly decreased to 19% due to less wind and small hydro generation.

- Adelanto Solar Power Project

  On July 23, 2012, the Adelanto Solar Power Project was commissioned as LADWP's first utility-scale solar power plant. The 10 MW(AC) project was built by LADWP crews and is owned and operated by LADWP, making it the largest municipally-owned solar project in the nation. The project makes use of existing LADWP land and ties directly to an existing electrical switching station. The project will provide valuable experience and data regarding solar plant operations, the integration of variable renewable resources, and the financial requirements (capital costs, O&M costs, etc.) associated with building and operating a large solar facility. The experience gained from this project will facilitate the construction of future solar projects.

- Energy efficiency

  LADWP continues its commitment to energy efficiency through numerous programs and services to customers, encouraging the adoption of energy saving practices and installation of energy-efficient equipment. Since 2000, LADWP energy efficiency programs have resulted in 1,377 GWh of energy savings, or over 5% of energy sales.

  In 2012, the Board of Water and Power Commissioners adopted a goal of 10% energy efficiency by 2020, with a target of 15% pending the results of a new potential study to be conducted in 2013.

- Solar Incentive Program and Feed-in-Tariff (FiT)

  As of September 1, 2012, LADWP has encouraged the installation of over 36 MW of solar capacity at over 6,200 customer locations through its ratepayer-funded Solar Incentive Program. Separately, a FiT pilot program was conducted, which will enable a full-scale program launch for 150 MW by 2016.

- Emissions reduction

  As of 2011, CO_2 emissions from power generation are 21% lower than 1990 levels. The lower emissions are attributed to discontinued generation from the Colstrip and Mohave generation stations, increased generation from renewable resources, and the ongoing repowering of the in-basin natural gas units.

AR0069934

Due to the installation of advanced pollution control equipment at all of its in-basin generating stations, NOx emissions from LADWP's local generating plants are at least 98 percent lower than 1998 levels.

- Once through cooling

  As a result of completed repowering projects, LADWP has reduced the use of once-through ocean water cooling by 17% from 1990 levels. The current plan calls for a complete phase-out of ocean water cooling by 2029.

- Haynes 5 & 6

  The September 2011 groundbreaking ceremony signified the start of construction for the replacement of Haynes Units 5 and 6. The original units, which date back to the mid 1960's, will be replaced with efficient modern units that will facilitate the integration of intermittent renewable energy. This project is expected to be in service by May 2013, and is one of many projects that that will eliminate the use of ocean water for cooling by 2029.

- Castaic

  The seven units of the Castaic Hydroelectric Plant are currently being rotated out of service for modernization. This multi-phase process began in 2004 and is expected to continue through 2014. To date, five units have been completed. The associated increase in efficiency is projected to add up to 80 MW of renewable qualifying capacity to Castaic. The increased capacity also results in more reserves available to reliably meet peak system demands.

- Power Reliability Program (PRP)

  The PRP is a comprehensive long-term power reliability program developed by LADWP to replace aging infrastructure and make permanent repairs to generation, transmission, and distribution infrastructure. Through the program, LADWP successfully reduced the number of distribution outages by 28% between 2006 and 2009 by accelerating the replacement of transformers, poles, underground cables, and other equipment. In FY 2011-12, 1,813 poles, 2,054 transformers, and 51 miles of underground cable were replaced. See Section 1.6.3 and Appendix D for more information.

- Green Power Program

  LADWP offers its customers an opportunity to participate in the Green Power Program. "Green Power" is produced from renewable resources such as wind energy, geothermal, or other renewable resources, rather than conventional generating plants. In 2011, 17,700 LADWP customers participated in the program, receiving approximately 74,000 MWh of renewable energy. Since program inception in 1999 to the end of 2013, 872,131 MWh of renewable energy was procured, making it one of the largest voluntary green pricing programs in the nation.

AR0069935

- Upgraded capacity on the Southern Transmission System (STS)

  In May 2011, the 488-mile Intermountain Power Project DC Line was upgraded from 1920 MW to 2400 MW, allowing the import of additional amounts of renewable energy from Utah. Of the 2400 MW total capacity, LADWP's share is 1128 MW.

- Navajo Generating Station (NGS) retrofitted with low NO_x burners

  In March 2011, NGS completed a three-year project that retrofitted the boilers of all three units with low NO_x burners and separated over fire air systems. This project was successful in reducing NO_x emissions by ~40% which represents an annual NO_x emission reduction of 11,000 tons per year.

- Barren Ridge Switching Station

  The Barren Ridge Switching Station, located 15 miles north of Mohave, was completed in 2009. This substation is a key component of the Barren Ridge Renewable Transmission Project (BRRTP), which will enable LADWP to interconnect approximately 1,400 MW of wind, solar, and other renewable resources that will be available in the next several years from the Mohave Desert and Tehachapi Mountain areas. The Environmental Impact Report for the BRRTP was approved by the Board of Water and Power Commissioners in September 2012. For more information see Section 2.4.4.

- Milford II Wind Project

  In May 2011, LADWP began receiving over 100 MW of new wind energy. Milford II is an expansion of the 200 MW Milford I wind farm project. Together, Milford I and II are providing approximately 2.6% of LADWP's total energy sales.

- Electric Vehicles Incentive for Home Chargers

  To encourage the transition towards electric vehicles, LADWP launched a demonstration program in April 2011 providing a $2,000 rebate for home charging systems. LADWP also worked with other City agencies to streamline the process time for permitting and installation of these systems.

- Initiated Coal Replacement

  Processes to replace coal generation from the IPP and Navajo stations have been initiated and are in progress. At Navajo, LADWP is planning to divest from the project by the end of 2015, which is four years ahead of the date required by SB 1368. At IPP, LADWP is working with the other participants to establish the contractual structure to enable a conversion from coal to natural gas. The date of conversion will likely be established before next year's 2013 IRP.

- Demand Response and Smart Grid

  LADWP is developing and enhancing its Demand Response and Smart Grid programs, which are important components of its future resource plan. To date, 60 MW of load shifting and interruptible load has been secured. Program managers

AR0069936

and support staff have been established to move these programs forward, and appropriate resources have been budgeted

AR0069937

1.6 Key Issues and Challenges

LADWP faces a number of concurrent issues and challenges that require careful assessment. Long term strategies must focus on these issues so they can be addressed in the most cost effective manner without compromising reliability, compliance and environmental stewardship. The major issues around which the strategies of this IRP are centered include: ensuring reliability, greenhouse gas emission reduction, increasing the amounts of renewable generation resources, and addressing once-through cooling.

1.6.1 Adequate Multi-year Funding to Support Programs

To support the recommended projects and programs, adequate funding is necessary. Due to the delay of the rate action that was previously anticipated in 2011, many of the programs were scaled down, delayed or deferred. The rate process that concluded on October 5, 2012 is a positive step towards LADWP's fulfillment of its responsibilities and regulatory obligations which are discussed throughout this 2012 IRP.

Properly funded programs will enable LADWP to achieve the following objectives:

- Modernize its coastal generation units to replace aging equipment and to satisfy once-through cooling and local emissions regulatory requirements
- Implement early coal divestiture and replacement to accelerate the reduction of greenhouse gas emissions and to enhance integration of renewable energy and energy efficiency measures
- Secure the state-mandated amounts of renewable energy
- Increase the use of local distributed solar generation and combined heat and power to support State goals
- Through the Power Reliability Program, reduce the number and duration of distribution outages and improve system reliability
- Implement necessary transmission improvements to maintain reliability and support new resources, including renewables.
- Provide energy efficiency and customer solar programs for participation by our customers through the Customer Opportunities Program
- Achieve energy efficiency and other demand-side resource target levels
- Implement Smart Grid initiatives.
- Comply with FERC-approved reliability and Cyber-security standards

Securing adequate multi-year funding is crucial to ensure LADWP's ability to stay on track towards meeting its future long term goals and obligations.

AR0069938

1.6.2 Ensuring Reliability

Challenges to ensuring continued reliable electric service include the replacement of aging generation facilities, maintaining grid reliability, the integration of intermittent renewable energy resources, and the replacement of poles, power cables, transformers and other elements of the local distribution system (distribution reliability is further discussed in Section 1.6.3 below).

Aging Facilities and Infrastructure

LADWP's generating plants sited within the Los Angeles Basin were primarily built in the late 1950s and early 1960s. While many generating units at these plants have undergone extensive upgrades, others are approaching the end of their service lives. Replacement of these older units (also known as "repowering") began in 1984, and will continue through 2029. The new repowered units will be substantially cleaner, more reliable, community-friendly, and efficient than the units they are replacing. Repowering LADWP's gas-fired units will also assist in integrating intermittent renewable resources into LADWP's energy mix by providing quick response, back-up generation capacity.

Grid Reliability

LADWP's local transmission system cannot be reliably operated without generation from local thermal generating plants. The amount of generation required to provide transmission reliability is termed Reliability Must Run (RMR) generation. Repowering these local units will maintain transmission reliability by maintaining the reliability of RMR generation.

Historically, LADWP's local generation has provided voltage control for the basin transmission system. Over the years, as imports into the basin transmission system have increased, fewer local generators are needed on-line at any given time to supply power, reducing voltage control options for Power System operators. LADWP is countering this with plans to install static capacitors and reactors at strategic locations throughout the city. These installations are increasingly important as more renewables are imported.

LADWP's latest Ten-Year Transmission Assessment Plan has identified a number of infrastructure improvements that are needed to avoid potential overloads on key segments of the Basin transmission system. These overload conditions, if encountered, could lead to load shedding events (intentional power outages) to minimize the overall impact on the Power System.

Integration of Intermittent Renewable Energy

The integration of renewable energy into the grid poses major challenges. Integrating renewables will, paradoxically, require additional gas-fired generation to provide reserves and maintain system reliability. Because renewable resources like wind and solar produce electricity variably and intermittently (i.e., only when the wind is blowing or

AR0069939

when the sun is shining), integration of these resources requires that controllable generators are online to smooth significant and often rapid changes to energy production. This stabilizing activity is known as "regulation" (see discussion box). A potential solution would use energy storage to regulate delivery of energy and reduce the severity of integration problems. For regulation, LADWP currently uses gas-fired combustion turbines and hydro resources, including pumped water storage. Batteries and compressed air offer alternative storage solutions, but those technologies are still in development and have not yet been proven commercially viable. See Section 2.4.5 for a discussion of LADWP's energy storage development activities.

"Regulation" is necessary because the amount of electricity generated must always match system load, or electricity demand. If load and generation do not match, the power frequency would vary from the target frequency, resulting in problems that can damage motors, appliances and other equipment, and may lead to system collapse and power outages.

LADWP is conducting studies to determine the maximum levels of intermittent energy resources that can be integrated reliably and to identify the investments necessary to maintain power grid reliability with intermittent resources contributing significantly to its energy portfolio.

1.6.3 Power Reliability Program (PRP)

Between 2003 and 2005, LADWP experienced a growing number of distribution outages due to, among other things, aging infrastructure (poles, lines, transformers, etc.), and deferred maintenance and asset replacement. To illustrate, Figure 1-4 shows the number of electrical distribution poles categorized by age. As shown, more than 50 % of the poles are 50 years or older and more than 25% already exceed the average life span of 60 years.

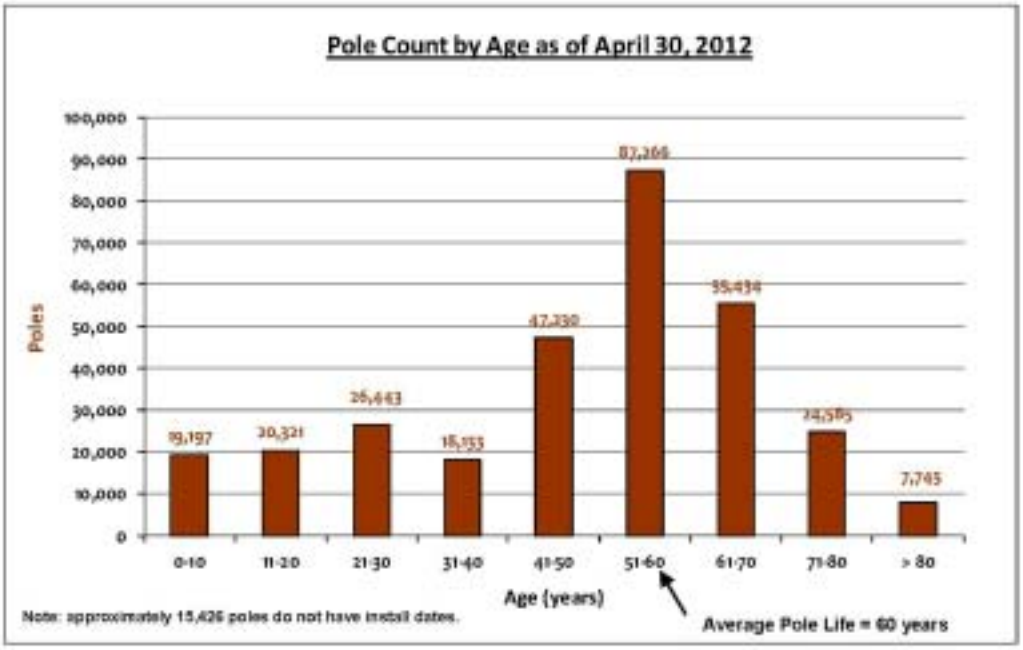

Figure 1-4. Pole count by year range installed.

AR0069940

Like all other electricity utilities in the US, LADWP uses a number of metrics to measure the performance and reliability of its electric power system. The two primary metrics are called SAIFI and SAIDI.

The System Average Interruption Frequency Index (SAIFI), is the average number of sustained service interruptions per customer during the year. It is the ratio of the annual number of interruptions to the number of customers. In other words, it measures how many times the average customer has been out of service. 1.1 is the recent national average. In 2002, LADWP's SAIFI index was 0.49; in 2011 it was 1.03.

The System Average Interruption Duration Index (SAIDI), is the average duration of interruptions per customer during the year. It is the ratio of the annual duration of interruptions (sustained) to the number of customers. In other words, it measures how long the average customer was without power. 90 minutes is the recent national average. In 2002 LADWP's SAIDI index was 59.29; in 2011 it was 214.44.

The trends for both SAIDI and SAIFI are shown in Figure 1-5.

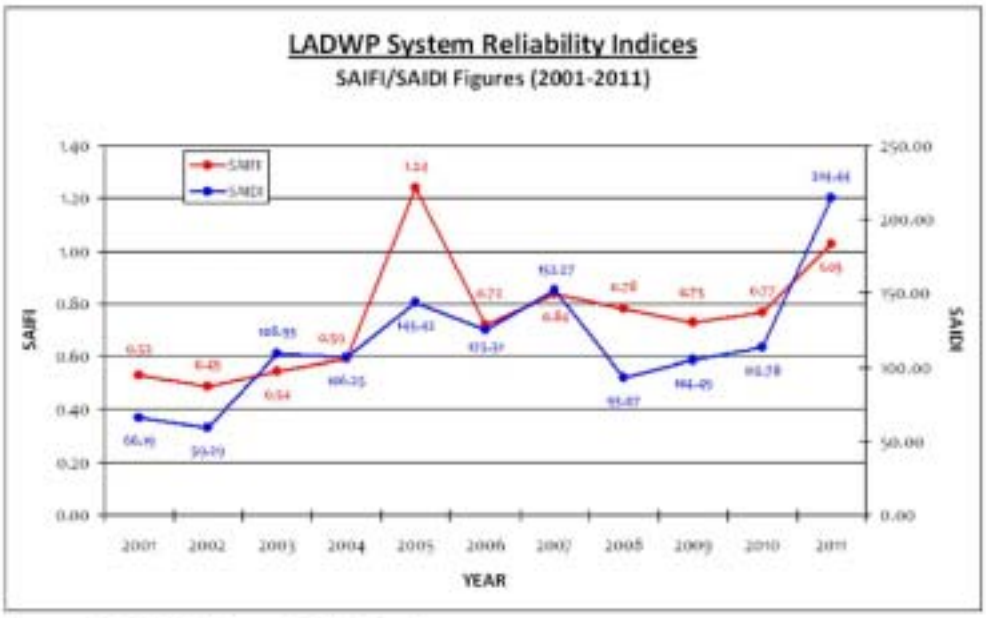

Figure 1-5. LADWP's reliability indices.

In response to the decline in service reliability, LADWP established a comprehensive Power Reliability Program (PRP) in 2006 which provided increased funding to address the growing maintenance backlog. The goals of the program include: (1) mitigating problem circuits and stations based on the types of outages specific to a given facility, (2) implementing proactive maintenance and capital improvements to avert problems before they occur, and (3) establishing replacement cycles for facilities that are in alignment with equipment life cycle.

AR0069941

PRP funding has been inconsistent since its inception. As shown in Figure 1-6, the initial years of the program resulted in some reliability gains as outages decreased from 6,323 in 2006 to 4,523 in 2009. Funding levels since then, however, have declined and the number of outages has remained above 4,500 per year.

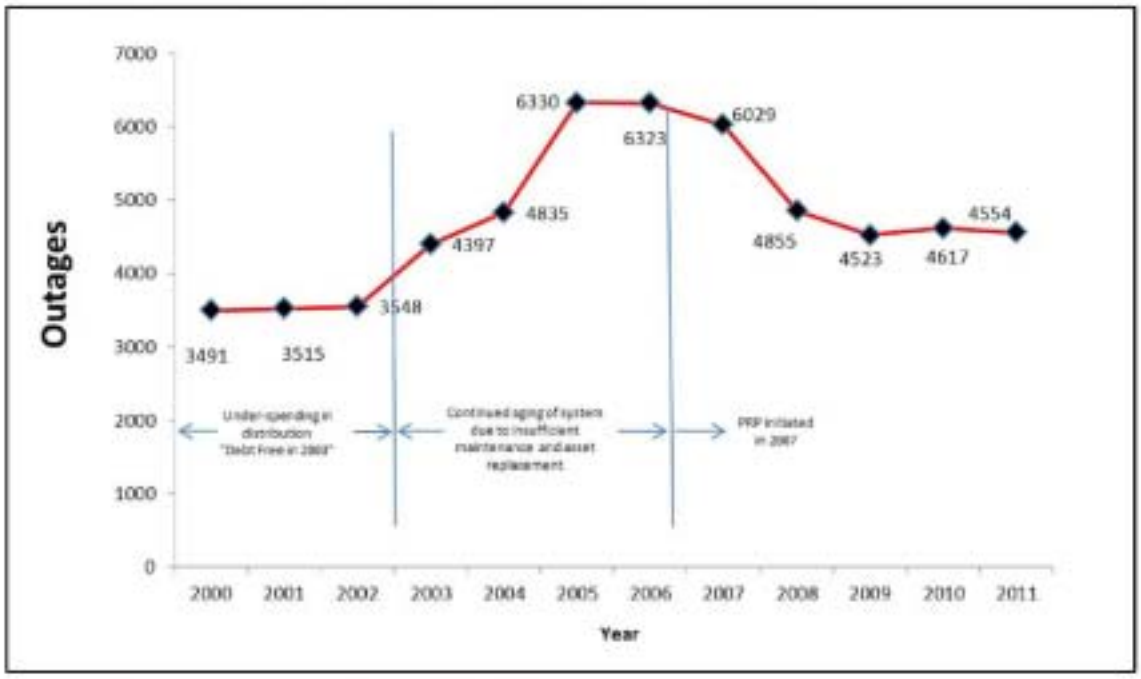

Figure 1-6. Total outages between 2000-2011.

Adequate funding is necessary to get the PRP back on track towards its goal of reducing outage levels. Additional information on LADWP's PRP can be found in Appendix E.

1.6.4 GHG Emissions Reduction

The focus of LADWP's GHG emissions reduction strategy is early replacement of coal-fired generation. Because coal emits relatively high levels of CO_2, switching to energy efficiency, renewables and other fuels will significantly lower overall emission levels. Early coal replacement facilitates LADWP's compliance with AB 32's upcoming cap and trade program.

LADWP's GHG emissions reduction strategy must comply with state and federal regulations:

- SB 1368, the California Greenhouse Gas Emissions Performance Standard Act, enacted in 2006, prohibits LADWP and other California utilities from entering into long-term financial commitments for base load generation unless it complies

AR0069942

with the GHG emissions performance standard. The GHG emissions level must be equal, or below, that of a gas-fired combined cycle units (i.e., 1,100 lbs per MWh). This standard also applies to existing power plants for any long-term investments or contractual extensions, thus effectively prohibiting LADWP from continued coal-fired generation beyond the current contractual expiration dates for NGS (2019) and IPP (2027).

- Assembly Bill (AB) 32, the California Global Warming Solutions Act of 2006, calls for reducing the state's CO2 emissions to 1990 levels by 2020. The regulations for implementing a greenhouse gas emissions Cap and Trade program under AB 32 were finalized and adopted on October 20, 2011 by the California Air Resources Board (ARB). Enforcement and compliance with the trading program will begin January 1, 2013. LADWP has been granted an administrative allocation of emission allowances that reflects its resource projections through 2020.

LADWP has historically relied upon coal for base load generation. In calendar year 2011, 41 percent of the energy delivered to LADWP customers was generated from NGS and IPP. The NGS's operating agreement and land lease expires in 2019 but has a stipulation for a 25 year extension. IPP's Power Purchase Agreement (PPA) contract is in effect until 2027. These stations have provided dependable, low cost base load generation to Los Angeles. However, as coal-fired electricity emits about twice as much CO_2 as energy generated with natural gas, this 2012 IRP focuses on early coal replacement options as a means to lower LADWP's GHG emission levels. Section 2.4.2.3 presents more detail on LADWP's early replacement plans, and Sections 3 and 4 discuss the alternative coal replacement case options that were modeled and analyzed.

AR0069943

1.6.5 Increasing Renewable Resources

Initiatives to utilize renewable resources to generate electricity support the goal of reducing GHG emissions and decrease our reliance upon fossil fuels.

- State legislation – SB 2 (1X) – which was passed in April 2011 and became effective December 10, 2011, requires utilities to procure eligible renewable energy resources of 33 percent by 2020, including the following interim targets:
  - Maintain at least an average of 20 percent renewables between 2011 and 2013
  - Achieve 25 percent renewables by 2016
  - Achieve 33 percent renewables by 2020 and maintain this level in all subsequent years

- SB 32, signed into law on October 12, 2009, requires LADWP to make a tariff available to eligible renewable electric generation facilities until LADWP meets its 75 MW share of the statewide target. Through this program, owners or operators of eligible renewable energy systems may sell their energy directly to LADWP. The purchase of energy will include all environmental attributes, capacity rights, and renewable energy credits which will apply towards LADWP's 33 percent renewable requirement.

- Former Governor Schwarzenegger signed the California Solar Initiative (CSI), outlined in SB 1, on August 21, 2006. The CSI mandated that all California electric utilities, including municipals, implement a solar incentive program by January 1, 2008. The goal of the CSI is 3,000 MW of net metered solar energy systems over 10 years with expenditures not to exceed $3.35 Billion. Expenditures for local publicly owned electric utilities shall not exceed $784 Million. The LADWP cap amount is $313 Million, based on its serving 39.9% of the municipal load in the state.

- The LADWP Board of Commissioners has adopted a policy to achieve 20 percent renewables by 2010, and 33 percent by 2020. The Board and City Council have approved projects and long-term power purchase agreements that achieved the 20 percent RPS goal in 2010. The policy has been revised to incorporate SB 2 (1X) requirements, and is included as Reference D-2 of Appendix D.

In addition, SB 2 (1X) sets certain conditions regarding renewable energy contracts entered into on or after June 1, 2010, as shown in Table 1-1.

AR0069944

Table 1-1. SB 2 (1X) CATEGORY REQUIREMENTS FOR RPS ENERGY CONTRACTS

Portfolio Content Category[1]	RPS % Target		
	Compliance Period 1 (1/1/2011 – 12/31/2013)	Compliance Period 2 (1/1/2014 – 12/31/2016)	Compliance Period 3 (1/1/2017 – 12/31/2020)
1	Minimum 50%	Minimum 65%	Minimum 75%
2	See footnote 2	See footnote 2	See footnote 2
3	Maximum 25%	Maximum 15%	Maximum 10%

[1]Categories are defined as follows:

Category 1 = Energy and RECs from eligible resources that

- Have the first point of interconnection with a CA balancing authority or with distribution facilities used to serve end users within a CA balancing authority area; or
- Are scheduled into a CA balancing authority without substituting electricity from another source. If another source provides real-time ancillary services to maintain an hourly import schedule into CA, only the fraction of the schedule actually generated by the renewable resource will count; or
- Have an agreement to dynamically transfer electricity to a CA balancing authority.

Category 2 = Firmed and shaped energy or RECs from eligible resources providing incremental electricity and scheduled into a CA balancing authority.

Category 3 = Energy or RECs from eligible resources that do not meet the requirements of category 1 or 2, including unbundled RECs.

[2]Remainder % of resources which are neither in Category 1 nor Category 3.

The legislation allows for the California Energy Commission to issue a notice of violation and correction, and to refer all violations to the California Air Resources Board. Failure to achieve the targets may result in significant penalties.

The challenges of adopting more renewable resources such as wind, solar and geothermal, are: (i) obtaining local and environmental rights and permits for renewable projects and the associated transmission lines needed to deliver energy to Los Angeles; (ii) establishing reliable and cost-effective integration of large scale wind and/or solar projects into the LADWP balancing area through the addition of regulation-capable generation; and (iii) developing geothermal sites which are potentially scarce, require large capital costs, impose exploration risks, and have limited transmission line access. In addition, energy from renewable resources is generally more expensive than energy from conventional fossil fuel resources, and must be fully funded through customer rates.

1.6.6 Once-through Cooling

Once-through cooling (OTC) is the process of drawing water from a river, lake, or ocean, pumping it through a generating station's cooling system, and discharging it back to the original body of water. OTC is a utility regulatory issue, stemming from the Federal Clean Water Act Section 316(b) and administered locally by the State Water Resources Control Board (SWRCB). The interpretation of rules and development of guidelines for OTC have been several years in the making. See Appendix C for details.

AR0069945

OTC regulations affect LADWP's three coastal generating stations – Scattergood, Haynes, and Harbor. To comply with OTC regulations, generation units at those stations that utilize ocean water for cooling will be repowered with new units that do not use ocean water. The amount of generation capacity affected by OTC is significant – approximately 2,600 MW of LADWP's total in-basin plant capacity of 3415 MW. The amount of expenditures required is also significant, on the order of $2.2 billion. Because of the size and scope of the effort required, the work to comply with OTC regulation is a long term program, extending to 2029.

It should be noted here that many of the units being replaced are older units that would have eventually been replaced even without the OTC requirement. However, the OTC mandate requires a significant reduction in the use of ocean water and therefore, OTC is being eliminated and replaced with closed cycle cooling. Satisfying the OTC mandate accelerates the replacement schedule of the affected generation units.

Discussions between LADWP and the SWRCB have resulted in the following timeline for OTC compliance (Figure 1-7).

Figure 1-7. Timeline for OTC compliance.

There are many constraints and considerations that were factored into the development of the OTC compliance timeline. Because the LADWP Power System relies on the in-basin units to provide transmission system reliability, as well as local sources of power generation, it is important to keep all of the units available to meet local capacity requirements. An existing unit that is being replaced cannot be decommissioned (shut down) until the new replacement unit is built, tested, and ready to go on-line. This requires a strict sequencing of the separate repowering projects, as shown on Figure 1-7.

There are many challenges to meeting the target dates. The limited space available within some of the generating station property boundaries presents planning and construction difficulties. Other issues include the long lead times required for environmental

AR0069946

permitting, engineering design, and equipment procurement. Any unforeseen delay – for example, a delay in acquiring an environmental permit or a delay in delivery of new plant components – will adversely affect the schedule. The timeline shown in Figure 1-7 represents LADWP's best effort to comply with the mandated compliance deadlines while also meeting its reliability responsibilities.

The effects of the repowering program on ocean water use are shown in Figure 1-8. As individual units are replaced with new units that do not use ocean water, OTC levels decrease. The overall goal of the program is the total elimination of OTC by 2029. Additional discussion regarding LADWP's compliance with OTC regulations can be found in Appendix C.

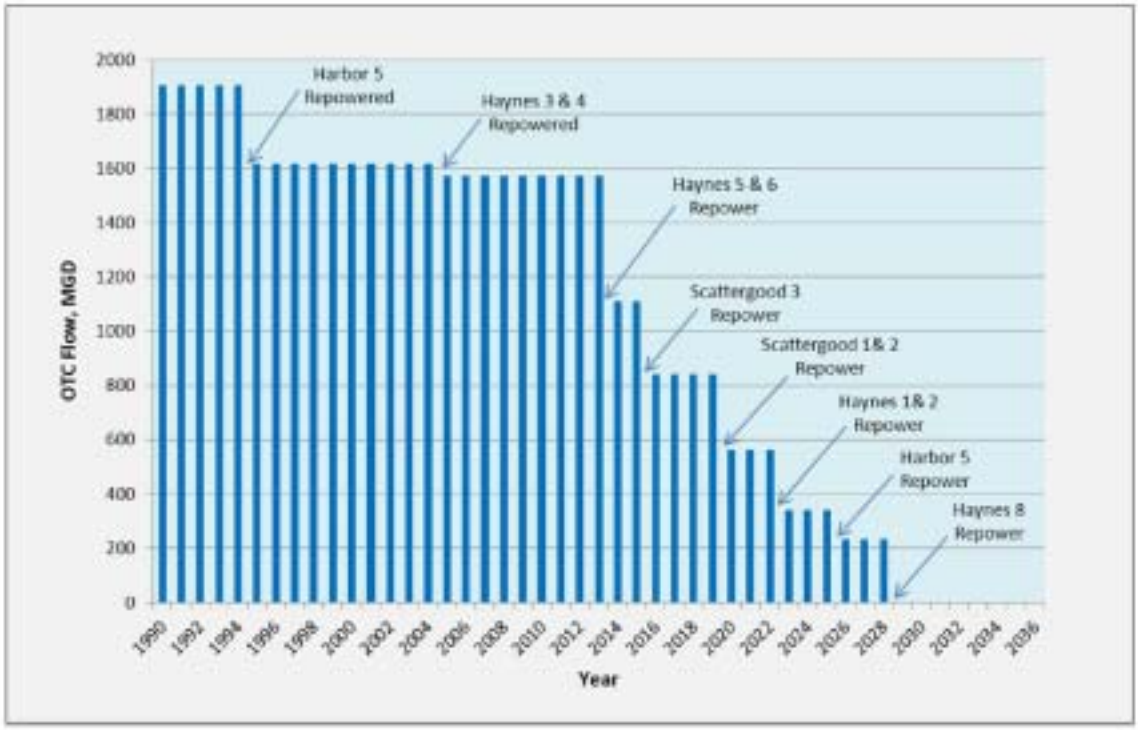

Figure 1-8. LADWP's reduction in once-through cooling from 1990 to 2029.

1.6.7 Workforce Development

To effectively implement the programs and projects recommended in this IRP, an effective human resources strategy is required. The Power System is challenged to develop a sustainable workforce development plan that addresses the following human resources elements:

AR0069947

Adequate Staffing
Ensure adequate staffing so that LADWP can comply with mandated deadlines and fulfill its regulatory obligations. The Power System employs approximately 4,000 employees in 150 civil service classifications who perform core work related to generation, transmission and distribution of electricity. Workload requirements and competencies are continuously reviewed to determine the composition and number of employees needed. Achieving and maintaining proper staffing levels is complicated by the fact that a significant number of employees are expected to retire in the next 3-5 years.

Proper Skill Sets
New and expanded work areas such as renewable energy facility operations, energy efficiency, solar distributed generation, power reliability and smart grid deployment will require analysis to identify the skills, knowledge, abilities, and staffing levels required to perform these functions in a safe, effective and efficient manner. New job classifications may be required for new or specialty areas.

Training/Professional Development and New Technologies
Developing and promoting the development of both new and existing employees is a key human resource management objective. LADWP supports employee development by providing various computer based training programs, and offers tuition reimbursement for those who return to school to enroll in work-related courses and advanced degree programs. Across the Power System, different work groups are encouraged to develop training specific to their particular functions and needs. This is especially important as new and emerging technologies become applicable to various work functions. Applied correctly, technology increases employee productivity, enhances safety, and enables new and expanded customer services.

Recruitment
Recruiting the best qualified employees assumes an effective workforce capable of meeting the near term and long term challenges identified in the IRP. Working with source institutions such as colleges and vocational schools will expand LADWP's candidate pool, from which the highest qualified individuals can be offered positions. To promote the local economy, strategic recruiting is planned in areas of the City which have historically been untapped as sources for entry-level craft jobs. Continued use of LADWP's website and social media to promote career opportunities will sustain public awareness and help ensure that the best qualified individuals consider joining the LADWP workforce.

1.6.8 Additional Challenges

Additional challenges that LADWP must address include an increased risk from natural gas price volatility, a push towards higher levels of distributed generation, a need for more robust and precise transmission planning, addressing cyber security legislation, hydro-plant re-licensing, the future effects of climate change on power generation and operations, and improving system load factor.

AR0069948

- Natural Gas Price Volatility

  To the extent that LADWP seeks to reduce its GHG footprint, but cannot meet all its future needs through renewable resources and DE/DSM programs, a greater percentage of generation utilizing natural gas will be forthcoming. To reduce the price risk inherent when relying so much on a single fuel type, LADWP will need to continue to develop and implement strategies to hedge against natural gas price volatility. These strategies are designed to protect LADWP from potential future price fluctuations, and include financial hedging products, ownership of gas reserves to supply a portion of its fuel needs, and other potential products and contractual arrangements.

- Distributed Generation

  The Governor has called for a statewide goal of 12,000 MW of renewable power generation within the local distribution grid. LADWP's portion of that would amount to approximately 1,200 MW. While this IRP investigates higher levels of distributed generation (see Cases 7 and 8 in Section 3 and 4), a number of complicating factors could make this a difficult goal to attain. Having adequate reserves, addressing operational impacts, and loss revenues that would have to be made up elsewhere are some of the factors that need to be considered and analyzed. This issue will require on going attention and assessment beyond this current IRP and should be an item for discussion in subsequent IRPs.

- Transmission Planning

  As resource planning has become more dynamic and complex in response to the growing number of external drivers and influencing factors, so too are the demands on transmission planning to support it. It is important that transmission considerations be connected to resource planning so that alternative options are evaluated in a realistic and effective manner. Importing new renewable energy from distant locations, dealing with intermittent energy, switching away from coal which may free up transmission capacity, the transmission needs for potential new power plants; these and other resource planning considerations all require adequate transmission. As LADWP controls a large amount of transmission in the state, it should leverage those assets to best meet the needs of the City and the ratepayers.

- Cyber Security Legislation & Regulation

  Congress is currently contemplating several Cyber Security Bills, all of which have their unique approach to protect the nation's critical infrastructure against cyber-attacks. The two prominent approaches to cyber security legislation range from Information Sharing to Federal Oversight and the development of new cyber security standards. Public power is working with House and Senate representatives to develop a bill that focuses more on information sharing and which would allow a utility to take voluntary actions as they see best for their organization.

  Along with Cyber security legislation, electric utilities are also concentrating on the development and implementation of NERC cyber security reliability standards.

AR0069949

NERC is currently working with industry on version 5 of these standards in order to prevent cyber incidents that could lead to misoperation or instability in the bulk electric system

- Castaic FERC Re-licensing Program

On January 31, 2022, the Federal Energy Regulatory Commission's (FERC) license to operate Castaic Pumped-storage Hydroelectric Plant will expire. The license is a co-license between LADWP and the Department of Water Resources (DWR) and includes a number of hydro power plants along the California Aqueduct. Both parties have initiated the joint re-licensing process that, on average, requires ten years to complete. Through 2015, LADWP expects to complete preliminary studies, contract negotiations, and prepare a filing strategy. In 2016, LADWP expects to file a notice-of-intent (NOI) and initiate the formal studies and applications.

- Effects of Climate Change Global Warming

While LADWP is actively working to reduce its GHG emissions and thus lower its contribution to the problem of global warming, it must also look at the consequences of climate change and how it affects power generation and operations. Warmer temperatures, more volatile weather patterns, an increase in the number and duration of heat waves, stressed water availability and rising sea levels are some of the impacts that must be considered to ensure adaptation of the Power System to those future conditions. See Section 2.4.6 and Appendix M.

- Load Factor Improvement

Load factor represents how constant energy usage is over a given day. A 100 percent load factor means that the same amount of power is used throughout the day, so the system is getting full use of its generation, transmission, and distribution resources. A low load factor results in generators being started more often to serve load for a few hours a day, which is not optimum. As an analogy, a car traveling at constant speed will get the best gas mileage and reduced wear and tear than a car in stop-and-go traffic.

From the 1990s through 2005, annual system load factors were trending slowly upward, which is a positive movement. Since 2006, however, system load factors are trending down. Some of this decline is due to the fact that much of the historic energy efficiency effort is directed at lighting, which has higher impact on energy sales when compared to peak demand. Also, most customers are making greater efforts to conserve energy, but during extreme weather events safety and comfort predominate over conservation causing the peak to spike. LADWP will consider programs to shift load from peak hours to off peak hours to reverse this trend and improve system performance.

AR0069950

1.7 Public Process

The 2012 IRP process includes a public outreach effort to provide information and gather public input.

Public outreach began with two stakeholder meetings held in early 2012. LADWP staff met with key major customers and business representatives in February, and in March with key environmental organization representatives. Comments received during these stakeholder meetings were considered in the development of the preliminary cases that were analyzed.

These preliminary results were documented in the 2012 Draft IRP document and were presented at three additional stakeholder meetings with major account customers, environmental organizations, and neighborhood councils, and discussed at an additional general public workshop held on October 11, 2012. The 2012 Draft IRP was made available for public comment through the LADWP website.

www.ladwp.com/ladpowerplan

Comments were accepted through November 5, 2012. Considering the public comment and input received, a final set of recommendations was made.

A summary of the public comments received is included in Section 5 and Appendix O.

AR0069951

1.8 2012 IRP Development Process

The IRP is prepared by a group of engineers dedicated to LADWP resource planning and preparation of the IRP. While this group performs the production model and report preparation for the IRP, the bulk of the work is collaborative across the numerous work groups and functional areas of the Power System, including wholesale marketing, grid operations, renewable procurement, environmental and legislative affairs, and financial services.

The IRP is developed in multiple stages, including:

1 Gather stakeholder input

Meetings are held with stakeholder groups to discuss the key strategic planning issues and to gather input. This is done early in the process to ensure those concerns expressed are given due consideration in the establishment of goals and objectives, and in the development of the alternative cases for study and analysis.

2 Establish clear goals and objectives

The overarching goal of LADWP's IRP planning efforts is to produce a long term plan that ensures a future supply of electricity that is reliable, competitively priced, and is secured in a manner consistent with environmental stewardship. Through the planning and development process, specific initiatives, programs and projects (many which are in progress) are identified and assessed. The planning effort is collaborative among cross functional organizations within LADWP. Each initiative, program and project will have its own appropriate set of goals and objectives, which in turn supports the collective goal of reliable, affordable electricity that is sensitive to the environment.

3 Identify and approve key assumptions

The assumptions form the basis for subsequent analyses, and include such factors as load and fuel price forecasts, renewable resource percentage targets, CO_2 allowances and pricing, projected energy efficiency implementations, repowering schedules, etc. Assumptions are prepared and approved by the internal LADWP organizations responsible for the respective subject areas. The assumptions are then presented to LADWP management for comments and acceptance.

4 Establish strategic case alternatives

Each of the strategic cases is developed by IRP staff with input from each of the internal LADWP organizations. The strategic cases are designed to consider alternative future resource portfolios, and reflect real decision points and plans that LADWP will have to implement. The current major decision areas for LADWP is coal replacement, energy efficiency, and distributed generation, therefore, this IRP considers cases which offer alternative options for these three subject areas. Each case is vetted through LADWP management and working meetings are held to agree on final cases to be assessed.

AR0069952

5 Conduct computer modeling of Power System operations

Simulations of the case alternatives are made using the Planning and Risk (PAR) software. PAR is a widely used hourly production cost model that commits and dispatches resources to minimize the cost of serving electric load. PAR is used by many utilities across the US and the world. The modeling results are vetted for quality. Post model analysis is then conducted to account for non-generation system costs, including transmission and distribution. The final results compare each case in terms of reliability, costs, and CO_2 emissions reduction. The results are reviewed by management for comments and acceptance. If needed, modifications are made to the model input assumptions for new computer runs.

6 Present preliminary Findings and gather public comments

Public meetings are held where the findings of the case analysis are presented. These results are considered preliminary at this point. Following public input, a final analysis of the cases is then conducted. It is possible that one or more of the cases may be modified as a result of public input.

7 Recommend and approve a preferred case

Based on the results of the final analysis, a preferred case is recommended. The preferred case is then presented to management for review and acceptance.

The IRP development process includes coordination among multiple LADWP organizations responsible for different aspects of Power System operations. Recommended positions at the various stages are presented to LADWP's leadership team, including Division and Section Heads. The approval process for recommendations is based on consensus from the managers of each area of responsibility.

AR0069953

1.9 Summary

LADWP is in the process of transforming its Power System. Approximately 70% of its Power System generation will be replaced within the next 15 years. Numerous challenges are being addressed concurrently, including meeting renewable resource requirements, once-through cooling, natural gas repowering, coal replacement, GHG reduction, energy efficiency, demand response programs and others. Meeting all of these challenges requires considerable amounts of labor and capital resources, which applies upward pressure on LADWP's electric rates.

LADWP is focusing on both near-term and long-term solutions. To achieve the objectives and goals documented in this 2012 IRP, LADWP will continue to implement its existing programs and projects, but will also introduce and expand new initiatives and program areas. The following list shows the major activities that require action over the next 3-5 years (for more information, see the referenced IRP sections).

Major Power System Activities 2012–2017

Programs Already in Progress

- **Haynes 5&6 Repowering** (Sections 1.6.6, 2.4, 3.3, 5.3, Table 5-4, Appendix F)
- **Scattergood Repowering** (same as Haynes 5&6 references)
- **Coal Replacement Planning and Implementation** (Sections 1.6.4, 2.4.2.6, 3.3, 3.5, 4 and 5)
- **Replacing aging distribution infrastructure** (Sections 1.6.7, 1.6.8 and 2.4.2.3, Appendix E)
- **RPS procurement** (Sections 1.6.5, 2.4.3, 3.4, and 5, Appendices D and N)
- **Solar Program Development** (Sections 2.4.3, 3.2.4 and 5, Appendices D, G, and N)
- **Existing EE program elements** (Section 2.3, Appendix B)

New and Expanded Program Areas

- **Demand Response Program** (Sections 2.3.2, 5.3, and 5.6, Table 4-2)
- **New EE program elements** (Section 2.3, Table 1-6, Appendix B)
- **Smart Grid Implementation** (Section 2.4.5, Table 4-6, Appendix L)
- **Transmission Line Improvements** (Sections 2.4.4, Appendix J)
- **Grid Reliability Improvements** (Sections 2.4.4 and 5.1)
- **Haynes 1&2 Repowering** (Sections 1.6.6 and 5.3, Table 4-6)
- **Distributed Generation** (Sections 2.3.3, 3.5, 4.3.3.1, Appendices G and N)

2.0 LOAD FORECAST AND RESOURCES

2.1 Overview

Through an IRP, utilities forecast the demand for energy and determine how that demand will be met. Meeting forecasted demand is accomplished by the planning and delivery of electric power generating ("supply-side") resources through transmission and distribution systems. Another key element of IRP planning is to determine how to reduce energy demand and increase the efficiency of the utility customer's use of electricity, known as "demand-side resources."

This section of the IRP addresses the following:

- Forecasting of future energy demand
- Demand-side Resources (DSR), including Energy Efficiency and Demand Response
- Distributed Generation
- Supply-side Resources
- Transmission/Distribution, including grid reliability
- Advanced Technologies, including Smart Grid and Energy Storage
- Climate Change Effects on Power Generation
- Reserve requirements

The discussions include the technical, regulatory, and economic factors that affect LADWP's planning and execution of programs and projects.

Data for this analysis comes from publicly available reports from organizations such as the California Energy Commission (CEC), California Public Utilities Commission (CPUC), the North American Electric Reliability Corporation (NERC), the Federal Energy Regulatory Commission (FERC), other industry forecasts, and internal LADWP sources. Also highlighted in this IRP are additional studies that are either underway or will be performed in the near future to provide additional clarity regarding the boundaries and needs of the system.

AR0069956

2.2 Forecast of Future Energy Needs

This IRP utilizes LADWP's 2012 Load Forecast, dated March 7, 2012, of customer demand for energy over the next 20 years (the complete 2012 Load Forecast is included in Appendix A). Econometric models are used to forecast retail sales and peak demand. Net Energy for Load (NEL) is defined as the production necessary to serve retail sales. NEL, and its allocation across various times of the day, are functions of the retail sales and peak demand forecasts. The retail sales forecast is the sum of seven separate customer class forecasts. The classes are residential, commercial, industrial, plug-in electric vehicle (PEV), intradepartmental, streetlight, and Owens Valley. The drivers in the retail sales models include normalized weather, population, employment, construction activity, and personal consumption. The NEL forecast is derived from the retail sales forecast by applying a normalized loss factor of 11.5 percent. Losses can vary depending on the sources of energy production. NEL load growth becomes a driver of the peak demand forecast. Peak demand is also a function of temperature, heat buildup, and time of year. The NEL forecast is allocated using the Loadfarm algorithm developed by Global Energy. The inputs into the algorithm are NEL, peak demand, minimum demand, and system load shape.

2.2.1 2012 Retail Electrical Sales and Demand Forecast

The effect of the recent recession and slower than normal recovery, combined effective energy efficiency programs depressed electricity sales by approximately 6.4 percent off their fiscal year 2007-08 peak. Economic activity in commercial sectors such as construction, real estate, retail, and leisure are forecasted to recover as the economy expands.

The electricity consumption within LADWP's service territory is forecasted to rise 0.8% over the next five years as energy efficiency and solar rooftop expansion offset growth from economic activity. The growth in annual peak demand over the next twenty years is predicted to be about 0.6 percent – approximately 40 MW per year – with less growth over the next few years due to the current recession. After 2018, some of the growth will not be realized at the meter depending on the adoption of energy efficiency and distributed generation technologies.

The 2012 forecast is LADWP's official Power System forecast. This forecast is used as the basis for LADWP Power System planning activities including, but not limited to, integrated resource planning, transmission and distribution planning, and wholesale marketing. The forecast is a public document that uses only publically available information.

Table 2-1 summarizes the data sources used to develop the forecast and where these data sources have been updated from previously published forecasts.

AR0069957

Table 2-1: LOAD FORECAST DATA SOURCES

Data Sources	*Updates*
1. Historical Sales through December 2011 are reconciled to the General Accountings Consumption and Earnings Report.	*Historical Sales, Net Energy for Load and weather data is updated through December 2011.*
2. Historical NEL, peak demand and losses through December 2011 are reconciled to energy accounting data.	
3. Historical weather data is provided by the National Weather Service and Los Angeles Pierce College.	*Weather is updated through December 2011.*
4. Historical Los Angeles County employment data is provided by the State of California Economic Development Division using the March 2010 benchmark.	*Employment data is updated through December 2011 using the March 2010 benchmark.*
5. Historical population and forecasts is provided by the State of California Department of Finance.	Population data is updated through January 2012.
6. The long-term Los Angeles County economic forecast is provided by UCLA Anderson Forecast.	
7. The construction activity forecast is provided by McGraw-Hill Construction.	*Building permit data is updated through December 2011.*
8. The plug-in electric vehicle (PEV) forecast is based on the California Electric Vehicle Coalition which has been adopted as the statewide PEV forecast.	
9. The port electrification forecast is provided by the Port of Los Angeles.	
10. The housing forecast is informed by the City of Los Angeles "Housing that Works" plan.	

2.2.2 Five-year Sales Forecast

The Retail Sales Forecast represents sales that will be realized at the meter through Fiscal Year Ending (FYE) 2017. After FYE 2017, some of the forecasted sales will not be realized at the meter due to the incremental impacts of LADWP-sponsored energy efficiency programs.

The historical accumulated energy efficiency and solar savings are from 1999 forward and only include LADWP installed savings. Since July 1, 2008, LADWP installed energy efficiency savings are 715 GWh for which LADWP recovers lost revenue. In the forecast, energy efficiency and solar savings are expected to occur uniformly throughout the year as a simplifying assumption. Installation schedules are difficult to prepare because they rely on the customers allowing the installation to occur.

Retail sales decrease of 0.6 percent in FYE 2014, as shown in Figure 2-1, is attributed to the full ramp up of the lighting efficiency requirements of AB 1109 (approved in 2007 and known as the "Huffman Bill") and accelerated incremental savings rates in

AR0069958

LADWP's energy efficiency programs. Beginning January 2012, the Huffman Bill significantly raises the efficiency standard of light bulbs. The 0.5 increase in FYE 2015 is due to the projected completion of port electrification projects and a decline in the LADWP incremental energy efficiency savings rate.

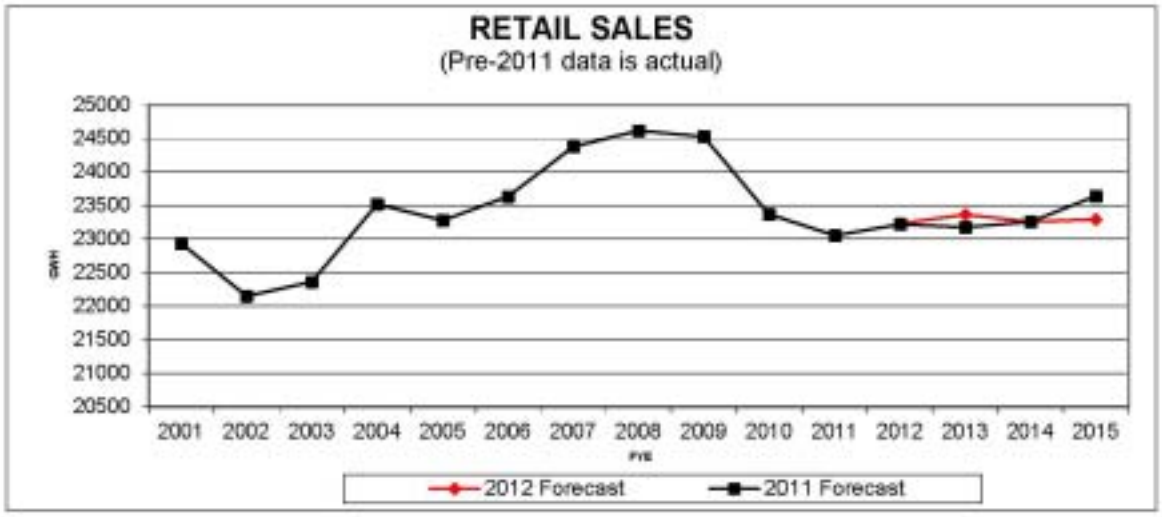

Figure 2-1. Retail sales net of energy efficiency and distributed generation.

Table 2-2 shows projections of short-term retail sales growth:

Table 2-2. SHORT-TERM GROWTH

Fiscal Year	Retail Sales		Additional Load if not for EE & Solar Savings
Ending June 30	(GWH)	Growth Rate (Year-Over-Year)	(GWH)
2010-11	23,053	-1.50%	0
2011-12	23,232	0.8%	255
2012-13	23,364	-0.4%	592
2013-14	23,256	-0.6%	928
2014-15	23,294	0.2%	1302

For IRP modeling and analysis, adjustments are made to the approved load forecast to account for the alternative energy efficiency targets and customer net-metered solar projections. These adjustments are shown in Appendix N.

AR0069959

2.2.3 Electrification

A result of AB 32 will be to encourage increased electrification as a means to reduce GHG emissions. This has added a degree of uncertainty to the forecast of future electricity needs in terms of both additional resulting load and the speed of implementation of electrification programs.

In the transportation sector, fuel switching from diesel and gasoline to electric power can result in air quality improvements if the sources of electric power are clean. Figure 2-2 shows the forecasted number of plug-in electric vehicles (PEVs) within the LADWP service area over the next 20 years. To support the adoption of electric vehicles, LADWP launched a pilot program in May 2011 that provides 1000 customer rebates of up to $2,000 towards the purchase and installation of electric vehicle home charging systems. Supporting the City's electric vehicle infrastructure, LADWP is also in the process of retrofitting 117 vintage chargers on City property.

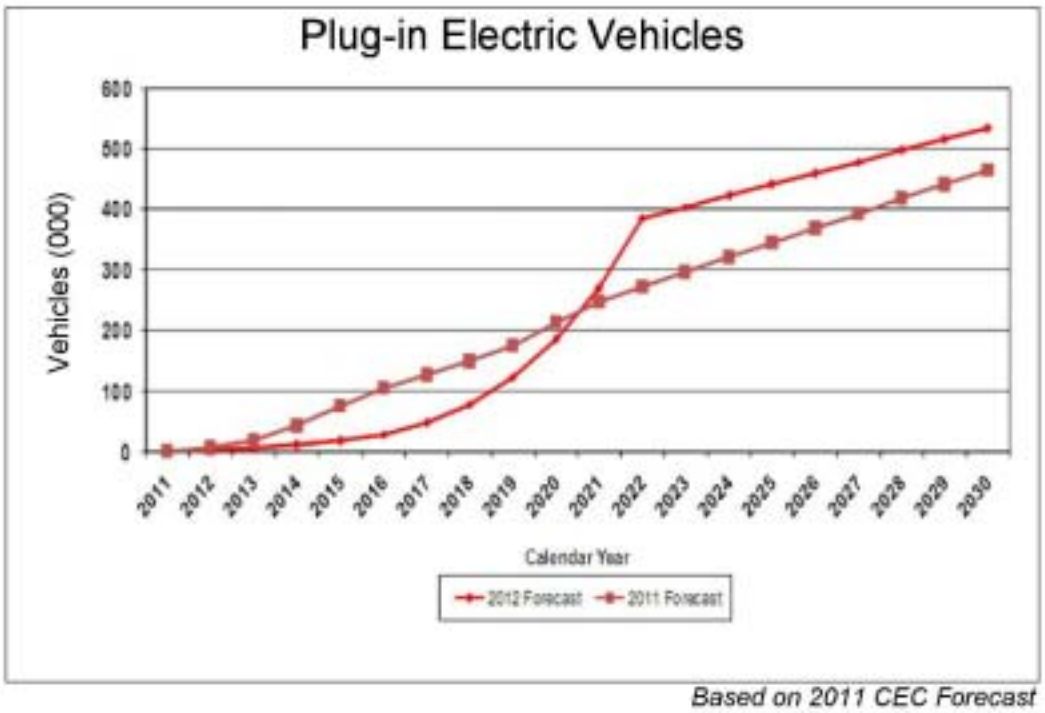

Figure 2-2. Forecasted number of plug-in electric vehicles.

Other agencies in the LA air basin have initiatives underway for "electrification" to replace existing diesel fueled trucks and gasoline powered cars with electric power. In addition, planned expansions to light railway and the metro system would add additional electric load to the system. Another example of transportation sector electrification is the Clean Air Action Plan developed jointly by the Port of Los Angeles and the Port of Long Beach to reduce air pollution from their many mobile sources as well as some fixed

AR0069960

sources. This includes trucks, locomotives, ships, harbor craft, cranes, and various types of yard equipment. One of the programs, Alternative Marine Power (AMP), allows AMP-equipped container vessels docked in port to "plug-in" to shore-side electrical power instead of running on diesel power while at berth.

Plug-in Electrical Vehicles (PEVs)

Large scale deployment of electric vehicles will significantly affect the way electricity is consumed. It is estimated that by 2015, the United States will have one million EVs in deployment, 10% of which is expected to be in California. The introduction of electric vehicles in Southern California brings a challenging set of planning, regulatory and cost issues. Because EVs require a unique infrastructure, including specialized charging equipment and adequate electric service, it is essential to anticipate and predict the grid impact in Southern California from the EV deployment.

Regulated utilities in California are now responding to regulatory direction to submit plans for large-scale EV initiative with full delineation of costs and benefits. This regulatory initiative is an aggressive step, seeking to promote accelerated adoption of EVs. The EV deployments and the associated utility customer features are proceeding throughout the State of California. Energy needed for PEVs will come partially from the utility electric grid. It is expected that the "fuel shift" from traditional transportation fuels will increase customers' demand for electricity from the electric grid.

PEVs also present an opportunity to influence charging patterns by incentivizing charging during off-peak time periods, resulting in better system load factor. Currently 80% of PEV charging in Los Angeles occurs during off peak hours (per US DOE)

LADWP will use a part of the $120 million Smart Grid demonstration grant award from DOE to demonstrate the integration of electric vehicles into the LADWP-managed electric system. The demonstration will use internal fleet equipment, privately owned EV chargers, and will include electric vehicle fleets from both UCLA and USC. These complementary fleets provide the opportunity to test EVs in both the controlled environment of a corporate fleet and the "real world" usage of individuals. These opportunities will test the integration of EVs into the grid, along with acquisition of EV communications to the grid management.

AR0069961

2.2.4 Peak Demand Forecast

Growth in annual peak demand over the next ten years is 1.0 percent as shown in Table 2-3.

Table 2-3: FORECASTED GROWTH IN ANNUAL PEAK DEMAND

Fiscal Year End June 30	Base Case Peak Demand (MW)	Growth rate Base Year 2010-11	One-in-Ten Peak Demand (MW)
2011-12	5635[1]		6046
Forecast			
2015-16	5591	0.8%	6028
2020-21	5791	1.0%	6244
2030-31	6381	1.1%	6885
2040-41	6992	1.1%	7546

[1] Weather-normalized. Actual peak was 5907 MW

In 2010, the System set its all-time annual net energy for load peak at 6142 MW on September 27, 2010 on a day that was a one-in-thirty-five year weather event. The weather-adjusted one-in-two peak for 2011 is 5635 MW. Figure 2-3 presents the one-in-ten peak demand forecast, which is used for integrated resource planning. In the 1990s through 2005, annual system load factors were trending slowly upward. Since 2006, system load factors are trending down. Two factors are generally thought to be contributing to this effect. Most customers are making greater efforts to conserve energy but during extreme weather events safety and comfort predominate over conservation causing the peak to spike. Much of the historical and forecasted energy efficiency effort is lighting which has a greater impact on consumption rather than peak which lowers the load factor.

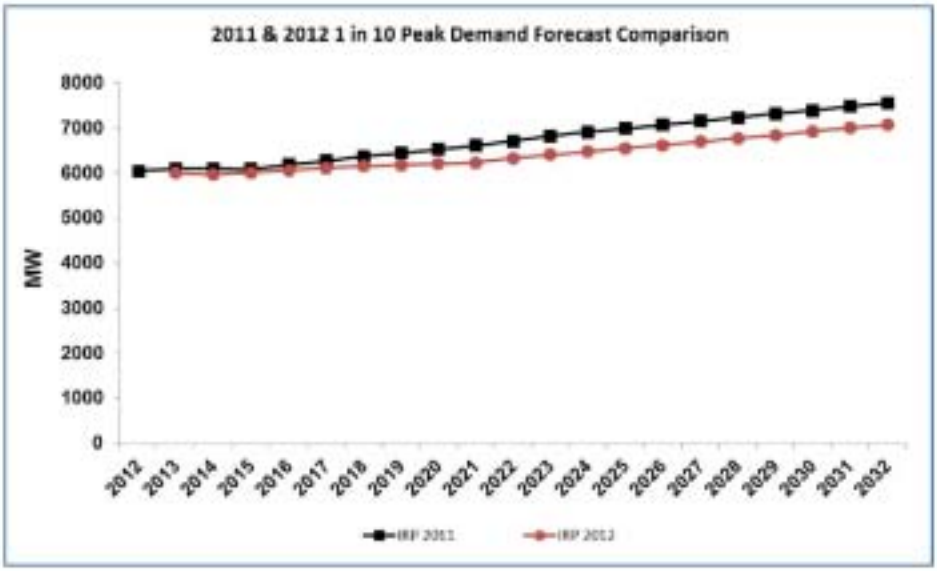

Figure 2-3. One-in-ten peak demand forecast comparison.

AR0069962

2.3 Demand-Side Resources

Demand Side Resource (DSR) programs, including energy efficiency, have become important elements of IRP planning. Also known as Demand Side Management, DSR programs help to counter or minimize energy demand growth and thereby lessen the need to build more physical generation assets and improve load factor. This section discusses the following DSR initiatives:

- Energy Efficiency (EE)
- Demand Response (DR)
- Distributed Generation (DG)

Key DSR data assembled for this IRP included:

- The energy efficiency forecast, which was based on the Board-approved AB 2021 objectives, the City of Los Angeles Green Plan, and Demand Forecast Energy Efficiency Quantification Project working papers. Historical installation rates were referenced as part of the forecast.
- An estimate of the amount of solar rooftop and other distributed generation.
- An assessment of existing and developing technological improvements in large scale battery systems for energy storage.

2.3.1 Energy Efficiency

Energy Efficiency (EE) is a key strategic element in LADWP's resource planning efforts. EE is an overall cost effective resource in LADWP's supply portfolio and serves an important and multi-faceted role in meeting customer demand. One of the most widely recognized examples of an EE program is the replacement of incandescent lights with compact fluorescent lamp (CFL) bulbs. CFLs consume up to 75% less energy than incandescent bulbs while producing an equivalent amount of illumination and last up to 10 times longer.

Since 2000, LADWP has spent approximately $315.2 million in capital and O&M on its energy efficiency (EE) programs and these programs have reduced consumption by approximately 1,377 GWh. LADWP is committed to implementing comprehensive programs with measurable, verifiable goals as well as implementing robust, cost effective energy efficiency programs.

Under Assembly Bill 2021 (AB 2021), publicly-owned utilities such as LADWP, must identify, develop and implement programs for all potentially achievable, cost-effective EE savings and establish annual targets.

AR0069963

Furthermore, utilities are required to conduct periodic "Potential" studies to update their forecasts and targets. LADWP's most recent study, carried out in late 2010, is the basis for the EE recommendations contained in last year's 2011 IRP and was used to develop the initial financial plan and proposed rates for fiscal year ending (FYE)[1] 2013 and FYE 2014. LADWP is currently proceeding with the 2013 EE Potential Study, to be completed in 2013.

2.3.1.1 Recommended Target - 10% by 2020

The base plan for energy efficiency programs established in December 2011 puts LADWP on a path to achieve energy savings equivalent to 8.6% of 2010's energy consumption by 2020. This level of savings reflects the findings of the latest energy efficiency potential study and was approved by the LADWP's Board of Commissioners in December 2011. The 2010 reference point is specified by AB 2021, which encourages the state's electric utilities to achieve cumulative savings of 10% of total energy consumption levels by 2020. The Board's adoption of an 8.6% energy savings goal by 2020 was an interim goal. In that adoption, the Board requested LADWP to evaluate options to increase the rate of energy efficiency savings to achieve the targeted goal of 10% by 2020. LADWP determined that a 10% goal by 2020 was indeed achievable, and the Board formally adopted this target on May 24, 2012.

LADWP's baseline EE spending in the initial financial plan for FYE 2013 and 2014 (based on the 8.6% target) is $87M and $99M, respectively. In order to achieve the 10% level of GWh savings, LADWP recommended increasing spending on EE programs. This change would add funding to existing programs, modify existing programs or develop new programs that provide additional GWh savings necessary to put the utility on a projected path to achieve 10% savings by 2020. Other changes included reallocating costs from support functions to programs, capitalizing the vast majority of the programs, and updating assumptions related to other programs. The Board adopted the increased EE budget for 2013-14 at the same time as the 10% savings goal, on May 14, 2012.

On May 24, 2012 the Board also acknowledged plans to conduct a new updated energy efficiency potential study to be completed by June 30, 2013. The new potential study will be used to develop a long-term plan for the scope and estimated costs to achieve 10%, 12.5%, and 15% savings by 2020. The energy efficiency planning scenarios resulting from the new study will be considered for inclusion into future IRPs.

2.3.1.2 Total Additional EE Investment Required to Reach Required 10% GWH Savings

As shown in Figure 2-4 and Table 2-3 below, LADWP recommended an additional $41 million and $40 million in expenditures in FYEs 2013 and 2014 respectively. This level of additional spending is well above LADWP's historic and current levels and produces

[1] FY 2013 refers to 7/1/2013 to 6/30/2014. FY 2014 refers to 7/1/2014 to 6/30/2015. LADWP's fiscal year begins on July 1 and ends on June 30.

AR0069964

the GWh savings required in the next two fiscal years to put LADWP on a path which, if continued beyond FYE 2014, would reach at least the 10% required by year 2020 per AB 2021. Notably, this level of funding puts LADWP on par with California's Investor Owned Utilities (IOUs) in terms of EE investment on a per-ratepayer basis, giving LADWP the third largest portfolio of EE programs in California. Moving forward with this level of commitment then allows LADWP to prepare plans beyond the next two fiscal years to achieve the 10% energy efficiency savings by 2020, or to consider even further energy efficiency improvements beyond 10% if deemed appropriate.

The yellow line in Figure 2-4 represents the level of energy savings required to pace LADWP towards the 10% reduction target. Expenditures for this level of savings were approved in the recently concluded rate process.

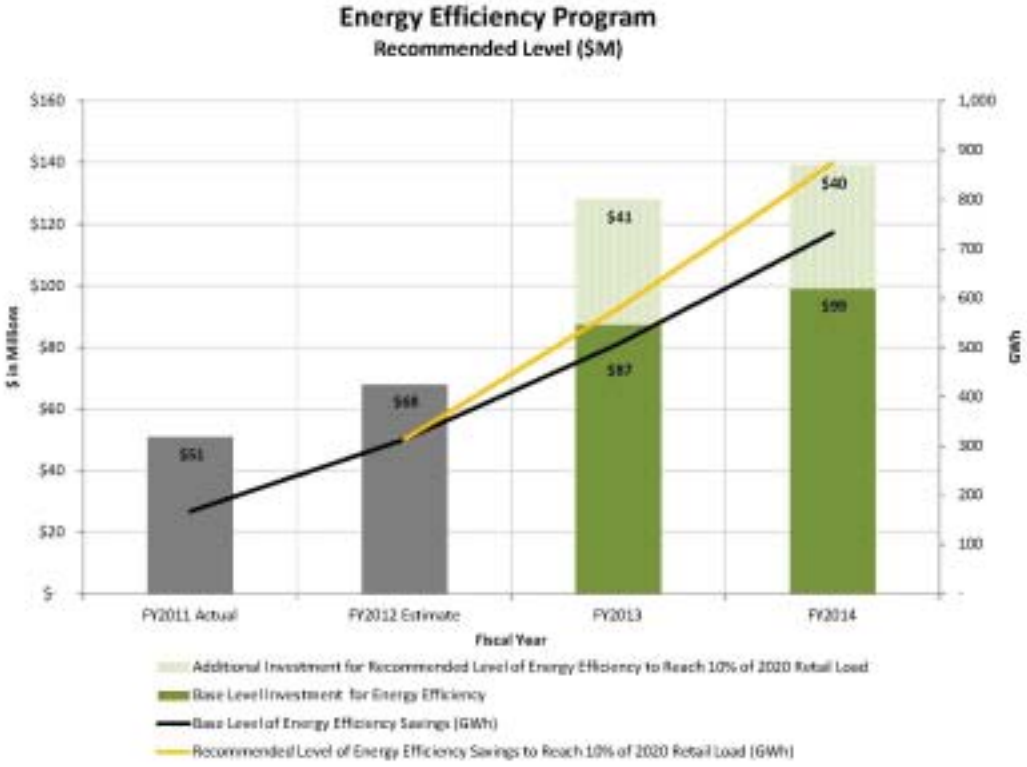

Figure 2-4. Energy efficiency recommended investment and energy savings through FYE 2014.

Table 2-4 below shows proposed spending for the next two years, along with an extended outlook through FYE 2017.

AR0069965

Table 2-4. TOTAL ENERGY EFFICIENCY EXPENSES AND USAGE SAVINGS

Energy Efficiency Program	Proposed Rate Period Cost ($000s)		Extended Outlook Cost ($000s)			Total Five Years FY 2013 to FY 2017		
	FY 2013	FY 2014	FY 2015	FY 2016	FY 2017	Cost ($000s)	GWh Savings	Cost ($/kWh)

TOTAL ENERGY EFFICIENCY PROGRAM	$127,197	$137,736	$143,379	$152,034	$179,747	$740,094	1,523.5	0.079

Note: LADWP reserves the right to adjust programs, budgets, and individual program savings target at any time in order to respond to changing business conditions and market needs.

AR0069966

The spending shown in Table 2-4 results in cumulative savings of 1,523.8 GWh in FYE 2013 through FYE 2017 combined at an average cost per kWh of $0.079

2.3.1.3 Program Descriptions

The different EE program elements are briefly described as follows

Residential Programs

Refrigerator Recycling Program. The program provides free pick-up and recycling of old, inefficient refrigerators along with a cash incentive of $50 for each recycled refrigerator

Refrigerator Exchange Program. Provides new energy-efficient refrigerators to low-income customers in exchange for existing inefficient older models. Program planning includes improved outreach and continued expansion to apartment owners

Consumer Rebate Program (CRP). The CRP is designed to both educate and encourage the LADWP's residential customers to purchase high efficiency refrigerators, air-conditioners, appliances, and other energy-saving products that meet or exceed Energy Star efficiency rating

Home Energy Improvement Program. This program, offers residential customers the opportunity to reduce their energy bills by allowing qualified Department staff to make energy efficiency and water conservation upgrades to their home. For residential customers residing in multi-family dwelling, common area efficiency upgrades will also be addressed. All residential customers may apply, however, first consideration will be given to registered low-income and lifeline customers, and Tier 2 residential customers who demonstrate the greatest economic need

Residential Lighting Program. This program is currently under development

Behavioral Programs. Provides residential end-users with information on their energy use, comparisons with usage by others, goal setting, rewards and additional tactics that encourage efficient energy use. This is a new program not included in the base energy efficiency program.

Energy Upgrade California. This is a collaborative program administered by the California Energy Commission in partnership with public and private utilities, the California Public Utilities Commission and participating counties. The program is funded by grants and contracts from the U.S. Department of Energy, the Energy Commission, and California utility customers. This is a new program not included in the base energy efficiency program.

AC Tune Up. Provides qualifying residential customers with Air Conditioning refrigerant charge adjustments and condenser coil cleaning. Program is currently in development

Non-Residential Programs

Commercial Lighting Efficiency Offer. Provides menu-based rebates for energy efficient lighting technologies, including T8 and T5 lamps with electronic ballasts, high bay linear fluorescent fixtures, induction lamps, LED exit signs, LED channel signs, occupancy sensors, and others.

AR0069967

Chiller Efficiency Program. Rebates are available for all types of chillers (air-cooled and water-cooled). In addition, water-cooled centrifugal chillers now can be tested at either standard Air-conditioning and Refrigeration Institute (ARI) or non-standard ARI conditions provided the cooling tower meets specific performance criteria. Higher rebate levels are based on the percentage that the chiller's Integrated Part-Load Value performance exceeds California's Current Title 24 requirements for chillers.

Refrigeration Program. The new Refrigeration Efficiency Program encourages best practices and retrofit measures and technologies to reduce energy in fixed store refrigerator cases and cold storage facilities.

HVAC Program (5 to 20 tons). Offers incentives for replacing inefficient package units with high efficiency units. This is a new program not included in the base energy efficiency program.

Custom Performance Plus. An enhanced version of the Custom Performance Program that is in the base level EE plan, targeting industrial process efficiency improvements with minimum energy saving requirement of one GWh. Program is currently in development. This is a new program not included in the base energy efficiency program.

Custom Performance Based Program. This program continues offering savings-based incentives for the installation of energy savings measures, equipment or systems that exceed Title 24 or minimum industry standards, with differing incentive rates established for three categories of efficiency measures (lighting, HVAC, other).

New Construction Program. This program is being redeveloped. Plans are underway to offer incentives for projects exceeding current Title 24 requirements for energy efficiency.

Energy Efficiency Measures for LAUSD. Los Angeles Unified School District (LAUSD) is the largest power customer of the utility. LADWP is presently working with LAUSD to develop a focused energy efficiency program to reduce energy use at LAUSD facilities that are within the City of Los Angeles[1]. LADWP has proposed to LAUSD undertaking specific energy efficiency measures in FYE 2013 while LADWP works with LAUSD to develop a detailed energy usage and energy efficiency potential study of LAUSD facilities that will provide the basis for a multi-year energy efficiency plan that LADWP and LAUSD would collaboratively undertake as part of LADWP's overall energy efficiency investment program. The Energy Efficiency Alternative Plan presented herein provides for an allocation of funding and target energy savings for the next two fiscal years. This plan will be developed in more detail in cooperation with LAUSD.

Small Business Direct Install Program (SBDI): This program will retrofit the existing lighting of qualifying business customers to new, high efficiency lighting systems. The SBDI will initially target the smallest business customers in the A1 rate class, but may be expanded to other customer segments. This program is expected to operate for three years.

Retrocommissioning (RCx) Express. (RCx Express) program is a continuation of the American Recovery and Reinvestment Act (ARRA) grant-funded pilot program for non-residential customers, replacing the ARRA grant funding with Department funding from rate revenue. The pilot program design is based on lessons learned from SCE's Retrocommissioning program. The

[1] Some of the LAUSD facilities are located outside of the boundaries of the City of Los Angeles and are served by Southern California Edison.

AR0069968

LADWP program offers a cash incentive (rebate) to those who undertake a "tune-up" of their existing building system equipment and bring it back up to its original performance level. The program does not require a Retrocommissioning study, but offers a menu of 13 items that qualify for incentives. Program offerings include incentives for replacement or repair of certain lighting sensors, air conditioning economizers, restoration of fan and pump variable frequency drives, operations set point strategies for supply air, temperature or duct pressure, chilled water and condenser water, operating schedules and boiler lockout.

Other Programs

Other programs in support of residential and industrial energy efficiency programs includes: (1) development of an on-bill financing mechanism for third party financing and LADWP collection of payments for such financing; (2) program outreach and community partnerships; (3) marketing to increase awareness of energy efficiency programs; and (4) measurement and verification of energy efficiency program savings.

2.3.1.4 Effect of EE on Electric Rates and Bills

The key factor that determines EE's effect on electric rates and customer bills is the comparison of its costs to the cost of the generation it is replacing. The following Table 2-5 conceptually illustrates the three possibilities – EE costs are lower, the same, or higher than the costs of the generation resources being replaced.

Table 2-5. EFFECT OF EE ON RATES AND BILLS

Are EE costs lower, the same, or higher than the generation it is displacing?	Effect on Total Cost $ (Which Must Equal Revenue Collected)	Effect on Total Energy Sales kWh	Effect on Rates $/kWh	Effect on "System-wide" Average Bill
Lower	Lower	Lower	see discussion below	Lower
Same	Same	Lower	Higher	Same
Higher	Higher	Lower	Higher	Higher

When EE costs are lower than the generation it is replacing (see Row 1 in Table 2-5), there are overall reductions in both total costs and energy sales. This could result in upward rate pressure since there are less kWhs to spread the costs over. However, the reduction in total costs may be large enough to keep rates flat, and more so in the long term as avoided cost benefits accrue over time. Lower total costs also means less revenue collected from customers; hence the "System-wide" average customer bill is lower, which benefits all customers. Those who implement energy efficiency measures will see further reductions.

AR0069969

Table 2-5 also illustrates the case where EE costs are higher than the generation it is replacing. If EE is replacing less expensive resources (such as or coal, notwithstanding CO_2 allowance costs), the effect is a higher rate *and* higher "average" bill due to the higher total system costs.

As a practical consideration, there is little choice regarding which generation will be replaced by energy efficiency. While the effect of EE on Power System operations is to lower energy consumption and thus lower the amount of generation to be dispatched on a given day, the methodology for dispatch continues to be based on the economics of the generation available. Thus, the key measure of EE's impact on overall rates and bills is the comparison of its cost to the Power System's avoided cost of generation. As long as the cost of EE is lower than the avoided cost of generation, there is the beneficial effect of lower total costs and lower total revenue required.

The variations in EE costs, based on the different measures available, are identified in the energy efficiency potential study, and are factored into the development of EE program elements. A new potential study is planned for completion in 2013 and will provide updated information to modify the overall EE program.

Further information regarding LADWP's EE program is included in Sections 4 and 5, and Appendix B. A detailed discussion of avoided costs of generation can be found in Section 4.3.3 and Appendix N, Section N.4.

2.3.2 Demand Response

Demand Response (DR) is an important energy management tool that facilitates the reduction in energy use over a given time period in response to a price signal, financial incentive, or other triggering mechanism. The objective of DR is to lower energy usage at critical peak demand periods, in a manner which decreases overall system costs. LADWP's DR programs will be based on incentives to encourage customer participation based on lower rates, rebates, or other financial incentives.

The benefits of demand response are many:

> ***Increased Reliability.*** The ability to strategically lower energy consumption is one way to help overcome supply-demand constraints and reduce the chance of overload and power failure. This is especially important at those few critical peak times each year when demand is at its highest, as well as those times when generation units are off-line, whether due to a forced outage or scheduled maintenance.
>
> ***Lower System Costs.*** DR eliminates or defers the need to build additional power plants and the associated transmission and distribution infrastructure. Additionally, DR may reduce purchased energy costs by reducing the amount of energy that would otherwise be purchased to meet load, especially during the expensive peak demand periods. The overall effect is to save money which helps keeps rates low.

AR0069970

Less Environmental Impact By eliminating or deferring the need to build additional infrastructure, the associated construction and operational impacts are also eliminated or deferred. Furthermore, the reduction in energy usage results in less operational impacts, including less fuel consumption, less carbon emissions, and less transmission use.

Help Integrate Renewables Under certain circumstances, DR can enable customer loads to respond to fluctuations in generation from wind and solar power.

DR is a relatively new demand-side resource, and LADWP plans to develop an active program over the next several years. As discussed in Section 5, one of the recommendations of this 2012 IRP is to provide funds to develop and implement DR. The analysis of all strategic cases considered in this 2012 IRP (discussed in more detail in Section 4) calls for a small 5 MW DR program beginning in 2013 that will build to 200 MW by 2020 and 500 MW by 2026. This gradual expansion will facilitate the development of in-house expertise that will ensure a sound DR program by the end of this decade, and will also allow time to deploy the supporting IT infrastructure and to implement required IT systems and processes.

A variety of program elements are being considered for LADWP's DR program. The following are some of the offerings that are commonly adopted in the industry. Depending on the circumstances of how energy is used, certain programs will be more suitable to particular customer segments than others. LADWP's initial planning focus is on items 1 and 2 below.

1- Curtailable/Interruptible Commercial/Industrial customers who sign up are on call for curtailment of power, and are provided credit even if an event is not triggered. However, curtailments are firm and mandatory; penalties are assessed for under performance or non-performance.

2- Direct Load Control Customers sign up and agree to be subjected to demand reductions as-needed based on power system needs and constraints. The typical example is a customer's central air conditioning system which may be remotely shut down by the utility during high peak conditions. In exchange, the customer gets an incentive payment or bill credit.

3- Peak Rebate Pricing Customers who participate in the Peak Rebate Pricing are notified in advance in which the retail electric rates are temporarily adjusted up, typically as a response to events or conditions such as extreme high peak load. The customer receives a rebate for reducing or shifting their load during the peak load event, but there is no penalty if the customer does not reduce load during the peak load event.

4- Critical Peak Pricing Similar to the Peak Rebate Pricing, customers who participate are notified in advance of the event and can avoid the higher prices by decreasing their energy use during this time period. The customer incentive to participate is a lower base rate throughout the year.

5- Real Time Pricing Retail rates are varied on an hourly basis or other short-term basis and are typically tied to variations in the commodity market prices for wholesale power supplies. Consumers are provided with access to the changing market prices on a continuous basis, and

AR0069971

can change their usage patterns accordingly to lower their energy costs. The premise is that customers will reduce usage during the expensive high peak periods.

6- Demand Bidding – Commercial/Industrial customers are given the opportunity to receive a credit for voluntarily reducing load when an event is called. The customer is not penalized if they are unable to meet their reduction target.

7- Aggregation Programs – DR aggregators are third party contractors who work with groups of customers to make combined loads available for reduction or interruption. The aggregator works with LADWP and the combined load is assigned to the appropriate DR program. Customers work directly with the aggregator. Terms, conditions and payment may vary per aggregator.

In designing the overall program, a number of parameters need to be established, such as the specific program elements to offer, and for each program element: customer eligibility, the type and size of incentives, contract duration, event duration, number of events, notification lead times, automation, billing requirements, etc.

This 2012 IRP recommends funding to initiate a formal DR program with the capacity targets as shown in Table 2-6:

Table 2-6. DEMAND RESPONSE TARGET SCHEDULE (NEW MW CAPACITY)

Yr.	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026
Target	5	10	20	40	75	100	150	200	250	300	350	400	450	500

DR will play a significant long-term role in securing adequate system capacity, especially in the case of early coal replacement. Section 4 discusses the strategic cases in detail. As shown in the case analysis, DR is a strategic component of LADWP's future resource portfolio.

2.3.3 Distributed Generation

Distributed Generation (DG) is the concept of installing and operating small-scale electric generators located at or near the electrical load. These numerous small generators are "distributed" across the service area, as opposed to the traditional configuration of a few large centralized generating stations. DG sources can be utility-owned or customer-owned. A large subset of DG is combined heat and power systems, also known as cogeneration, which are primarily owned and operated by industrial and commercial customers.

Many categories of electrical generation fall under the DG definition, with the key characteristic being that they are located at or near the service load. The most common technologies used today for DG are turbines and internal combustion engines. Solar PV is a newer technology that is forecasted to account for an increasing percentage of DG. Other DG technologies are microturbines and fuel cells. Under a pilot project, LADWP installed a total of four 200-250 kW fuel cell power plants in various locations in Los Angeles. Although the pilot project is now

AR0069972

complete and inactive, it has provided considerable operational data and experience. LADWP continues to closely monitor fuel cell development. More details regarding DG can be found in Appendix G.

AR0069973

2.4 Generation Resources and Transmission Assets

The Supply-Side Resources discussed in this section include

- Existing Generation Resources
    - Natural Gas
    - Coal
    - Nuclear
    - Large Hydro
    - Existing Renewable energy resources (small hydro, wind, solar, biogas, and geothermal)
- Spot Purchases

The major issues affecting generation are presented, including the need to repower the in-basin natural gas units and the future disposition of coal-fired generation.

This section concludes with

- Future Renewable Resources
- Transmission and Distribution Facilities-Grid Reliability
- Advanced Technologies and Research and Development
- Climate Change Effects on Power Generation
- Reserve Requirements

The LADWP Power System has a diverse mix of generating resources. Figure 2-8 shows LADWP's Power System capacity and energy breakdown as of December 31, 2011 as well as what the capacity and energy mix was at the end of 2006.[1] The largest change between these two periods is the decrease in coal-fired energy from 47 percent in 2006 to 41 percent in 2011, and the corresponding increase in energy from renewable resources, from 7 percent in 2006 to 19 percent in 2011.

[1] "Capacity" is a measure of the capability to produce power or the rate at which energy is transferred. The term is applied to the amount of electric power delivered or required to meet the power demand, and is expressed in Megawatts (MW) or Gigawatts (GW). "Energy" is a measure of the quantity of electricity used or generated over time period and is expressed in Megawatt-hours (MWh) or Gigawatt-hours (GWh).

AR0069974

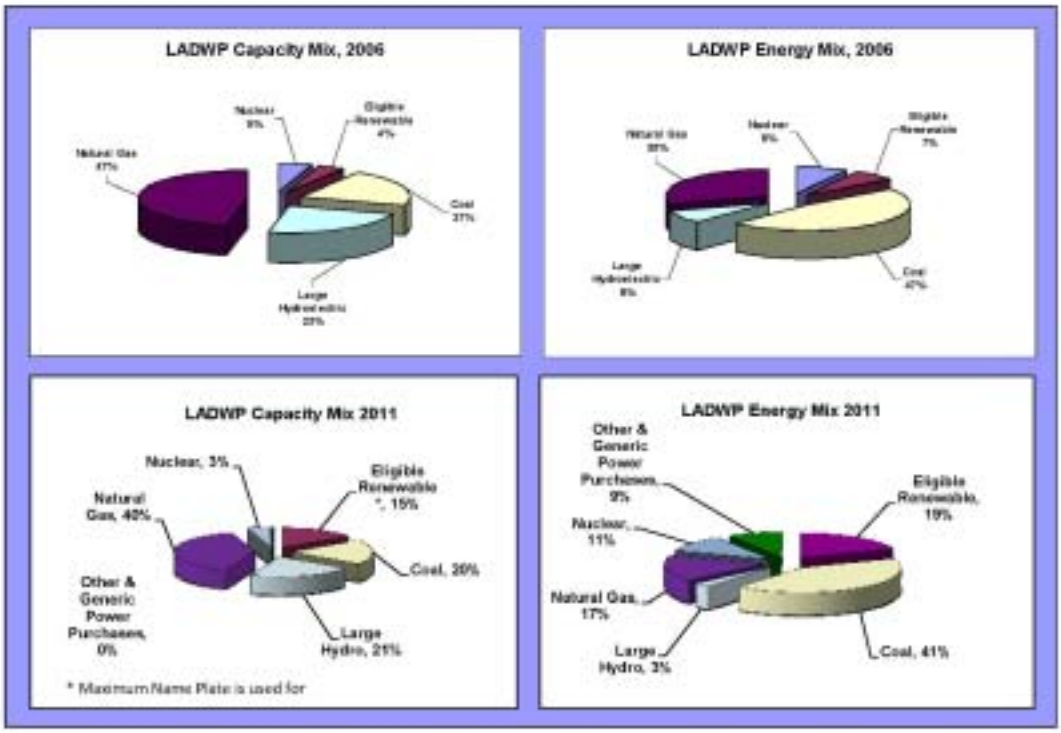

Figure 2-5: LADWP capacity and energy mix for 2006 and 2011.

2.4.1 Generation Resources

LADWP is vertically integrated, both owning and operating the majority of its generation, transmission and distribution systems. Generation resources that are not wholly owned by LADWP are available as entitlement rights resulting from undivided ownership interests in facilities that are jointly-owned with other utilities. Table 2-7 lists existing LADWP generation resources.

AR0069975

Table 2-7. CAPABILITY OF EXISTING LADWP GENERATING RESOURCES[1] (AS OF APRIL 2012)

Name of Plant	Fuel Source	Unit No.	In Service Date	Age (Years)	Net Maximum Unit Capability (MW) [2]	Net Maximum Plant Capability (MW) [3]	Net Dependable Plant Capability (MW) [4]	Comments

Total Net Capability of LADWP Resources						**8,509**	**7,469**	
California State Capacity Entitlement						-120	-56	Note [6]
Total Net Capability of LADWP System						**8,389**	**7,413**	Note [7]

Notes:

1. Power source data are based on Power System Engineering Division's January 2012 Generation Ratings and Capabilities Sheet and power purchase agreements for contract sources.
2. All units can attain maximum capability only when the weather and equipment are simultaneously at optimum conditions.
3. Reflects: water flow limits at hydro plants, sum of unit output at in-basin thermal or renewable plants, or LADWP contract entitlement of external thermal plants.
4. Reflects: year- round outputs adjusted for low-generation season. For hydro plants, winter is the low-generation season.
5. Owned or contracted renewable projects in wind, solar, hydro, landfill gas, biomass, and distributed generation in-service as of April 2012.
6. The maximum State (CDWR) Capacity Entitlement from Castaic Power Plant is 120 MW. The average for FY 09-10 was approximately 55 MW. The actual amount varies weekly.
7. Total Net Capability of LADWP System may vary due to unit outages, de-ratings and sales obligations.

AR0069976

Natural Gas

LADWP is the sole owner and operator of the following four electric generating stations in the Los Angeles Basin (the "In-basin stations"):

- Haynes Generating Station, located in Long Beach
- Harbor Generating Station, located in Wilmington
- Scattergood Generating Station, located in Playa del Rey
- Valley Generating Station, located in the San Fernando Valley

A map of the in-basin generating stations is shown in Figure 2-6.

Figure 2-6. LADWP in-basin generating stations.

Each station consists of multiple generating units, with each unit ranging in size between 43 MW and 450 MW. A summary of each station's capabilities is shown in Table 2-7. Detailed information on each generating station is included in Appendix F.

AR0069977

While all of these stations utilize natural gas as a fuel source, a special arrangement has been made that enables the Scattergood Generating Station to also use digester gas from the adjacent Hyperion Sewage Treatment Plant. The digester gas currently accounts for 16 MW of Scattergood's generation output. The agreement enabling this arrangement will end by 2015, but will be extended to account for a potential physical plant reconfiguration at the Hyperion Plant Facility.

Securing continued local generation capacity is important for grid reliability. LADWP's local transmission system cannot be reliably operated without generation from local thermal generating plants. The amount of generation required to provide transmission reliability is termed Reliability Must Run (RMR) generation. RMR generation is incorporated into all of the strategic cases considered in this IRP.

The major issues facing the in-basin stations include the need to replace some of the older units that are approaching the end of their service life, compliance with regulations related to ocean water cooling and NOx emissions, and fuel price volatility. Natural gas fuel prices and procurement issues are presented in detail in Appendix H.

Natural gas will continue to be the essential fuel for LADWP's generation due to abundant supply levels. Natural gas will be used to supply base load (as is currently used), and will also provide for the integration of intermittent renewable generation. Natural gas is also a major component of LADWP's coal replacement strategy.

Coal

LADWP's coal generating capacity comes from the Navajo Generating Station (NGS) and the Intermountain Generating Station (IGS). IGS is also referred to as the Intermountain Power Project (IPP). The amount of capacity available to LADWP from these stations is 477 MW from NGS and up to 1,200 from IPP. A summary of each station is included in Table 2-7. Further details and discussion is provided in Appendix F.

Contractual arrangements for power from IPP will expire on June 15, 2027. LADWP and the other participants at IPP are considering plans to convert the facility to natural gas. LADWP is one of thirty-six purchasers of IPP energy, and any future plans must be agreed to by all parties involved. Proposed amendments to the existing contracts are being considered by the purchasers which would require IPP to switch fuel from coal to natural gas no later than July 1, 2025 (two-years before the legal deadline). These amendments require unanimous approval and final purchaser decisions are expected by the end of 2013. Although the results of these discussions will not be available for this 2012 IRP, it is hopeful that the plan will completed in time for inclusion into next year's IRP process.

NGS operates under a co-tenancy agreement that remains effective throughout the initial term of its land lease until December 31, 2019. LADWP has been working with its partners on arrangements that would allow it to divest early from NGS, in 2015. See Section 2-12.3 for more details.

AR0069978

Nuclear

LADWP has contractual entitlements totaling approximately 387 MW of capacity from the Palo Verde Nuclear Generating Station (PVNGS). PVNGS, located approximately 50 miles west of Phoenix, Arizona, consists of three generating units. Of the 387 MW capacity available to LADWP, approximately 159 MW is available through a power sales agreement with the Southern California Public Power Authority (SCPPA). Further details are provided in Appendix F.

Large Hydro

LADWP's large hydroelectric facilities include the Castaic Pumped-storage Hydroelectric Plant and an entitlement portion of the capacity of Hoover Dam. The Castaic Pumped-storage Hydroelectric Plant, located in Castaic, California, is LADWP's largest source of hydroelectric capacity and consists of seven units. Hoover Dam, located on the Arizona-Nevada border, consists of seventeen units. Details of these plants are provided in Appendix F.

A distinction is made between "large hydro" and "small hydro." According to a provision of SB 2 (1X), small hydro includes a facility which consists of generating units with a nameplate capacity not exceeding 40 MW for each unit that is operated as part of a water supply or conveyance system. LADWP's small hydro units are located along the Los Angeles Aqueduct. These units qualify as renewable resources for electricity generation.

Current Renewable Energy Projects

LADWP's existing renewable resources total over 1,200 MW of capacity, and consist of wind, small hydro, solar, biogas and geothermal resources. More detailed information is presented in Section E.2.5 of Appendix F. A listing of existing renewable projects by resource type is as follows:

- Wind Resources
  - Linden
  - Pebble Springs
  - Pine Tree
  - PPM Wyoming
  - Wilkes Creek
  - Windy Point
  - Mifford I
  - Mifford II
- Small Hydro
  - Aqueduct, Owens Valley and Owens Gorge projects
  - North Hollywood
  - Sepulveda
  - Castaic Efficiency Upgrades

AR0069979

- Solar
  - LADWP In-Basin
  - Customer Net Metered
  - Adelanto Solar Project

- Biogas/Biomass
  - Bradley
  - Lopez Canyon
  - Toyon
  - Atmos and Shell
  - Hyperion Digester Gas

Additional renewable energy comes from market purchases.

Figure 2-7 presents the profile for LADWP's renewable resources portfolio as of 2011.

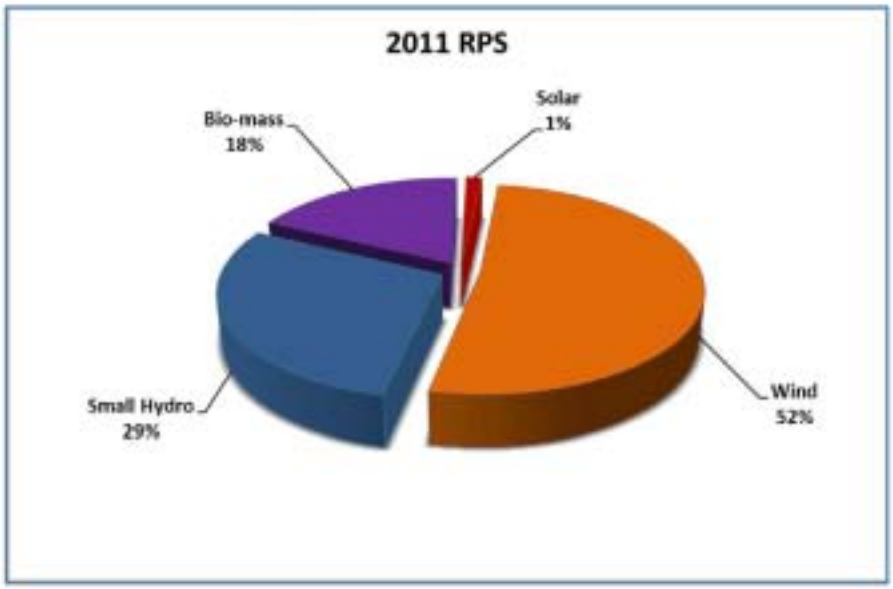

Figure 2-7: 2011 LADWP renewable energy mix.

Spot Purchases

Although LADWP's policy has been to be self-sufficient and capable of generating all of its energy needs from resources it owns or controls, it also participates in energy markets if it is in the City's best economic interest. This happens when energy can be acquired from the wholesale market for a cost which is less than which LADWP can produce such energy. Periodically, capacity and energy is purchased from providers within the Western Electricity Coordinating Council (WECC) jurisdiction under short-term "spot" arrangements to be delivered to the

AR0069980

LADWP transmission system. These purchases are used by LADWP in conjunction with other resources for economical Power System operation.

The cost and availability of economical energy on the spot market has fluctuated greatly in recent years. While LADWP currently continues to execute economical spot purchase opportunities, it cannot guarantee the future availability of economic energy from either the Pacific Northwest or the Southwest at prices below LADWP's costs for producing power from its own resources.

Spot Sales

LADWP often has a surplus of generating capacity and energy. Consistent with prudent utility practice, LADWP offers this surplus into wholesale electricity markets within the WECC at prices above LADWP's production costs. This way, LADWP's ratepayers benefit both by receiving the lowest cost energy in the Power System and from economic purchases, in addition to economic benefits resulting from wholesale revenue generated from sales.

2.4.2 Major Issues Affecting Existing Generation Resources

Three major issues affecting LADWP's existing generation fleet are: (1) the need to rebuild or "repower" some of its in-basin generating units, (2) compliance with state and local regulations regarding once-through cooling and NO_x emissions, and (3) strategies for replacement of coal-fired energy to accelerate GHG reductions.

2.4.2.1 Repowering Program to Replace Aging Infrastructure

There is a need to modify or replace some of LADWP's older gas-fired generation facilities located at the Haynes and Scattergood generating stations. These units were primarily built in the late 1950s and the early 1960s and are approaching the end of their service lives. LADWP must modernize these plants to maintain system reliability, improve efficiency, and better integrate renewable resources.

- System reliability

  As facilities age, they require more maintenance and become more susceptible to operational limitations and outages. The units to be replaced at Haynes and Scattergood Generating Stations are between 44 and 53 years old, and are among the oldest remaining units in LADWP's generation fleet. LADWP's local basin transmission system was never intended to be reliably operated without generation from these plants. By virtue of their location within the basin transmission system, Haynes and Scattergood generation ensures that loading on basin transmission lines remain within the circuits' ratings, and system voltage remains within acceptable limits. Minimizing outages at these locations is therefore especially important. Variable-energy resources, such as solar or wind power, can augment existing in-basin gas-fired generation, but the variable resources cannot replace the role local gas-fired generation plays in transmission reliability. The amount of generation required to provide

AR0069981

transmission reliability is termed Reliability Must-Run (RMR) generation. Repowering these local units will maintain transmission reliability by increasing the availability of RMR generation.

- Increased efficiencies

  New units will operate more efficiently, generating more energy and less emissions with the same amount of fuel. Operational costs per energy output will decrease.

- Integrating renewables

  The new units will incorporate new technologies which will enable faster start-up and faster ramping of generation output. This ability to increase or decrease generation on short notice, measured by what is termed "ramp rate," is an important requirement for integrating renewable resources. Wind resources produce power when the wind is blowing. When the wind suddenly begins blowing or stops blowing, the energy being delivered also changes but the customer load (the amount of energy the power system requires) remains substantially the same. Solar photovoltaic resources are subject to even greater output variability as clouds pass overhead and vary the intensity of available sunlight. To compensate for these fluctuations, natural gas "peaker" units (which are included in the new unit configurations) are able to quickly start, stop, and ramp up and down so that the total energy generated continuously matches customer load. Integrating significant amounts of intermittent renewable resources, such as wind and solar photovoltaic, will not be possible without the fast load-following and renewable energy generation following capability that the repowering program will provide.

2.4.2.2 Repowering Program to Comply With Regulatory Requirements

In addition to the reasons stated in Section 2.4.2.1, the repowering program is necessary to comply with State and Federal regulations related to once through cooling as well as local NO_X emission mandates.

- Once through cooling

  Once-through cooling (OTC) is the process where water is drawn from the ocean, is pumped through equipment at a power plant to provide cooling, and then is discharged back to the receiving water source. A cooling process is necessary for nearly every type of conventional electrical generating station and an OTC process utilizing ocean water is a major reason why many electrical generating stations were sited along the coastline. Typically, the water used for cooling is not chemically changed in the cooling process, however, the temperature of the water increases before it is returned to the ocean.

  LADWP operates three coastal generating stations – Scattergood, Harbor, and Haynes – that utilize OTC. The combined net capacity of these stations is 2,839 MW. Further information regarding repowering can be found in Section 1.6.6.

AR0069982

In order to comply with the statewide OTC policy, LADWP has chosen to eliminate OTC and replace it with closed cycle cooling. Interim requirements are necessary until a facility is deemed fully compliant, including the funding by LADWP of mitigation projects to alleviate impacts, such as habitat restoration with the development of wetlands, in addition, feasibility pilot studies are required for the installation of alternative technologies to reduce impingement and/or entrainment in the interim. These issues are discussed in more detail in Appendix C.

- NOX compliance

  In mid-2000, during the statewide energy crisis, LADWP predicted that NO_x emissions from the in-basin generating units would exceed the available supply of NO_x RECLAIM Trading Credits issued by the South Coast Air Quality Management District (SCAQMD). Although LADWP's NO_x emissions ultimately did not exceed its allocation in 2000, on August 29, 2000 the SCAQMD Hearing Board issued a "Stipulated Order for Abatement" to the LADWP. Under the terms of the Order, LADWP was required to perform a series of repowering projects at its in-basin generating stations. The Stipulated Order was later superseded by a Settlement Agreement to accommodate scheduling and other issues. This agreement was revised in September 2011 and addresses the current repowering projects at the Haynes and Scattergood Generating Stations.

2.4.2.3 Coal-Fired Generation

SB 1368, the California Greenhouse Gas Emissions Performance Standard Act, enacted in 2006, prohibits California utilities from entering into long-term financial commitments for base load generation unless it complies with the GHG emissions performance standard. As this standard also applies to existing power plants for any long-term investments or contractual extensions, it affects LADWP's coal-fired generation resources.

SB 1368 Compliant Coal-Fired Generation

As presented in Section 3, the analysis of future potential resource portfolios includes a set of strategic cases that accelerate compliance with SB 1368 for coal-fired generation. The feasibility of adopting and implementing this will depend on a number of factors, including (1) resolving contractual issues, (2) the cost of alternatives (and LADWP's ability to cover its costs) and (3) other legislative and regulatory factors.

SB 1368 compliant power will reduce the GHG emissions for LADWP, reduce regulatory compliance costs, and spur development of renewable resources in the western United States. SB 1368 established a greenhouse gas emissions performance standard that limits long-term investments in base load generation by the state's utilities to power plants that meet an emissions performance standard, which was jointly established by the California Energy Commission and the California Public Utilities Commission. Subsequently, the Energy Commission designed regulations that establish a standard for base load generation owned by, or under long-term contract to publicly owned utilities, of 1,100 lbs CO_2 per megawatt-hour (MWh).

There are several methods to achieve SB 1368 compliance, for example: replace coal generation

AR0069983

with energy efficiency, renewable energy, natural gas-fired generation, carbon sequestration, coal gasification, or the application of other potentially emerging technologies. Since coal generation operates as a base load resource for LADWP, any replacement option would also need to provide some base load generation around the clock while reducing GHG emissions.

Intermountain Power Project

The Intermountain Power Project (IPP) is a coal-fired generating station located near Delta, Utah. IPP consists of two generating units with a combined capacity of 1800 MW. LADWP is the operating agent. LADWP is also the largest single purchaser and has a power purchase agreement for 44.617 percent (803 MW) of IPP's total output. LADWP has additional purchase obligations for up to 22.168 percent (399 MW) of additional output. These additional obligations are dependent on the power usage of the Utah and Nevada participants. The power sales contract for IPP expires in 2027.

In addition to the generating units, IPP includes four important transmission lines, a 500-kV DC transmission line from the generating station to Adelanto, California (a distance of 490 miles), two parallel 345-kV AC transmission lines from the generating station to Mona, Utah, 50 miles away, and a single 230-kV AC transmission line from the generating station to the Gonder Switchyard near Ely, Nevada about 144 miles away.

At IPP, LADWP has no ownership rights in the generating station or the transmission lines. Rather, LADWP has a long-term power purchase contract which expires in 2027 and which also includes renewal option rights. With firm "take or pay" obligations, LADWP is contractually committed to the project to 2027. LADWP is one of 36 participants that purchase power. The owner of IPP is the Intermountain Power Agency (IPA), a separate entity and a political subdivision of the State of Utah.

IPP Coal Conversion

For some time, the 36 participants and IPA have been considering the future disposition of the IPP facility. In addition to satisfying SB 1368 requirements, pending and potential federal legislative and regulatory actions regarding CO_2, NO_x, fly ash, etc., have introduced uncertainty to the future operating economics for the facility. Considering these uncertainties, as well as other changes across the coal industry and factors unique to the IPP organizational structure, the IPP parties have investigated alternatives to the continued use of coal as a fuel source.

The feasibility of converting the IPP site from coal to natural gas has been studied, and efforts to convert have been initiated. The method and timing of a conversion requires concurrence from all participants and IPA, and establishing a new contractual structure. Some of the considerations that concern LADWP are:

- LADWP and the other IPP participants are contractually obligated to continued debt payments through 2023. An early exit from IPP prior to the end of the debt payment schedule will incur a financial penalty, not only for LADWP but for all of the 36 project participants.

AR0069984

- The existing power purchase contract extends to June 15, 2027. These are "take or pay" contracts which LADWP could not walk away from without incurring monetary/legal penalties
- Any penalties incurred by LADWP through the preceding bullet points would be incurred by the LADWP ratepayers
- By remaining with the project, LADWP can continue to use the project's transmission assets to deliver renewable energy from the Utah region
- In addition to the transmission, LADWP can also continue to use the site, the staffing and the other related infrastructure that has been developed over the years at IPP

In response to these and other considerations, a new power purchase contract is being drafted to construct a natural gas replacement facility located at the IPP site. The in-service date for the new facility will likely be sometime between the debt payment completion schedule at the end of 2023 and the end date for the existing power contracts in June 2027. For modeling purposes, until the contract is finalized a date of December 31, 2023 will be used as an assumed early conversion date (see Case 4 in Section 3.5).

As of this writing, the IPP participants are considering the conversion to natural gas. The following steps have been identified to establish the new contractual structure and are in progress:

1. Amend the Utah Interlocal Cooperation Act and Electric Power Facilities Act completed by the Utah legislature in March 2012
2. Amend the IPP Organization Agreement between the 23 Utah municipal members
3. Adopt the Second Amendatory Power Sales Contract between all 36 power purchasers
4. Adopt Renewal Power Sales Contracts
5. Adopt Renewal Excess Power Sales Agreements

Assuming the timely completion of the new agreements, the new conversion date will be incorporated into the 2013 IRP model runs.

Navajo Generating Station

The Navajo Generating Station (NGS) is a coal-fired generation station located near Page, Arizona. It consists of three units with a combined capacity of 2,250 MW. Salt River Project is the Operating Agent. As one of six owners, LADWP has a 21.2 percent ownership share in the station's generation. NGS operates under a co-tenancy agreement which shall remain effective throughout the initial term of the land lease with the Navajo Nation and throughout the lease extension thereafter.

While LADWP is contractually committed to NGS until December 31, 2019, significant progress has been made to exit from the project by 2015. Early divestiture of NGS is in LADWP's best interest for a number of reasons:

1. A better sales price than waiting until the 2019 deadline

AR0069985

2. Avoids the risk that pending federal regulations could potentially encumber the plant with expensive mitigation requirements.
3. Better availability of replacement generation.
4. Reduced CO_2 emissions, relieving LADWP from having to purchase emission credits within the soon-to-be implemented statewide cap and trade program.
5. Makes room on the transmission network for importing additional solar and geothermal resources.
6. Maximizes the value of the plant to help pay for renewables and energy efficiency.
7. Provides time to handle contingencies, and to ensure that competition is going to benefit our ratepayers.

The coal replacement options considered in this IRP analysis are presented in Section 3 – "Strategic Case Development."

2.4.3 Future Renewables for LADWP

SB 2 (1X)

The increase of renewables, as a percentage of electricity sales, to the regulatory mandated 33% by year 2020 requires the continued diligence of LADWP to pursue renewable projects and power purchase contracts. The development of a solar feed-in tariff and continued encouragement for customer net-metered solar is also necessary to support increased solar capacity. Because the acquisition of additional renewables is mandated by law, all of the strategic cases analyzed in this IRP include portfolios with the required amount of renewable resources. The 2012 recommended Case 5 with 150 MW of FiT includes the following targets for new renewable acquisitions between 2011 and 2020[5]:

New Renewable Installed Capacity (MW) 2012-2020			
Geothermal & Biomass	Non-DG Solar	Distributed Solar	Generic
242	842	382	39

Furthermore, maintaining at least 33% of renewables beyond 2020 requires additional renewables to account for system loading, project turnover, and output degradation as projects age. The 2012 recommended Case 5 with 150 MW of FiT includes the following additional targets for new renewable acquisitions between 2021 and 2030[4]:

New Renewable Installed Capacity (MW) 2021-2030			
Geothermal & Biomass	Wind	Distributed Solar	Generic
41	54	114	75

[5] The DG/EE Cases 5-8 have alternative renewable mixes due to higher levels of Solar DG and EE.

AR0069986

SB 1 Solar Requirements

Former Governor Schwarzenegger signed the California Solar Initiative (CSI), outlined in Senate Bill 1 (SB 1), on August 21, 2006. The CSI mandates that all California electric utilities, including municipals, implement a solar incentive program by January 1, 2008. The goal of the CSI is 3,000 MW of net-metered solar energy systems over 10 years with expenditures not to exceed $3.35 Billion. Expenditures for local publicly owned electric utilities shall not exceed $784 Million. The LADWP cap amount is $313 Million, based on its serving 39.9% of the municipal load in the state, representing 280 MW of the 1,000 MW goal.

SB 32 – FIT

SB 32, signed into law on October 11, 2009, requires LADWP to make a tariff available to eligible renewable electric generation facilities within its service territory until LADWP meets its 75 MW share of the statewide target. Through this program, owners or operators of eligible renewable energy systems may sell their energy directly to LADWP. The purchase of SB 32 qualifying energy includes all environmental attributes, capacity rights, and renewable energy credits. This energy is just one of the many renewable energy sources that will apply towards LADWP's 33 percent renewable requirement.

Power Purchase Agreement (PPA) Option to Own Clause

As policy, PPAs for renewable energy are required to contain purchase options which LADWP may choose to exercise at different times during the term of the agreement. LADWP's goal is to own (either directly or through joint powers authority) at least 50% of its eligible renewable energy resource portfolio. For more detailed information regarding LADWP's Renewable Portfolio Standard Policy and Enforcement Program, see Reference D-2 in Appendix D.

Further information regarding renewables can be found in Appendices D.1 and N.

2.4.4 Transmission and Distribution Facilities/Grid Reliability

Electricity from LADWP's power generation sources is delivered to customers over an extensive transmission and distribution system. To deliver energy from generating plants to customers, LADWP owns and/or operates approximately 20,000 miles of alternating current (AC) and direct current (DC) transmission and distribution circuits operating at voltages ranging from 120 volts to 500 kilovolts (kV). Major transmission lines connecting to out-of-basin generating resources are shown in Figure 2-8. Appendix I provides more details regarding LADWP's transmission system.

In addition to using its transmission system to deliver electricity from its power generation resources, LADWP arranges for the transmission of energy for others through its Open Access Same Time Information System (OASIS) when surplus transmission capacity is available and saleable. LADWP uses its extensive transmission network to sell its excess energy and capacity

AR0069987

in the California, Northwest, and Southwest energy markets. Revenues from these excess energy sales are used to reduce costs to ratepayers and for capital improvements.

In critical times, neighboring utilities look to LADWP's surplus energy and transmission resources to bolster their power system and avoid blackouts. For example, while the nearby San Onofre Nuclear Generating Station remains offline without a set return-to-service date, the California Independent System Operator is attempting to secure the delivery of replacement energy from other potentially available generation sources.

Transmission for Renewable Energy

Since renewable resources are often located long distances from the City of Los Angeles and where transmission facilities do not exist, accessing renewable resources will require extensive infrastructure improvements, including the construction of new transmission lines, upgrades to existing long and short transmission lines, and improvements at transmission facilities and stations to increase their transfer capability. Following is a summary of the major projects:

Barren Ridge Renewable Transmission Project

The Barren Ridge Renewable Transmission Project, scheduled to be completed in 2016, will increase the capacity of the existing 230-kV Barren Ridge-Rinaldi transmission segment from 450 MW to approximately 2200 MW. As of May 2012, approximately 3085 MW from a combination of wind and solar projects are being investigated for potential interconnection. This project will also increase the transmission capacity to the Castaic Pump Storage Power Plant, providing enhanced operational flexibility and integration of variable renewable energy.

Important components of the Barren Ridge Renewable Transmission Project are as follows:

- New Haskell Canyon Switching Station
- New double-circuit 230-kV transmission line from the Barren Ridge Switching Station to the new Haskell Canyon Switching Station
- New 230-kV circuit on existing structures from Haskell Canyon to the Castaic Power Plant
- Reconductor the existing 230-kV transmission line from the Barren Ridge Switching Station to the existing Rinaldi Receiving Station, through the Haskell Canyon Switching Station
- Expand the existing Barren Ridge Switching Station

Up-to-date information on this project is available at:

https://www.ladwp.com/ladwp/faces/ladwp/aboutus/a-power/a-p-projects

AR0069988

Pacific Direct Current Intertie (PDCI) Upgrade

LADWP and its PDCI partners are considering increasing the capacity of the PDCI from 3160 MW to as much as 3650 MW. The benefit of such an undertaking would be a higher-capacity corridor for renewable wind and hydro energy from the Pacific Northwest to Los Angeles. LADWP, as the PDCI operator, is currently developing a cost estimate for the project that considers transmission and station upgrades and the increased dispatch and energy costs during construction to cover the reserve margin. Toward that end, preliminary estimates based on a Light Detection and Ranging study in 2011 indicate the transmission component of the project may cost up to $150 million and require as much as six years to construct. Less aggressive options with lower capacity benefits are also being investigated to facilitate an informed decision by the PDCI partners.

LADWP and its southern DC partners have signed a letter of agreement with the Bonneville Power Administration (BPA) to implement an initial 120 MW capacity increase of PDCI, if the cost is reasonable. In any case, BPA has committed to an extensive overhaul of Celilo HVDC Converter Station which requires coordination at the southern end of the HVDC line at Sylmar HVDC Converter Station. The projected completion date for BPA's Celilo upgrade project is January 2016.

The Haskell Canyon-Olive Transmission Line Project

LADWP plans to reconnect the existing Power Plant 115-kV Transmission Lines 1 and 2 to the new Haskell Canyon Switching Station, and then convert the 115-kV towers to a single circuit 230-kV transmission line from the new Haskell Canyon Switching Station to the existing Olive Switching Station. This project will maintain system reliability and increase the transfer capability from the new Haskell Canyon Switching Station to the Los Angeles Basin transmission system.

The Victorville-Los Angeles (Vic-LA) Project

The Vic-LA Project involves making infrastructural and operational improvements to the existing system between the Victorville area and the Los Angeles Basin in three phases which will allow LADWP to add 500-600 MWs of transfer capacity, subject to operational requirements. The Vic-LA Project can be defined in short, mid, and long term actions, as follows.

1. Short term actions
   - Upgrade the terminal equipment at Rinaldi and Toluca Receiving Stations and modify system protection of the line transformers
   - Add a second Victorville 500/230-kV transformer (Bank K1)
   - Upgrade Victorville-Century transmission system
   - Upgrade the terminal equipment at the Century and Velasco Receiving Stations
   - Trip non-firm resources to maintain the post-contingency flow within the existing Vic-LA system operating limit

AR0069989

Mid-term actions

- Re-conductor the Victorville-Century 287-kV transmission lines to increase the rating
- Upgrade Banks F & G at Century Receiving Station to increase emergency rating

Long-term actions

- Convert the Victorville-Century 287-kV transmission lines to DC, which is described below

Conversion of the Victorville-Century 287-kV Circuit

Conversion of the Victorville-Century 287-kV AC lines is a potential future project that would increase the transfer capacity by converting the lines from AC to DC. The existing Victorville-Century circuit spans about 84 miles between Victorville and South LA. Converting the lines to DC would require a change-out of insulators along the line, and the installation of AC to DC converter equipment at each end. The transmission towers themselves will not require any modification. Preliminary studies indicate a potential 3-fold increase in power transfer capacity as a result of this project.

Regional transmission plans have shown that in order for LADWP and its Western counterparts to meet their renewable energy goals at minimal cost, additional transmission improvements will be needed. While the projects listed in this subsection have a high priority and a high likelihood of construction, they may not be sufficient to meet future needs. LADWP will continue to evaluate transmission needs and opportunities as necessary.

Grid Reliability

LADWP annually performs a Ten-Year Transmission Assessment Plan. In compliance with the North American Electricity Reliability Corporation (NERC) Compliance Enforcement Program, LADWP's 2012 plan identified a number of transmission improvements that are needed to maintain reliability. These projects include:

- Installation of a new Scattergood-Olympic 230-kV Line 1
- Upgrade circuit breakers and disconnects at RS-L
- Install a variable 90 MVAR shunt reactor bank at Scattergood 230 kV and a variable 90-MVAR shunt reactor bank at RS-K 230 kV
- Relocate the 230/115 kV Banks from Olive Switching Station (SS) to Haskell Canyon SS
- Convert the existing twin 115 kV circuits between Haskell Canyon SS and Olive SS with a new double 230 kV circuit along existing right-of-way

AR0069990

These infrastructure improvements are critical to avoid potential overloads on key segments of the Los Angeles Basin transmission system.

FERC Order 1000 - The California Transmission Planning Group

With the release of Federal Energy Regulatory Commission (FERC) Order 1000 in July 2011, to direct regional and interregional transmission planning and cost allocation, FERC-jurisdictional (investor-owned) electric utilities are now required to reorganize transmission planning functions to collectively achieve state and federal public policy goals. Order 1000 builds upon the directives of FERC Order 890, issued in February 2007, to open regional and local planning to stakeholders to ensure transparency and non-discriminatory access to transmission service.

LADWP has a longstanding history of working with its Western Electricity Coordinating Council counterparts on regional transmission planning to ensure bulk power reliability and to leverage economies of scale; regional transmission plans are reviewed and approved through a formal process. Since the California Transmission Planning Group (CTPG) was formed in 2009, LADWP has been active in that transmission planning forum. CTPG was formed to comply with Order 890 by providing the increased coordination and public participation mandated while ensuring the electric needs and goals of Californians are reliably and efficiently met. In February 2011, the 2010 California Transmission Plan (California Plan) was released http://www.ctpg.us/images/stories/ctpg-plan-development/2011/02-Feb/2011-02-09_final_statewide_transmission_plan.pdf.

The CTPG was not able to reorganize quickly enough to meet Order 1000's deadline for FERC-jurisdictional entities to join a specific type of regional planning group and to file a regional planning methodology with FERC. In order to meet this timeline, CTPG members resorted to membership in additional regional organizations. CTPG members inside the CAISO footprint joined the CAISO Region, while other CTPG utilities joined the WestConnect Region. LADWP joined the WestConnect Region in November 2012. Other CTPG members in the WestConnect Region include the Sacramento Municipal Utility District, the Imperial Irrigation District, and the Western Area Power Administration.

Because of the large geographical extent of the LADWP transmission system, LADWP's planning takes place in various forums for sub-regional, regional, and inter-regional issues. Membership in WestConnect will allow LADWP to engage with the changes to regional planning caused by Order 1000. At the same As CTPG member utilities evaluate their options, they continue to press forward with their current transmission assessment to ensure California's electric power policy goals are reached efficiently and without undue hardship to the consumer or to the electric grid. California's electric power policy goals include:

- Attainment of renewable portfolio standard goals as promulgated by SB 2 (1X), which was passed in April 2011 and became effective December 10, 2011
- Satisfaction of repowering/retirement deadlines of fossil-fueled Once-Through Cooling power plant units as negotiated with the State Water Resources Board to comply with Federal Clean Water Act §326(b)

AR0069991

As a municipal utility, LADWP is outside FERC jurisdiction, so, in a technical sense, Order 1000 is not a mandate. Consistent with its response to other FERC Orders, however, LADWP is seeking to conform to this order with the same consideration as it would to an industry standard.

LADWP's extensive network of transmission resources is described in Appendix I. Figure 2-8 shows its major out-of-basin generation resources. Noteworthy is the fact that while LADWP customers represent roughly ten percent of California's electrical load, approximately 25 percent of the state's total transmission capacity is owned by LADWP. LADWP also differentiates itself from its counterparts by continuing to operate as a vertically integrated electric utility – owning and operating its generation, transmission, and distribution resources rather than as a parent company with subsidiaries carrying out the various functions that comprise the supply chain.

AR0069992

Figure 2-8: Major out-of-basin generating stations and major transmission lines.

AR0069993

2.4.5 Advanced Technologies and Research and Development

LADWP is looking ahead to technologies that will benefit operations and enhance reliability, including smart grid applications and energy storage systems. Many programs, such as demand response and electric vehicles, will rely on deployment of Advance Metering Infrastructure to support their functionality and effectiveness. The implementation of Smart Grid technologies will provide enhanced information systems, automation of system functions, and advanced methods of outage management. Although energy storage technologies (except for Pumped Water Storage) are still being developed and are not currently cost effective for large scale applications, their potential for altering how electricity is generated and consumed is high.

2.4.5.1 Smart Grid

"Smart Grid" is a term used to describe a variety of advanced information-based utility improvements. Smart Grid refers to intelligent data gathering and advanced two-way digital communication capabilities overlaid on electric distribution networks to provide real-time data that enhances the utility's ability to optimize energy use. Smart Grid is a national policy evolving from the Energy Policy Act of 2005, and is a major enabler for many existing and potentially new DSR/EE programs.

Smart Grid technologies can turn every point in the existing network—including every meter, switch and transformer—into a potential information source, able to feed performance data back to the utility instantly. Smart Grid Technologies will provide utilities with the information required to implement real-time, self-monitoring networks that are predictive rather than reactive to instantaneous system disruptions. It can enable the utility and consumer to make decisions to optimize the use of energy, improve reliability, and reduce the consumption of fossil fuels.

A smart grid has the following characteristics:

- *Enables new products, services and markets*
- *Enables active participation by consumers through self-monitoring and more responsible consumption decisions*
- *Auto-selects safest and most efficient forms of storage and generation based on real-time energy needs and concerns*
- *Provides power quality for the digital economy*
- *Optimizes asset utilization and operates efficiently*
- *Anticipates and responds to system disturbances (self-heals)*
- *Operates resiliently against attacks and natural disasters*

AR0069994

LADWP is implementing nine major Smart Grid initiatives.

1. Renewable Integration to support the adoption and utilization of renewable resources
2. Transmission Automation to better monitor the transmission system to predict instability and take corrective actions before they escalate into major problems
3. Substation Automation to enable remote monitoring and control of substation feeder lines
4. Distribution Automation to optimize operational efficiency.
5. Advanced Metering Infrastructure which will enable a number of demand-side capabilities
6. Demand Response is a tool that will provide reduction of peak loads at critical times to relieve system stress during periods of overload
7. Advance Telecommunications will enable real-time control and observation of deployed automation equipment
8. System and Data Integration will optimize the communications and integration of separate systems and sub-networks
9. Cyber Security to protect the Smart Grid from physical and cyber attacks.

Demonstration Program

In addition to the Smart Grid initiatives, LADWP, through a US Department of Energy grant awarded in 2009 is leading a group of local research institutions in a regional demonstration program. The program includes pilot projects in four interrelated areas – Demand Response, Consumer Behavior, Cyber Security and Electric Vehicle Integration.

More information on this demonstration program and all of LADWP's Smart Grid initiatives can be found in Appendix I.

2.4.5.2 Energy Storage

California Assembly Bill (AB) 2514, which became law on January 1, 2011, requires governing boards of local publicly-owned electric utilities, including LADWP, to identify and procure viable and cost-effective Energy Storage (ES) Systems. The targets must be formally approved by the Board of Water and Power Commissioners by October 1, 2013, and be implemented in two phases – by the end of 2016 and the end of 2021. Accordingly, LADWP has initiated a process to develop an ES plan which will include the appropriate ES targets per AB 2514.

Although LADWP does not currently have a formal ES plan, it has been practicing energy storage since 1973 through its daily operation of the Castaic Pump Storage Power Plant. In developing its formal Energy Storage Plan (ES Plan), LADWP's investigation will include options to leverage and/or augment the ES capabilities of the Castaic facility.

AR0069995

Some of the key considerations for the ES Plan are as follows:

- LADWP will look for ES programs and projects that will support its unique electric grid, resource plan, and projects that will facilitate renewable integration, distributed generation and demand-side management; and programs that address resource adequacy and reliability issues.

- A review of the current state of ES technologies will be required, including current cost projections.

- Per AB 2514, the ES systems shall be cost-effective.

To support its ES planning efforts, LADWP will consider the following two initiatives as a means to provide valuable technical information:

1. LADWP is participating in a working group with the US DOE for the development of an ES protocol for use in measuring and quantifying the performance of ES system applications. It is anticipated that the protocol will assist LADWP to evaluate the performance of ES and to make more informed decisions as potential applications are consider for implementation.

2. DWP is planning to incorporate into its ES Plan the results from three ES research projects conducted by the Electric Power Research Institute:

    a. Strategic Intelligence and Technology Assessments of Energy Storage and Distributed Generation, Project 94.001 – This project provides analysis and strategic information on ES and distributed energy resource systems. It includes assessments and evaluations of various technologies.

    b. Distributed Energy Storage Options for Power Delivery and End Use, Project 94.002 – This project provides information and guidelines for using distributed ES and distributed generation systems for power delivery and end user applications such as peak management, peak shifting, etc.

    c. Bulk Power Energy Storage Solutions, Project P94.003- This project provides information and guidelines for using bulk ES to shift off-peak energy and integration of variable renewable generation.

A status update of the ES Plan will be provided in next year's 2013 IRP document. Per AB 2514, the ES targets are to be approved no later than October 1, 2014.

For more information, see Appendix K.

AR0069996

2.4.6 Climate Change Effects on Power Generation

Because the energy sector is an acknowledged contributor to the problem of climate change, much discussion and effort has been directed towards mitigation strategies – mainly in the form of GHG emissions reduction. However, as climate change is increasingly being accepted as a reality, it is important to also consider the energy sector as one that will be subjected to the impacts of global warming. Rising average temperatures, changes in precipitation amounts and patterns, more frequent extreme weather events and a rise in sea level are some of the consequences that may be expected. Understanding how these effects impact power generation and incorporating that knowledge into the planning process facilitates adaptation of the power system to respond in ways that mitigates potential problems and takes advantage of any opportunities.

The influence of climate change on resource planning can be addressed on two levels: (1) how it affects *energy consumption*, and thus how much generation should be planned for and secured, and (2) how it affects *power generation* operations and the siting of new facilities.

Energy Consumption

Mean temperatures in Los Angeles are expected to rise. Additionally, extreme heat conditions, such as heat waves and very high temperatures, may last longer and become more common place.[1] In response to these conditions, electricity consumption will increase, mainly due to increased air conditioning demand. These effects are reflected in LADWP's energy and demand forecast. It is important to ensure that the latest findings and conclusions continue to be incorporated into future load forecasts.

A recent study by the UCLA Department of Atmospheric and Oceanic Sciences[2] focuses on temperature changes in the local region in years 2041-2060. The study concluded that annual average temperatures will increase between 3.7 °F and 4.4 °F across the City of Los Angeles. While the UCLA study looked at temperature changes in the 2041-2060 timeframe (which is beyond the 20-yr planning horizon for the 2012 IRP), the findings corroborate other studies and supports the expectation of higher future temperatures which will increase electricity use. More information on this study can be found in Appendix M.

Power Generation

An increase in frequency and duration of heat waves, and potentially more volatile weather patterns will add stress to the utility infrastructure. Areas may become more prone to flooding, and river flows may increase or decrease depending on location. At the same time, other areas may become more drought stricken, affecting water available for power plant cooling. Thermal efficiencies will decrease as temperatures rise, resulting in more fuel required to generate the same amount of power. New facility siting will have to account for these new environmental and weather-related conditions. Sea level rise, although not a foreseeable problem within the 20-year

[1] Global Climate Change. California Energy Commission. CEC-600-2006-013. page 2.
[2] Hall, et al., 2012. Mid-Century Warming in the Los Angeles Region. Available at: www.escience.LA

AR0069997

planning horizon of this IRP, will need to be monitored and mitigation measures implemented, if required.

Actions to Address Climate Change

LADWP should continue its efforts towards reducing GHG emissions. These efforts include adopting more renewable resources, repowering its older natural gas generating stations, investing in energy efficiency and demand response programs, and pursuing coal replacement. To prepare for and adapt to climate change, LADWP should ensure that its load forecast continues to properly incorporate expected higher temperatures (and the corresponding higher electricity demand) due to global warming, and that its Power Reliability Program is fully funded to optimize the resiliency of its infrastructure to better withstand the more volatile weather patterns that will be expected.

As the science of climate change continues to evolve, LADWP should stay abreast of the latest findings and conclusions. Subsequent IRPs will monitor developments in climate change and develop/refine recommendations to mitigate any negative impacts as part of the resource planning process.

More detailed information regarding climate change and its effect on power generation can be found in Appendix M.

2.4.7 Reserve Requirements

Two important aspects of electric power system reliability are "resource adequacy" and "security." Resource adequacy refers to the availability of sufficient generation and transmission resources to meet customer's projected energy needs plus reserves for contingencies. Security refers to the ability of the system to remain intact after experiencing sudden disturbances, outages or equipment failures.

LADWP, as part of the electric power grid of the western United States and Canada (and a small section of northern Mexico), is required to meet operational, planning reserve and reliability criteria, and the resource adequacy standards of the WECC and the North American Electric Reliability Corporation (NERC). Based on these standards, the system reserve margin requirements and other criteria which LADWP uses to plan and operate and are defined as follows:

Generation Capacity Requirement – Net Power Demand – System Reserve Requirement
System Reserve Requirement – Operating Reserve – Replacement Reserve
Operating Reserve – Contingency Reserve – Regulation

The "Net Power Demand" is the total electrical power requirement for all of LADWP's customers at any time. The other reserve requirements are defined below, as well as numerically calculated.

AR0069998

The loss of the largest single contingency of generation or transmission is a key reserve margin determinant for LADWP and defines the Contingency Reserve as well as the Replacement Reserve requirements. Based on current NERC Standards, at least 50 percent of the Contingency Reserves must be Spinning Reserve. The Replacement Reserve requirement is to restore Operating Reserves within 90 minutes of a contingency event. The Regulation Requirement of 75 MW is related to system load variations due to customer load changes. This regulation requirement is anticipated to increase in the future as additional amounts of intermittent renewable generation are added to the generation mix. Given LADWP's current total generation portfolio, the system reserve requirement is approximately 1,100 MW. Therefore, if the system demand is 5,000 MW, LADWP must have a total of 6,100 MW of dependable and dispatchable generating capacity (and the transmission for that capacity) to meet the 5,000 MW demand.

Due to the variable and intermittent nature of some renewable resources, particularly resources such as wind and solar photovoltaic, their generation capacity cannot be fully depended upon to meet peak demand conditions. As LADWP acquires a larger proportion of such resources, studies on the characteristics of these variable and intermittent resources will need to be carried out to determine their effect on reserve and regulation requirements. Refer to Appendix J for additional information on issues associated with integrating intermittent energy resources.

The capacity value of a generating resource is based on its ability to provide dependable and reliable energy and capacity during peak periods when the system requires reliable resources for stable operation. Resources that can provide firm capacity will have a higher capacity value than resources that cannot. For purposes of planning LADWP's reserves adequacy calculations, it is assumed that the dependable capacity of wind would be 10 percent of its nameplate capacity (unless a firming and shaping contract is in place), and the dependable capacity of solar photovoltaic would be 27 percent of its nameplate capacity. Because dependable capacity is an on-going area of study, these percentage values are subject to change. Any changes will be incorporated into future IRPs.

Local Resources for Grid Stability and Contingencies

As a subset of the reserve requirements, LADWP has located a significant amount of generating resources within the Los Angeles (LA) area. The specific amount of capacity that needs to be located in the LA Basin is approximately 3,000 MW, but varies, depending on the combination of which units are operating and how much power is flowing on the transmission system at the time. LADWP's local transmission system cannot be reliably operated without generation from local thermal generating plants. The amount of generation required to provide transmission reliability is termed Reliability Must Run (RMR) generation. RMR generation is incorporated into all of the strategic cases considered in this IRP.

This local requirement is particularly important in the context of deciding how to schedule the repowering of units that use once through cooling. It is for this reason that no unit will be taken out of service before an equivalently-sized, locationally-equivalent replacement unit is constructed, tested and ready to be placed in-service.

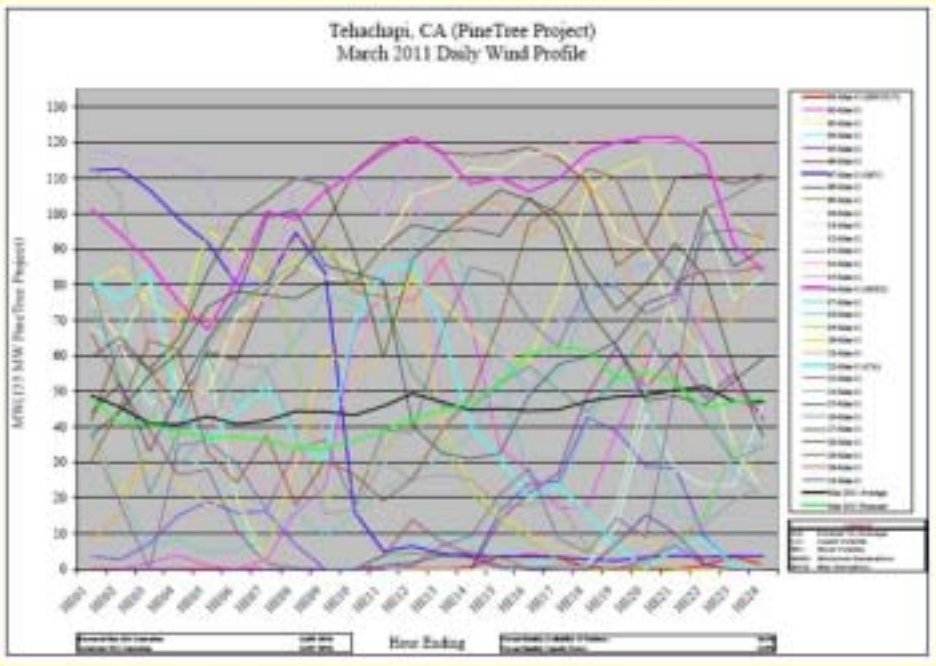
AR0069999

Integration of Intermittent Energy

One of the main responsibilities of power system operators is to maintain the balance between the total aggregate electrical demand of the power system's customers and the amount of energy generated to meet that demand on an instantaneous basis. Conventional electrical generation technologies, such as nuclear, coal, natural gas and large hydro are controllable and dispatchable by the power system operators throughout the day to maintain this instantaneous balance between demand and generation.

With the much higher percentage of renewables coming on line, a variety of modifications will need to be made to the Power System to successfully and reliably integrate these higher penetrations of renewable resources. In preparation, LADWP has conducted preliminary studies on integrating renewable resources, and has also reviewed many renewable resource integration studies published over the last several years.

Individual wind farms tend to have a high variability in the amount of energy produced (see figure below), but multiple wind farms located in diverse geographic areas are thought to reduce the overall variability in the amount of aggregated wind energy production.



Energy generated from Solar PV technology is highly sensitive to cloud cover. These PV systems can experience variations in output of ± 50 percent in 30 to 90 seconds, and ± 70 percent in five to 10 minutes. When a single large sized PV facility experiences these rapid changes in output, the Power System must also be able to react just as quickly with other generation resources to accommodate such rapid changes. The capabilities of a power system's dispatchable resources will limit the size of a single PV facility.

See Appendix J for more details regarding integrating intermittent resources.

3.0 STRATEGIC CASE DEVELOPMENT

3.1 Overview

IRP planning is an on-going process and as such, the development of the 2012 IRP strategic cases incorporates the latest changes that have occurred in the regulatory landscape and tactical plans developed by the Power System. This 2012 IRP also includes many updated assumptions that have been developed over the past year. These assumptions have influenced the composition of potential resource portfolios that can fulfill LADWP's goals of reliability, competitive rates and environmental stewardship.

The coal cases analyzed in this 2012 IRP consider different replacement dates for LADWP's two coal resources – the Navajo Generating Station (NGS), and the Intermountain Power Project (IPP). The coal replacement dates for Cases 1, 2 and 3 are similar to the cases analyzed in last year's 2011 IRP. The replacement date of December 2023 for IPP (Case 4) is new for this year.

In addition to the coal cases, this 2012 IRP also analyzes four additional cases to consider higher levels of energy efficiency and solar distributed generation.

The 2012-13 fiscal-year financial planning process included many of the assumptions and recommendations that were used in the 2012 IRP. This is a continual process that requires the budget and the IRP model to be guided by the same assumption set although these assumptions change frequently based on market conditions for fuel, energy resource availability and pricing, regulatory environment, load forecasts, and the reliability needs of our system.

Primary regulations and state laws affecting the Power System, including AB 32, SB 1368, SB 1, SB 2 (1X), SB 32, and US EPA 316(b), have become more certain over the last 2 years although many details are still being finalized mainly involving existing renewable projects and their applicability towards meeting in-state or out-of-state qualifications. This 2012 IRP attempts to incorporate the latest interpretation of these major regulations and state laws as we understand them today.

Section 3.2 summarizes the major changes from last year's model assumptions. Section 3.3 discusses the legislative and regulatory mandates that have a bearing on the resource portfolios being considered for this IRP. Section 3.4 describes the development process for the candidate strategic cases, and Section 3.5 presents the final candidate cases that were analyzed. The analyses and comparison of the case results are presented in Section 4.

AR0070002

3.2 2012 IRP Model Assumptions

At the heart of the IRP analysis effort is the computer-based production cost modeling of the LADWP Power System. To perform this modeling a significant amount of input data is developed. The production model and input assumptions are covered in detail in Section 3.2.2 and Appendix N. This section summarizes the major changes in the assumptions since last year's IRP, followed by a discussion of the general price inputs that were applied to this 2012 IRP.

3.2.1 Major Changes From the 2011 IRP Assumptions

Major assumption changes from last year's IRP are summarized here. Additional detail regarding the assumptions can be found in Appendix N.

Load Forecast

As shown in Table 3-1, the new load forecast is lower than the previous forecast used in the 2011 IRP. Compared to the prior forecast, electricity sales in the calendar year 2020 decreased by 5.3 percent mostly due to increased levels of energy efficiency. The new forecast reduces the overall need for renewable energy (assuming 33% RPS) by approximately 461 GWh in 2020 and 745 GWh in 2030. The complete load forecast is included in Appendix A. Adjustments made to the approved load forecast to account for the latest projections of energy efficiency savings and customer-net-metered solar are shown in Appendix N.

Table 3-1. TOTAL ADJUSTED ELECTRICITY SALES IN GWH

	2020	2030
New Forecast – 2012 IRP	22,958	24,424
Old Forecast – 2011 IRP	24,239	26,665
Difference	-1,281	-2,241

Energy Efficiency

The Energy Efficiency (EE) forecast used in the 2012 IRP includes higher levels of funding for the 2012/13 thru 2019/20 fiscal years to achieve 10 percent EE from 2010 thru 2020. This represents 1,084 GWh of additional EE savings by 2020 as compared to the 2011 IRP. Higher funding levels required to achieve this target were approved through the recent rate action for the 2012/13 and 2013/14 fiscal years. As a comparison, the 2011 IRP forecasted a 6 percent EE achievement during the same period 2010 thru 2020.

AR0070003

On December 6, 2011, the Board of Water and Power Commissioners approved an advanced EE program with a goal of 8.6 percent of sales by the end of fiscal year 2019-20 and beginning fiscal year 2010-11. Subsequently, on May 24, 2012 the Board of Water and Power Commissioners approved a target of 15 percent energy efficiency subject to the results of an updated energy efficiency potential study to be completed by June 30, 2013. The potential study will be used to develop a long term plan for the scope and estimated costs for additional programs to achieve 10 percent, 12.5 percent, and 15 percent energy efficiency savings by 2020. Inclusion of the 12.5 percent and 15 percent energy efficiency savings by 2020 will be considered for inclusion in future IRP's.

The cumulative EE savings incorporated in the 2012 IRP will reach 2,705 GWh (Net 2,500 GWh) from 2010 thru 2020 and 4,117 GWh (Net 3,800 GWh) from 2010 thru 2032. Using The Total Sales to Ultimate Customers for 2010/11 fiscal year as the baseline and using net EE savings, the 2012 IRP forecasts a 10 percent energy efficiency savings by 2020 and 15 percent energy efficiency savings by 2032. Historical efficiency savings of 1,256 GWh from 2007 to 2010, equivalent to 5.5 percent of customer sales, are already embedded in the load forecast. Figure 3-1 below shows the projected cumulative gross savings from 2001 through 2032.

Federal and State efficiency standards create fewer opportunities to give financial incentives to customers to install products that exceed the higher efficiency standards. This reduces the effectiveness of incentives to realize incremental energy savings targets. To combat this natural decline, additional programs requiring direct installation of energy efficiency measures at customer sites will be required to implement these higher savings. Although savings from Federal and State efficiency standards cannot be counted in the achievements made by the utility, these savings are nevertheless accounted for in the sales load forecast and do contribute to reducing overall sales and load growth.

AR0070004

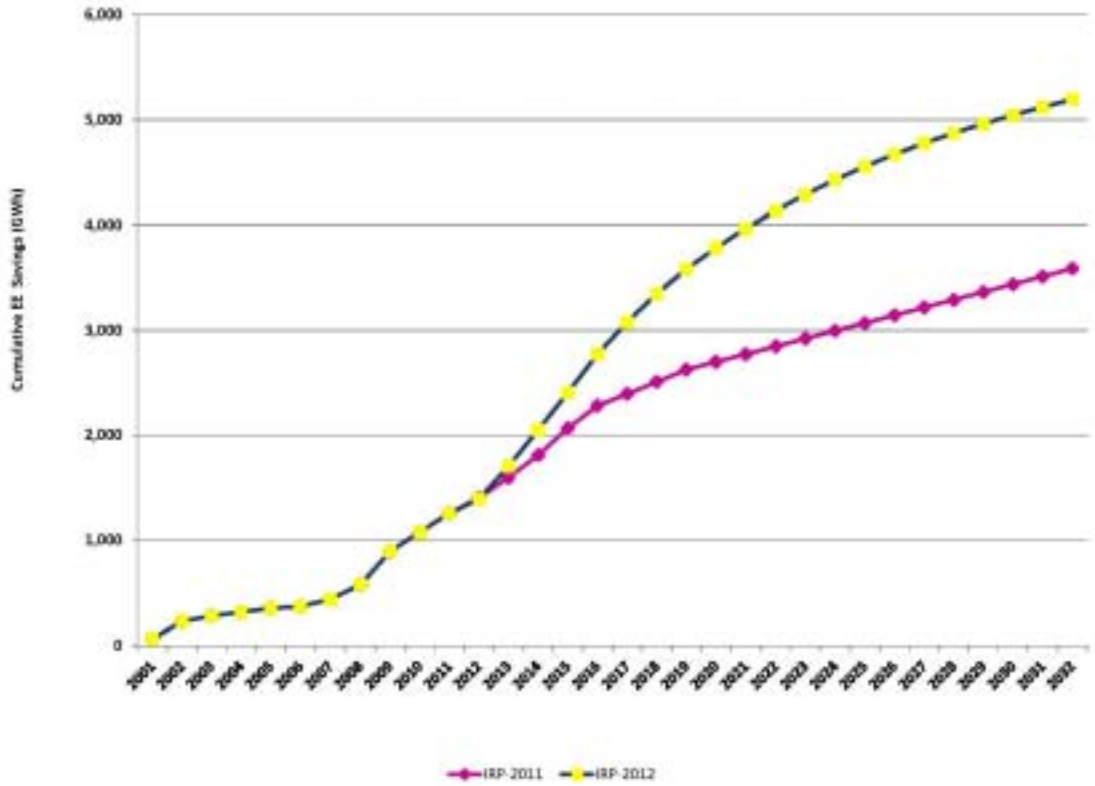

Figure 3-1. Comparison of 2011 and 2012 IRP gross energy efficiency forecasts by fiscal year.

Solar C-N-M and FiT

The solar Customer-Net-Metered (CNM) program (a.k.a. Solar Incentive Program) and Feed-In-Tariff (FiT) programs used in the 2012 IRP are shown in Figure 3-2. CNM solar starts out lower than last year's forecast, but quickly catches up and surpasses it, reflecting the recent program delay followed by a re-commitment of funding. Continued strong interest in the program is expected. FiT is lower in 2012-2014 due to a delay in implementation of the program due to budget constraints, but quickly reaches 150 MW or 210 GWh by 2016, reflecting the plan to accelerate the program to take advantage of tax benefits available through 2016.

AR0070005

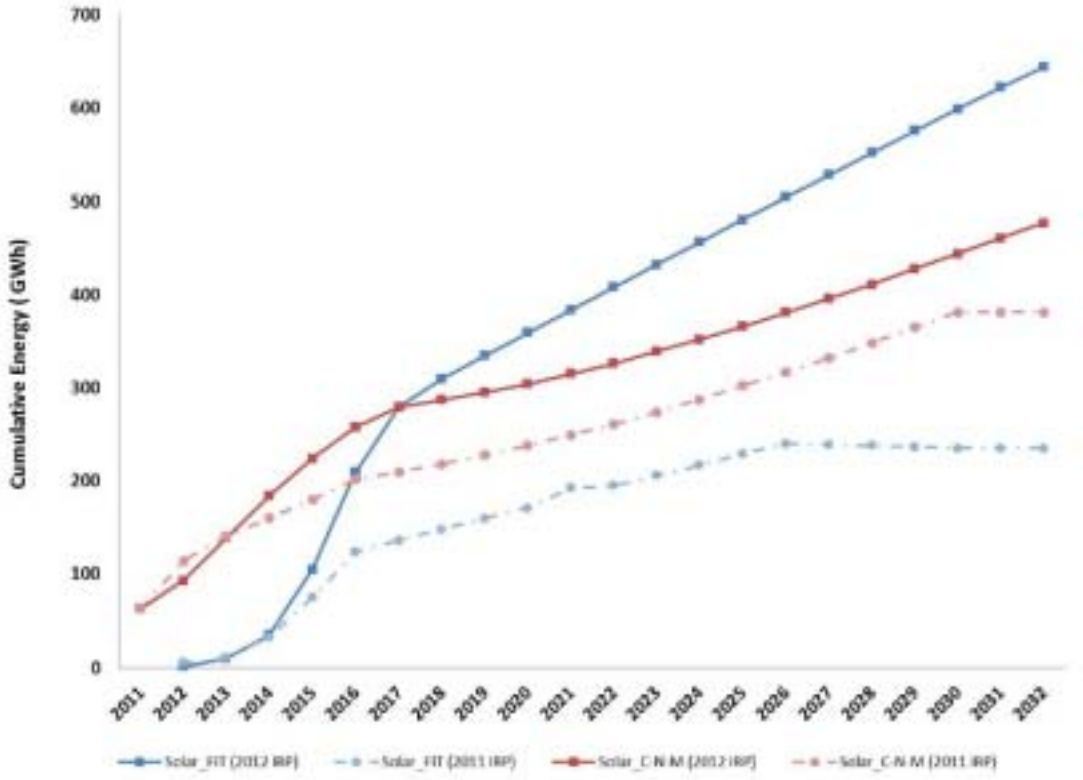

Figure 3-2. Comparison of FiT and CNM (SIP) solar projections, 2012 vs. 2011.

Renewables

Table 3-2 is a comparison of the overall renewable additions planned for the 2012 IRP vs. the 2011 IRP:

Table 3-2. RENEWABLE ADDITIONS, 2011 VS. 2012

		2020	New Renewable Installed Capacity (MW) 2012 – 2020					New Renewable Installed Capacity (MW) 2012 – 2032				
Case ID	Resource Strategy	RPS Target	Geo / Biomass	Wind	Non-DG Solar	Dist. Solar	Generic	Geo / Biogas	Wind	Non-DG Solar	Dist. Solar	Generic
All Cases in 2011 IRP	33% RPS SB 2 (1X) Compliant	33%	243	492	401	325	0	308	492	451	466	162
Base Case in 2012 IRP	33% RPS SB 2 (1X) Compliant	33%	242	0	887	337	39	283	54	915	496	114

Compared to last year's IRP, solar now holds a more prominent position in the overall portfolio mainly replacing future planned wind projects as prices for solar PPAs have dropped significantly over the last year while the availability of competitively priced in-state wind projects has decreased. Solar is also well suited to utilize the Navajo and

AR0070006

Barren Ridge transmission line capacity that will become available in 2016. Increased use of solar will further diversify the renewable resource mix which already contains a strong wind focus.

GHG Costs

Projected GHG cost assumptions resulting from the California Air Resources Board's Cap and Trade Regulation have been lowered. The forecast assumes GHG pricing will start at $15 per metric ton in 2013 and escalate to $30 per metric ton in 2020 with a $3 per metric ton increase for every year in between. In the 2011 IRP, GHG pricing started at $24 per metric ton in 2013 and escalated to $45 per metric ton in 2020.

Gas Prices

Long term natural gas price forecasts have been revised downwards from last year with recent prices reaching very low levels over the last year. However, it is expected that these unusually low prices will eventually reach an equilibrium supply/demand level over the next year as new gas drilling continues to decline and new sources of demand come on-line. Opal and SoCal expected gas prices used in the 2012 IRP were 16 percent lower on average, in the short term (2011-2020), and were 8 and 9 percent lower on average, respectively, in the long term (2021-2030) as compared to the 2011 IRP. The Pinedale gas reserves owned by LADWP continue to provide a low cost source of gas and hedge against future gas volatility and estimates of gas volumes to be produced from Pinedale have not been revised since the 2011 IRP.

Coal Prices

IPP forecasted coal prices are 4 percent lower for the period 2012 thru 2027 as compared to the 2011 IRP. Navajo coal prices are 14 percent lower for the period 2012-2019 as compared to the 2011 IRP.

IPP Payoff

IPP capacity is a function of the capacity recalled by Utah participants under the IPP Excess Power Sales Agreement. Estimates for these excess shares put to LADWP by Utah participants has risen from 222 MW assumed in the 2011 IRP to 318 MW in the 2012 IRP thereby increasing our share of the IPP capacity entitlement. This raised the energy and capacity expected from IPP generation in the 2012 IRP. This trend is believed to be occurring because of the lower gas prices relative to coal.

AR0070007

3.2.2 General Price Inputs

General price assumptions are presented here for supply side resources, fuel, and GHG allowances. More details are provided in Appendix N.

Supply-side Resources

Table 3-3 presents a summary of the major price assumptions for supply-side resources. Generally lower prices for solar and geothermal have been incorporated into the 2012 IRP modeling as price competition has lowered prices for both resources. Dependable capacity is an on-going area of study and could change in future IRP's as more data becomes available.

Table 3-3. SUMMARY OF SUPPLY-SIDE RESOURCE ASSUMPTIONS

Resource	Levelized Cost[1] ($/MWh)	Capacity Factors	Dependable Capacity
Solar Photovoltaic – PPA	$116	25% - 32%	27%
Solar Photovoltaic - LA Solar – Public/Private Partnership In-Basin	$154	20-23%	27%
Solar Photovoltaic – LA Solar – Public/Private Partnership Owens	$153	25%	27%
Solar Customer-Net-Metered	$130	18%	27%
Solar Feed-In-Tariff	$152	19%	27%
Wind	$105	24% - 37%	10%
Geothermal	$109	91%-95%	90%
New Combined Cycle Gas (310 MW)	$80	59%	100%
New Simple Cycle Gas (50/100 MW)	$225	9%	100%

[1]Net Present Value (annual costs, 2012-2032) / NPV of Energy Produced

AR0070008

Natural Gas Prices

High, low, and medium natural gas price forecasts were developed to test each portfolio against a range of potential natural gas prices. The medium or expected gas forecast originates from Platts and is the standard used by LADWP for financial and fuel procurement planning. The high and low forecast, shown on Figure 3-3, are fundamental forecasts obtained from Wood Mackenzie that consider a range of future assumptions including economic growth, supply and demand, and environmental regulations.

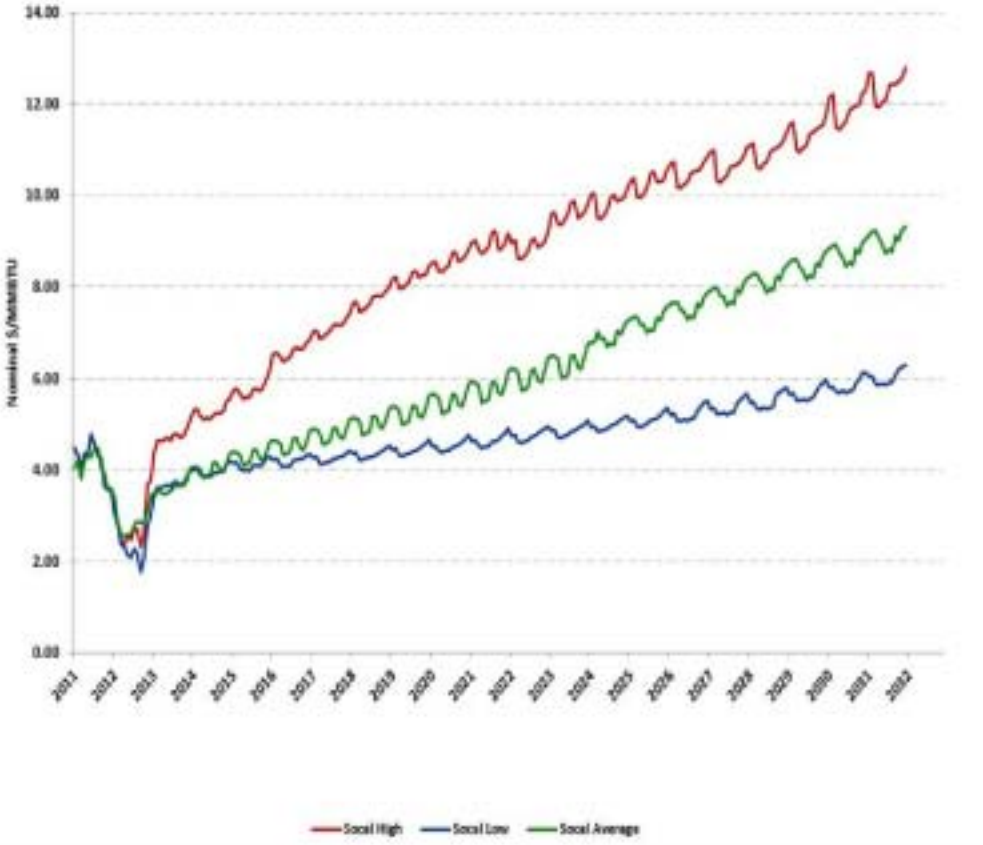

Figure 3-3. Natural gas price forecast (SoCal).

Note: Unless otherwise stated, forecasted costs in all charts in this IRP are "nominal."

AR0070009

Coal Prices

A +20 percent factor was applied to the expected coal fuel price provided by LADWP's External Generation Division, to determine a high and low range for coal prices. Actual coal fuel prices have intentionally been left out of this IRP to comply with non-disclosure agreements with coal suppliers.

GHG Emissions Allowance Prices

Price scenarios were also developed and tested for GHG allowance prices using staff estimates and price forecasts available from recent brokerage transactions. The forecast assumes GHG pricing will start at $15 per metric ton in 2013 and escalate to $36 per metric ton in 2020 with a $3 per metric ton increase for every year in between. Forecasts of further GHG costs beyond 2020 and sensitivity around GHG allowance prices were not considered for the 2012 IRP. Considering the allocation administratively provided to LADWP and the planned divestiture of Navajo and implementation of further renewables reducing our overall GHG emissions, the overall cost impact of the CARB Cap and Trade Regulations is expected to be relatively neutral when considering the entire 8 year program (it should be noted that the initial years of the Cap and Trade program may require the purchase of allowances).

The likelihood of a future Federal Carbon Tax or a continuation of the CARB Cap and Trade regulations beyond 2020 are speculative at this time and will be addressed in future IRP's as necessary.

Figure 3-4 depicts the GHG allowance prices used to evaluate the portfolios.

AR0070010

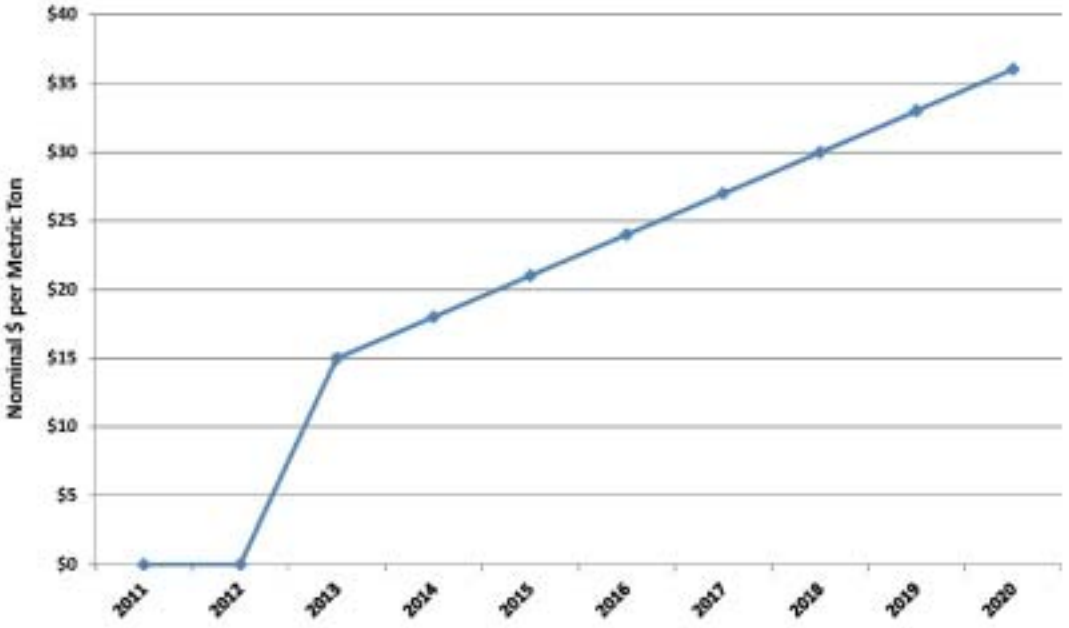

Figure 3-4. Assumed GHG emissions allowance prices.

AR0070011

3.3 Addressing Legislative and Regulatory Mandates

The 2012 IRP strategic cases must satisfy the requirements of the most-recently implemented environmental and RPS regulations. In many cases, the regulations have predetermined a limited set of resources that can be considered to meet future generation needs. The net effect is to constrain and limit the set of alternatives that can be analyzed.

Coal Replacement/GHG Reduction

SB 1368 requires that imported base load energy from outside California meet a GHG emissions performance standard of 1,100 lbs per MWh. To comply with this requirement, all future base load generation outside the LA Basin will need to come from either highly efficient combined cycle gas turbines (if fossil fueled), or from renewable energy resources. This eliminates the use of coal-fired generation, at least until future coal combustion and sequestration technology improves sufficiently to make this a viable option. As a result, four coal replacement cases have been considered in this 2012 IRP to define the costs and operational impacts that replacement of these facilities will have in meeting future energy and capacity load requirements.

OTC

Once-through cooling regulations effectively prohibits the use of ocean water cooling in all of the coastal power stations, which comprises 3 of the 4 in-basin gas-fired generation facilities, and sets specific deadlines to repower this generation prior to 2029. The limited resources available to repower these in-basin generation units under the accelerated time frame further limits the flexibility of altering repowering schedules based on system operation and capital requirements. Therefore, all strategic cases considered include the same repowering schedule as shown in Figure 3-5 below:

Figure 3-5. Timeline for OTC repowering projects.

AR0070012

Out-of-State Renewables, Energy Efficiency and Distributed Generation

As discussed at the end of Section 1.6.5, SB 2 (1X) defines categories with predefined percentage limitations on the amount of out-of-state renewable generation and renewable energy credits that can be used to meet renewable portfolio standards. Wind, small hydro, and biogas provide the largest contributions to LADWP's current portfolio as shown in Figure 2-7. Future renewable generation will rely heavily on solar PV and wind resources located within the State to fulfill the in-state percentage requirements of SB 2 (1X). This limits the potential use of renewable resources located outside of California. The strategic cases evaluated in the 2011 IRP established a diversified resource mix for the next 20 years including goals for estimated MW's installed for each renewable technology. The 2012 IRP retains the same diversified renewable mix goals set forth in the 2011 IRP recommended case while including a more solar-focused portfolio.

As shown in Table 3-2, all Coal Replacement cases being considered in the 2012 IRP use the base renewable resource plan. However, the energy efficiency and distributed generation cases described in Table 3-3 include different potential renewable portfolios for the High DG and Advanced EE options to account for the effects these demand resources have on reducing customer sales. Future IRP's will likely address different renewable resource mixes as the CEC further develops specific qualifying criteria for meeting in-state and out-of-state category requirements.

The 2012 IRP Strategic Cases were developed to assist policymakers and ratepayers to make informed decisions regarding the accelerated replacement of Coal resources to promote GHG reduction prior to SB 1368 compliance, advanced levels of energy efficiency to comply with and exceed the 10 percent by 2020 goals set forth by AB 2021 and higher levels of solar distributed generation to help achieve the Governor's statewide goal of 12,000 MW of solar distributed generation by 2020.

AR0070013

3.4 Candidate Portfolios Development Process

A candidate portfolio is a set of renewable and non-renewable generation resources, demand side resources, regulatory constraints, policy goals, and assumptions that are used to model strategic scenarios. Candidate portfolios are selected to cover a spectrum of possible scenarios, providing decision makers information on which portfolios are likely to be the most desirable. Additionally, each candidate portfolio must ensure resource adequacy – the ability to meet total peak demand.

3.4.1 Public Input

Before developing candidate portfolios, LADWP met with and gathered input from key ratepayer, customer and business representatives, as well as key environmental organization representatives. Comments received from these early discussions were factored into the overall objectives, goals and policy guidelines used in the initial construction of the draft candidate portfolios. Subsequent public review of the preliminary findings provided further input which was considered prior to finalizing a recommendation.

3.4.2 Net Short and Resource Adequacy

The first step in developing the 2012 IRP candidate portfolios was to determine how LADWP can meet and maintain its renewable energy policy goals: 20 percent renewables by 2020 and 33 percent renewables by 2020. The net short – the gap between renewable energy policy goals and current renewable generation – was calculated for each strategic case, and the contribution of its renewable energy component towards resource adequacy was determined. Energy efficiency, demand response, combined-cycle gas generation, and term purchases were then considered to supply the remaining deficiency in resource adequacy. Details regarding net short calculations and resource adequacy are included in Section 4.3.1.1 and Appendix N.

3.4.3 Renewable Resources Selection Process

Over the last ten years, LADWP has issued several requests for proposals for renewable energy and gained a thorough understanding of the nature and availability of the different renewable resource technologies. This knowledge was used in developing the candidate portfolios. Additionally, LADWP largely considered renewable resources within the Western Governors' Association's Western Renewable Energy Zones (WREZ). In the WREZ initiative, Qualified Resource Areas were defined as areas of dense, high-quality renewable energy resources, meeting various resource size, quality, environmental, and technical criteria. LADWP screened all resources to ensure they are located near available LADWP transmission infrastructure, or can be delivered to areas under LADWP's balancing authority.

A valuation process designed to provide a single ranking value to a resource was then applied. This step is intended to identify resources with the combination of lowest cost

AR0070014

and highest value. The valuation approach is similar to the bid evaluation process many utilities use when procuring renewable resources. Some of the considerations in selecting these resources are as follows:

- Cost differences for different renewable technologies and projects
- Cost trends that reflect decreasing prices
- Variable integration costs and operational impacts
- Technologies that deliver more energy during peak hours
- Preference for local projects
- Proximity of projects to transmission
- For PPA resources, tax credits that can be passed along as cost savings
- PPA proposals that provide future ownership opportunities
- Overall diversity of resource mix and geography
- Satisfying category, or "bucket," requirements according to CEC RPS regulation and guidelines (see Section 1.6.3)

After applying the appropriate constraints, resources were selected and added progressively to its renewable resource mix based on lowest rank cost and transmission availability until the net short was mitigated.

In this 2012 IRP, the overall renewable portfolio levelized cost is $98/MWh, which represents an $13/MWh decrease from last year. This cost reduction was achieved by selecting a more optimized and diverse portfolio that increases the contribution from cost-effective large central solar projects and biogas resources. Although LADWP continues to evaluate and develop wind and geothermal resources, they tend to be very site specific and typically lie a greater distance from existing transmission, or require transmission that must be purchased from other utilities. Another factor considered were solar tax credits which extend beyond those for wind and geothermal. Biogas uses the existing gas delivery infrastructure and existing combined cycle generating units making this a very cost effective and fully dependable resource. By maintaining flexibility in the selection of cost-effective renewable resources, LADWP is able to secure the best pricing for its ratepayers, as market conditions evolve.

3.4.4 Distributed Generation Levels

This year's IRP considers higher levels of Distributed Generation (DG), partly in response to the Governor's State-wide initiative for 12,000 MW of local renewable DG. Due to reliability and operational concerns, the maximum amount of DG considered is limited to 15% of the maximum annual peak load per circuit.* Because this is a relatively new area of study, LADWP is proceeding cautiously until it has a better understanding of the impacts intermittent resources will have on its distribution grid. Potential impacts include cost increases for infrastructure enhancements, the need for curtailment during

* Refer to "Updated Recommendations for Federal Energy Regulatory Commission – Small Generator Interconnection Procedures Scenarios" Prepared by Sheehan and Cleveland, July 2010, and "Model Interconnection Procedures" by the Interstate Renewable Energy Council, 2009 Edition.

AR0070015

high generation/low load periods, and new procedures to maintain reliability. As more experience is gained along with more industry-wide research in this area, it is possible that future IRPs will consider higher DG levels.

AR0070016

3.5 2011 IRP Strategic Cases

The 2012 IRP analyses a focused set of strategic cases expanding on the results from the 2011 IRP. A streamlined set of 4 coal replacement cases and 4 energy efficiency and solar distributed generation cases were evaluated for the 2012 IRP. Unlike other areas that are constrained by mandated regulatory requirements (such as renewable resources), the decision to divest from coal earlier than legally required, and accelerate energy efficiency programs or solar distributed generation programs is discretionary and thus appropriate for analysis. The 2012 IRP strategic cases are designed to assist policymakers and ratepayers to make informed decisions regarding these major initiatives particularly with regard to the environmental benefits and resulting resource and financial impacts.

Tables 3-4 and 3-5 provided a detailed description of each of the strategic cases.

It should be noted that the same renewable resource plan applies to Cases 1 thru 5. Cases 6 thru 8 include different renewable resource plans to adjust for increasing amounts of solar distributed generation and reductions in forecasted sales resulting from additional energy efficiency and CCSM solar distributed generation. Table 3-5 summarizes each renewable portfolio. For comparison purposes, the recommended case from the 2011 IRP is also included.

The different cases require distinct resource strategies to replace coal generation capacity and to meet future load growth. These strategies include the construction of new natural gas units, renewable generation, electricity purchases in the 3rd Quarter as needed to fill short term resource adequacy deficiencies, and the implementation of demand response and energy efficiency programs. A detailed breakdown of these strategies is discussed in Sections 4 and 5.

The candidate portfolios were modeled and the case results were compared against each other. The analysis included measurements of power costs, emissions, and fuel usage. High and low scenarios based on fuel prices were also modeled for the coal replacement cases to quantify the risk associated with fuel price volatility. Section 4 discusses the modeling results to facilitate a dialogue with our stakeholders and ratepayers with a goal of selecting the recommended case for the 2012 IRP.

Section 5 discusses in greater detail Case 5 with early Navajo divestiture which is a variation of the recommended case from the 2011 IRP with updates including 50% energy efficiency, enhanced solar focus including increased local distributed solar, and other updated assumptions. This discussion primarily involves the impact on Power System revenue requirements, rates, and customer bills.

AR0070017

Table 3-4. DESCRIPTION OF STRATEGIC CASES

Case ID	Description
Case 1 (Coal Base Case)	No Early Coal Replacement – This case assumes coal resources will be replaced with combined cycle natural gas and renewable resources upon the expiration of coal contracts with no early compliance with SB 1368. Maintains the 33 percent standard renewables mix recommended to comply with SB 2 (1X) and the 10 percent energy efficiency savings by 2020 to comply with AB 2021.
Case 2	Navajo Early Divestiture Strategy – This case considers early divestment of Navajo on 12/31/2015, or 4 years prior to contract expiration, with IPP replacement at the end of contract expiration in 2027. Maintains the recommended 33 percent standard renewables mix to comply with SB 2 (1X) and the 10 percent energy efficiency savings by 2020 to comply with AB 2021.
Case 3	Navajo and IPP Early Replacement Strategy – This case considers early divestment of Navajo on 12/31/2015, 4 years prior to contract expiration, and early replacement of IPP on 12/31/2020 or 7 years prior to contract expiration. Maintains the recommended 33 percent standard renewables mix to comply with SB 2 (1X) and the 10 percent energy efficiency savings by 2020 to comply with AB 2021.
Case 4	Navajo and IPP Early Replacement Strategy (Alternate) – This case considers early divestment of Navajo on 12/31/2015, 4 years prior to contract expiration, and early replacement of IPP on 12/31/2023 when the IPP debt burden is fully paid 3.5 years prior to contract expiration. Maintains the recommended 33 percent standard renewables mix to comply with SB 2 (1X) and the 10 percent energy efficiency savings by 2020 to comply with AB 2021.
Case 5 (EE and DG Base Case)	Base Energy Efficiency and Base Solar Distributed Generation - Indentical to Case 2 and used as a baseline comparison to Cases 6 thru 8.
Case 6	Advanced Energy Efficiency and Base Solar Distributed Generation - Considers early divestment of Navajo with 10 percent energy efficiency savings by 2020 and an additional 500 GWh of energy efficiency savings between 2020 thru 2032.

AR0070018

Case 7	Base Energy Efficiency and High Solar Distributed Generation - Considers early divestment of Navajo with 10 percent energy efficiency savings by 2020. Increases solar distributed generation thru the FiT program from 75 MW to 150 MW by 2016 and 150 to 305 MW by 2026 and increases CNM (SIP) solar from 145 to 183 MW by 2020 and 252 to 363 MW by 2032
Case 8	Advanced Energy Efficiency and High Solar Distributed Generation - Considers early divestment of Navajo with 10 percent energy efficiency savings by 2020 and an additional 500 GWh of energy efficiency savings between 2020 thru 2032. Increases solar distributed generation thru the FiT program from 75 MW to 150 MW by 2016 and 150 to 305 MW by 2026 and increases CNM (SIP) solar from 145 to 183 MW by 2020 and 252 to 363 MW by 2032.

4.0 STRATEGIC CASE ANALYSIS

4.1 Overview

Section 3 discussed the development process for alternative case options, and presented the resulting 8 cases being considered for study. This Section 4 presents the analysis of the 8 cases, including the modeling methodology and the analysis results.

The analysis was performed on the generating resources using an hourly chronological production cost model. The model simulated the operation and electric loading of the LADWP Power System over a 20-year planning horizon with different portfolios of generating resources. The objective function of the production cost model is to minimize system cost, which is achieved by finding the least cost method to meeting the electric system demand using the specified generating resource portfolios.

The resources defined in the model consist of existing LADWP generating resources, generation currently under differing stages of development, and generic types of future generating resources with locations or projects that are not yet identified. The resource mix of renewable generating resources and thermal generating resources must satisfy: (1) resource adequacy requirements for reliability, (2) specific increasing targets of renewable resources as a percentage of total energy sales, and (3) other goals and objectives such as 10 percent energy efficiency, reliable integration of renewables, etc.

The 2012 IRP continues to evaluate the coal replacement strategies considered in the 2010 and 2011 IRPs with updated cost and assumptions information. Additionally, a new case (Case 4) was also developed with the goal of divesting of Navajo on December 31, 2015 and replacing IPP by the end of 2023. The date of 2023 was selected because this is the earliest practical transition point considering that the capital bonds to build IPP will be paid in full at the end of 2023. Any earlier divestiture would significantly increase ratepayer costs by expending debt payments on a facility that was not providing energy. Every year, LADWP purchases a percentage (~60%) of IPP generation from its owner, Intermountain Power Agency (IPA). LADWP's obligations to make payments with respect to IPP are unconditional "take-or-pay" obligations, obligating LADWP to make such payments as operating expenses of the Power System whether or not the applicable project is operating or operable, or the output thereof is suspended, interfered with, reduced, curtailed, or terminated in whole or in part. Since LADWP is just one of 36 utilities purchasing energy from IPA, any agreement to replace IPP will need the cooperation of all power purchasers involved. This new Case 4 also targeted an early IPP replacement date of 2023 so LADWP can avoid the financial burden of paying for both the replacement CC units and the IPP associated cost from 2024 to 2027. The actual replacement date may vary based on the final agreement with the other power purchasers. However, for evaluation purposes, this is a reasonable transition point to consider.

As a new addition for the 2012 IRP, four new scenarios (Cases 5 – 8) have been developed, focusing on alternative energy efficiency (EE) and solar distributed generation (DG)

AR0070022

strategies over the next 20 years. These four new EE+DG scenarios include the same coal replacement timeline with Navajo divested in 2015 and IPP replaced in 2027. The detailed discussion on the scenarios and the analyzed results can be found in Sections 3 and 4.3.

All 8 cases were modeled, and the results were tabulated and compared against each other. Each strategy was ranked on average dollars per megawatt hour generation cost and the total million metric tons of CO_2 emissions. All of the strategic cases meet electric system reliability requirements per WECC and NERC standards.

Load forecast, prices of natural gas and coal, GHG emissions levels, capital, and O&M costs are the major cost drivers for bulk power in the cases analyzed. All cases meet the mandated RPS percentage targets and renewable resources are adjusted for each case analyzed depending on energy sales adjustments needed based on varying amounts of distributed solar generation and energy efficiency.

Section 4.2 reviews the modeling considerations for the cases that were presented in Section 3, along with the model assumptions and analysis methodology. Section 4.3 presents the modeling results, including cost comparisons and the rate impact results of the different cases. Section 4.4 presents the strategic case conclusions and the recommended case.

Section 5 includes long and short-term actions that are recommended towards implementation of the recommended case, including an estimate of the revenue requirements and electricity rate schedule needed to support it.

AR0070023

4.2 Strategic Case Modeling Considerations

The cases analyzed in this 2012 IRP were introduced in Section 3.5 and are briefly discussed here. The timing of coal replacement and the variations in energy efficiency and distributed generation quantities and the resultant changes in resource mix are the key parameters that differentiate the 8 cases evaluated. Table 3-5 summarizes the portfolios for each case.

The following inter-related resource parameters were assumed to occur in the 8 coal and EE/DG potential resource strategies:

- OTC Repowering Schedule per Figure 1-15
- Net Energy efficiency penetration of approximately 3500 GWh by FY 2032 for base EE and 4000 GWh by FY 2032 for advanced EE
- RPS Resource Mix, schedule per Table 3-5
- GHG allowance allocations and prices shown in Appendix N
- Gas and Coal Fuel prices, as discussed in Section 3.2.2.
- IPP capacity and recall schedule shown in Appendix N

Coal strategic cases were also subjected to high and low scenario runs, which were based on high and low values for natural gas and coal prices. High and low fuel scenario runs were not performed for the EE/DG cases evaluated. The high and low scenarios simulated production over the same 20-year horizon, and provided a measure of the level of risk due to potential future fuel price volatility.

4.2.1 Modeling Methodology

4.2.1.1 Planning & Risk (PROSYM)

Simulations were performed using Planning & Risk (PAR), a third-party software program sold and distributed by Ventyx Corporation. PAR is an hourly chronological production cost model that commits and dispatches resources with certain operational constraints applied to the system to minimize the cost of serving electric load. It utilizes the PROSYM unit commitment and dispatch algorithm. PAR is a widely used production cost model used by many utilities across the US and the world to help plan and optimize power systems. Additional information on the model can be found in Appendix N.

4.2.1.2 Model Assumptions

To perform model simulations, a large set of input data is required. The key parameters that influence the analysis results are fuel prices, load forecast (including adjustments for energy efficiency and other demand side management programs), coal replacement strategies, and operational inputs regarding future gas-fired units. Details regarding the model assumptions are provided in Section 3 and Appendix N

AR0070024

4.2.1.3 Net Short of Renewables

In developing the future renewable portfolio mix, the primary requirement was to meet the SB 2 (1X) goals for RPS percentage (see Section 1.6.5 for details) which includes meeting the RPS portfolio content categories as shown in Table 1-1. Other considerations included costs, resource and geographical diversity, and proximity to existing transmission. The process by which the renewable resource portfolio was constructed is described in Section 3.4.

4.2.1.4 Resource Adequacy

As a prerequisite for any potential future portfolio, all cases considered must satisfy Resource Adequacy (RA) requirements. RA is the ability to supply the aggregate demand and energy requirements of customers at all times, taking into consideration future load growth and planning reserve margins. In calculating RA for a given portfolio, generation resources are assigned a percentage of their nameplate capacity, known as "Net Dependable Capacity" that can be counted towards the RA requirement. The net dependable capacity values vary depending on the type of generation resource. Throughout the energy industry there is an on-going debate on how much variable energy resources can be relied upon during the summer system peak. Table 4-1 lists the net dependable capacities of the different resource technologies assumed for this IRP analysis.

Table 4-1: NET DEPENDABLE CAPACITY ASSUMPTIONS FOR NEW RESOURCES

Plant Technology	Net Dependable Capacity
Natural Gas Combined-Cycle	100%
Natural Gas - Gas Turbine	100%
Wind	10%
Solar PV	27%
Solar Thermal	68%
Geothermal	90%

The specific RA analyses for each of the four coal strategic cases are presented later in Section 4.3.1.1.

4.2.1.5 Model Runs and Scorecards

The evaluation of each strategic case yielded a tremendous amount of information about the LADWP Power System. In order to organize and interpret the modeling results, a scorecard system was developed to rank and check the output results. The scorecard is a very detailed and complex Microsoft Excel based spreadsheet that summarizes all the important inputs and outputs and includes metrics such as total system power costs, plant generation, CO_2 emissions, and fuel costs.

AR0070025

4.2.1.6 Post Modeling Analysis

While the production cost modeling provides detailed information on estimated bulk power costs, reliability and mandated regulatory program revenue requirements are evaluated through analysis external to the production cost model. The results of this analysis are provided in Section 4.3 to provide a more complete view of the total cost components that make up total Power System costs. This Section also illustrates the revenue requirements to fund these specific programs to maintain a reliable electric system while also complying with regulatory requirements for renewable portfolio standards, local solar, once-through-cooling, and energy efficiency.

AR0070026

4.3 Modeling Results

The modeling results are presented in terms of LADWP's overall goals of: (1) reliability, (2) environmental stewardship and (3) economic, or cost, considerations.

4.3.1 Reliability Considerations

Resource strategies are not designed to totally avoid the chance of a power outage due to inadequate supply resources. Such a strategy would be very expensive and would mean that some resources would be built with a small chance of ever operating, or would have an unacceptably low capacity factor. Most power outages are distribution based (e.g., a winter storm that knocks down local distribution lines) and not a result of insufficient generation resources. The reliability criterion of "1 day in 10 years" attempts to quantify what is an acceptable amount of loss of load (i.e. a power outage). The generally accepted industry interpretation of the criteria is that a system is considered reliable if there are no more than a total of 24 hours of loss of load in a 10 year period (87,600 hours). This criterion translates to a 0.03 percent chance that load will not be served.

Based on the reliability calculation, no single resource strategy is significantly more or less reliable than another strategy, and all strategies meet this criteria. The economic aspects of each of the resource strategies are only valid if the resource strategy meets the NERC reliability standard of "1 day in 10 years." For this evaluation on reliability, each resource strategy was considered equal in terms of the reliability criteria.

4.3.1.1 Resource Adequacy

The process of ensuring resource adequacy for each strategic case is iterative. Initially, a model run is made for each case without any resource additions. The results indicate the amount of resource surplus or shortfall into the future. Without any resource additions, a deficit is eventually reached as a result of coal replacement, generation unit retirements and the expiration of power purchase contracts on the supply side, as well as load growth adjusted for resources such as EE and Solar DG on the demand side. Figure 4-1 presents the resource shortfalls for the four coal replacement cases prior to any resource additions. For planning purposes, the figures focus on the most critical months of each year – July through October.

AR0070027

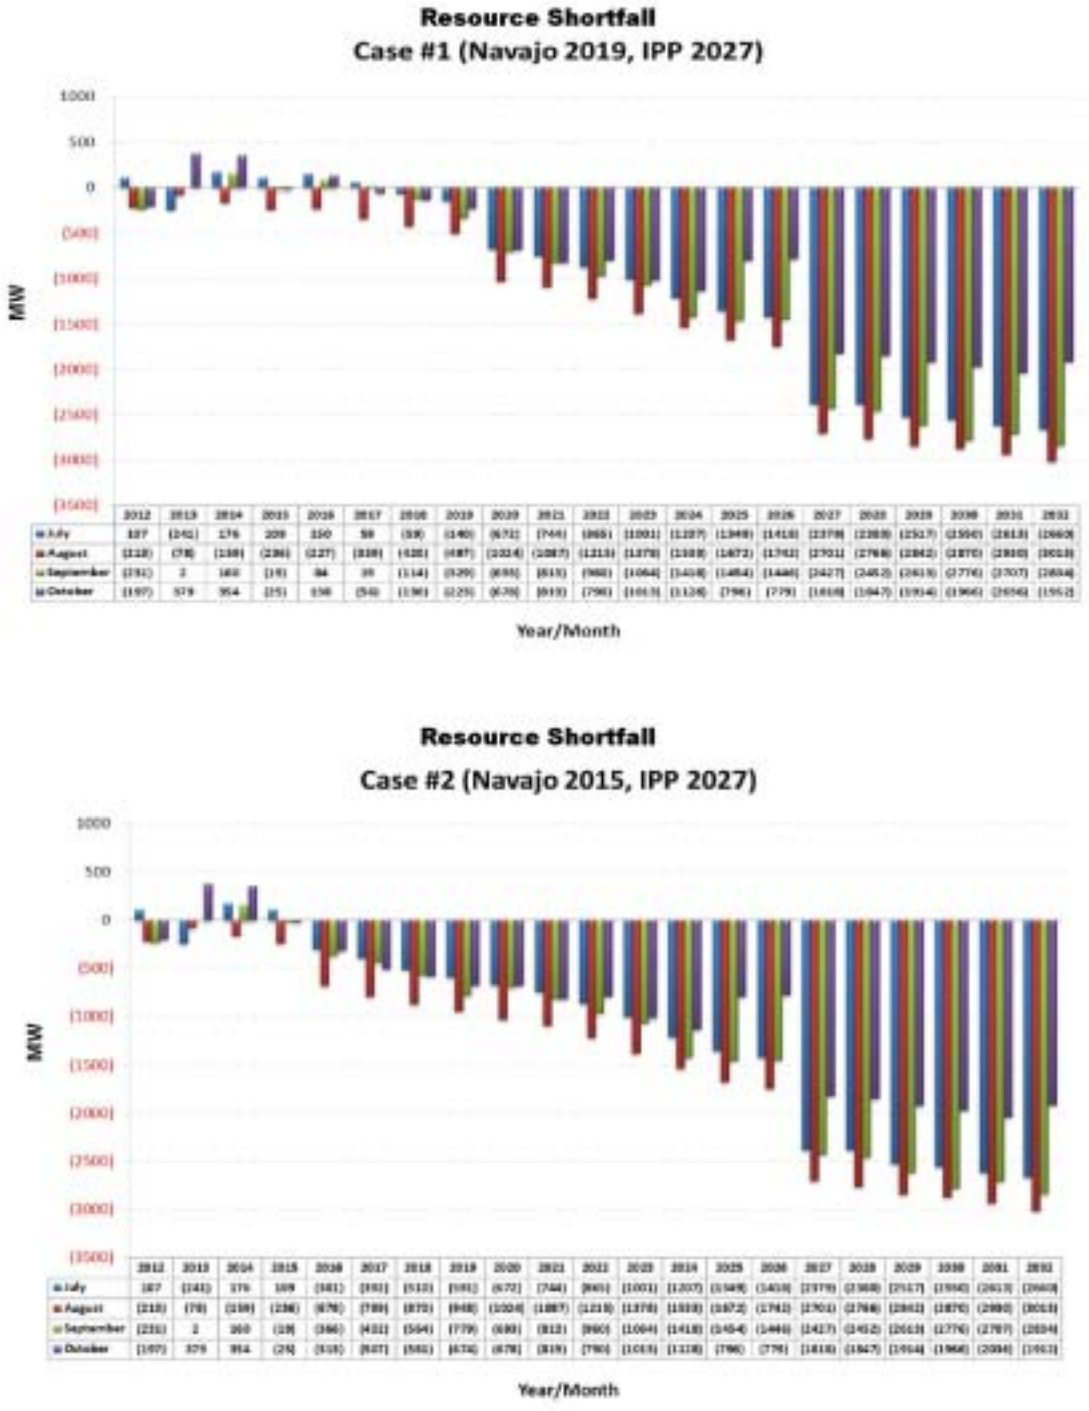

Figure 4-1. Summer months resource adequacy shortage for Cases 1-4, by calendar year ("1 in 10" reliability criteria)

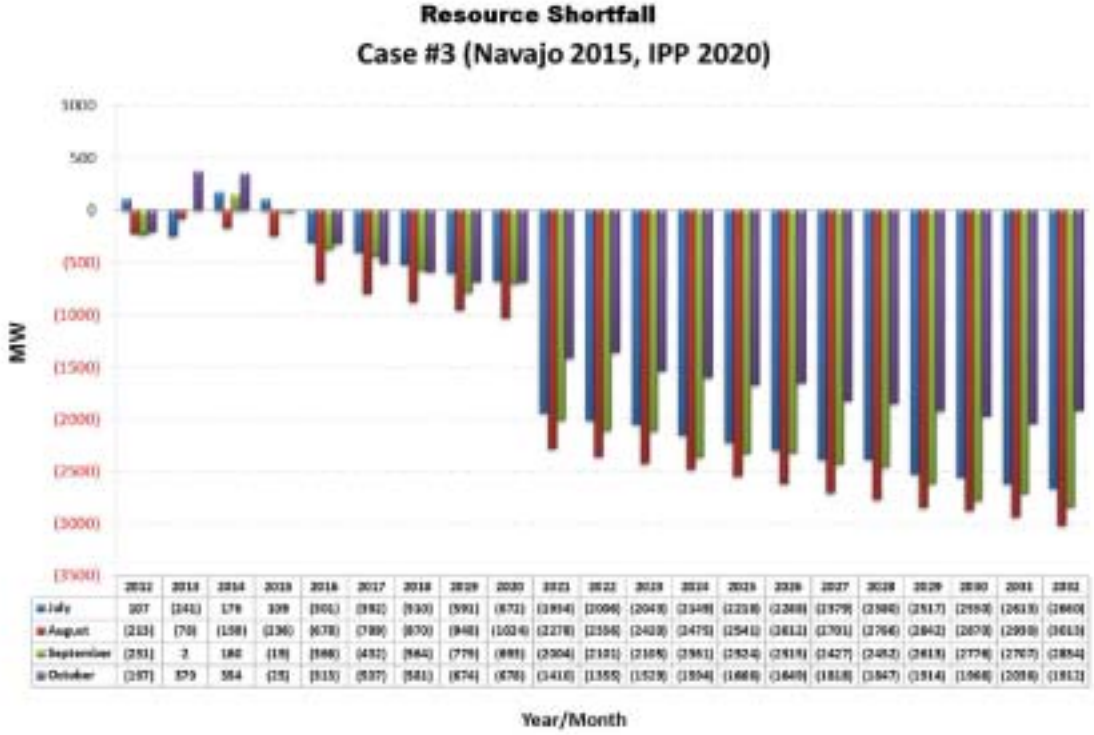
AR0070028



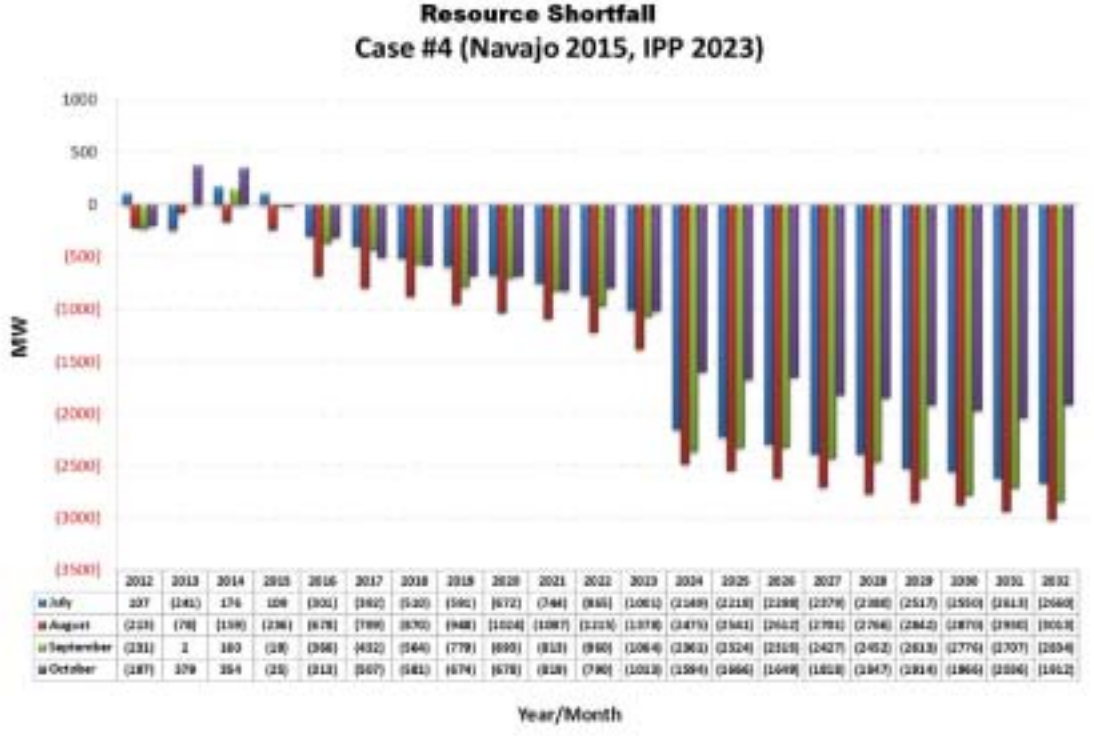


Figure 4-1. (continued)

AR0070029

Once the deficits have been quantified, the means of satisfying the shortfall is assessed. Some of the considerations that LADWP accounted for in identifying potential solutions include:

- Any additional renewables will increase LADWP's overall renewable resource portfolio and help achieve compliance with SB 2 (1X).
- Energy efficiency, demand response, peak season Q3 term purchases, and replacement gas fired generation were considered to provide the most economical and well diversified blend of resources.
- The additions had to be separate and distinct from the in-basin OTC repowering projects which are already included in the shortfall calculation.
- Large scale generation additions were located out-of-basin to take full advantage of the existing transmission infrastructure and to comply with local environmental regulations.
- Where feasible, the new generation sites should make use of existing transmission and fuel supply infrastructure.
- As with all planning activities, the solution must address reliability, costs, and environmental stewardship.

After careful consideration, LADWP's IRP team consisting of the IRP staff, Power System Management, Environmental Affairs, and the Energy Efficiency Group, developed a resource replacement strategy for each case and briefed the General Manager. The resource solution employs a mix of new renewable generation, energy efficiency, demand response, new gas-fired combined cycle units, and Q3 Term Purchases to replace Navajo and IPP Coal and to supplement load growth adjusted for demand side resources. Table 4-2 shows the breakdown of the replacement resources recommended for the four coal cases. Replacement resources for the 4 EE-DG cases were also developed and are shown in Appendix N.

AR0070030

IPP Replacement CC	0	0	0	0	0	0	0	0	0	0	0	0	1150	1150	1150	1150	1150	1150	1150	1150	1150
Q3 Term Purchase	200	171	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	50	121
Total Replacement	244	257	165	342	760	861	875	1084	1346	1313	1420	1511	1750	2911	2822	2506	2854	2867	2980	3043	3130

Figure 4-2 shows the net dependable capacity profiles for the 4 coal cases after including the recommended resources to satisfy resource adequacy requirements. In each case, Navajo is replaced with new renewable generation and a 300 MW replacement combined cycle gas-fired unit upon divestiture. Energy efficiency, demand response, and Q3 term purchases supply capacity that primarily contributes to peak load growth. Figure 4-3 presents the generation profiles for the same 4 coal cases.

When IPP energy ceases in 2027 for Cases 1 and 2, 2020 for Case 3, and 2023 for Case 4, that production is replaced entirely with two 575 MW combined cycle natural gas units. The larger combined cycle units will be necessary to reduce Q3 term purchases and to provide energy and capacity for additional load growth. By 2020, most of the renewable portfolio will have already been built to replace Navajo, with continued load growth being offset by renewables, energy efficiency, demand response, Q3 term purchases, and a portion of the two 575 MW combined cycled gas-fired units.

Q3 term purchases are meant to satisfy peak load growth in the summer months where capacity is needed only over a short period of time, typically over a few weeks of the summer months. The planned addition of Q3 term purchases helps to limit the amount of capital intensive resources that would be necessary to supply peak load growth. Continual evaluation

AR0070031

of future market conditions will be needed to ensure that the market possesses adequate depth and reasonable pricing so that these term purchases can be relied upon to fill system capacity needs.

In Cases 2, 3 and 4 with the Navajo Generating Station (NGS) divested in 2015, the 300 MW combined cycle gas-fired unit and demand response resources are fulfilling two purposes, (1) replacing capacity and energy that would have been provided by NGS and (2) providing dispatchable resources to enable the integration of increasing amounts of intermittent renewable energy as these resources are ramped up from the current 20% RPS to 33% RPS in 2020.

4.3.2 GHG Emissions Considerations

The primary objective of coal replacement is to reduce overall GHG emissions. Energy produced from coal emits approximately twice the amount of GHG emissions, when compared to energy produced from natural gas. The reductions of GHG emissions are reflected in the production cost model simulations. Figure 4-4 illustrates a comparison of the resulting GHG emission levels of the four cases. Divestiture of Navajo results in an average 1.81 Million Metric Tons (MMT) reduction in GHG each year while IPP results in an average 2.78 MMT reduction each year. GHG reductions are accelerated in Cases 2, 3 and 4 with the replacement of Navajo and IPP prior to the expiration of existing power contracts with these facilities. Case 1 represents the normal course of emissions reductions with no early replacement. Reduction levels are eventually reached in all cases in 2019 and then again in 2027 when SB 1368 essentially prohibits the importation of energy produced from coal when the existing power contracts expire.

Current total GHG emissions levels are approximately 14.1 MMT which is 21 percent below 1990 levels due to the elimination of Mojave and Colstrip Coal, completed repowering of units at Haynes and Valley generating stations with cleaner gas-fired replacements, and increased renewable generation from 3% in 2003 to 20% in 2010. Using Case 1 (Navajo divestiture in 2019, IPP replacement in 2027) as a baseline, early divestiture of Navajo in Cases 2, 3 and 4 results in approximately 7.2 MMT less GHG emissions between 2016 and 2019. For Case 3 (IPP replaced in 2020) there is an additional post-2020 cumulative reduction of 19.5 MMT. For Case 4, the post-2020 reduction is 9.3 MMT. These GHG emission reductions are shown below in Figure 4-4 and Table 4-3.

AR0070037

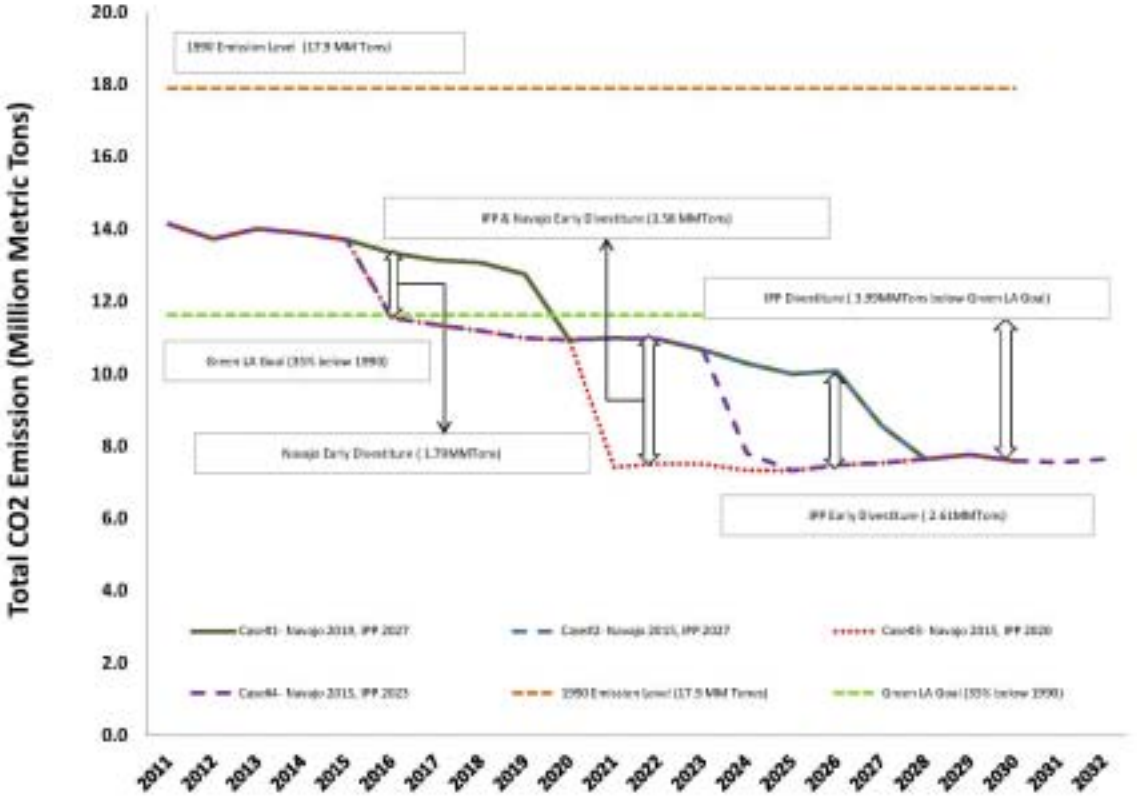

Figure 4-4. GHG emissions comparison by calendar year.

Table 4.3 GHG EMISSIONS REDUCTION LEVELS IN MMT

Case	Reduction 2016-19	Reduction 2020-27	Total Reduction 2016-27
1	Baseline	Baseline	Baseline
2	7.2	0.0	7.2
3	7.2	19.5	26.7
4	7.2	9.3	16.3

Emission levels for the energy efficiency and solar distributed generation, Cases 5 thru 8 were also evaluated as shown in Figure 4-5. Advanced levels of EE were found to result in slightly lower emissions of CO_2 as compared to the Base EE cases. Higher levels of Solar DG were found to have little effect on reducing CO_2 emissions since Solar DG would have been replaced with other zero emissions resources. Although these higher levels of EE and distributed generation have a small impact on emissions compared to the base EE, it is important to note that the base level of energy efficiency in and of itself has a very significant impact on reducing overall CO_2 levels as shown by the "No More EE" curve illustrated in Figure 4-4. If no additional EE were implemented, annual GHG emissions levels would be

AR0070038

approximately 2.0 MMT higher by 2032. This is equivalent to removing 385,000 cars from the road. For reference purposes, the CARB emissions allocation for LADWP as part of the AB 32 Cap and Trade program being implemented in 2013 and ending in 2020 is shown in Figure 4-5.

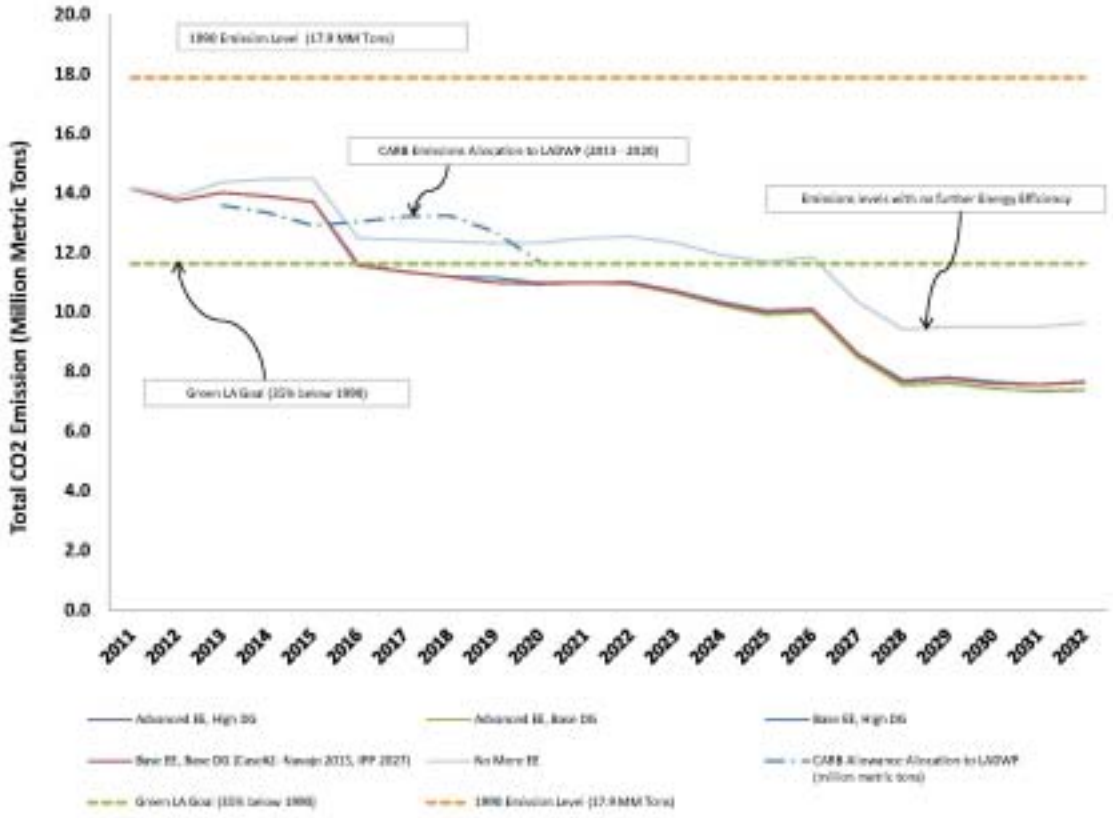

Figure 4-5. GHG emissions comparison for Energy Efficiency and Solar Distributed Generation cases by calendar year.

In addition to GHG, Oxides of Nitrogen (NO_X) were also measured within the production model. Figure 4-6 summarizes NO_X emissions for each of the four cases. With the installation of SCR equipment since 1989, NO_X emissions of in-basin generation has been reduced by 90 percent.

AR0070039

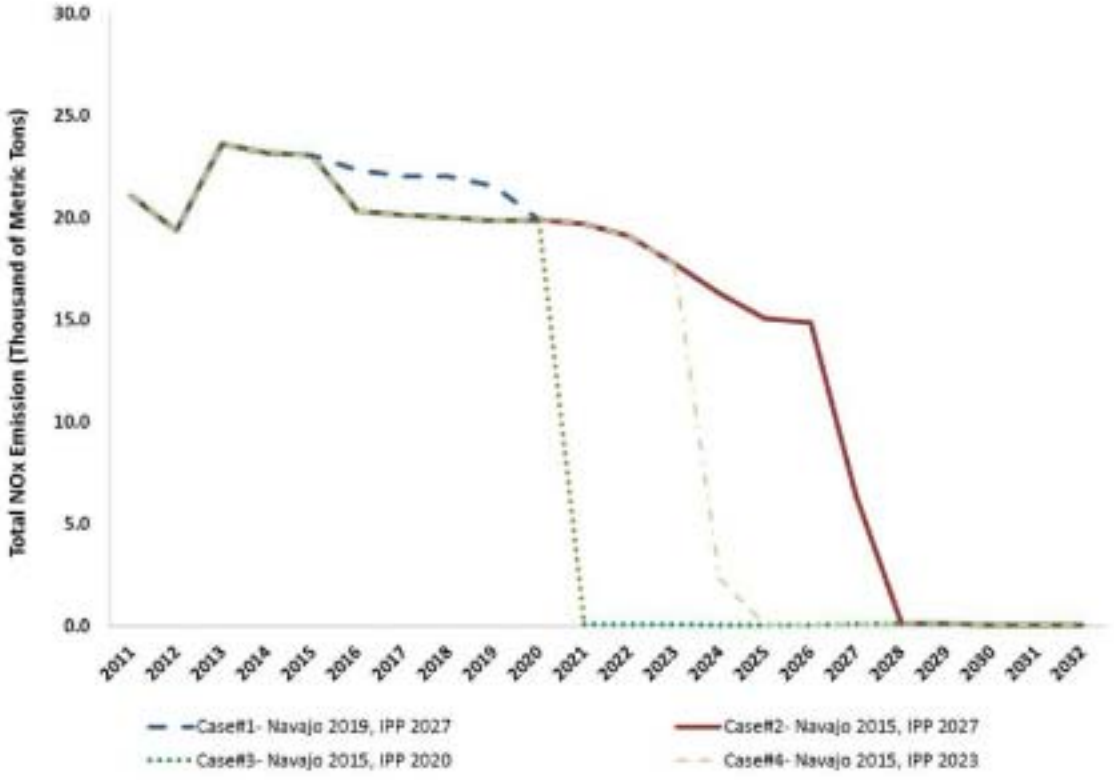

Figure 4-6. NO_X emissions comparison by calendar year

4.3.3 Economic Considerations

The economic considerations for the eight coal and EE/DG cases included a comparison of fuel and variable costs. The coal cases were further subjected to fuel price stress tests to account for potential future price volatility which affects possible ranges of bulk power costs related to coal replacement. Reliability and regulatory revenue requirements are also addressed to quantify the impact of these programs on future total Power System costs.

4.3.3.1 Cost Comparison Between EE and DG Cases 5 thru 8

Two scenarios of Energy Efficiency (EE) were considered including a Base EE case and an Advanced EE case. By using FY 2010-11 Total Sales to Ultimate Customers (23,053 GWh) to calculate the energy savings percentage, the Base EE case forecasts LADWP will achieve 10% of Net EE savings by 2020 and 15% EE savings by 2032. The Advanced EE case forecasts the same EE savings up to and including 2020 as in the Base EE case, but gradually adds another 500 GWh of savings by 2032. The Net EE savings in GWh for the two scenarios along with the projected budget are shown below in Figures 4-7 and 4-8.

AR0070040

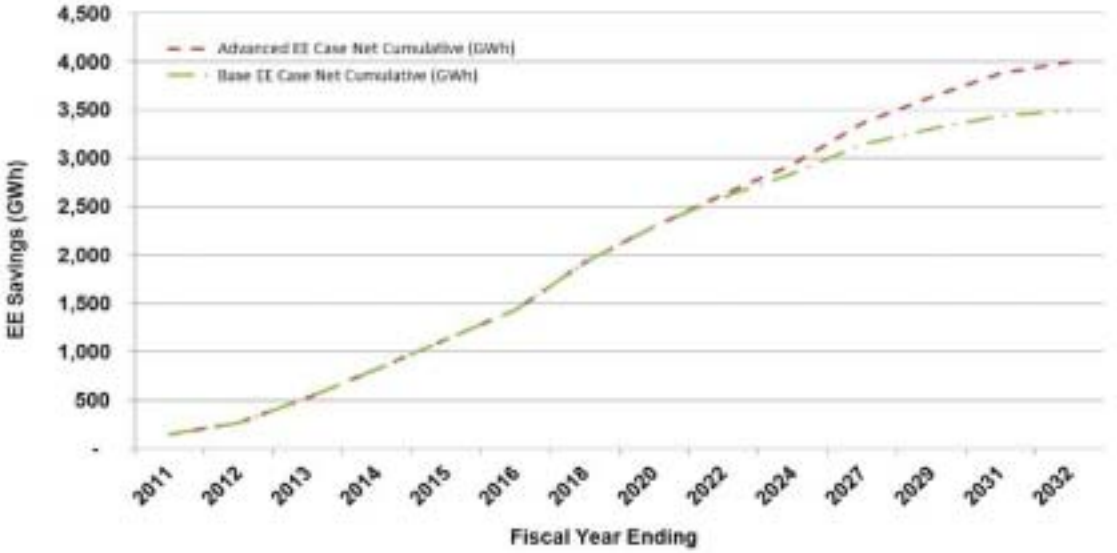

Figure 4-7. Advanced EE and Base EE GWh Comparison

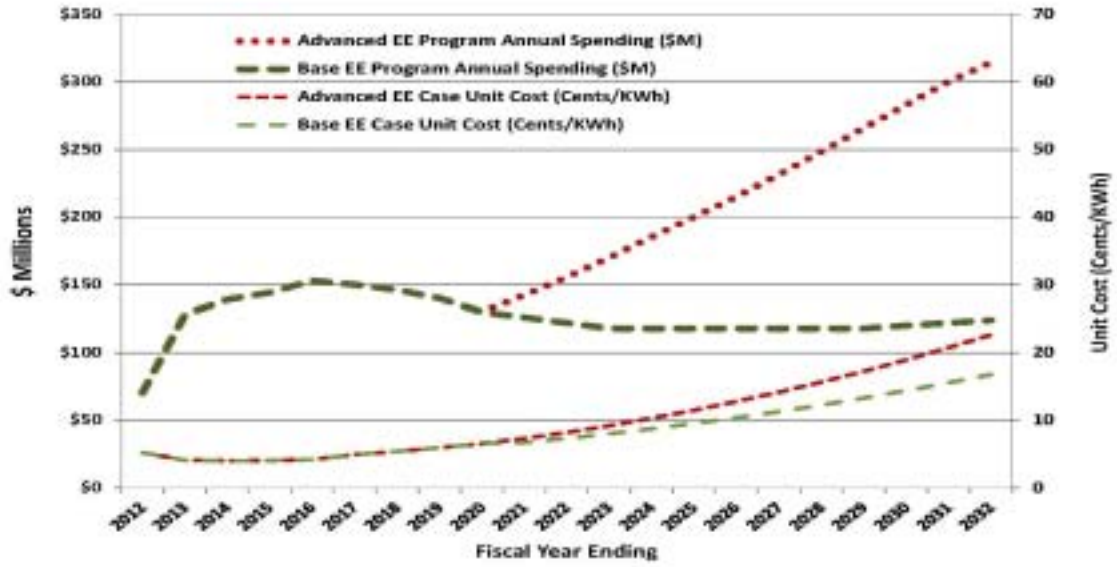

Figure 4-8. Advanced EE and Base EE Program Cost Comparison

Solar Distributed Generation (DG) includes local solar generation that is directly interconnected to the distribution system. Distributed generation comprises solar generation from the Feed in Tariff (FiT), Utility Built Solar (UBS), and customer net metered programs. UBS are solar projects that would be built and operated by LADWP, and may be located in the city or out-of-basin. The detailed Solar DG scenarios in GWh and unit cost are shown in

AR0070041

Figure 4-9, along with curves for LADWP's Utility Built Solar (UBS) program. The two scenarios for Solar DG consist of one Base DG case and one High DG case.

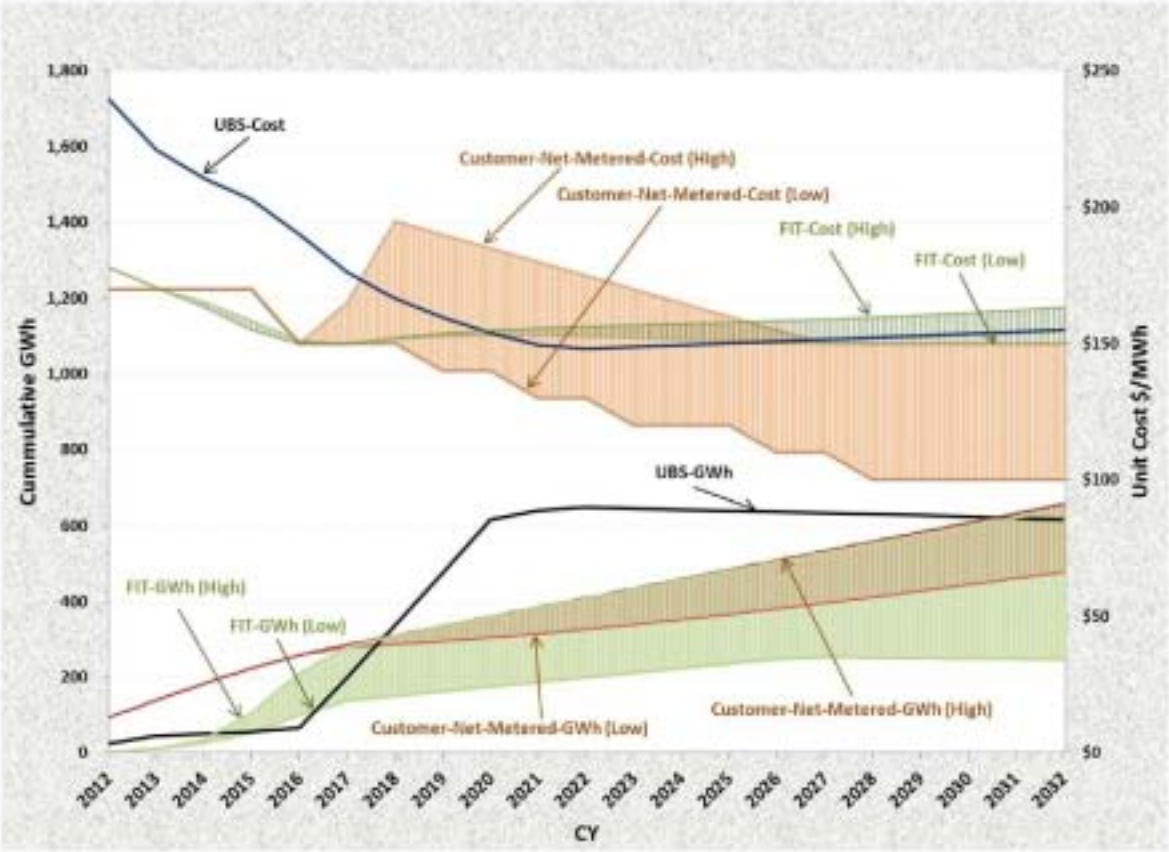

Figure 4-9. High and Base DG solar program cost assumptions and GWh comparison

The Base EE and Base DG energy forecasts are used in all four coal strategic cases evaluated in the 2012 IRP. The Base Case assumes divestment of Navajo Generating Station by December 31, 2015 and Intermountain Generating Station will be replaced by natural gas generation by June 15, 2027. Different combinations of EE and DG cases were analyzed in the production model simulations including: (1) Base EE with Base DG, (2) Base EE with High DG, (3) Advanced EE with Base DG, and (4) Advanced EE with High DG. The detailed analysis was conducted using the PROSYM production cost modeling software .

There are various resource changes associated with different EE and DG combinations due to RPS mandatory and system reliability requirements. For example, when the High DG and Advanced EE case is modeled, the more aggressive EE reduces both customer energy sales and load demand which relaxes the requirements on RPS and peak demand. Also, with higher Solar DG some non-solar-DG renewable resources were reduced or even eliminated to avoid unnecessary expenditures on renewable energies beyond the amount mandated by SB 2 (1X).

AR0070042

Demand-Side Resources – Total Revenue Requirements

Due to the load reduction nature of energy efficiency and solar customer-net-metered "demand-side" programs, analysis of the revenue requirements of these specific programs must be handled in a different manner than other distributed generation programs such as solar feed-in-tariff and utility built solar. The modeling results were analyzed to determine the net revenue loss due to reduced sales and the program costs which consist mainly of incentive payments paid to customers to subsidize the cost of these demand-side measures. While the program costs are relatively straight forward to evaluate, determining the net revenue loss is a more complex process that requires first determining the costs that the utility avoids by implementing these programs which is simply described as "avoided costs."

Determining Net Revenue loss involves first determining the avoided costs from implementation of demand-side energy savings, including: fuel, variable O&M, emissions, transmission and distribution deferred upgrades, capital investments for new generation, fixed O&M, and energy transport losses. The avoided costs and fixed billing charges from demand and minimum billing charges are then subtracted from the gross revenue loss to determine the net revenue loss as shown in Figures 4-10 through 4-13 below. A full detailed discussion of avoided costs and revenue loss results are included in Appendix N.

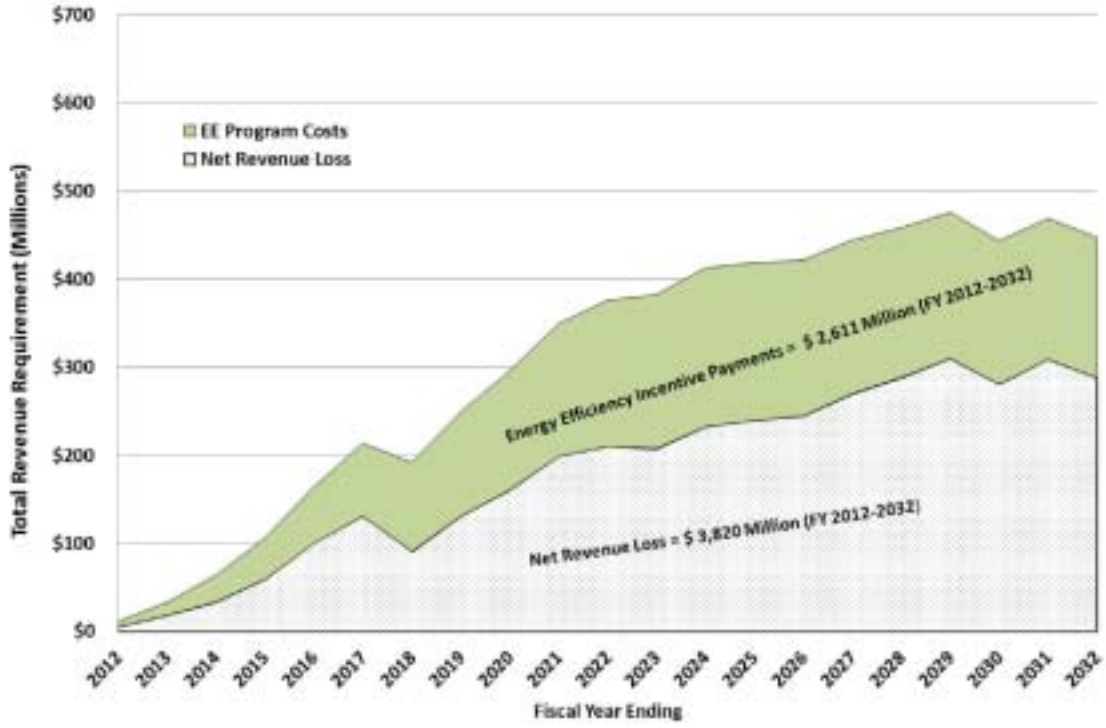

Figure 4-10. Base EE - Total Revenue Requirement

AR0070043

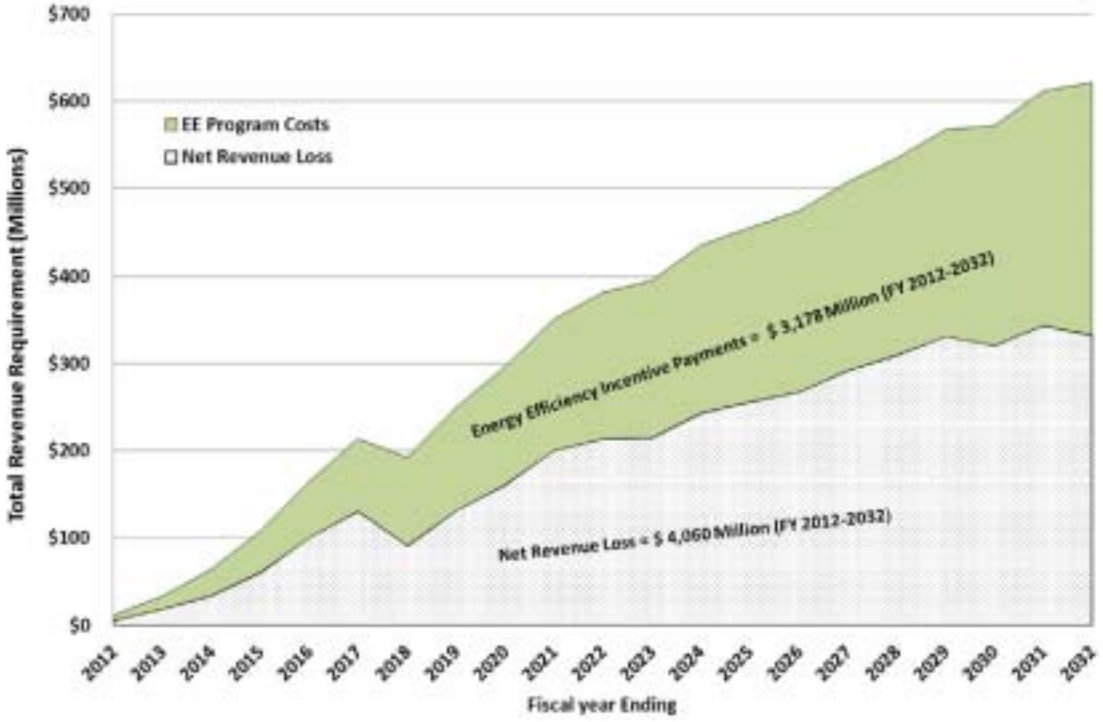

Figure 4-11. Advanced EE - Total Revenue Requirement

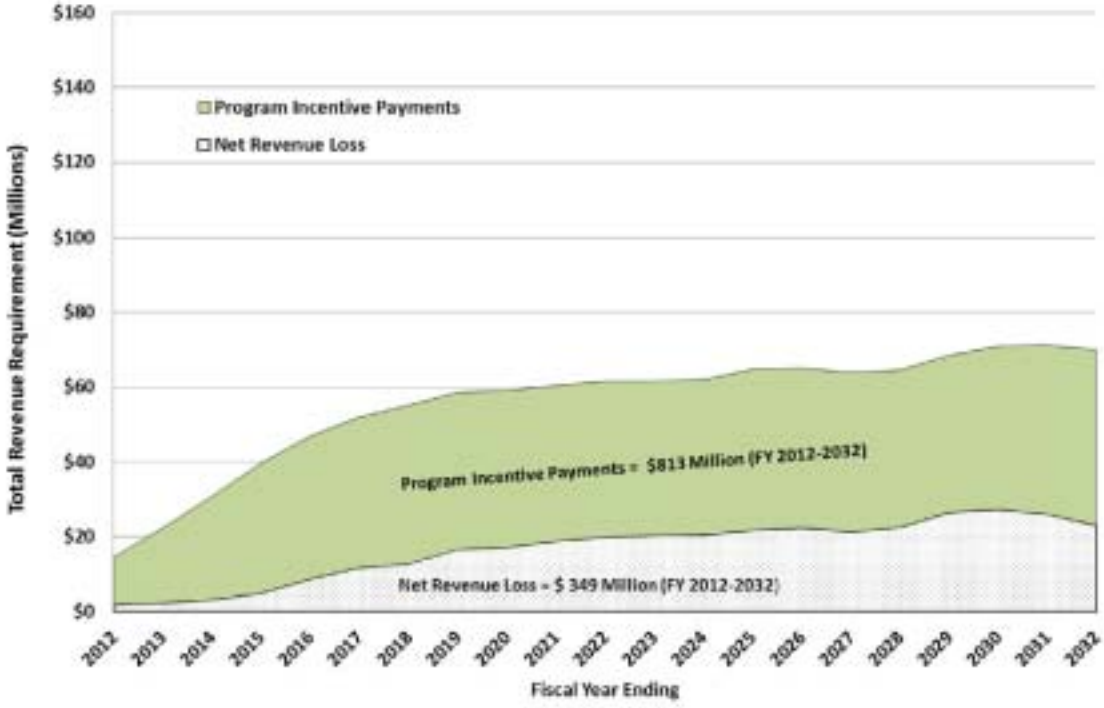

Figure 4-12. Base CNM Solar - Total Revenue Requirement

AR0070044

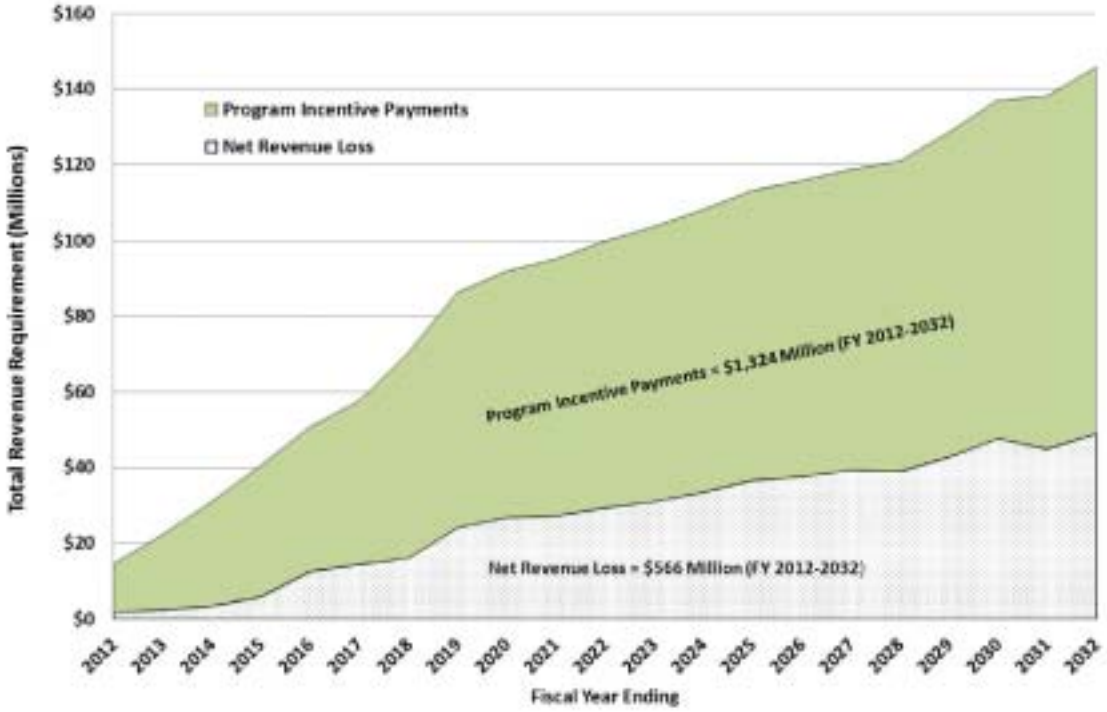

Figure 4-13 High CNM Solar - Total Revenue Requirement

Solar DG resources including Solar Feed-In-Tariff and Utility Built Solar do not result in revenue losses because these programs do not reduce customer sales. Therefore, the energy costs offset by the avoided costs savings of these programs must be calculated separately and then added to the demand-side EE and CNM costs to arrive at the final bulk power costs for the different cases as shown in Figure 4-14 below. FiT and UBS also result in avoided costs similar to EE and CNM with only slight differences. Although the evaluation considered the entire period of 2012 thru 2032, only the years 2020 thru 2032 are shown in Figure 4-14. The reason for this is that all cases have the same EE savings from 2012 thru 2020 and only slightly higher solar DG savings for this time period. Increased levels of EE and solar DG mostly occur in the later period from 2020 thru 2032 in the cases evaluated. Integration costs for solar resources, assumed to be $7/MWh based on recent studies performed by outside consultants, and all other bulk power resource costs were aggregated together to determine the total bulk power costs of the 4 EE/DG cases evaluated. The incremental differences between these 4 EE/DG cases can be seen in Table 4-4 below.

AR0070045

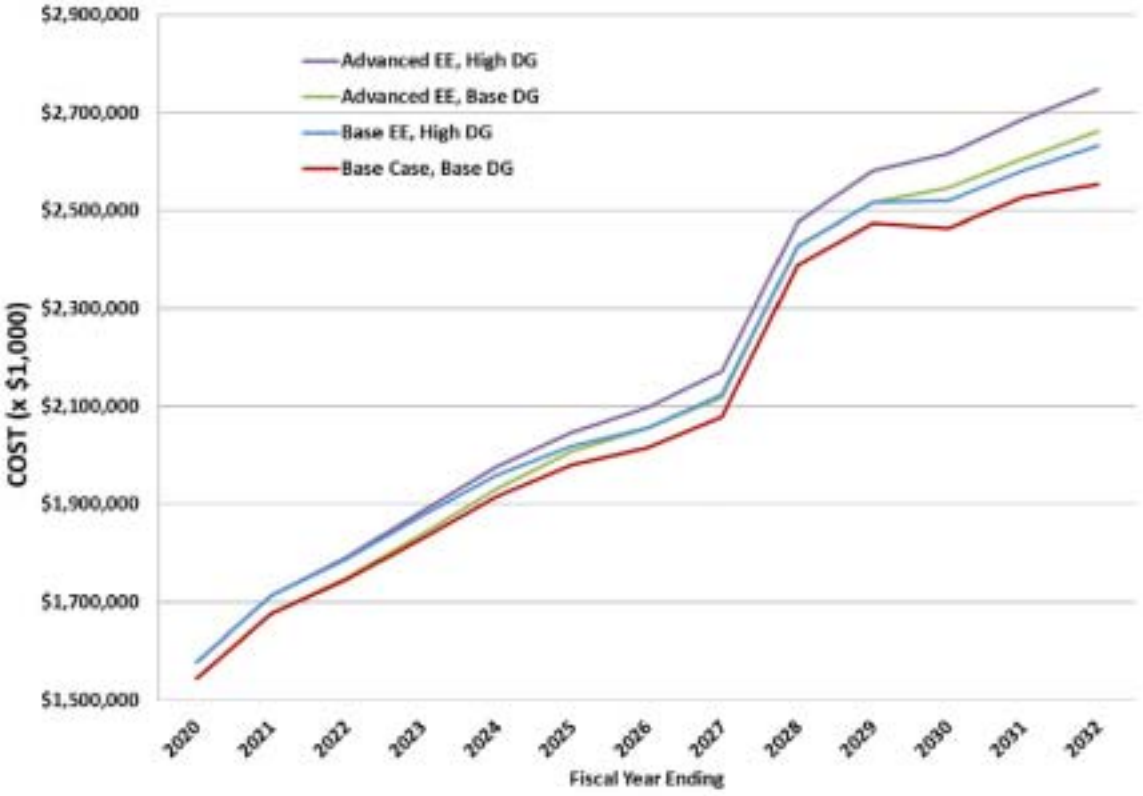

Figure 4-14. Bulk Power Cost Comparison of EE/DG cases (2020 thru 2032)

Table 4-4. Incremental Cost vs. Base EE, Base DG Comparison

	Base EE & Base DG	Base EE & High DG	Advanced EE & Base DG	Advanced EE & High DG
Fuel & Program Costs $M	$0	$428	$254	$766
DG Integration Costs - DG $M	$0	$39	$0	$39
T&D Savings - FIT, UBS $M	$0	($15)	$0	($15)
Net Lost Revenue - EE CNIM $M	$0	$217	$240	$457
Total Incremental Revenue $M	$0	$669	$494	$1,247
Average Incremental Revenue ($M/yr)	$0	$32	$24	$59
Average Incremental Cost (Cents/kWh)	0.00	0.14	0.10	0.26

The results show that both higher levels of EE and DG must be carefully considered in the utilities overall finances as these programs tend to require higher levels of revenue as

AR0070046

compared to other alternatives. For customers that implement both EE programs and Solar CNM, the opportunity to realize savings in their use of electricity and associated savings can be substantial and should be encouraged. However, from the utility perspective, it is important that cost recovery mechanisms are established to recover reduced revenues that come from Solar CNM and Energy Efficiency to minimize the impact on other programs that require appropriate funding levels to maintain reliability of the electric grid and comply with existing laws and regulations. Careful planning of these resources must also be evaluated periodically as new cost information becomes available (e.g., Energy Efficiency Potential Study) to provide the most economical mix of future resources.

4.3.3.2 Cost Comparison Between Coal Cases 1 thru 4

The total fuel and variable costs for the 4 coal replacement cases are shown in Figure 4-15 below. The natural gas price used in the production model was the 20-yr long-term natural gas price forecast from Platts and is also considered as the expected natural gas price in the stress test study in Section 4.3.3.3.

Figure 4-15. Total fuel and variable cost comparison by fiscal year (Includes renewable project costs).

Replacement of IPP and Navajo results in higher fuel and variable O&M costs, as less expensive coal is replaced with relatively higher cost gas-fired energy. The resulting increase in fuel costs from the Navajo divestiture is due to a blended increase of in-basin and out-of-basin gas fired generation. In reality, resources replacing Navajo consist of a blend of new

AR0070047

energy efficiency, new renewable energy, and new replacement gas-fired combined cycle units. The gas-fired replacement resources for Navajo can be better seen in Table 4-5. Because all 4 coal cases analyzed have the same renewable portfolio, the cost differences between the cases can only be attributed to increased gas cost; therefore, the costs shown in Table 4-5 do not include any incremental costs associated with new renewable resources.

Table 4-5. Increased incremental capital, fuel, and variable O&M costs related to replacement of Navajo and IPP by fiscal year

4.3.3.3 Fuel Price Stress Test

The importance of stress testing the model results of the 4 coal cases is to determine the range of exposure to economic risk due to fuel price volatility. Historically, natural gas prices have tended to be volatile and unpredictable and LADWP employs hedging techniques to constrain volatility within acceptable ranges. However, diversification of fuel resources is also an effective means to mitigate economic exposure to a single fuel source. For example, renewable energy supplies a necessary hedge against increased fuel price exposure and eliminates the fuel cost for 20 percent of our current fuel supply.

Coal purchased by LADWP over the last 30 years has traditionally been provided primarily through long term coal contracts where future costs are reasonably predictable. Additionally, a small portion of LADWP's coal supply is provided through short term coal purchases subject to market fluctuations. Therefore, natural gas prices become the primary concern when assessing future cost impacts. Replacing Navajo and IPP Generating Stations with gas fired generation would expose our ratepayers to fuel markets which may result in higher or lower fuel costs which are much less predictable.

Realizing the need for accurate fuel price forecasts, LADWP contracted with Wood Mackenzie Research and Consulting to provide natural gas price high and low forecasts to stress test future power production costs as shown in Figure 4-16. Also included in the high and low range forecasts were coal prices received from LADWP's External Generation Group. Based on the expertise and experience of the Coal Supply Group, a $\pm$20 percent factor was applied to the expected coal fuel price to determine a high and low range for coal prices.

AR0070049

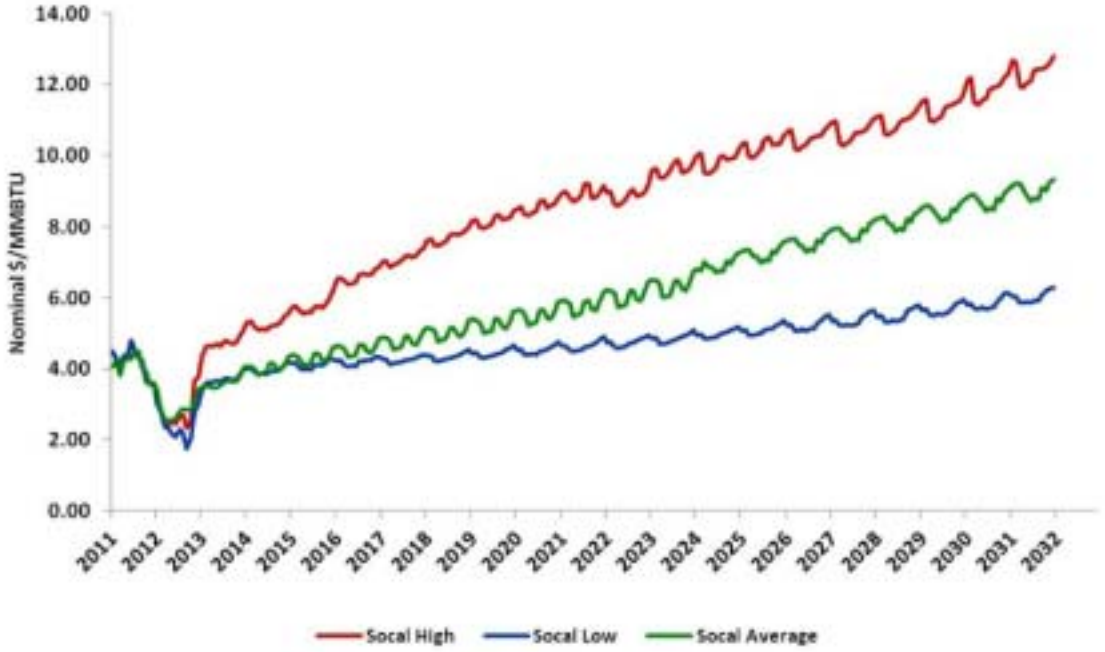

Figure 4-16. High, low, and expected natural gas price forecasts (So Cal Gas).

The natural gas price curves furnished by Wood Mackenzie Research and Consulting show a greater propensity towards higher than expected gas fuel prices, and less risk of experiencing lower than expected prices. This is wholly consistent with past historical gas prices which are shown in Figure 4-17 – the relative shape of the curve is asymmetrical with the forward tail (higher prices) extending further away from the mean of the curve.

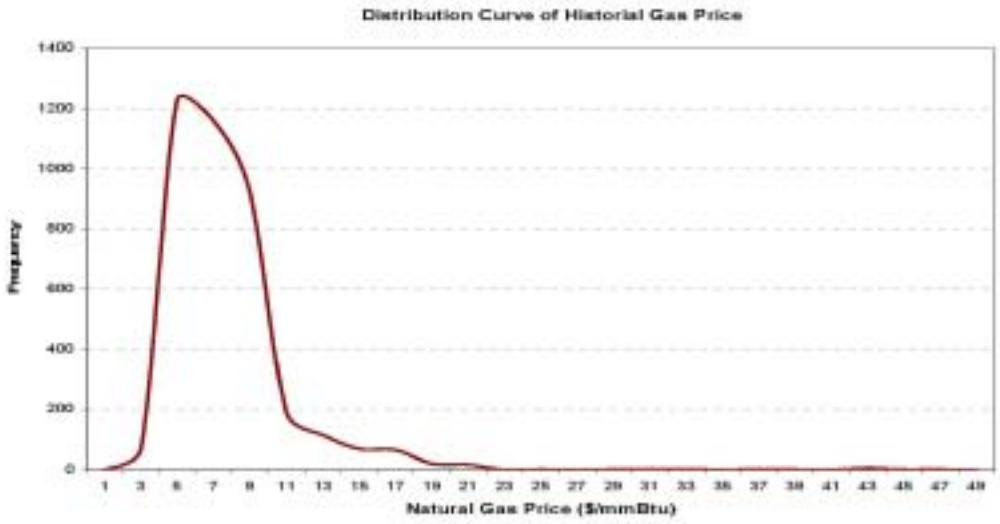

Figure 4-17. Historical distribution of natural gas prices (SoCal, 2005 through 2010).

AR0070050

The high and low fuel price ranges were then incorporated into the four strategic case model runs. The four charts shown in Figure 4-18 display the results of bulk power costs for each of the 4 coal cases. The wider the range from the high fuel case to the medium fuel case indicates increased exposure to risk from the higher fuel costs.

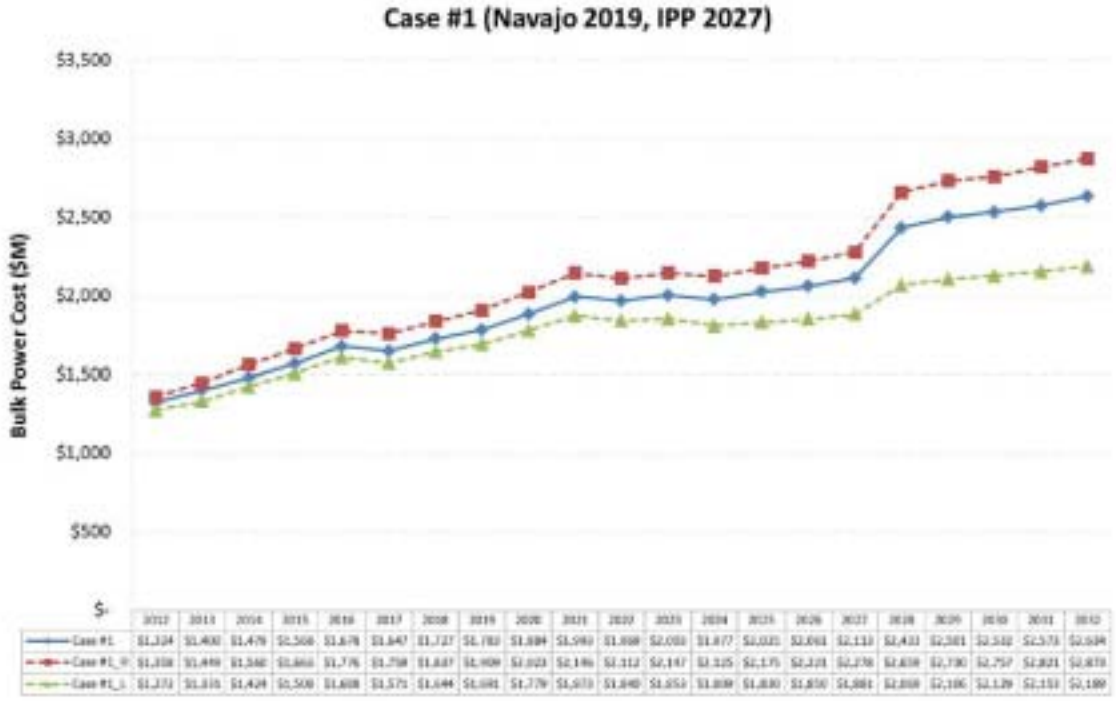

Figure 4-18. Bulk power cost comparison - high, low, and expected fuel prices.

AR0070051

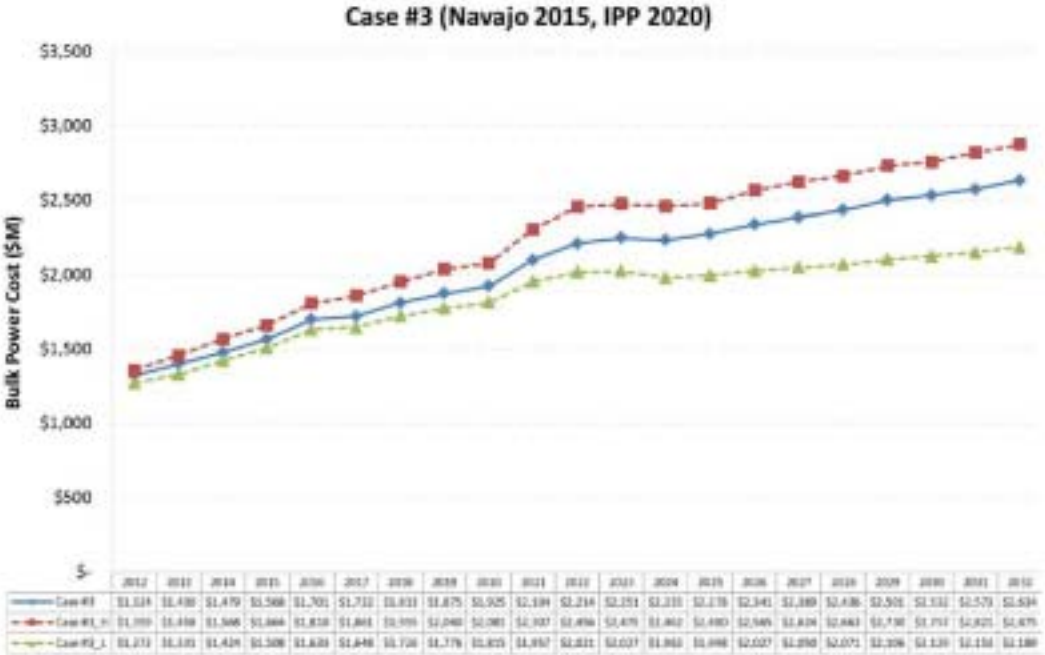

Figure 4-18. (continued)

AR0070052

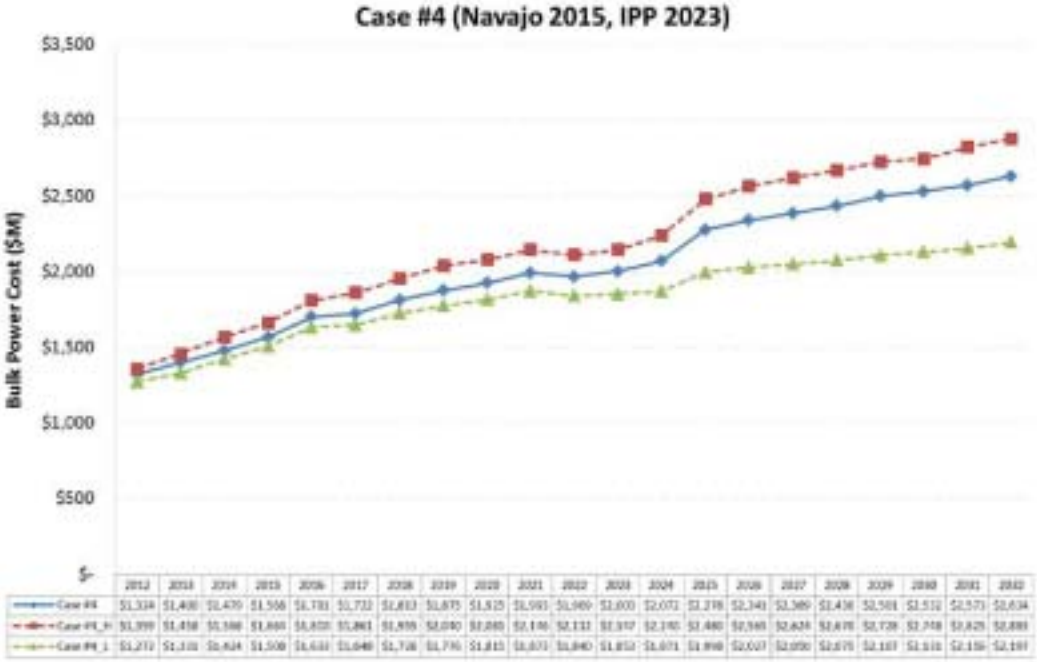

Figure 4-18. (continued)

An analysis of the effects of fuel price volatility was performed for the four coal cases and is shown in Figure 4-18. With the early divestiture of Navajo in 2015 and the IPP coal contract ending in June 2027, increased bulk power costs are expected with the replacement of each of these resources.

Elimination of coal involves the switch to more natural gas generation, which has higher fuel price volatility compared to coal. This higher volatility will increase the risk of fuel cost changes in the future and so warrants careful evaluation when comparing the different case scenarios.

It is important to note that bulk power costs shown in Figure 4-19 include fuel, renewable and other purchase power costs in addition to coal replacement costs. After applying high and low fuel prices to these bulk power costs, the replacement of these resources could result in large cost increases should fuel prices remain at higher than expected levels. Conversely, lower than expected fuel prices could have the opposite effect on bulk power costs

To help manage natural gas fuel price volatility, LADWP employs financial hedges for up to ten years, and physical hedges for up to five years. LADWP is in the process of developing a revised hedging strategy based on the newly approved rate ordinance.

AR0070053

Figure 4-19. Bulk power cost with high and low fuel costs by calendar year.

By the year 2020 NGS will retire in all four cases, with Case 3 and 4 showing IPP being replaced in 2020 and 2023, respectively, with two 575 MW combined cycle units.

With all coal generation being eliminated the exposure risk of much higher spending on fuel and variable costs will be present.

Increased risk exposure from high fuel costs may translate into higher customer electric rates. Figure 4-20 shows the potential rates that could be experienced under the 4 coal cases given high, expected, and low fuel ranges for both gas and coal fuel types. Today, overall coal costs represent approximately 65 percent of overall fuel expenditures. Once Navajo coal is replaced in 2015, this percentage will drop to 50 percent of overall fuel expenditures. From 2023 thru 2026, coal expenditures will gradually drop to 30 percent before reaching zero percent in 2027 when IPP coal is replaced, and future fuel price increases will be based solely on natural gas and nuclear.

AR0070054

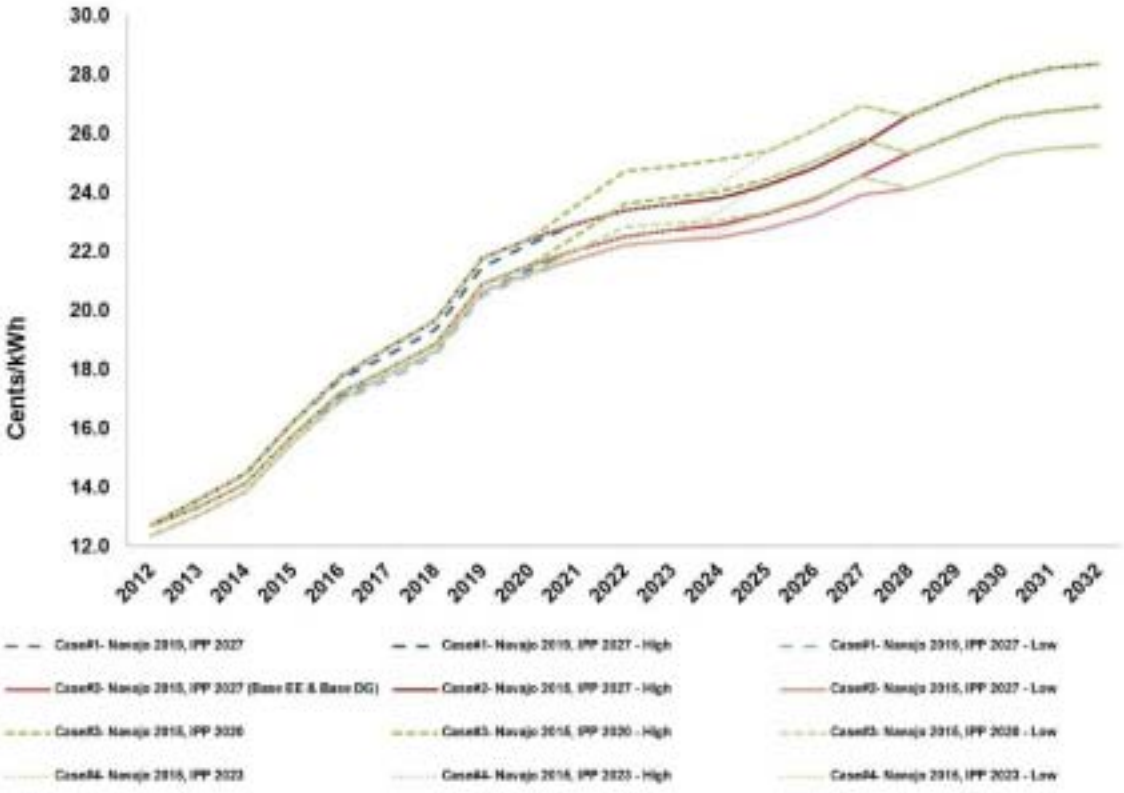

Figure 4-20. Estimated electric rate comparison with fuel price sensitivity over 20 years by fiscal year-ending

4.3.3.4 Reliability and Regulatory Revenue Requirements

Bulk Power costs discussed previously make up less than half of the cost to operate the electric power system. Continued investments in transmission, distribution, and generation resources are required to maintain a reliable electric system. While specific regulatory and reliability programs such as RPS, OTC, and PRP attract the most attention, investments in these programs are a subset of the generation, transmission, and distribution system that comprises the Power System. Besides fuel and inflation costs, these reliability and regulatory programs are the largest factors driving increases in Power System costs.

The revenue requirements of these programs are further illustrated in Figure 4-21 and Table 4-6. Today, these reliability and regulatory programs comprise 28% of all Power System costs and in 2020 these same programs will grow to approximately 42%.

AR0070055

Table 4-6 shows the breakdown of these reliability and regulatory costs with RPS and PRP programs clearly being the major drivers behind overall increases in Power System costs. The importance of adequately funding of these programs through consistent revenue increases over time is essential to achieving the goals of reliability, environmental stewardship, and maintaining competitive rates.

4.3.3.5 Total Power System Cost Comparisons

The total Power System cost for each case includes bulk power costs, depreciation costs related to transmission, distribution, and generation, bond debt-service, and city transfer[9] costs. These costs assume full funding of the Power System programs including the preferred Power Reliability Program and Energy Efficiency programs among others. Total annual Power System costs are shown in Figure 4-22 and reflect short-term spending reductions through 2011-12 fiscal year with subsequent years reflecting a restoration of funding levels to ensure that the longer term IRP recommendations can be realized. To the extent that energy efficiency costs are lower than the costs of generation it is replacing, its effect is to lower total costs. The costs shown in Figure 4-22 do not attempt to represent a thorough analysis of Power System finances. The main goal of this section is to illustrate the general trend of Power System costs relative to the 4 coal and 4 EE/DG cases analyzed.

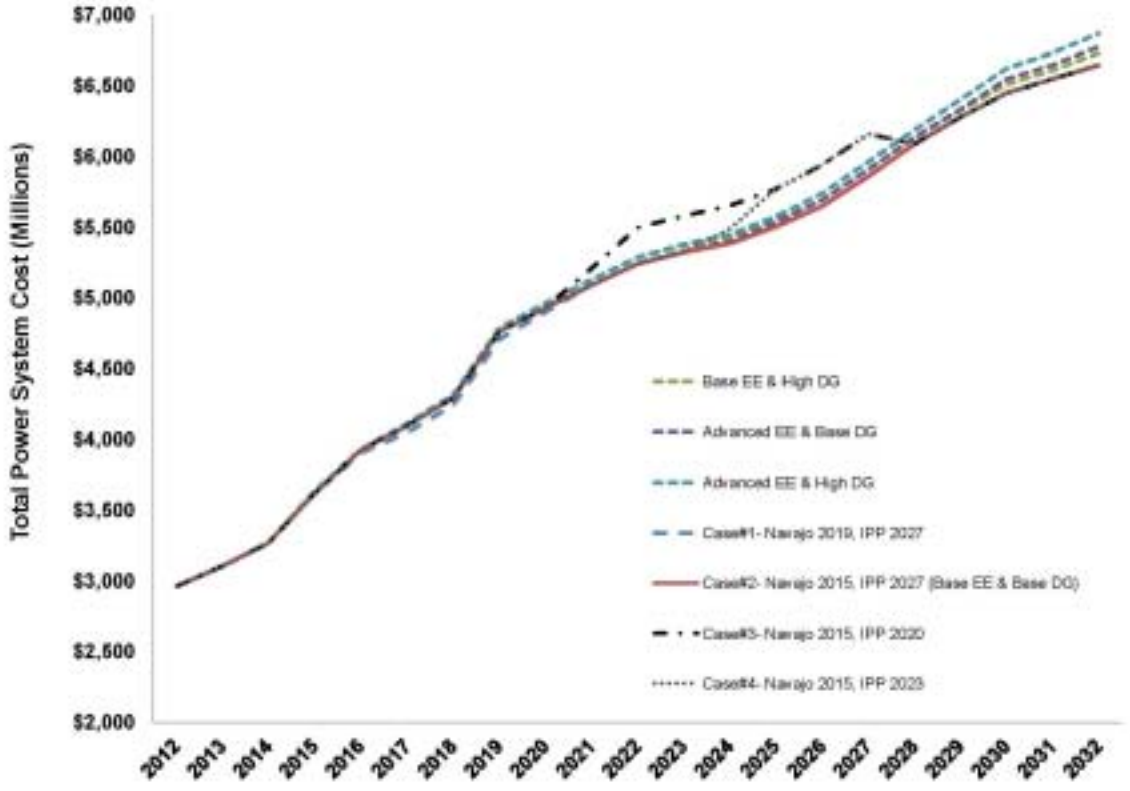

Figure 4-22. Comparison of annual Power System costs over the next 20 fiscal years.

[9] The city transfer payment is 8% of the previous year's operating revenue.

AR0070058

The cost differences between the cases are highlighted in Table 4-7, which presents the incremental costs of the 4 coal cases and the 4 EE/DG cases. For the coal cases, the values listed under the Case 2 column represent the incremental costs between Cases 1 and 2 – i.e., the cost of early divestment of Navajo. The values listed under Case 3 and Case 4 represent the additional incremental costs of early IPP replacement in 2020 and 2023, respectively.

All EE & DG cases assume Navajo divestment in 2015 and IPP replaced in 2027. The values shown for Cases 6, 7, and 8 represent each case's incremental costs when compared to Case 5.

TABLE 4-7 - INCREMENTAL COST COMPARISONS BETWEEN CASES

Coal Case Summary

	Case 1	Case 2	Case 3	Case 4
Case Description	Navajo 2019, IPP 2027	Navajo 2015	IPP 2020	IPP 2023
Total Incremental Revenue $M	$0	$205	$1,790	$980
Average Incremental Revenue ($M/yr)	$0	$51	$275	$280

EE & DG Case Summary

AR0070060

4.4 Strategic Case Conclusions and Recommendations

4.4.1 Reliability

All four cases were designed to satisfy Power System reliability requirements. Based on the loss of load probability and resource adequacy analysis discussed in Section 4.3.1, all four cases are considered equal in terms of meeting reliability. To ensure that reliability is maintained during the replacement of Navajo and IPP, specific replacement strategies should be employed to assure a smooth transition. Further analysis may be required to refine the appropriate blend of renewable, gas-fired, energy efficiency, and demand response resources to replace Navajo and IPP based on reliability considerations.

4.4.2 GHG Emissions Reduction

As expected, the sooner generation from coal is removed from LADWP's portfolio, the greater the reduction of GHG emissions is achieved. Case 2 removes NGS energy four years earlier than in Case 1 and results in 7.2 million metric tons less GHG emissions over the 20-year study period. In addition to early NGS divestiture, Case 3 accelerates the replacement of IPP seven years earlier than Case 2, results in a further reduction of 19.5 million metric tons over the 20-year period whereas Case 4 replaces IPP four years earlier which reduces an additional 9.3 million metric tons of GHG emissions. See Figure 4-4 and Table 4-3.

4.4.3 Economic

While the Base Case appears the least cost assuming moderate GHG emission costs, it fails to make significant progress toward the reduction of GHG emissions goals set forth by LADWP. The choice between coal replacement options of either Case 2, 3 and 4 depends on the level of rate increases ratepayers are willing to support while achieving the 33% required RPS by 2020, repowering of in-basin gas fired generation, funding and implementing local solar, Demand Response and Energy Efficiency programs, and providing additional external generation to supplement the lost generation resulting from coal replacement.

With early divestiture of Navajo, an additional revenue increase of $51 million per year or $205 million over four years would be necessary to achieve GHG reductions of 7.2 million metric tons between years 2016 and 2019. This equates to a cost of $28 to remove 1 metric ton of GHG. However, as previously discussed in Section 4.3.3.3, the early divestiture of Navajo will expose ratepayers to potentially higher natural gas fuel prices that may result in further revenue increases up to $141 million per year if gas prices were to remain at these higher levels.

Considering Case 3 with early replacement of IPP and Navajo, revenue increases of approximately $275 million per year or $1,790 million over 6.5 years would be necessary to achieve additional GHG reductions of 19.5 million metric tons between the years 2021 and 2027 due to the replacement of IPP. This equates to a cost of $92 to remove 1 metric ton of

AR0070061

GHG. With potentially higher natural gas fuel prices, additional revenue increases could be as high as $214 million per year if gas prices were to remain at these higher levels.

The new Case 4 presents a new scenario with early divestiture of Navajo and replacement of IPP in 2023 with a better financial plan as discussed in the beginning of this section, at the same time yielding significantly reduced GHG emissions. Case 4 will result in an increase of $245 million per year or $980 million over a four year period and would result in a cost of $105 to remove 1 metric ton of GHG.

4.4.4 Recommended Case

Decisions to fund coal replacement strategies, energy efficiency, or distributed generation cannot take place independent of other Power System programs. Maintaining reliability and meeting regulatory requirements are primary considerations before any discretionary coal replacement or EE/DG cases can be considered. However, this IRP presupposes funding of these programs so that the recommended case can be implemented.

Achieving the goals of reliability and environmental stewardship, while maintaining competitive rates, requires that costs be closely managed. Considering these factors, Case 5 with early Navajo coal divestiture in 2015, Base EE and Base DG with additional Local Solar FiT DG becomes the Recommended Case for the 2012 IRP. Whereas Case 5 has 75 MW of local solar FiT by 2016, the new recommendation is to adopt an additional 75 MW for a total of 150 MW by 2016 based on input that was received from the public outreach efforts. The increase in cost for the additional 75 MW of FiT is an average of 0.018 cents/kWh or a 9 cent increase in the typical residential monthly bill (500 kWh/month). Although Case 5 with the added FiT represents additional cost as compared to the 2011 Recommended Case, the additional costs to rate payers appears to be reasonable in light of the benefits of job growth and support of the local economy from adopting higher levels of DG solar. As described in the 2011 IRP, the environmental benefits of reducing GHG emissions by 7.2 MMT are still present with the early Navajo replacement. The cost to implement Navajo divestiture in terms of metric tons of GHG removed is $28/MMT. This represents a reasonable cost in line with the range of expected AB32 cap and trade allowance prices. Other benefits of early Navajo divestiture include a better sales price than waiting until 2019, and better availability (lower costs) of replacement energy. With Case 5 and the noted addition of FiT and Navajo divestiture in place, LADWP can begin to focus its attention on early replacement of IPP coal generation, prior to 2027, by working with the other power purchasers and the IPP plant owner.

The 2011 IRP included the same recommendation to accelerate divestiture of Navajo and this 2012 IRP further clarifies and supports this prior recommendation. This 2012 IRP recommended case presents a reasonable approach to achieving environmental goals and promoting job growth in the local economy without excessive costs to our ratepayers while limiting potential exposure to possible fuel price volatility to within manageable limits.

5.0 RECOMMENDATIONS

5.1 Strategic Overview

LADWP's recommended strategy set forth in this IRP for meeting its key objectives can be separated into two areas: (1) Regulatory and Reliability Initiatives, and (2) Strategic Initiatives. Regulatory and Reliability Initiatives are required actions to ensure system reliability and compliance with regulatory and legislative mandates. Strategic Initiatives are policy actions to achieve objectives established by the LADWP Board of Water and Power Commissioners and the Los Angeles City Council, and reflect their vision and leadership. These policies include, for example, establishment of LADWP's Energy Efficiency targets, social and economic development goals, early compliance with SB 1368, and investing in infrastructure reliability.

Regulatory and Reliability Initiatives

- RPS

  LADWP must increase its percentage of renewable energy per recently enacted state law, from the current 20 percent, to 33 percent by the end of 2020. SB 2 (1X) also establishes interim targets to ensure progress towards the 33 percent goal. In addressing this mandate, it is important that LADWP expand its renewable portfolio in the most cost-effective manner as possible. As two subsets of the RPS program, SB 1 requires $313 Million of expenditures towards solar incentives (Customer Net Metered), and SB 32 mandates a Feed in Tariff program of 75 MW (although LADWP by choice will exceed this mandate and provide 150 MW by 2016).

- Power Reliability Program (PRP) and System Infrastructure Investment

  LADWP must re-establish sustained funding to invest in replacing transmission and distribution infrastructure that are contributing to outages to ensure system reliability Recent funding shortfalls have resulted in an increase in the frequency and duration of system outages. Section 1.6.3 of this IRP discusses the importance of fully funding the Power Reliability Program (PRP). As discussed in Section 2.4.6, the PRP will also optimize the resiliency of the distribution infrastructure to better withstand the more volatile weather patterns that are expected due to climate change.

- Re-powering for Reliability and to Address OTC

  LADWP will continue to re-power older, gas-fired generating units at its coastal generating station for the reasons discussed in Section 2.4.2. The repowering program is a long-term series of projects through 2029 that will increase generation reliability and efficiency, reduce NO_X emissions, and eliminate the need for once-through ocean water cooling.

AR0070064

- AB 32 – GHG Cap and Trade

  LADWP will participate in the mandated greenhouse cap-and-trade system which is scheduled to start January 1, 2013. LADWP has been granted an administrative allocation of emission allowances that reflects its resource projections through 2020. At the same, it is uncertain if the program will extend beyond 2020, and if so, what LADWP obligations would be.

- Energy Efficiency (EE)

  LADWP will continue to pursue and implement EE programs per AB 2021 standards and as directed by the Board of Water and Power Commissioners, who have adopted a goal of achieving 10 percent EE by 2020, with a target of up to 15% by 2020 pending the results of an upcoming new EE Potential Study. The Base EE case evaluated in this 2012 IRP includes 10% EE by the year 2020, with higher levels of up to 15% by 2032. Next year's IRP will incorporate the findings and recommendations of the potential study as they are finalized and approved.

- SB 1368 Compliance

  LADWP's two coal-fired generation sources, the Navajo Generating Station and the Intermountain Power Project (IPP), must be compliant with the mandates established in SB 1368 by 2019 and 2027, respectively. IRP modeling determined that these units will be replaced earlier with a combination of renewable energy, demand response, EE, short term market purchases, and conventional gas-fired generation.

- Energy Storage

  Per AB 2514, LADWP is investigating Energy Storage (ES) technologies and will establish targets for implementation by October 1, 2014. LADWP will look for programs and projects that support its unique electric grid, resource plan, and projects that will facilitate renewable integration, distributed generation and demand response. As these projects are identified and scoped, they will be incorporated into and analyzed in future IRPs. See Section 2.4.5 for more information.

AR0070065

- Castaic FERC Re-licensing Program

  On January 31, 2022, the Federal Energy Regulatory Commission's (FERC) license to operate Castaic Pumped-storage Hydroelectric Plant will expire. The license is a re-license between LADWP and the Department of Water Resources and includes a number of hydro power plants along the California Aqueduct. Both parties have initiated the joint re-licensing process that, on average, requires ten years to complete. Through 2015, LADWP expects to complete preliminary studies, contract negotiations, and prepare a new application strategy. In 2016, LADWP expects to file a notice-of-intent (NOI) and initiate the formal studies and applications.

- Transmission

  LADWP's Ten-Year Transmission Plan is prepared each year to ensure that LADWP remains compliant with NERC Transmission Planning Standards. The planning process involves complex modeling of the LADWP system, and concludes with findings and recommendations to avoid potential future overload conditions. LADWP will continue to implement the recommended projects, including construction of a new transmission line between Scattergood Generating Station and Receiving Station K, and upgrades at various other receiving and switching stations.

Strategic Initiatives

- Early Compliance with SB 1368

  Regarding the Navajo Generating Station (NGS), while power imports can legally continue until 2019, LADWP recommends divestiture from NGS four years earlier, in 2015. There are many strategic advantages to early divestiture, including:

  1. Better sales terms and conditions than waiting until the 2019 deadline.
  2. Avoiding the risk of pending federal regulations that could potentially encumber the plant with expensive mitigation requirements.
  3. Better availability and pricing for replacement generation.
  4. Reduced CO_2 emissions, alleviating LADWP from subsequently having to purchase emission credits within the soon-to-be implemented statewide cap and trade program.
  5. Transmission network for importing additional solar and geothermal resources becomes available.
  6. Low load growth and increased renewable energy place less reliance on the plant for energy.
  7. Provides time to handle contingencies, and to ensure that competition for replacement resources is going to benefit our ratepayers.

AR0070066

Regarding the Intermountain Power Project (IPP), LADWP recommends modeling and planning to be compliant with SB 1368 by 2027. However, LADWP, the Intermountain Power Agency (IPA), and the other 36 participants are considering the conversion of IPP from coal to natural gas. A new contractual arrangement is in process, which will establish a firm conversion date that will be no later than, and possibly sooner, than 2027.

Strategically, it is important for LADWP to remain a participant at IPP to retain geographic diversity in its resource mix, access the regional fuel supply, and retain the project's transmission lines to access renewable energy from the region.

- Demand Response

  LADWP should accelerate its evaluation and implementation of Demand Response programs that will initially provide 5 MW of new peak demand capacity beginning in 2013 and gradually build to 200 MW by 2020 and 500 MW by 2026. Ramping the program in this manner will provide the development of in-house expertise, and will also allow time to deploy the supporting information systems necessary to implement these systems successfully.

- Local Solar

  Comments received at prior public workshops indicate local solar development should be a priority in LADWP's renewables procurement strategy. LADWP is recommending a policy action to allow 340 MW of its solar resources be sited locally by 2036, through initiatives including the Solar Incentive Program, feed-in tariffs, and installation of solar on City-owned properties. Local solar costs an estimated additional $36/MWh over utility-scale solar located outside the Los Angeles Basin, estimated to cost $176/MWh, primarily due to economies of scale and about 30% better solar insolation, even when considering transmission and distribution costs.

- Advanced Reliability Improvements

  LADWP is looking ahead to technologies that will enhance the reliability of its system, including smart grid, energy storage, enhanced information and management systems, automation of system functions, advanced methods of outage management, and weather forecasting. These advanced system enhancements will increase reliability, facilitate the integration of local solar generation and other variable renewable resources into the distribution network, enable smart charging of electric vehicles, and advanced demand-side management technologies. LADWP should continue to pursue grants, cost-sharing opportunities, and joint projects that advance the use and deployment of new technologies that meet its strategic goals.

AR0070067

- Provide Sufficient Generation

  Provide sufficient generation, demand response, and limited short term purchases in peak season Q3 to cover operating and replacement reserves in accordance to applicable federal and regional reliability requirements.

- Control of Transmission Assets

  In addition to the regulatory requirement to remain compliant with NERC Transmission Planning Standards, LADWP will maintain its policy of maintaining control of its transmission assets and continue to augment those assets commensurate with load growth, reliability needs, and renewable energy opportunities.

- Collaborate with Water System

  The LADWP Power System will continue to work with the Water System to develop programs that reduce the usage of electricity and conserve water, as well as optimizing hydroelectric energy production.

- Financial Targets

  To preserve and maintain its credit rating, the following financial targets have been adopted.

  - Maintain debt service coverage at 2.25 times
  - Minimum operating cash target of $300 million
  - Debt-to-capitalization ratio less than 68 percent

AR0070068

5.2 Incorporating Public Input

Through its public outreach efforts in 2012, LADWP received various suggestions from the community including increasing energy efficiency and conservation, eliminating coal from LADWP's resource mix, emphasizing local solar generation, maintaining competitive rates, and addressing infrastructure reliability issues. This input played a key role in shaping the recommendations set forth in this IRP. The major themes that emerged from the public input are listed below. Each theme is considered of equal importance and the themes are not listed in any order of priority.

Major Discussion Themes

Eliminate Coal From LADWP's Energy Portfolio

The majority of comments favored the early removal of coal from LADWP's resource portfolio. Some were concerned that Navajo would continue to operate after LADWP divestiture, and suggested the plant be shut down. Greenhouse gas emissions, along with other pollutants associated with coal energy were noted.

Incorporate More Renewables

Many public comments suggested higher levels of renewables, beyond the mandated 33% by 2020. Some promoted the idea of 50% and even 100% renewables. LADWP's approach regarding this is to proceed cautiously until more is known about the operational and financial implications of higher levels of renewables. The IRP is prepared annually, and it is possible that future IRPs will include cases that incorporate higher levels of renewables.

Incorporate More Local Solar

Many comments promoted the adoption of higher levels of local solar, noting the abundance of sunshine in southern California region. The benefit of providing local jobs was also noted as a supporting argument to increase penetration levels. One comment suggested installing solar on every house and building in Los Angeles. Regarding LADWP's current solar incentive program, multiple comments recommended hiring more inspectors to streamline the process which many see as too slow, especially when compared to other utilities.

Incorporate More Distributed Generation

Since the majority of LADWP's new Distributed Generation (DG) will come from local solar, this theme is somewhat associated with the More Local Solar theme. Most of the comments regarding more DG point to the governor's statewide goal for 12,000 MW, of which LADWP's proportionate share is assumed to be 1,206 MW. Within this 2012 IRP, the highest levels of new DG considered for analysis were 485 MW by 2022, and 852 MW by 2032. LADWP's concern with DG levels is maintaining reliability (see Section 3.4.4). Numerous utility studies have recommended a limit of 15% of the peak load circuit capacity, which for LADWP is approximately 900 MW. As LADWP adopts more DG per its current plan, and as more experience is gained along with more industry-wide research in this area, it is possible that future IRPs will consider higher DG levels.

AR0070069

Incorporate More Energy Efficiency

LADWP's Energy Efficiency (EE) targets, based on year 2030, have increased significantly, from 8.6% approved in December 2011, to 10% approved in May 2012, with a further anticipated increase to 15% pending completion of an updated potential study in 2013. Comments received supported incorporating more EE and Demand Response into LADWP future plans. As presented in this 2012 IRP, EE and DR is a vital component within all long term resource planning options. As the results of the upcoming potential study are developed and finalized, they will be adopted into the IRP planning strategy.

Reduce Greenhouse Gas Emissions

This was an overarching theme of the public comments received. Indirect societal costs, health effects, global warming, and super storm Sandy were cited as reasons for accelerating the timelines to reduce GHGs. In considering the GHG impacts of fuel consumption for electricity generation, many comments pointed to the additional impacts resulting from fuel production (coal mining and gas drilling). Comments pointed out the need for considering energy efficiency, demand response, load shifting, and other technologies such as shunt reactive support to offset future additions of gas-fired capacity.

Look at New Case Scenarios

Many comments suggested a scenario that contained no new gas-generation resources, an eventual portfolio of 100% renewables, and investments in EE, conservation, renewables and demand response. Some felt that multiple sets of potential renewable resource mixes should be considered. LADWP prepares a new IRP annually and will consider new scenarios within subsequent case optimization processes.

Financial and Rate Concerns
