The base rate is used to cover non-fuel, non-purchased power, and non-RPS related expenses. Base rate is used to cover expenses from debt service arising from capital projects except RPS projects, operational and maintenance expense except RPS related, public benefit spending, property tax, and pro-rated portion of the city transfer.

Since LADWP needs to sell substantial amounts of bonds in the near future to sustain its capital expenditures, maintaining an "AA" credit rating is essential to minimize financing costs. To maintain such a rating and mitigate potential rate increases, it is recommended the Board of Water and Power Commissioners approve the following policies: (1) maintain debt service coverage of 2.25, (2) maintain a minimum of $300 million of operating cash-on-hand, and (3) maintain a capitalization ratio not exceeding 65 percent, (4) maintain adjusted debt service coverage of 1.75, and (2) maintain full obligation coverage of 1.5.

Debt service coverage is the amount of cash available from operation divided by the debt service amount. The debt service amount contains only LADWP's direct debt. Adjusted debt service coverage has the debt service amount containing regular debt and off-balance sheet debt. Full obligation coverage deducted the city transfer from the cash available from operation and then divides the amount over the total of regular and off-balance sheet debt. Off-balance sheet debt is the debt owned by a third party, but LADWP will be responsible for the debt payment; for

AR0071205

example, debt raised by Intermountain Power Agency and Southern California Public Power Authority. Capitalization ratio is the ratio of the total direct debt divided by the total asset.

To achieve these various financial coverage parameters, the base rate factor will need to be increased as necessary to meet the objectives of this IRP.

5.5.1 Rates Analysis for Cases

The retail electric rates, including estimated CO_2 emission expenses, for all 3 strategies are shown on Figure 5-3 below. Factors driving the increases over the twenty-year period are: rising fuel price, increased power reliability program spending, replacement of aging basin generating units to meet once-through cooling and South Coast Air Quality District emission requirements, replacement of coal generation to lower CO_2 emissions, installation of renewables generation according to legislative mandates, and payment for emission allowances due to anticipated CO_2 cap-and-trade program requirements.

The capital cost and the associated O&M expense of any new generation resource is priced at 2011 dollars with 1.5 percent escalation except for certain solar projects, which are priced at levelized 2011 dollars due to anticipated pricing declines.

For each year, the retail rate through either the base rate or the energy cost adjustment factor is raised sufficiently high enough to meet the various financial ratios recommended by financial advisors to maintain LADWP's "AA" bond rating.

Under the Recommended Case, customer rates are estimated to increase on average 6 percent to 7 percent per year over the next five years, and 3 percent to 4 percent per year over the next 20 years (see Figure 5-3).

The CO_2 emission allowance price is estimated to range from $24 per Metric Ton in 2013 to $45 per Metric Ton in 2030. The California Air Resources Board established an allocation cap, and emissions exceeding this cap will require purchases of additional allowances or in some cases, emissions below the cap can be used in future compliance periods.

AR0071206

Assumptions used to model rate impacts can change. In order to reflect the variability in model assumptions, a sensitivity analysis was performed to determine a realistic range of rate impact trajectories. Figure 5-3 shows the retail price impact comparison of the 2011 IRP recommended case bounded by a high and low range fuel price with a comparison to the 2010 IRP recommended case. The high range assumes higher natural gas and coal costs while the low range assumes minimal natural gas and coal costs. The current recommended case retail price rate forecast is much lower than the 2010 IRP rate impact forecast for two major reasons. As described in Section 3.2, the fuel price forecast is significantly lower for 2011, and the assumption for GHG emissions cost was significantly lowered for 2011 after AB 32 regulations were finalized in October 2011.

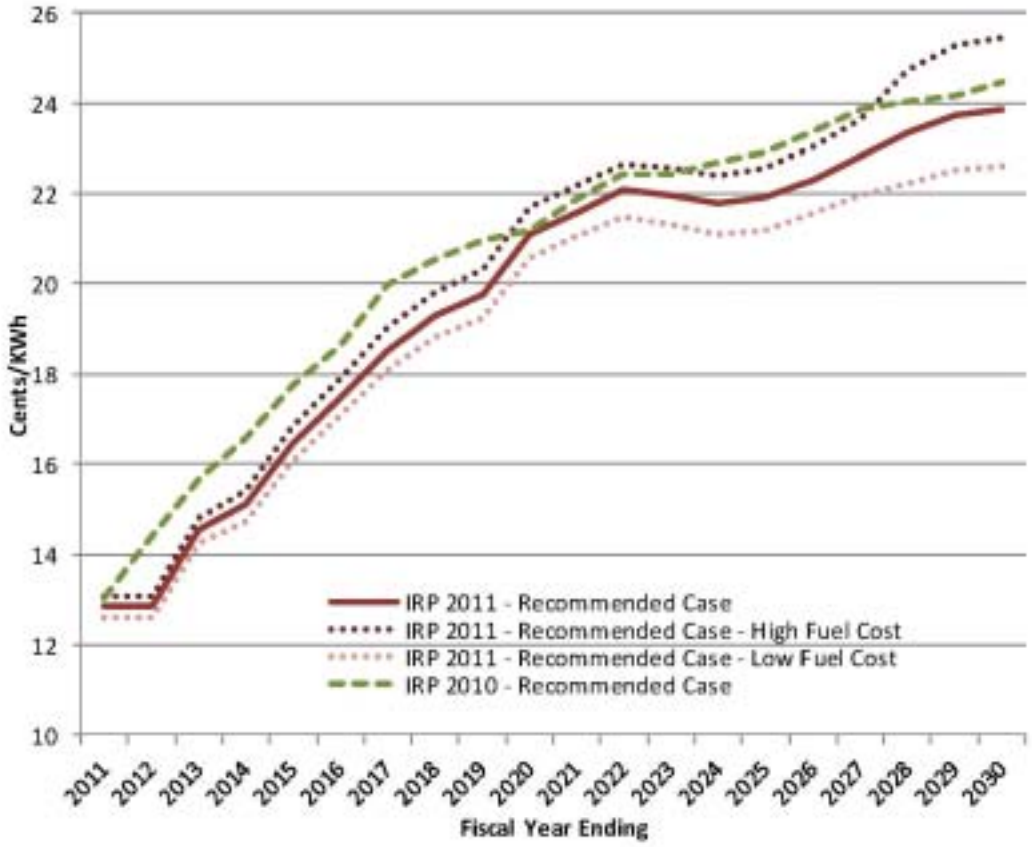

Figure 5-3. Recommended Case - retail price impact bounded by high and low range fuel with the 2010 IRP recommended case included for comparison.

Summarized in Figure 5-4 is the cost contribution from various environmental and reliability programs towards the retail rates. One can draw the conclusion that there is a significant cost to comply with various reliability and regulatory requirements while divesting of Navajo in 2015 and IPP in 2027.

AR0071207

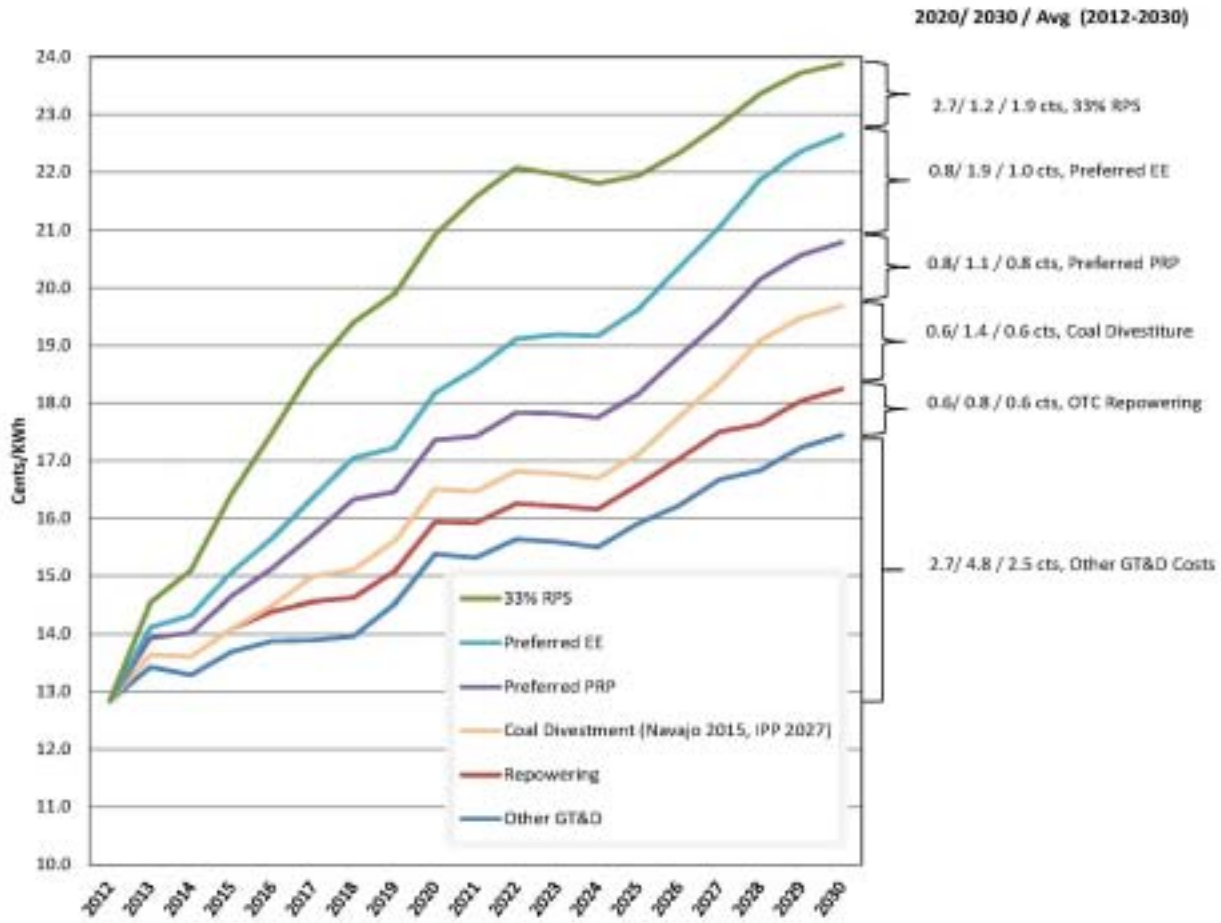

Figure 5-4. Electric rate contributions of environmental and reliability programs by fiscal year based on the 2011-12 budget forecast (preferred case).

A few observations from Figure 5-4 can be made regarding the RPS and EE program. Firstly, the influence of the RPS program on rates increases substantially through 2020 when the RPS percentage of sales reaches 33%. Beyond 2020, the RPS component of rates begins to decline as fuel savings increases over time with escalating fuel prices. Secondly, the EE program component of rates increases over time as power system fixed costs are distributed over the reduced energy sales attributable to the EE program.

The cost contributions from various environmental and reliability programs towards the retail rates are summarized in Table 5-4.

AR0071208

Table 5-4. Cost contributions from various environmental and reliability programs

Program	Retail Rate Impact at FY2020 (cents/kWh)	Retail Rate Impact at FY2030 (cents/kWh)	Average Retail Rate Impact 2011-2030 (cents/KWh)
33% RPS from 20% RPS	2.7	1.2	1.9
Preferred EE	0.8	1.9	1.0
Basic Power Reliability Program	0.5	0.4	0.3
Preferred Power Reliability Program	0.3	0.7	0.5
Coal Divestiture	0.6	1.4	0.6
OTC Repowering	0.6	0.8	0.6
Total - Recommended Case	**5.5**	**6.4**	**4.9**

Figures 5-5 and 5-6 further illustrate the impact to average residential and commercial/industrial customer monthly bills from these environmental and reliability programs.

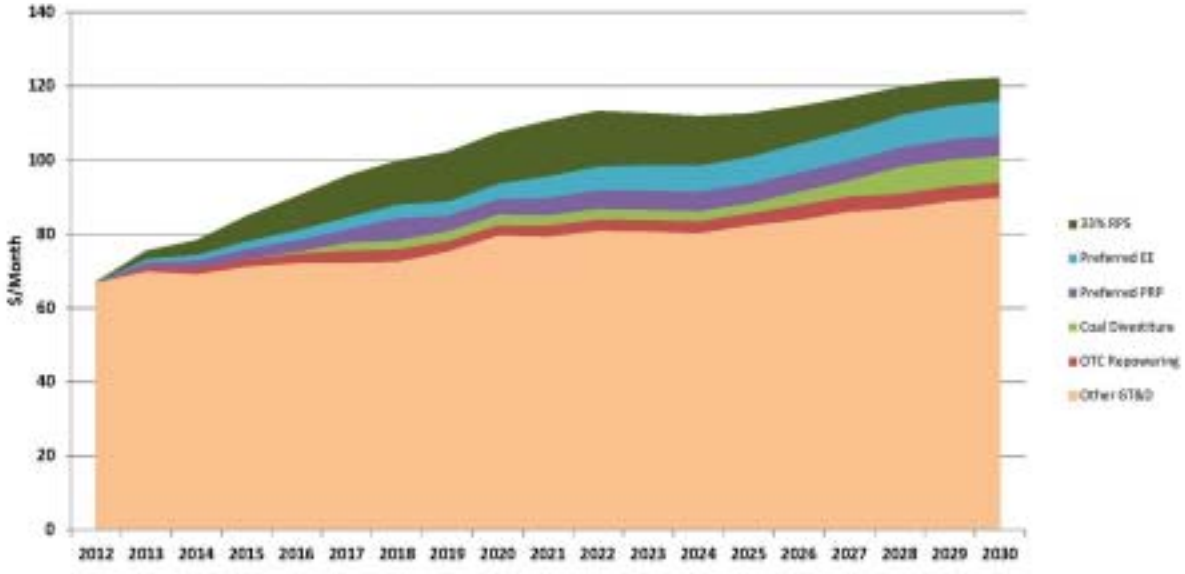

Figure 5-5. Average residential customer bill (500 kWh/month) with environmental and reliability programs by fiscal year based on the 2011-12 budget forecast (preferred case).

AR0071209

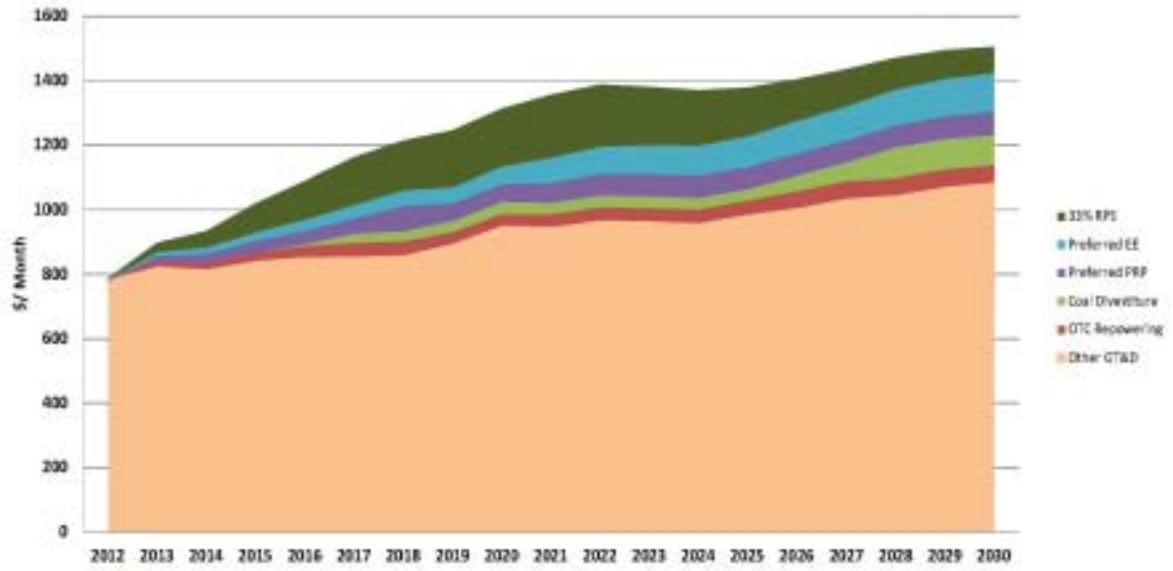

Figure 5-6. Average commercial/industrial customer bill (6,500 kWh/month) with environmental and reliability programs by fiscal year based on the 2011-12 budget forecast (preferred case).

Aside from the environmental and reliability improvement programs, increased fossil fuel expenses also drive the rate increase, for example: (1) coal that feeds IPP is projected to climb from 2011's $1.88/mmbtu to 2027's $3.72/mmbtu, and (2) natural gas at SoCal border is projected to climb from 2011's $4.10/MMBtu to 2030's $8.6/MMBtu. If these fuel increases do not materialize, then the average rate and cost curves shown in Figures 5-3 thru 5-6 will shift downward; however, the cost of environmental and reliability programs will remain substantially unchanged.

Because the analysis and conclusion are heavily dependent on a number of assumptions, LADWP will watch to see if these unfold as assumed. If expectations change (e.g., because of unanticipated technology changes, commodity price fluctuations, and policy changes), then the long-term plan will need to be revisited. Under all cases, it is assumed that the following items will occur, and that each will be central to LADWP regardless of the resource portfolio selected:

- Ensure that the power generation, transmission and distribution infrastructure operates in a reliable and efficient manner. Continue the Power Reliability Program initiated in 2007 which improves maintenance practices, addresses aging power system infrastructure, increases capital construction programs necessary to support load growth, and maintains staffing levels to support reliability related work.
- Support and advocate incremental requirements in Title 24 and other Green Building and appliance standards to reduce energy usage.

AR0071210

- Re-power Scattergood, Haynes, and Harbor end of life in-basin generation consistent with power system needs and environmental requirements
- Continue to be self-sufficient, by maintaining system generation resources equal to or greater than customer's electrical needs
- Provide sufficient generation, demand response, and limited short term purchases in Q3 to cover operating and replacement reserves in accordance to applicable federal and regional reliability requirements
- Maintain full control of transmission assets and continue to augment those assets commensurate with load growth and renewable energy opportunities
- Work with the Water System to develop programs that reduce the usage of electricity and conserve water, as well as optimizing hydroelectric energy production
- Maintain a "AA" credit rating, a debt service of at least 2.25 times, operating cash of $300 million, capitalization ratio not greater than 65 percent, and electric rates lower than neighboring investor owned utilities. In addition, LADWP will maintain net income sufficient to ensure stable City Transfers

Each of the targets listed above will be tested in the future to meet requirements for system reliability, fiscal responsibility and environmental stewardship. Modifications will be made as necessary to assure that these core principles are met.

AR0071211

5.6 Near-term Actions

The actions needed to be taken by LADWP in the next two to four years are very similar no matter what resource procurement strategy is chosen. From the development assumptions listed above and projected resource procurement needs, the following actions are recommended to be taken in the near-term:

1. Proceed with re-powering plans for generation units at the Haynes and Scattergood Generation Stations.
2. Continue to investigate the technical and contractual options for coal-fired generation to be compliant with SB 1368.
3. Replace the Navajo Coal Plant by 2015.
4. Implement recommendations contained in the recently completed Energy Efficiency Market Potential Study.
5. Implement recommendations contained in the Ten-Year Transmission Assessment Plan and the Reactive Power Management Study.
6. Develop a Demand Response Program to initially provide 5 MW of peak load reduction capability by 2013 which will ramp up incrementally to 200 MW by 2020 and 500 MW by 2026.
7. Develop renewable strategies for geothermal, biogas, solar, and wind resources to ensure increasing levels of renewable procurement in accordance with SB 2 (1X).
8. Complete a comprehensive study of issues associated with integrating increasing amounts of variable energy resources such as wind and solar to reflect possible megawatt limits for the LADWP electric power system.
9. Procure and develop advanced technologies in the areas of: weather forecasting energy scheduling, customer kWh metering, high speed communications and information systems, and large scale energy storage systems.
10. Develop and incorporate strategies to:
    a. Fully utilize existing transmission assets;
    b. Locate renewables as close as practical to the load center to reduce transmission losses;
    c. Preserve existing brown field sites to be repurposed for renewable or natural gas generation;
    d. Incorporate the concept of O&M cluster zones to maximize operational efficiencies;
    e. Assess and develop necessary transmission facilities to deliver electricity generated from new facilities.
11. Develop a renewable energy feed-in tariff program to encourage 30 MW of renewable generation resources to be developed by July, 2015.
12. Sign Power Purchase Agreements for an additional 200-300 MW of cost effective renewable energy projects by 2014.
13. Encourage the development of an additional 50 MW of customer owned solar projects before 2015.
14. Develop up to 30 MW of Solar on Los Angeles properties under public/private partnership projects before 2015.

AR0071212

15. Investigate the potential use of term physical gas supply arrangements, either with contracts for physical supplies or futures contracts to limit LADWP's exposure to volatile gas prices. Include the flexibility for closing these contracts as well.

AR0071213

5.7 Long-term Goals

The analysis and conclusions contained in this IRP are heavily dependent on a number of assumptions, such as the projected fuel and purchase power costs, RPS target goals, renewable generation costs, proposed state and federal mandates, and GHG emissions costs. If these assumptions were to change, LADWP's long-term strategies will need to change accordingly.

Integrated resource planning is an on-going process. LADWP will continue to adapt and refine the IRP as the uncertainties are better understood, and policy direction and requirements are solidified. A new IRP will be issued in 2012, and every two years thereafter.

AR0071214

Appendix A. Load Forecasting

A.1 Overview

The 2011 Retail Sales and Demand Forecast (2011 Forecast) is a long-run projection of electrical energy sales, production, and peak demands in the City of Los Angeles (City) and Owens Valley. A flowchart of the forecast process is illustrated on Figure A-1. The sections which follow describe the four key components shown on the flow chart: data collection, sales and Net Energy for Load (NEL) forecast, peak demand forecast, and hourly allocation.

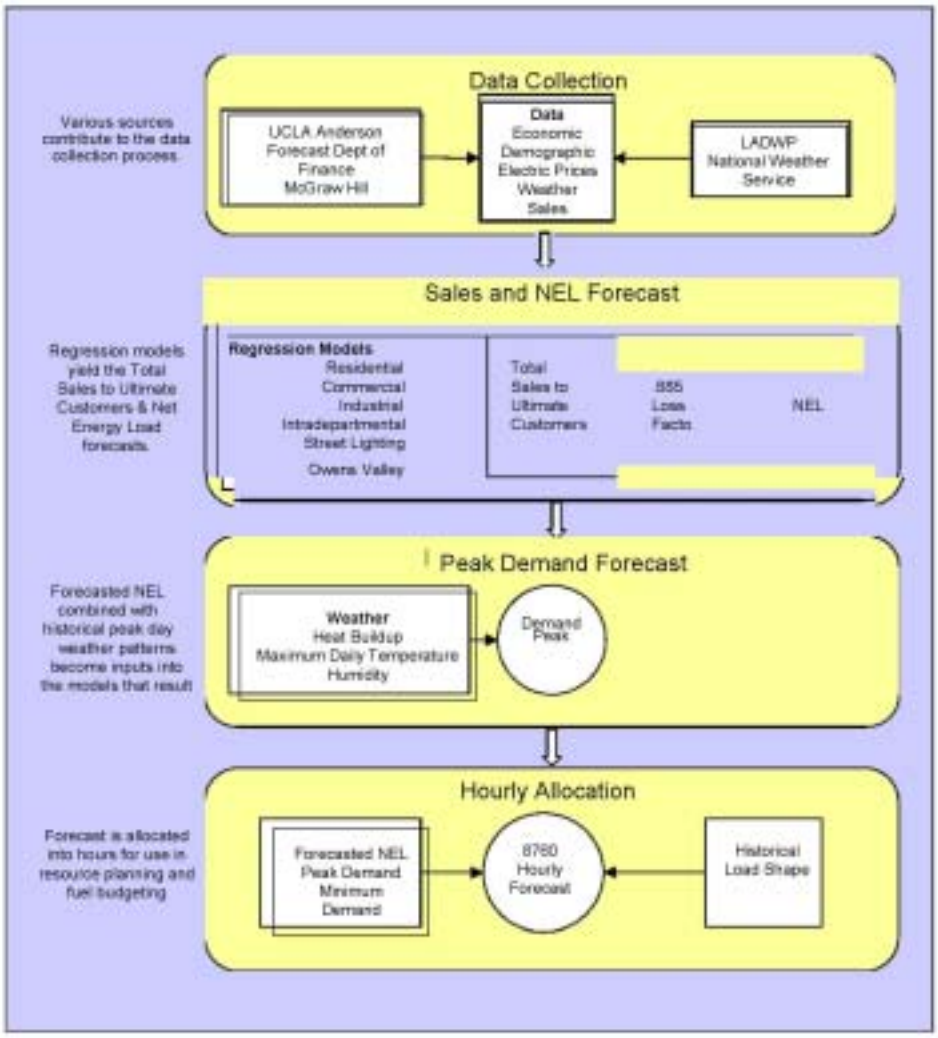

Figure A-1. Overview of the load forecasting process

AR0071215

A.2 Data Collection

Data collection is the first step in the process. LADWP purchases an economic forecast of Los Angeles County from the Los Angeles Modeling Group of the University of California of Los Angeles (UCLA) Anderson Forecast Project. The Los Angeles County Forecast provides time series data for various demographic and economic statistics beginning with year 1991 and continuing through the forecast horizon. For demographic history and projections, LADWP uses the State of California Department of Finance Demographic Research Unit.. To gain further insight into development patterns, LADWP purchases a construction forecast from McGraw-Hill Construction service. The construction forecast gives a five-year view of construction projects detailed by building types. Weather also affects energy sales and demand. Weather data is collected from three key stations – Civic Center, Los Angeles Airport, and Woodland Hills. The other key components in the forecast are from LADWP's own internal data. Historical sales, Net Energy for Load (NEL), billing cycles, electric price, and budget data is incorporated into the forecast. The economic, demographic, weather, and electric price data provide the key inputs to the models that forecast retail electric sales.

A.3 Sales and NEL Forecast

The retail sales forecast is divided into seven separate customer classes; residential, commercial, industrial, plug-in electric vehicle (PEV), intradepartmental, streetlight and Owens Valley. The residential, commercial, industrial, and streetlight classes are commonly used sales classes throughout the electric industry because they represent relatively homogeneous loads. Intradepartmental sales are sales to the Water System and are primarily related to water pumping activities.

The California Energy Commission's PEV forecast has been adapted to the LADWP service area. Further, PEV load is forecast as a separate class, which will facilitate financial modeling due to the expected subsidies and production modeling as PEV load has a unique load shape when compared to the residential class.

Owens Valley sales include all of the above sales classes. The Owens Valley service area is separate and discrete from the Los Angeles service area. Because of limited land available to be developed, Owens Valley sales exhibit very slow growth rates, and total sales are relatively small compared to total LADWP system sales. As such, Owens Valley sales are rolled into a single class and forecast separately.

The forecast model consists of six single equations plus the adapted PEV forecast. For the residential, commercial, and industrial sales classes, the equations are estimated using Generalized Least Squares regression techniques. Historical sales for each customer class are the dependent variables. Sales are regressed against a combination of the demographic, economic, weather, and electric price variables. Binary variables are used to account for extraordinary events like earthquakes, civil

AR0071216

disturbances, billing problems, and the California Energy Crisis. The equations fit historical data quite accurately, producing coefficients of determination (R-Squared) statistics greater than 80 percent. For the streetlight, intradepartmental, and the Owens Valley sales classes, time trend models are used. The results of the six equations plus the PEV forecast are summed to forecast Total Sales to Ultimate Customers (Sales).

The Retail Sales Forecast represents sales that will be realized at the meter. The NEL forecast is a function of the Sales forecast. The NEL is forecast by adjusting annual forecasted Sales upward by a historic average loss factor and then allocating a portion of the annual energy to each calendar month based on historical proportions. Loss factor has the potential to change on the way that the System is run. Electricity generated in distant places will have a higher loss factor than electricity generated located locally. The change in loss factor is accounted for in the resource planning models.

The 2011 Forecast includes committed energy efficiency and customer self-generation. Committed energy efficiency includes budgeted utility programs and expected energy efficiency gains from the Huffman Bill lighting standards. Expected Huffman Bill energy efficiency savings were developed by Global Energy for the 2010 LADWP Energy Potential study. Since the 2011 Forecast is created early in the planning process, budgeted utility energy efficiency programs are subject to change. Planners using the 2011 Forecast should be aware of the potential changes and make appropriate adjustments. Forecasting self-generation which currently is almost entirely focused on solar rooftops in the LADWP service area follows a process similar to the energy efficiency. Planners working with energy efficiency and self-generation data should be careful to include only the incremental impacts of the programs on retail sales In the Forecast, energy efficiency and self-generation savings are expected to occur uniformly throughout the year as a simplifying assumption.

A.4 Peak Demand Forecast

The next step is to forecast annual peak demand. The drivers for forecasted peak demand are temperature, load growth, and time of the summer. The temperature variable used in the estimation is the weighted-average of three weather stations. The temperature variable incorporates heat buildup effects and humidity. Temperature is then divided into splines using a unique megawatt- response per degree estimate for different levels of temperature. Ordinary Least Square regression techniques are used to model maximum weekday summer daily hourly demand against the temperature splines and the time of the summer. The constant that is estimated from the regression model is assumed to be the weather-insensitive demand at the peak hour. To forecast the peak demand, it is assumed that the peak will occur in August and that the peak day temperature is equal to the forty-year historical mean peak day temperature. Peak demand then is assumed to grow at the same rate as sales.

The forecast process described above produces the trend (or base case) forecast. LADWP also produces alternative peak demand forecasts. LADWP wants to ensure that it can meet native demand with its own resources. System response to weather is

AR0071217

uncertain. Temperature and humidity are the primary influences, but other variables such as cloud cover and wind speed can also influence the load. The problem is further complicated by the fact that LADWP serves three distinct climate zones including the Los Angeles Basin, the Santa Monica Bay Coast, and the San Fernando Valley. To prepare for these uncertainties, LADWP formulates its alternative cases by examining expected demands at different temperatures. Based on the Central Limit theorem, it is assumed that the normal distribution produces unbiased and efficient estimators of the true distribution of peak day temperatures. The normal distribution is estimated from the 40 year historical sample of peak day temperatures. From the normal distribution, the probability that the peak day temperature will be below a given temperature can be determined. For the one-in-ten case, it is the given temperature where ninety percent of the time the actual peak day temperature is expected to be below it and ten percent of the time the actual temperature will be above it. Similar calculations are performed for the one-in-five and one-in-forty cases. These temperatures are input into the peak demand regression model to provide the alternative peak demand forecasts.

In the Integrated Resource Plan, LADWP uses the One-in-Ten Case Peak Demand forecast rather than the Base Case forecast. LADWP's policy regarding obligation to serve is to be self-sufficient in supplying native load and not rely on external energy markets. The Base Case Peak Demand forecast falls short of this standard since it is expected that fifty percent of the time actual peak demands will exceed the Base Case Peak Demand forecast. The One-in-Ten Case provides LADWP ninety percent confidence that the forecasted peak demand will not be exceeded in any given year.

A.5 Hourly Allocation

The final step of the process is to forecast a monthly peak demand and load for each hour in the year. Monthly peak demands, outside of the August annual peak, are forecast using the load factor formula. The historical average monthly load factor and the forecasted NEL for each month are the known inputs. To forecast load for each hour of the year, the Loadfarm algorithm developed by Global Energy is used. The inputs into Loadfarm are a historical system load shape, monthly forecasted energy, and monthly forecasted peak demand. The system load shape is developed using a ranked-average procedure permuting historical loads so that all peaks occur on the fourth Thursday in August. Table A-1 contains the numerical 2011 Forecast.

AR0071218

Table A-1. TREND CASE ENERGY SALES AND PEAK DEMAND

	SECTOR SALES					Total Sales to Ultimate Customers	Net Energy for Load	Peak Demand
Fiscal Year	Residential (GWh)	Commercial (GWh)	Industrial (GWh)	Miscellaneous* (GWh)	PHEV (GWh)	(GWh)	GWh	(MW)*

2011 Retail Electric Sales and Demand Forecast

Overview

The 2011 Forecast (Forecast) supersedes the April 2010 Retail Electric Sales and Demand Forecast as the City of Los Angeles Department of Water and Power's (LADWP) Official Power System Forecast. The Forecast is the basis for LADWP Power System planning activities including but not limited to Integrated Planning, Integrated Resource Planning (IRP), Transmission and Distribution Planning and Wholesale Marketing.

Because the Forecast is a public document, only publically available information is used in its development. This practice has become a standard among California electric utilities. LADWP Planners wishing to use their own proprietary data should adjust the Forecast accordingly. The Load Forecast Group (LFG) is available to help Planners make adjustments and produces an Unadjusted and Gross Forecast to facilitate those adjustments.

Data Sources

1. Historical Sales reconciled to the Consumption and Earnings Report prepared by General Accounting
2. Historical NCT, Peak Demand and Losses reconciled to the Powermaster database located at the Energy Control center
3. Historical weather data is provided by the National Weather Service and Los Angeles Pierce College
4. Historical Los Angeles County employment data is provided by the State of California Economic Development Division using the March 2009 benchmark.
5. Historical population estimates and projections are provided by the State of California Department of Finance
6. The forecast Los Angeles County economic forecast with quarterly short-term updates is provided by UCLA Anderson Forecast
7. The construction activity forecast is provided by McGraw-Hill Construction
8. The plug-in hybrid electric vehicle (PHEV) forecast is based on the California Energy Commission's (CEC) statewide PHEV forecast
9. The port electrification forecast is provided by the Port of Los Angeles.
10. The housing forecast is referenced by the City of Los Angeles "Housing that Works" plan
11. The energy efficiency forecast is based on approved LADWP based programs through fiscal year 2013 and the forecasted impacts of the Energy Independence Security Act of 2007 (EISA) and the Huffman Bill on residential lighting. Historical installation rates are provided by the Energy Efficiency group
12. Historical solar rooftop installations and objectives are provided by the Solar Energy Development group
13. Electric Price Forecast is developed by Financial Services organization

AR0071223

Historical data is current through December 2010

Five-Year Sales Forecast

The Retail Sales Forecast represents sales that will be realized at the meter through Fiscal Year-end 2015. After FY 2015, some of the forecasted sales will not be realized at the meter due to the incremental impacts of LADWP-sponsored energy efficiency programs. Available in-house is a Gross Forecast which forecasts sales before the impacts of energy efficiency and solar rooftop. The purpose of the Gross Forecast is to allow modeling of different energy efficiency and distributed generation scenarios.

The historical accumulated Energy Efficiency and Solar Savings are from 1999 forward and only include LADWP installed savings. Since July 1, 2006, LADWP installed Energy Efficiency savings are 715 GWH for which LADWP received Customer Incentives. In the Forecast, energy efficiency and solar savings are expected to occur uniformly throughout the year as a simplifying assumption. Installations schedules are difficult to prepare because they rely on the customers although the mid-Quarter target is 15

Retail sales decrease of 3.4 percent in Fiscal Year 2010-11 is partially attributed to a cooler than normal summer as well has directly occurred. Likewise, the 4.7 percent increase in Fiscal Year 2011-12 includes the cooler summer in 2010 compared against normal summer weather.

Forecasted Energy Efficiency is based on the California Energy Commission definition of "committed" energy efficiency which is LADWP budget through FY 2018 and forecasted Ballroom ball savings. The long-term LADWP energy efficiency goal is to reach the AB 2021 objective of 10 percent savings during the time period 2007 through 2016. The targeted goal for rooftop solar installations is 348 MW by 2020

Short Run Growth

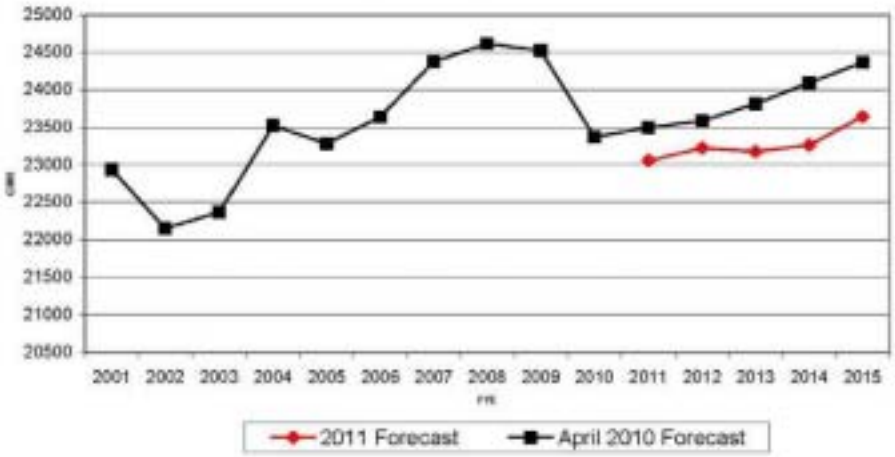
Fiscal Year	Retail Sales		Accumulated EE & Solar Savings	Gross Sales
Ending June 30	GWH	YOY Growth Rate	GWH	GWH
2009-10	23369		1289	24658
Forecast				
2010-11	23085	-1.2%	1483	24568
2011-12	23221	0.6%	1672	24894
2012-13	23279	0.2%	1862	25140
2013-14	23258	-0.1%	2017	25275
2014-15	23611	1.5%	2311	25922

Table A-2 Updated December 2011

Page 4

AR0071224

Retail Sales Net of Energy Efficiency and Distributed Generation



Peak Demand Forecast

Growth in annual peak demand over the next ten years is 0.8 percent.

Long-Run Growth

Fiscal Year End June 30	Base Case Peak Demand (MW)	Growth Rate Base Year 2010-11	One-in-Ten Peak Demand (MW)
2010-11	5589[1]		6042
Forecast			
2015-16	5809	0.8%	6277
2020-21	6211	1.0%	6710
2030-31	7000	1.1%	7560
2040-41	7780	1.1%	8403

[1]Weather-normalized. Actual peak was 6142 MW.

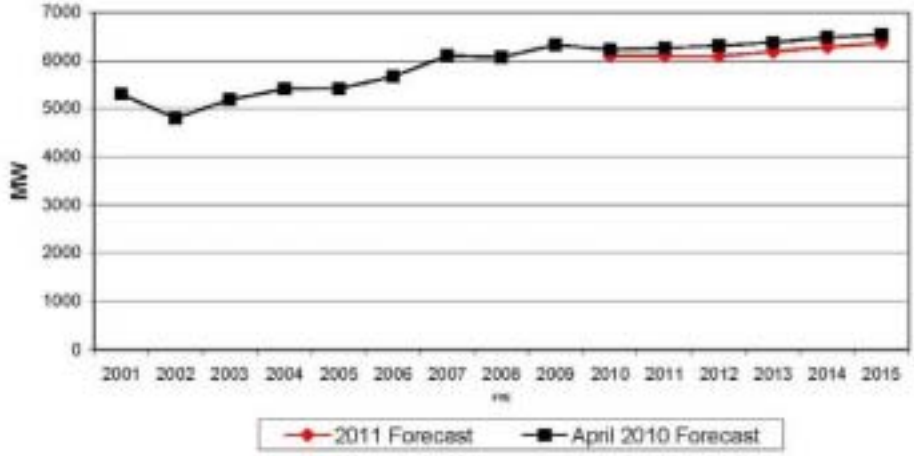
In 2010, the System set its calendar annual peak at 6142 MW on September 27, 2010 on a day that was a one-in-thirty-seven weather event. The weather-adjusted one-in-two peak for 2010 is 5589 MW. The following graph of the One-in-Ten peak demand forecast is used for the Integrated Resource Plan (IRP). In the 1990s through 2005, annual System load factors were trending slowly upward. Since 2006, System load factors are trending down. Two factors are generally thought to be contributing to this

Page 5

AR0071225

effect. Most customers are making greater efforts to conserve energy but during extreme weather events safety and comfort predominate over conservation causing the peak to spike. Much of the historical and forecasted energy efficiency effort is lighting which has a greater impact on consumption rather than peak which lowers the load factor.

One-in-Ten Peak Demand Comparisons



The Peak Demand Forecast is primarily used in the following areas:

1. Integrated Resource Planning
2. Wholesale Energy Marketing
3. Distribution Planning
4. Transmission Planning

In Integrated Resource Planning, LADWP uses the One-in-Ten Case Peak Demand forecast rather than the Base Case forecast. LADWP's policy is to ensure reliability in times of volatility by controlling its own generation capacity. Planning generation resources at the one-in-ten level has proven over the years to be an effective tool in meeting the reliability policy. The one-in-ten case is based on historical peak day weather events and uses a statistical model and the underlying retail sales forecast to forecast an annual peak demand.

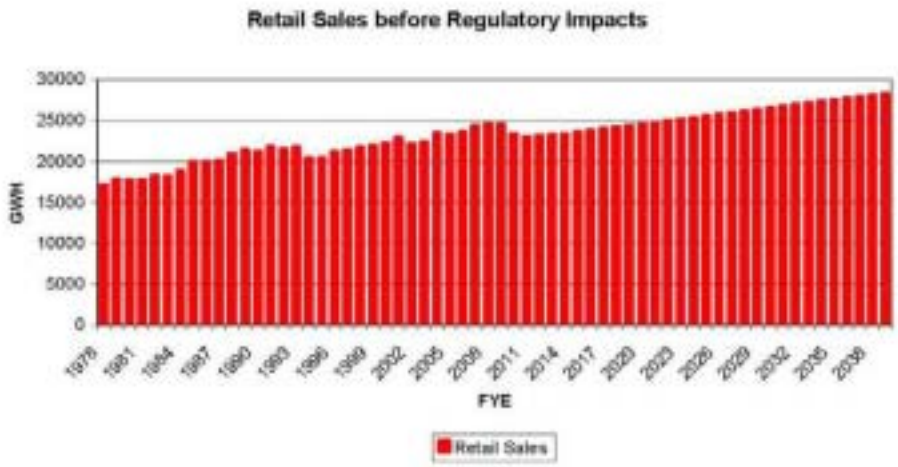
Plausibility

To measure plausibility we compare the current forecast to historical periods. Data is available electronically from 1978 forward. A direct comparison is not appropriate because the forecast period includes programs that reduce all forms of energy consumption due to an aggressive regulatory agenda primary aimed at reducing greenhouse emissions. Instead the unmitigated forecast is compared against history. The unmitigated forecast is the forecast that would occur before the impacts of AB 32 and AB 2021 are considered. It might also be considered a "business-as-usual" case.

AR0071226

The decline in forecasted sales 2008 through 2010 is most directly compared to the decline in sales between 1992 and 1994. The 1992 through 1994 time period was difficult for Los Angeles in many aspects. An economic slump occurred mostly created by the downsizing of the aerospace industry but it also was time of civil unrest and natural disaster. The combination of events caused a major migration of people leaving Los Angeles. Peak-to-Trough sales declined 7 percent in the 1992 through 1994 time period. The following table shows all the peak-to-through declines since 1978. The chart then gives visual evidence of the long-term perspective.

Peak-to-Trough Analysis		
Years	GWH Decline	Percent Decline
2008-2010	1,910	8.3%
1992-1994	1,421	7.0%
2000-2002	572	2.6%
1979-1980	322	1.8%
1981-1982	145	0.8%



Primarily due to the recession that began in December 2007 and ended in June 2009, the historical sales experienced a decline of 8.3 percent in the 2008 through 2010 time period. While the 1992-94 sales decline was specific to Los Angeles and the aerospace industry, in 2008-2010 the decline in Los Angeles mirrored the malaise in the national economy. Most economic models based on history would have predicted a faster economic recovery given the amount of publicly-announced fiscal and monetary stimulus. The actual fiscal stimulus was below the announced target. According to www.recovery.gov , only 40% of the funds made available by Recovery Act have been spent as September 2010. Monetary policy has worked for large firms that can reach international markets as the S&P 500 in 2010 neared historical peak earnings. S&P 500 companies have created over one million jobs in the USA according to Economy Policy

AR0071227

Institute. Small firms continue to struggle as loan requirements are stringent and there is reluctance to invest given the economic uncertainty. UCLA Anderson is forecasting the Los Angeles County to remain in the recovery phase until 2012. Historically, it will be the longest confirmed recession and recovery since World War II.

Variables in the Forecast

Population. Every United States Census was taken in April 2010. Local data is expected by June 2011. Historical population data is likely to be treated as interim data between forecasts is based on state total numbers. Los Angeles is particularly difficult place to estimate population due to the highly transient nature of the economy. Los Angeles experiences high levels of foreign immigration and domestic outmigration. It was thought that the majority of the outmigration was to Riverside and San Bernardino counties. Los Angeles workers moved to these counties to become homeowners. The housing crisis changed the migration pattern and there is uncertainty whether or not this long term historical pattern will resume.

SB 375. SB 375 favors statewide mandates onto local planning decisions. It favors infill development, known as brown field development, near transportation corridors over green field development. The goal is to reduce vehicle miles traveled thereby reducing emissions. Most development in Los Angeles is brown field development. However brown field development is more complicated and expensive than green field development so overall development could slow. The City of LA's Re-zoning the Way We Plan fits well into the SB 375 structure. Residential construction activity is forecasted to be historically slow during the recovery so it will take some time to see the ultimate outcome of SB 375 and the "Re-zoning the Way We Plan" plan.

Emission Allowances. AB 32 seeks to reduce emissions to 1990 levels using a cap-and-trade scheme to begin in 2012. Provisions are designed to avoid activities and companies that experience inflexible as that unintended consequences could arise as occurred during energy deregulation in the late 1990s.

Plug-in Hybrid Electric Vehicles (PHEVs). The Forecast adopted the CEC forecast for PHEV adoption rates. LADWP is making PHEVs a key strategic initiative so adoption rates could be faster. On the other hand, there are competing technologies to PHEVs that the public may choose. Other credible forecasts including the United States Energy Information Administration have significantly lower forecasts for PHEV adoption citing problems with battery technology. The forecast adopted an EPRI charging load profile for PHEVs. The LADWP may choose strategies to shift significantly alter that charging profile.

Energy Efficiency. According to the State of California's Strategic Plan, achieving the energy efficiency goals relies on new emerging technologies. The timing of the market availability and the adoption rates for these new technologies is unknown.

Smart Grid. It is unknown when LADWP will complete its Smart Grid program. Some believe that developing a Smart Grid system is a necessary precondition towards a successful PHEV program. The Smart Grid is an important component towards achieving energy efficiency goals in the residential sector.

AR0071228

Vacancy Factor in Residential Sector – Vacancy rose faster than expected in the recession. Some of the vacancy rate was due to households consolidating and living in the same structure. Vacancy could rapidly swing lower as the economy begins to expand. The forecast has vacancy rate returning to five percent which is the long term average by 2018.

Vacancy Factor in Commercial Sector – High vacancy factor is expected to remain more persistent in the commercial sector as models for delivery of services especially in retail change. The rise of big-box retail stores and the Internet have crowded out the small retail shop owner over the past twenty years. There is a smaller need for a physical presence.

AR0071247

Retail Sales

- Key Change Factors from April 2010 to 2011
  - Balance Sheet Recession means lengthy recovery period.
  - Commercial vacancy rates remain high.
  - Construction activity remains at low level for extended period.
  - Higher electric prices to meet 33% renewable goal.
  - Includes Huffman Bill energy efficiency savings as a committed resource.

AR0071248

Forecasted Accumulated Savings
Energy Efficiency and Solar Rooftops

- Components of Change
  - "Committed" LADWP EE programs through FYE 2013.
  - Huffman Bill savings.
  - "Uncommitted" EE will be accounted for as a resource.
  - Solar Rooftop Goal – 148 MW installed by 2020

AR0071249

Retail Sales

- Accuracy
  - EE and Solar were not modeled explicitly in Historical Forecasts.
  - Historical accuracy is -0.1% with a 1.6% deviation. However expect larger variation in accuracy due to uncertainty of new programs.
  - Forecast variation is a function of weather, economic forecasts, meeting program goals and model specification.

AR0071250

Peak Demand

- Cases
  - The variance around the 1-in-2 forecasted peak has widened.
  - Climate change research expects more frequent heat storms to occur of longer duration.
  - Based on the climate change finding, it is now expected that the System will approach its potential more frequently so the distance between the 1-in-10 and 1-in-40 forecasts is compressed.

AR0071251

Peak Demand

- Annual peak demand is dependent on the severity of the heat storms that are encountered during the year.
- The cases are built on the probability of a weather event occurring in a given year.

Fiscal Year	Base Case	1 in 5	1 in 10	1 in 20	1 in 40
2011-12	5,589	5,887	6,042	6,171	6,282

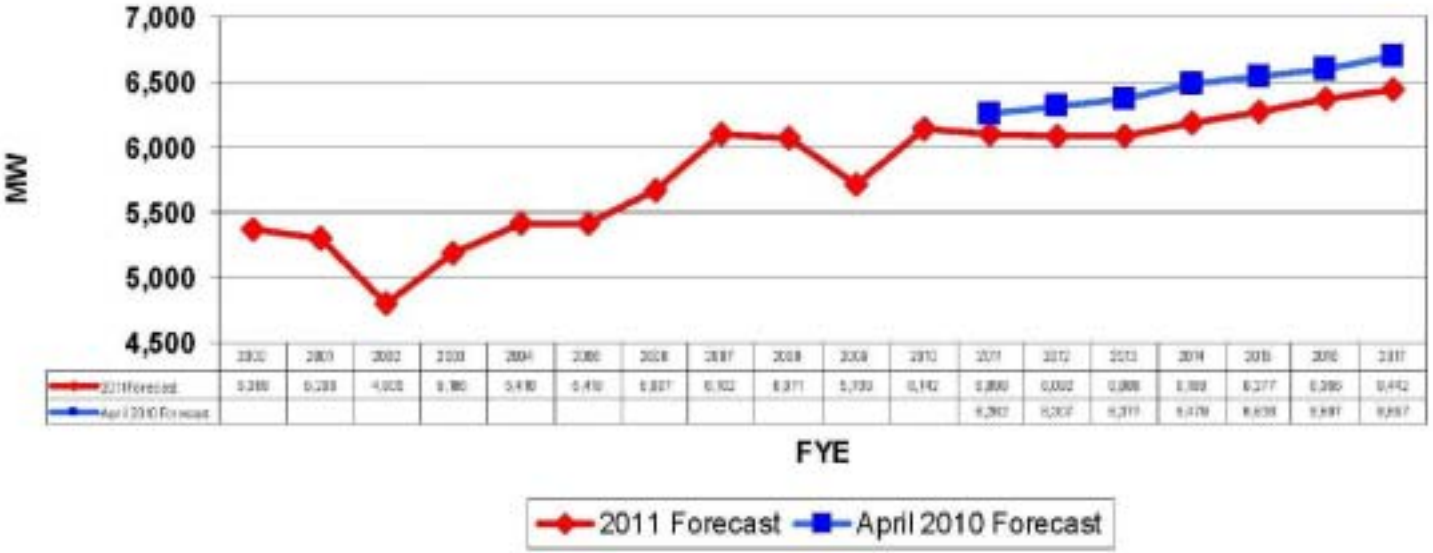
2039-40	7,626	8,027	8,236	8,410	8,559
2040-41	7,703	8,108	8,319	8,495	8,646

AR0071252

1-in-10 Peak Demand

- Resource Planning.
  - Weather-normalized peak in Summer 2010 was 5589 MW compared to the April 2010 forecast of 5797 MW.
  - The 1-in-10 Peak Demand Forecast is used in the Integrated Resource Plan.



AR0071253

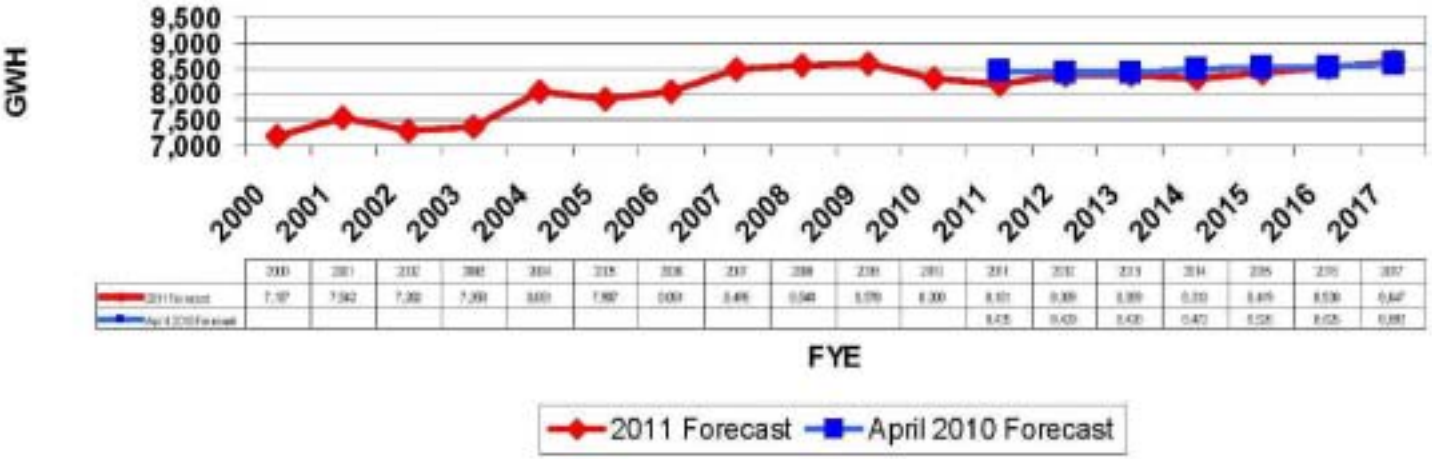
1-in-10 Peak Demand

- Probability accumulates over time.
  - There is a 69% chance of having a 1-in-10 weather event by 2020.
  - There is a 24% chance of having a 1-in-40 weather event by 2020.
  - $P_t=1-(1-P_e)^t$

AR0071254

Residential Energy Sales

- Components of Change
  - Higher weather response. All new units have air conditioning.
  - Fewer units built and higher vacancy factor.
  - Huffman Bill lighting impacts.



AR0071255

Residential Energy Sales

Number of Residential Customers

- Recent Evidence
  - Vacancy rising outstripping the growth in new units.
  - The majority of residential customers live in multi-family units.

2011 Forecast Chartbook

36

AR0071256

Residential Sales

12-month Moving Average Sales per Customer

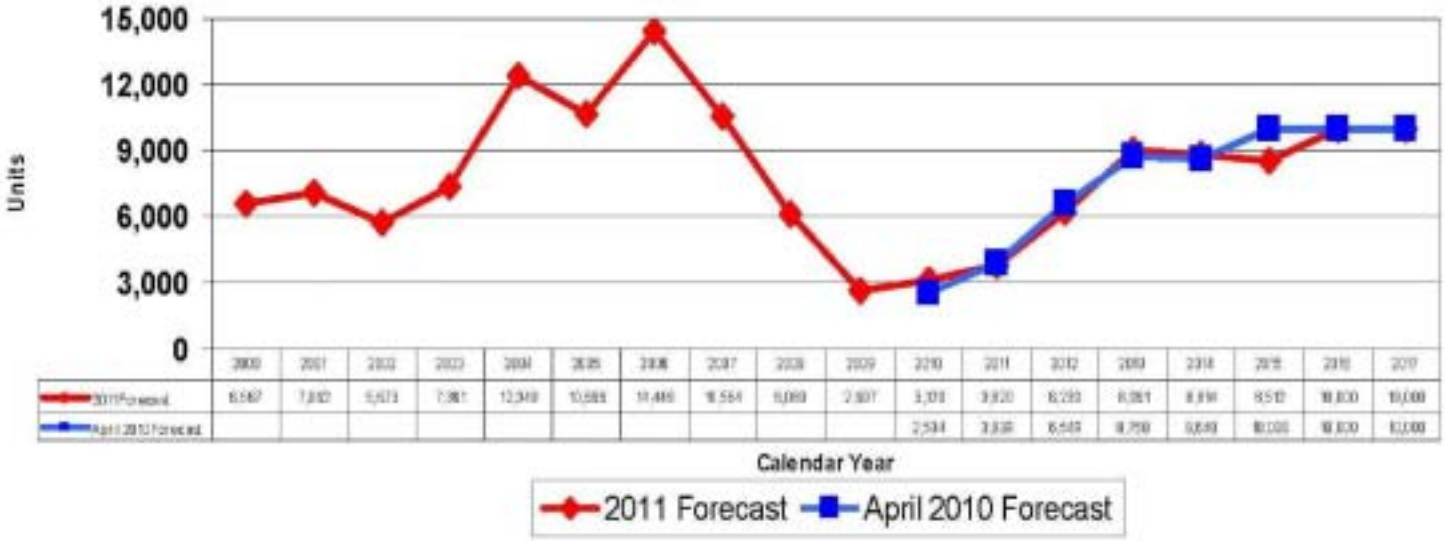
- Recent Evidence
  - Sales per residential customer reached an all-time high of 519 KWH per month in December 2008.
  - The November 2010 rate is 475 KWH per Month.
  - Replacing 2010 summer weather with normal adds 11 KWH to the November 2010 monthly rate.

AR0071257

Residential Energy Sales

New Residential Building Units

- Housing Forecast fundamentally unchanged.
- New units are 20% Single-Family and 80% Multi-family which lowers future average consumption per household.



AR0071258

Residential Energy Sales

Recent Economic Impact

- Real Personal Consumption.
  - Recovery ends and expansion begins in 2012.

39

2011 Forecast Chartbook

AR0071259

Commercial Energy Sales

- Components of Change
  - Commercial construction activity down.
  - Service employment forecast down slightly.
  - Higher real electric prices.
  - Committed energy efficiency included only through 2013. Some forecasted sales beyond 2013 will not be realized at the meter.

AR0071260

Commercial Energy Sales
Number of Commercial Customers

- Recent Evidence
  - The number of commercial customers peaked in June 2006.

2011 Forecast Chartbook

41

AR0071261

Commercial Energy Sales

Twelve-Month Moving Average Sales per Customer

- Recent Evidence
  - Sales per customer per month peaked in July 2008 at 9265 KWH per month.
  - Currently sales per customer per month are 8639 KWH.
  - Adjusting to normal summer weather for 2010 adds 262 KWH to current sales per customer.

AR0071262

Commercial Energy Sales

Local Employment in Service Sector

- LA County Commercial Services Employment
  - Balance Sheet Recession
  - Employment does not return to former level by 2020.

2011 Forecast Chartbook

43

AR0071263

Commercial Energy Sales

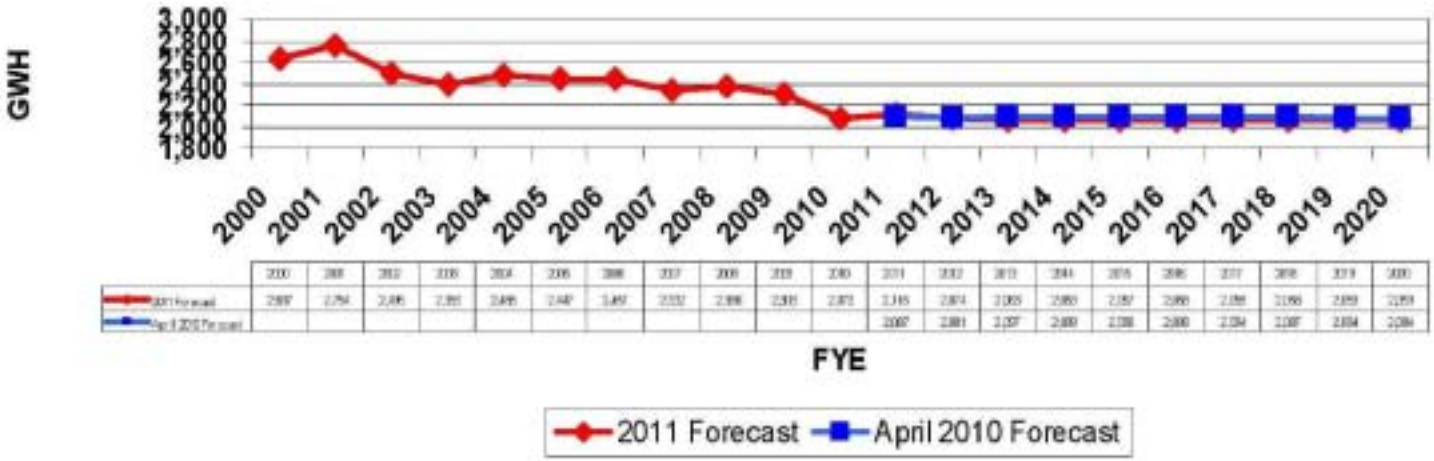
McGraw-Hill Construction Forecast

- Commercial Floorspace Additions
  - Construction activity at historically low levels.
  - Office vacancy rates in San Fernando Valley at 18 percent.
  - New models for delivering commercial services require smaller physical presence.
    - Big Box retailers
    - Internet

AR0071264

Industrial Energy Sales

- Components of Change
  - Land use issue: Once industrial land is vacated, residential and commercial building tend to replace it. 3 percent vacancy rates in the industrial sector.
  - Manufacturing continues to move offshore.
  - Higher real electric prices.
  - No EE or rooftop solar in the Industrial Forecast. All EE and solar assigned to Residential, Commercial and Streetlight sectors.



AR0071265

Industrial Energy Sales
Number of Customers

- Recent Evidence
  - The number of Industrial customers is continually and relentlessly declining.
  - The decline began in the 1970s.
  - The forecast is for the heavy industries to remain although no new heavy industry will be built. It is the light industry and assembly jobs that are disappearing.

AR0071266

Industrial Sales

Twelve-Month Moving Average Sales per Customer

- Recent Evidence
  - Sales per customer per month peaked in October 2006 at 15018 KWH per month. High consumption partially attributed to a large self-generation unit being off-line at a refinery.
  - Currently sales per customer per month are 13666 KWH.

Industrial Sales
Employment Outlook

- LA County Manufacturing Employment
  - Future employment forecast is slightly positive. If Los Angeles continues to lose manufacturing jobs then there will be a mismatch with the education level of the population and available high paying jobs. It could lead to significant population out-migration.

2011 Forecast Chartbook 48

AR0071268

Plug-in Hybrid Electric Vehicles

Potential New Load Growth

- Adopted the California Energy Commission Forecast.
- Forecast dependent on:
  - Improved battery technology.
  - Implementation of Smart Grid.
  - Implementation of Charging stations

AR0071270

Plug-in Hybrid Electric Vehicles
Charging Profile Assumption

- Based on EPRI research.
- Load Shape potentially could be engineered to optimize LADWP production function.

2011 Forecast Chartbook

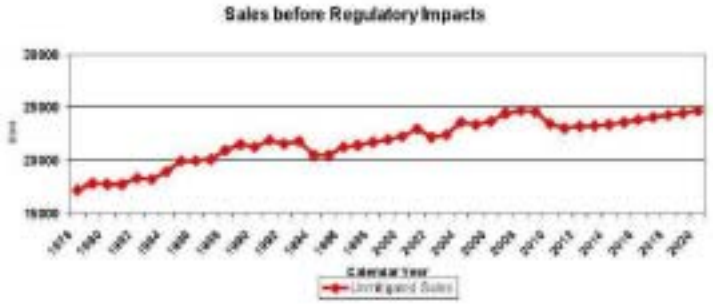
51

AR0071271

Plausibility

- Comparing unmitigated 2011 Sales Forecast to historical sales.
  - Unmitigated means forecasting sales based on economics alone before the impacts of environmental programs are considered.
  - Forecasted sales decline from 2008 to 2011 is largest in the past 30 years.
  - Next decade similar to what occurred in the 1990s before additional regulation.

Peak-to-Through Analysis		
Years	GWH Decline	Percent Decline
2008-2011	1,910	8.3%
1992-1994	1,421	7.0%
2000-2002	572	2.6%
1979-1980	322	1.8%
1981-1982	145	0.8%



AR0071272

Appendix B Energy Efficiency

Energy Efficiency (EE) is a key strategic element in LADWP IRP planning efforts. EE is a very cost-effective supply-side resource, and serves an important and multi-faceted role in meeting customer demand. One of the most widely recognized examples of EE is the replacement of incandescent lights with compact fluorescent lamp (CFL) bulbs. CFLs consume up to 75 percent less energy than incandescent bulbs while producing an equivalent amount of illumination, and last up to 10 times longer.

The reduction in energy demand that EE enables, translates into a number of benefits:

- Deferred need to build physical generation assets
- Reduced RPS compliance costs
- Reduced environmental footprint, including lower GHG emissions
- Potential for local job creation opportunities

The following subsections summarize the background of LADWP's EE program, and then present the recently completed EE market potential study. Based on the study results, a plan is recommended with identified savings and costs targets. For more specific details regarding the potential study, see the reference at the end of this appendix.

B.1 Background

LADWP has active EE programs that have been in place for several years. Since 2000, LADWP has spent approximately $282 million on its EE programs, which have reduced long-term peak demand and consumption by approximately 303 MW and 1,256 GWh, respectively. LADWP continues its commitment to developing robust, cost-effective EE programs with measurable and verifiable goals.

LADWP offers numerous EE programs and services for residential, commercial, industrial, governmental, and institutional customers to promote the efficient use of energy through the installation of energy efficient equipment. Examples include:

- The Commercial Lighting Efficiency Offer (CLEO), which provides rebates for a variety of high efficiency lighting measures to retrofit existing buildings. The CLEO program enjoys sustained high rates of participation and has achieved 433 GWh of energy savings since 2000.
- The Chiller Efficiency Program, which provides incentives for customers to replace old electric chillers with new, high-efficiency units. Chillers provide space conditioning for larger buildings and the program has reduced associated peak electrical demand by more than 52 MW since 2001.
- The Small Business Direct Install (SBDI) Program, which assists eligible small businesses (A1 rate customers) in Los Angeles in becoming more energy efficient through free lighting assessments and free lighting retrofits (up to $2,500 in cost). SBDI began in 2008 and has achieved 149 GWh of energy savings since its inception.

AR0071273

- The Custom Performance Program, which provides performance-based incentives for energy efficiency measures not included on LADWP's menu-based EE programs. Measures supported include controls and control systems, high efficiency motors, and data server virtualization, The Custom Performance Program has achieved 200 GWh of energy savings since 2006.
- The Refrigerator Exchange Program, which delivers new Energy Star refrigerators to eligible residential customers, and picks-up/recycles customers' old, inefficient refrigerators. This program has replaced and recycled more than 53,000 refrigerators since 2007, achieving an energy savings of 49 GWh.
- A recent program, which distributed two free CFLs to LADWP's 1.2 million residential customers through direct-to-door distribution. The intent of the one-time direct-to-door distribution was to achieve cost effective energy savings and increase customer awareness of this inexpensive, yet effective, EE measure. CFLs are also distributed at events and in connection with other energy efficiency programs.

However successful LADWP's EE program has been, for a variety of reasons it did not meet targets that were set back in 2006. A summary the program since 2006 is presented in Table B-1.

Table B-1. LADWP EE PROGRAM PROGRESS-TO-DATE

	FY 06-07	FY 07-08	FY 08-09	FY 09-10	FY 10-11	Cumulative FY 06-11
LADWP Adopted Targets (2006) - Net GWh	58	275	315	300	280	1,228
Actual Energy Savings Achieved - Net GWh	58	118	270	156	154	756
Actual % of Adopted Target	100%	43%	86%	52%	55%	62%
Actual Energy Savings - Gross GWh	68	139	318	184	181	890
Approved EE Budget ($million)	28	79	77	93	69	346
Revised EE Budget ($million)	n/a	n/a	n/a	>50	50	
Actual EE Funds Spent ($million)	14	38	68	44	50	214
Actual % of Budget	51%	48%	88%	48%	72%	62%
Effective Cost - $/kWh	$0.018	$0.023	$0.018	$0.020	$0.023	

Some key points regarding Table B-1 are as follows:

- The economic outlook in 2006, which the targets were based on, was more elevated then what actually transpired. As the higher outlook in 2006 failed to materialize, in retrospect the prior EE targets were overly ambitious.
- Since 2006, regulatory requirements have increased (OTC, RPS, GHG, etc.), resulting in additional demands outside of the EE program.
- Revenue streams required to support EE programs did not materialize. A spending freeze in 2009 and spending cutback in 2010 resulted in underfunding which hindered the attainment of program goals.

AR0071274

- Actual load profiles were less than forecasted, further affecting program performance.

An assessment of LADWP's EE program was undertaken in 2010. The assessment, also known as a Market Potential Study, includes an updated plan for moving forward.

B.2 Market Potential Study

Per Assembly Bill 2021 (AB 2021), publically owned utilities such as LADWP, must identify and develop all potential achievable, cost-effective EE savings and establish annual targets. Furthermore, utilities are required to conduct periodic "Market Potential" studies to update their forecasts and targets. The most recent study was carried out in late 2010 and is the basis for the EE recommendations contained in this 2011 IRP.

For more in-depth information, see the study referenced at the end of this appendix. This section presents a brief summary of the methodology and findings.

The 2010 Market Potential Study objectives were as follows:

- To estimate savings possible through utility programs and other interventions (such as the American Recovery and Reinvestment Act)
- Identify energy-efficiency technologies and measures that will produce savings
- Link the energy saving measures with utility programs to achieve savings
- Provide guidance for setting 10-year targets for CEC

The analysis methodology is shown in Figure B-1.

AR0071275

Figure B-1. 2010 Market Potential Study analysis approach.

Some of the key factors that were considered in the study include:

- Changes in the customer base since the last study
- Building codes
- Adoption of new appliance standards
- Naturally-occuring conservation
- Trends in appliance satuations
- How customers use electricity today
- Technological changes in appliances and equipment

The resulting baseline forecast for the overall customer base is shown in Figure B-2.

AR0071276

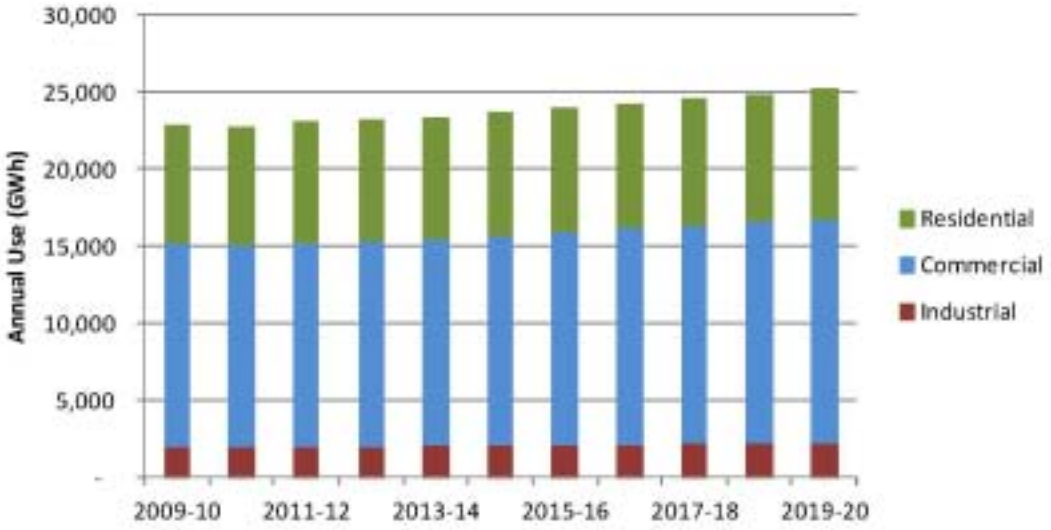


Figure B-2. Baseline forecast results through 2019-20.

Segmented forecasts for the industrial, commercial, and residential sectors are shown in Figures B-3, B-4, and B-5.

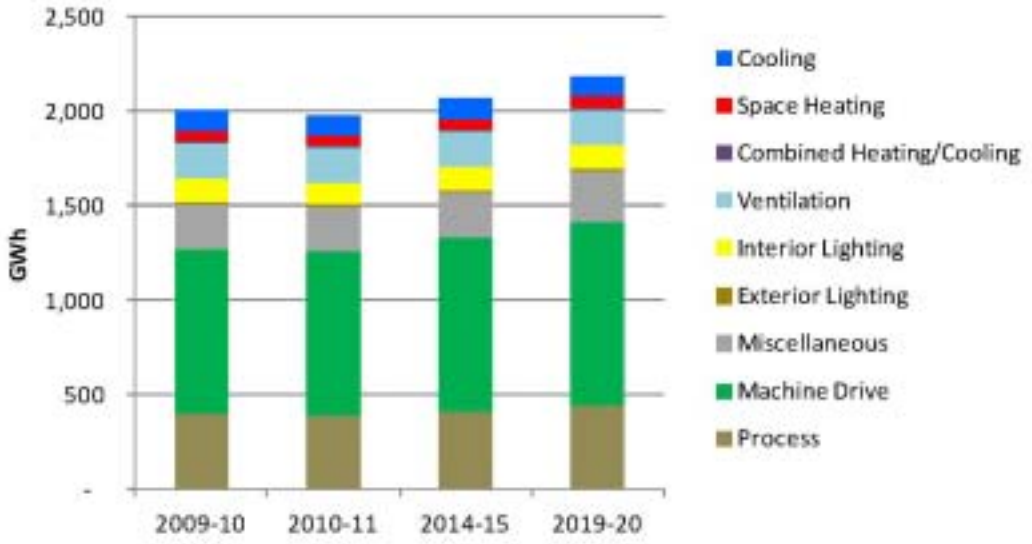

Figure B-3. Industrial sector baseline forecast results.

AR0071277

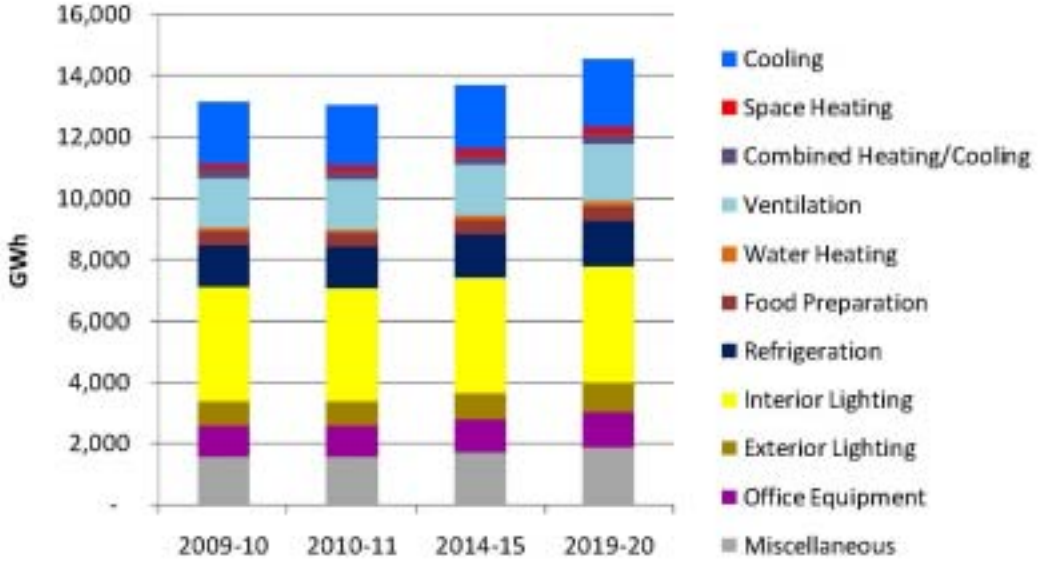

Figure B-4. Commercial sector baseline forecast results.

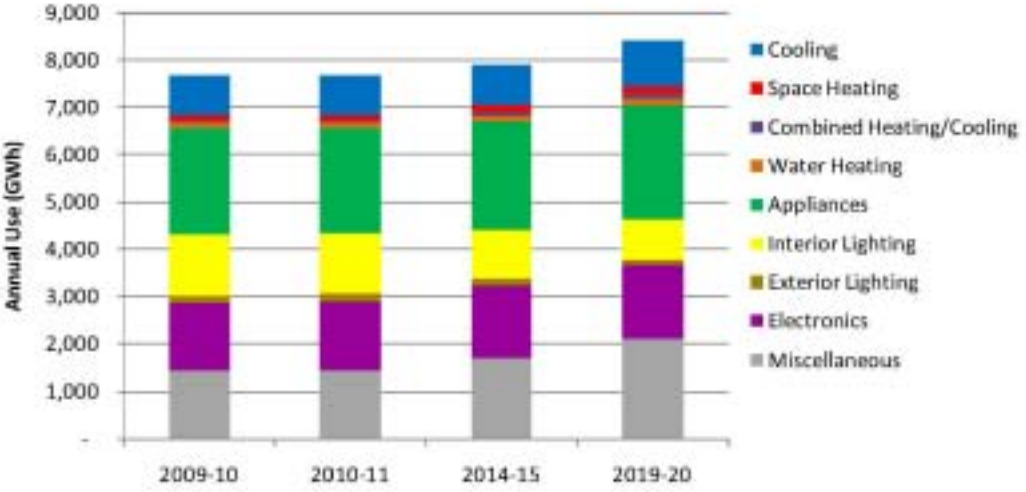

Figure B-5. Residential sector baseline forecast results.

The study evaluated a multitude of measures for potential inclusion into LADWP's EE program, including:

- Existing program elements
- High-efficiency air conditioners (higher efficiency levels, variable refrigerant flow systems)
- High-efficiency lighting (CFLs, LED lamps)
- Upgraded insulation in buildings
- Retrocommissiong and routine maintenance
- Programmable Communicating Thermostats and Energy Management Systems

AR0071278

B.3 EE Study Results and Plan

To understand the study results the following terms are defined:

2010 Potential Study Definitions

Term	Definition
Technical Potential	Customers are assumes to install most efficient option regardless of costs.
Economic Potential	Customers are assumed to install most efficient cost-effective option.
Maximum Achievable Potential	Sets maximum targets for savings. Assumes "ideal" implementation conditions and customer preferences.
Realistic Achievable Potential	Includes realistic parameters for implementation; incorporates real-world limitations: Advance program potential: Utility pays 100% of incremental cost to upgrade to EE measures. Base program potential: Utility pays 50% of incremental cost.

Key drivers/assumptions influencing EE potential levels are:

- Program budgets are assumed to grow over time
  - Financing impacts
  - Federal grants impact
- Staffing levels and other required resources will increase with program expansion
- Avoided costs will rise with changes to the generations mix

The study found that there is a realistic potential to reduce energy consumption from the baseline forecast by 8.6% by year 2019-20. Figure B-6 shows the cumulative % energy savings through fiscal year 2019-20, and Figure B-7 shows the cumulative absolute savings.

AR0071279

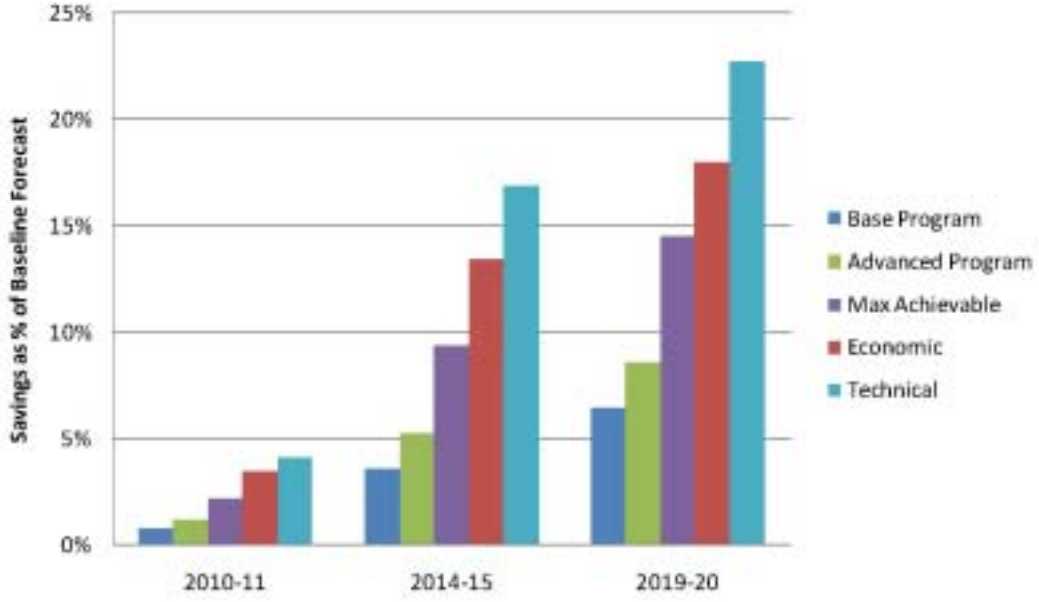

Figure B-6. Cumulative energy savings as a percentage of the baseline forecast.

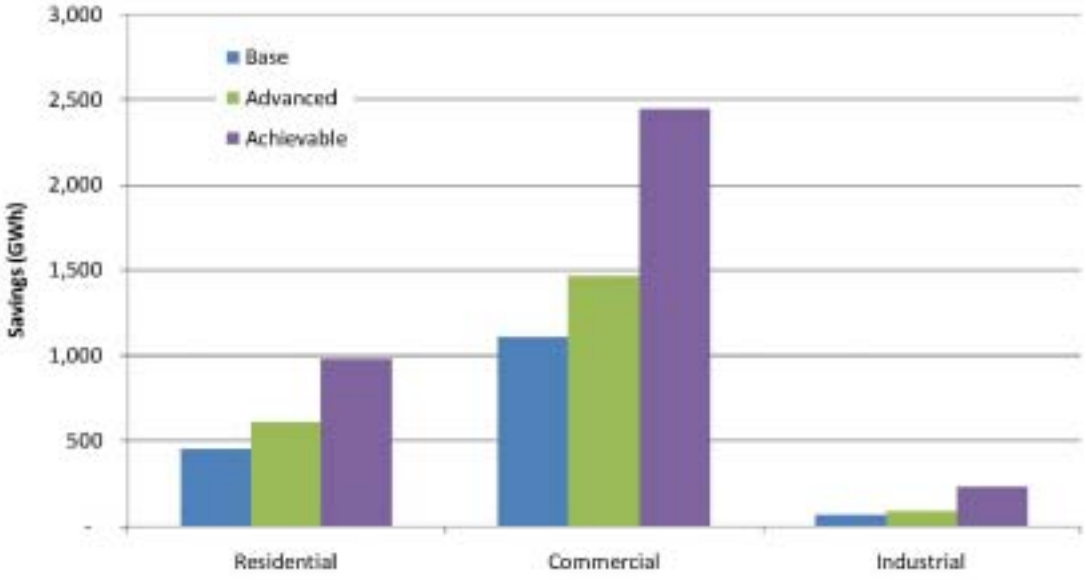

Figure B-7. Cumulative energy savings in GWh.

The Potential Study found that the net present value of avoided energy costs exceeds the NPV of program costs (including incentive payments, administrative costs and customer contributions) in both the Base and Advanced programs. Table B-2 and Figure B-8 illustrate the cost and benefit findings.

AR0071280

Table B-2. Financial Metrics

	Total Savings (GWh)	Total Cost ($Million)	Total Benefits ($Million)	Net Benefits ($Million)	Benefit/ Cost	Cost of Conserved Energy (cents/kWh)
Base Program	18,719	$1,073	$1,092	$18	1.02	5.73
Advanced Program	25,290	$1,411	$1,483	$72	1.05	5.58
Max Achievable	46,209	$2,139	$2,681	$542	1.25	4.63

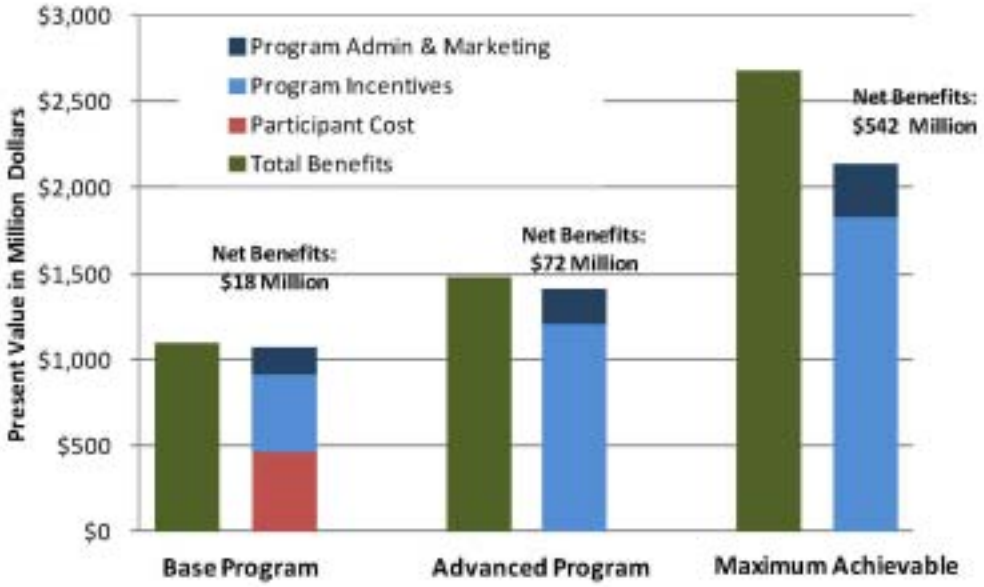

Figure B-8. Cost and benefits for base and advanced programs.

The analysis includes an assessment of the current program portfolio and the development of recommended changes.

Residential Programs

LADWP currently has the following existing residential EE programs:

Consumer Rebate
Refrigerator Turn-In and Recycle
Low Income Refrigerator Exchange
Compact Fluorescent Lamp (CFL) Distribution

AR0071281

The following recommendations resulted form the 2010 potential study:

1. LADWP should keep its existing programs, with the exception of CFL Distribution which should be replaced with a broader lighting initiative adapted to revised lighting standards.
2. Two new programs should be adopted, (1) Low-income, and (2) Whole House Performance.

A continued effort towards public outreach is also recommended to maintain and broaden public awareness of available EE benefits, and to promote participation.

Figure B-10 illustrates potential residential EE program savings for fiscal year 2019-20.

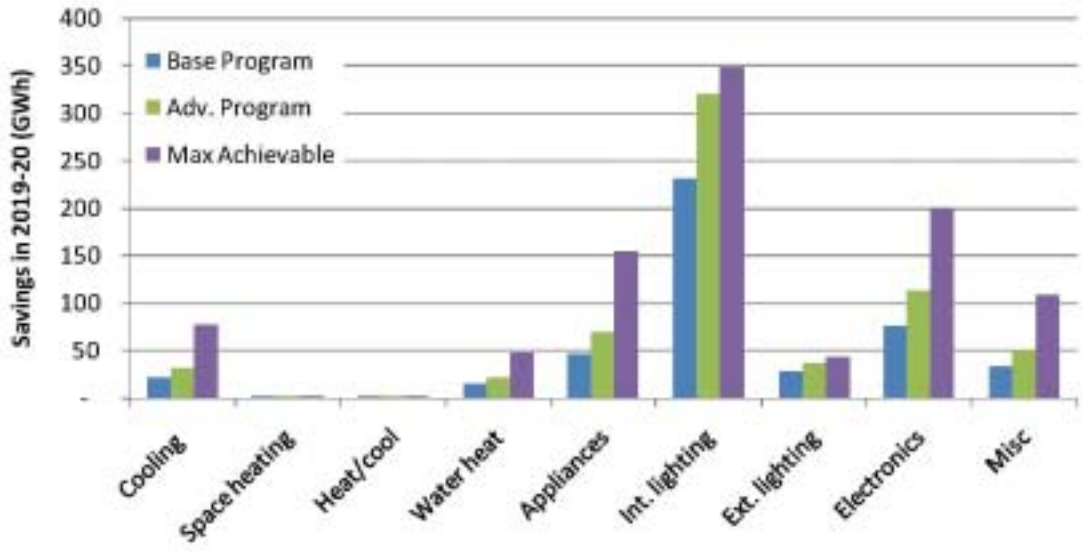

Figure B-10. Potential residential EE program savings in 2019-20.

Commercial and Industrial (C&I)

LADWP currently has the following existing C&I EE programs:

Commercial Lighting Efficiency
Chiller Efficiency
Refrigeration
Customer Performance
Small Business Direct Install
New Construction Incentive
Financing Programs
Energy Audits
Technical Assistance

AR0071282

The following recommendations resulted form the 2010 potential study:

1. LADWP should keep its existing program elements, but should adapt the lighting program to educate customers on the expanded choices in energy efficiency bulbs available that will comply with new lighting standards.

Figures B-11 and B-12 illustrate potential commercial and industrial savings for year 2019-20.

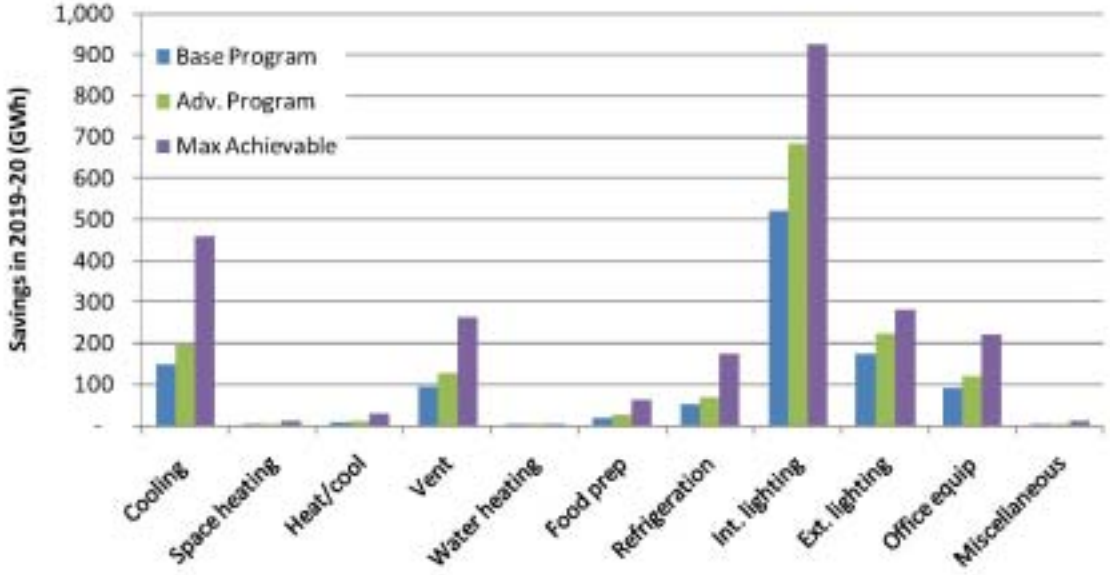

Figure B-11. Projected commercial EE savings in 2019-20.

Appendix C Environmental Issues

C.1 Overview

LADWP's mission includes a role as an environmentally responsible public agency. LADWP continues to develop and implement programs to improve the environment, including:

- Increasing the use of renewable energy to meet the needs of LADWP's customers (20 percent by December 31, 2010 and 35 percent by December 2020 through the development of wind, solar, geothermal, and biomass energy sources and acquiring the associated transmission required to transmit such energy to Los Angeles.
- Prioritizing the use of Energy Efficiency (EE), Demand Side Management (DSM), renewable Distributed Generation (DG), and other renewable resources.
- Continuing the modernization of LADWP's in-basin generating stations, including the repowering of four older, less-efficient utility steam boiler units with advanced gas turbine generating units.

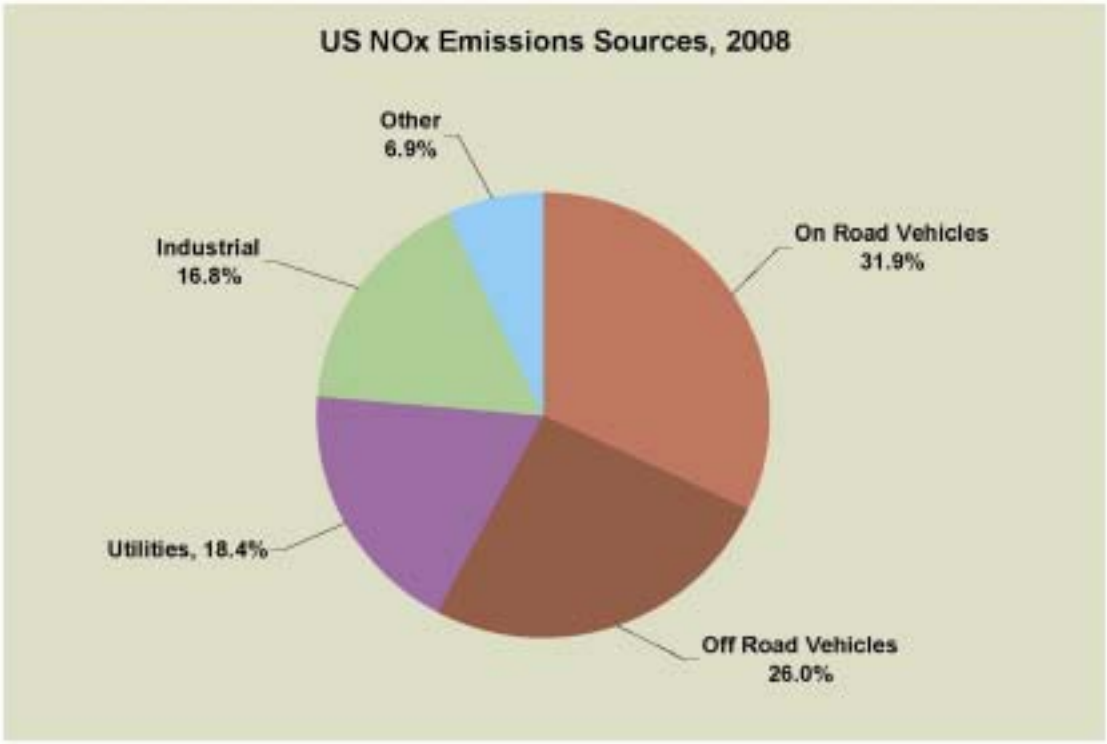
This Appendix provides information on a number of environmental issues and policies including oxides of nitrogen (NO_X) emissions, GHGs and climate change, power plant once-through cooling, (OTC), and mercury emissions.

C.2 Emissions of Oxides of Nitrogen (NO_X)

Oxides of nitrogen, or NO_X, is the generic term for a group of highly reactive gases, all of which contain nitrogen and oxygen in varying amounts. Many of the oxides of nitrogen are colorless and odorless. However, one common pollutant, nitrogen dioxide (NO_2), is a major precursor for "smog," which can be seen as a reddish-brown layer over many urban areas. Oxides of Nitrogen is also a precursor to the formation of ozone, and the South Coast Air Basin (SCAB), in which Los Angeles is situated, has the one of the highest ozone levels in the United States.

NO_X forms when fuel is burned at high temperatures, as in a combustion process. Figure C-1 shows the primary man-made sources of NO_X as reported by the United States Environmental Protection Agency (U.S. EPA) in 2008.

AR0071287

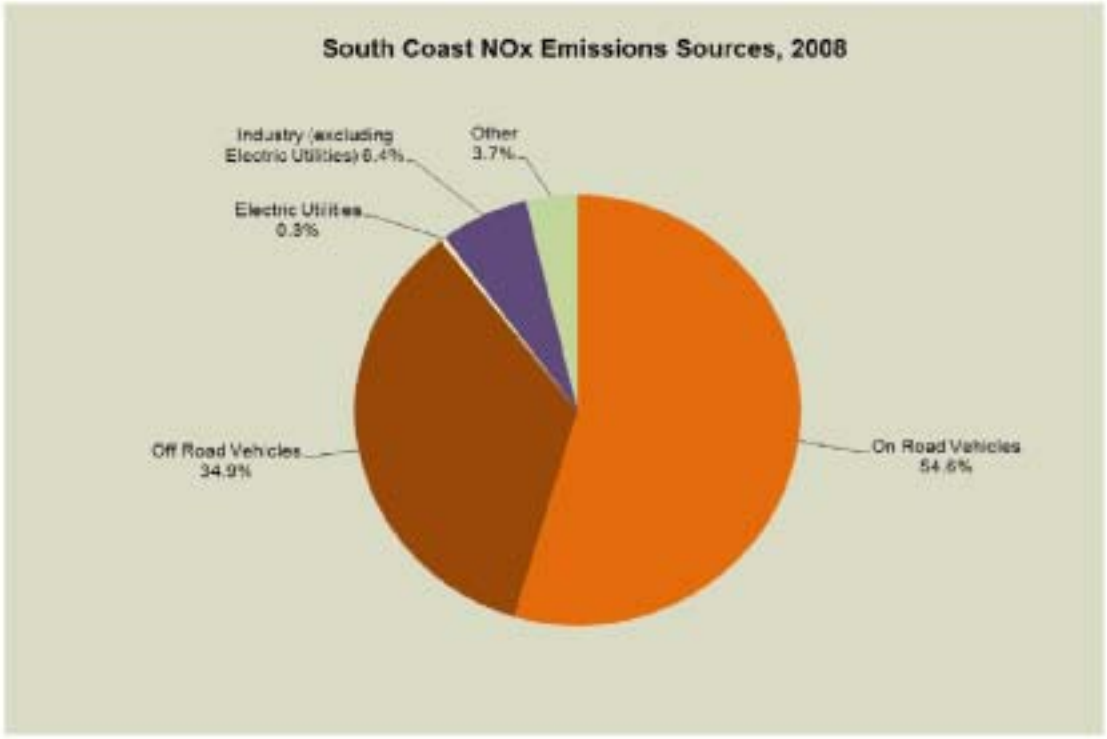


Source: U.S. Environmental Protection Agency

Figure C-1. NO_X emission sources in the U.S.

The SCAB (including Los Angeles, Orange, San Bernardino, and Riverside counties) has some of the worst air quality in the United States due in part to the level of NO_X emissions. The majority of NO_X emissions result from mobile sources such as on-road and off-road vehicles, and not stationary sources such as power plants. The California Air Resources Board (CARB) estimates in its 2010 Almanac of Emissions and Air Quality that emissions in the SCAB will be 742 tons of NO_X per day. This is down from 820 tons per day in 2008 due to greater regulation of stationary sources and more efficient vehicles. Roughly 90 percent of these emissions are from vehicles, as shown in Figure C-2.

AR0071288



Source: California Air Resources Board, 2008 Estimate

Figure C-2. Local NO_X sources in 2010.

For comparison, the average daily NO_X emissions from LADWP's in-basin generating stations (Harbor, Haynes, Scattergood, and Valley) combined was 0.65 short tons of NO_X per day in 2008, which represents 0.08 percent of the 2008 average daily NO_X emissions in the South Coast Air Basin. The low NO_X emissions from LADWP's in-basin generating stations are due to the use of natural gas at all facilities and the installation of advanced emissions control systems.

Forecasts project that South Coast Air Basin NO_X emissions will continue to decrease over the next decade. Targets for 2015 are 580 tons per day, while the 2020 target is 468 tons per day. The majority of this reduction is expected to come from a reduction in vehicle emissions; total tons emitted from stationary sources during this time period are only projected to decrease from 56 tons per day to 52 tons per day.

A major tool employed by the SCAQMD to reduce NO_X emissions from stationary sources is the RECLAIM (Regional Clean Air Incentives Market) trading program. RECLAIM is a market-driven regulatory program started in 1994 that superseded the SCAQMD's existing NO_X rules for facilities with NO_X emissions exceeding 4 tons per year. These "command and control" rules limited the emission rates of stationary combustion equipment and have been replaced by a facility-wide emissions cap, which gradually declines each year. Facilities receive emission allocations, called RECLAIM Trading Credits (RTCs), in which one credit grants the right to emit one pound of NO_X. Facilities must have sufficient RTCs in their RECLAIM facility accounts to cover their actual emissions. RECLAIM is a market-driven program because the RTCs can

AR0071289

be bought and sold, which allows for the emissions reductions to be made in the most cost-effective manner.

All of LADWP's in-basin power plants now have advanced pollution control equipment, which reduces NO_X emissions by at least 90 percent. However, the allocation of RTCs to each of LADWP's power plants declines over time, and the entire future allocation of RTCs was reduced about 22.5 percent by the SCAQMD in 2005. Using the resource planning studies and other considerations, the environmental assessment results show that the projections meet LADWP's NO_X goals.

C.3 Greenhouse Gas Emissions and Climate Change

C.3.1 Federal Efforts To Address Climate Change

Federal Climate Change Legislation

Several Congressional bills have been proposed in recent years to regulate GHG emissions under a federal cap-and-trade program, but none have garnered enough support for passage by both the House of Representatives and the Senate. In June 2009, the U.S. House of Representatives took historic action with the passage of H.R. 2454: The American Clean Energy and Security Act of 2009, introduced by Representatives Waxman (D-CA) and Markey (D-MA), which set a goal of 17 percent below 2005 levels by 2020, 83 percent by 2050. The U.S. Senate considered a similar cap-and-trade bill, S. 1733: The Clean Energy Jobs and American Power Act, introduced by Senators Kerry (D-MA) and Boxer (D-CA), which set a goal of 20 percent below 2005 levels by 2020, 83 percent by 2050. Other legislative proposals have offered different approaches, such as the Carbon Limits and Energy for America's Renewal Act, introduced by Senators Cantwell (D-WA) and Collins (R-ME) that focused on a cap-and-dividend that would return a portion of auction revenues to consumers directly or the American Power Act, introduced by Senators Kerry and Lieberman (I-CT). In 2010, focus shifted to the U.S. EPA and the authority it has to regulate GHG emissions under the Clean Air Act (discussed in more details below). Subsequently, four bills were introduced in 2011 that would limit U.S. EPA's authority to regulate GHG emissions in varying degrees, but none were successful.

Federal Regulation of Greenhouse Gases Under the Clean Air Act

In the absence of federal legislation, GHG emissions may still be regulated through the U.S. EPA through its authority under the Clean Air Act. In April 2007, the Supreme Court ruled in *Massachusetts v. EPA* that the U.S. EPA must make a determination when it comes to regulating motor vehicle emissions. The Supreme Court ruling gives the U.S. EPA the authority to regulate GHGs under the Clean Air Act for mobile and stationary sources. On December 7, 2009, the U.S. EPA Administrator signed two distinct findings regarding GHGs under section 202(a) of the Clean Air Act:

- Endangerment Finding: The Administrator found that the current and projected concentrations of the six key well-mixed GHGs--carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6)--in the atmosphere threaten the public health and welfare of current and future generations.

AR0071290

- Cause or Contribute Finding: The Administrator found that the combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG emissions which threatens public health and welfare.

In December 2009, U.S. EPA published its findings in the *Federal Register*, stating: "The Administrator finds that greenhouse gases in the atmosphere may reasonably be anticipated both to endanger public health and to endanger public welfare." The impacts of climate change that will cause harm to human health and welfare of current and future generations include but are not limited to: increased drought; more heavy downpours and flooding; more frequent and intense heat waves and wildfires; greater sea level rise; more intense storms; and harm to water resources, agriculture, wildlife, and ecosystems.

EPA Tailoring Rule for Regulating Stationary Sources under the Clean Air Act

The Environmental Protection Agency finalized its "Tailoring Rule," which establishes a phased timetable for implementing Clean Air Act permitting requirements for GHG emissions from large stationary sources. The rule provides that Prevention of Significant Deterioration (PSD) requirements will first apply to GHG emissions effective January 2, 2011. This initial phase will apply to new and modified facilities that would already be required to obtain PSD permits as a result of their non-GHG emissions, and whose construction will result in an increase in GHG emissions of at least 75,000 tons CO_{2e} per year. A second phase of the program will commence on July 1, 2011, and will impose PSD requirements on new facilities that emit at least 100,000 tons CO_{2e} per year, as well as modified facilities whose emissions will increase by at least 75,000 tons CO_{2e} per year. In addition to these PSD requirements, the Tailoring Rule sets comparable emission thresholds and timetables for new and existing facilities to obtain operating permits under Title V of the Clean Air Act. It is anticipated that LADWP's Scattergood generating station will be subject to the new permitting requirements under the EPA's Tailoring Rule insofar as the permit will be completed in the 2011 timeframe.

C.3.2 Western Climate Initiative (WCI)

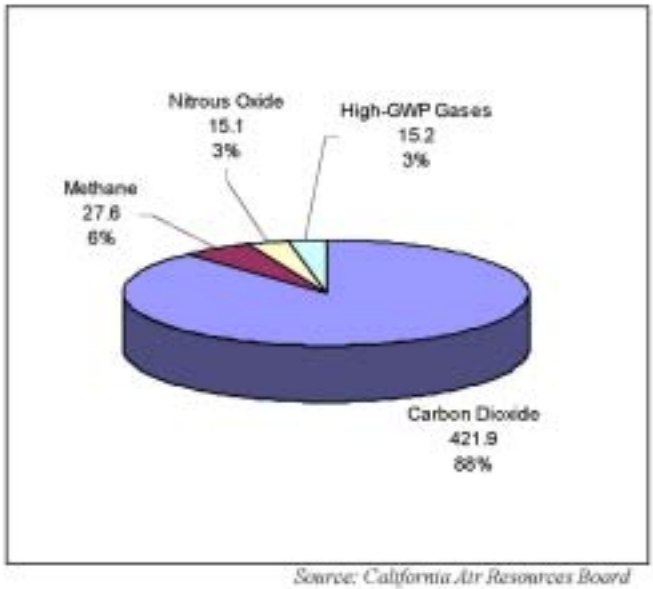
Originally established by the Western Governor's Association in February 2007, the WCI is currently a collaboration of California and four Canadian provinces (British Columbia, Manitoba, Quebec, and Ontario) to reduce GHG emissions 15 percent below 2005 levels by 2020 from their power generation, industrial, petrochemical, and transportation sectors. The primary mechanism for achieving this reduction would be through a regional cap-and-trade program.

The WCI finalized its design for a regional cap-and-trade program in July 2010. Under this plan, entities and facilities annually emitting 10,000 metric tons or more of the regulated GHGs, measured in CO_{2e}, will have to begin reporting their 2010 emissions in early 2011. Although the program is scheduled to begin in 2012, the jurisdictions that are expected to move forward have all indicated they will not be ready for compliance to begin until January 1, 2013. The first phase of the cap-and-trade program will cover power generation, including electricity imported into the WCI region, industrial fuel combustion, industrial processes, and petrochemical companies emitting 25,000 metric tons or more of CO_{2e} each year. The second phase will begin in 2015 and will cover emissions from transportation fuel use as well as residential and commercial fuel use. Before WCI jurisdictions will be able to trade allowances between each other, separate linkage agreements will be required that establish the conditions for interfacing between trading systems.

AR0071291

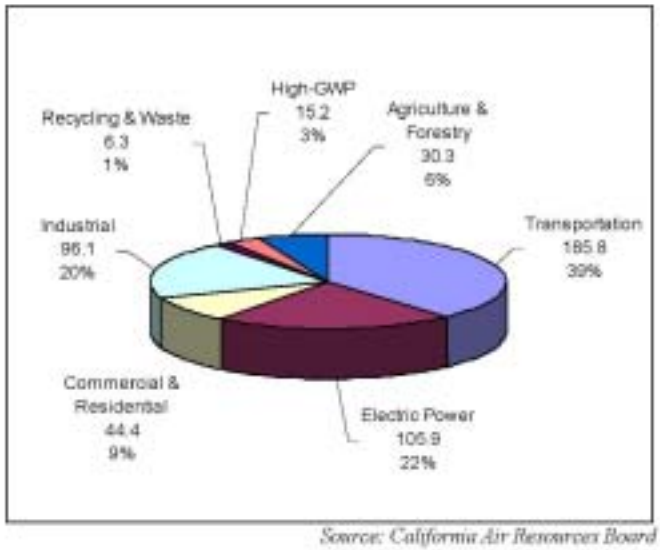
C.3.3 California Efforts to Address Climate Change

This section describes California's GHG emissions inventory and policies and actions to reduce GHG emissions. Figures C-3 and C-4 show California's 2006 statewide GHG emissions by pollutant and by sector.



Source: California Air Resources Board

Figure C-3. California GHG emissions by GHG (2006)



Source: California Air Resources Board

Figure C-4. California GHG emissions by sector (2006)

AR0071292

Based on the ARB's Update to the Scoping Plan (2011), the 2020 emissions baseline used in the 2008 Scoping Plan is 596 $MMTCO_{2e}$. This estimate of statewide 2020 emissions was developed using pre-recession 2007 IEPR data and reflects GHG emissions expected to occur in the absence of any reduction measures in 2010. ARB staff re-evaluated the baseline in light of the economic downturn and updated the projected 2020 emissions to 545 $MMTCO_{2e}$. Two reduction measures (Pavley I and the Renewables Portfolio Standard (12% - 20%)) not previously included in the 2008 Scoping Plan baseline were incorporated into the updated baseline, further reducing the 2020 statewide emissions projection to 507 $MMTCO_{2e}$. The updated forecast of 507 $MMTCO_{2e}$ is referred to as the AB 32 2020 baseline. Reduction of an estimated 80 $MMTCO_{2e}$ are necessary to reduce statewide emissions to the AB 32 Target of 427 $MMTCO_{2e}$ by 2020.[1]

California Governor's Executive Order S-3-05

On the state level, Governor Schwarzenegger signed Executive Order #S-3-05 on June 1, 2005 which established the following GHG targets:

- By 2010, reduce emissions to 2000 levels
- By 2020, reduce emissions to 1990 levels
- By 2050, reduce emissions to 80 percent below 1990 levels.

California SB 1368: Greenhouse Gas Emissions Performance Standard

SB 1368 was signed into law on September 29, 2006 and requires the California Public Utilities Commission (CPUC) and the California Energy Commission (CEC) to establish a GHG emissions performance standard and implement regulations for all long-term financial commitments in baseload generation made by load serving entities (LSEs) including local publicly-owned electric utilities (POUs). The CPUC adopted its regulations for the investor-owned utilities and other LSEs in January, 2007. The CEC adopted similar regulations for POUs in August 2007. Strategies implemented by the CPUC and CEC under SB 1368 are expected to result in a combined GHGs emissions reduction of over 15 million metric tons (MMT) CO_{2e} by 2020. The GHG emissions performance standard is based on the emissions profile of combined-cycle, natural gas fired generating units. The CEC's regulations establish an emissions performance standard of 1,100 pounds (0.5 metric tons) of CO_2 per megawatt hour (MWh) of electricity. This standard was established in consultation with the CPUC and the CARB and is the same as the emissions performance standard adopted by the CPUC for the LSEs.

The broad objectives of these regulations are to internalize the significant and under-recognized cost of emissions and to reduce potential financial risk to California consumers for future emission control costs. Specifically, these regulations are intended to prohibit any LSE from entering into or renewing a long-term financial commitment for baseload generation that exceeds the GHG emissions performance standard, currently set at 1,100 pounds per MWh.

[1] ARB Status of Scoping Plan Recommended Measures.
http://www.arb.ca.gov/cc/scopingplan/status_of_scoping_plan_measures.pdf

AR0071293

These regulations would require POUs, within 10 days of making a long-term financial commitment in a baseload facility, to certify to the CEC that such a commitment complies with these regulations and provide back-up material to support such commitment. The regulations then provide for CEC review of these compliance filings and a determination of whether or not the commitment, and the underlying facility as described in the commitment, complies with these regulations. Additionally, the CEC may open an investigatory proceeding and gather additional information if it believes that covered procurements made by a POU do not comply with these regulations.

AB 32: The California Global Warming Solutions Act of 2006

In 2006, the California Legislature passed and Governor Schwarzenegger signed Assembly Bill 32, the Global Warming Solutions Act of 2006, which declared that global warming poses a serious threat to the economic well-being, public health, natural resources, and environment of California. It set into law a 2020 GHG emissions reduction goal that would require the reduction of statewide emissions of GHGs[2]. In 2007, the ARB established a 1990 statewide greenhouse gas emissions baseline of 427 MMT of carbon dioxide equivalent (CO_2e)[3] and adopted a regulation for mandatory emissions reporting from the most significant sources that contribute to statewide emissions, including all electricity consumed in the state as well as imported electricity. The 2020 target was set at the 1990 baseline level of 427 MMT CO_2e.

The AB 32 Scoping Plan

In December 2008, the CARB adopted the AB 32 Scoping Plan, which serves as California's blueprint for reducing greenhouse GHG emissions. Key elements of the AB 32 Scoping Plan's recommendations for reducing California GHG emissions to 1990 levels by 2020 include:

- Expanding and strengthening existing energy efficiency programs as well as building and appliance standards
- Achieving a statewide renewables energy mix of 33 percent
- Developing a California cap-and-trade program that links with other Western Climate Initiative partner programs to create a regional market system
- Expand use of Combined Heat and Power (CHP) by 30,000 GWh statewide
- Establishing targets for transportation-related GHG emissions for regions throughout California, and pursuing policies and incentives to achieve those targets.
- Adopting and implementing measures pursuant to existing State laws and policies, including California's clean car standards, goods movement measures, and the Low Carbon Fuel Standard.
- Creating targeted fees, including a public goods charge on water use, fees on high global warming potential gases, and a fee to fund the administrative costs of the state's long term commitment to AB 32 implementation.

[2] GHGs covered by AB 32 include the following: carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

[3] Carbon dioxide equivalent or CO_2e means the amount of carbon dioxide by weight that would produce the same global warming impact as a given weight of another greenhouse gas, based on the best available science, including from the Intergovernmental Panel on Climate Change.

AR0071294

All programs developed under AB 32 contribute to the reductions needed to achieve this goal, and will deliver an overall 15% reduction in greenhouse gas emissions compared to the "business-as-usual" scenario in 2020 if nothing was done at all. In 2010, the ARB made revisions to the expected 2020 emission reductions in consideration of the economic recession and the availability of updated information from development of measure specific regulations. ARB staff re-evaluated the baseline in light of the economic downturn and updated the projected 2020 emissions to 545 MMTCO$_2$e. Two reduction measures (Pavley I and the Renewables Portfolio Standard (12% - 20%)) not previously included in the 2008 Scoping Plan baseline were incorporated into the updated baseline, further reducing the 2020 statewide emissions projection to 507 MMTCO$_2$e. The updated forecast of 507 MMTCO$_2$e is referred to as the AB 32 2020 baseline. Reduction of an estimated 80 MMTCO$_2$e are necessary to reduce statewide emissions to the AB 32 Target of 427 MMTCO$_2$e by 2020.

Executive Order S-21-09

On September 15, 2009, Governor Schwarzenegger signed Executive Order S-21-09, which, among other things, ordered CARB to work with the Commissions to ensure that a regulation adopted under authority of AB 32 to encourage the creation and use of renewable energy sources shall build upon the RPS program developed to reduce GHG emissions in California and shall regulate all California publicly owned utilities, like LADWP. In addition, Executive Order S-21-09 provides that CARB may delegate policy development and implementation to Commissions, that CARB is to consult with the CAISO and other balancing authorities on impacts on reliability, renewable integration requirements and interactions with wholesale power markets in carrying out the provisions of Executive Order S-21-09, and that CARB is to establish the highest priority for those resources with the least environmental costs and impacts on public health that can be developed most quickly and that support reliable, efficient, and cost-effective electricity system operations including resources and facilities located throughout the Western Interconnection.

AB 32 Cap-and-Trade Regulation (Adopted October 20, 2011)

The cap-and-trade program is a key element in California's climate plan. The cap-and-trade program sets a statewide limit on sources responsible for 85 percent of California's greenhouse gas emissions, and establishes a price signal needed to drive long-term investment in cleaner fuels and more efficient use of energy. The program is designed to provide covered entities the flexibility to seek out and implement the lowest-cost options to reduce emissions. The program covers about 350 businesses, representing 600 facilities and it starts in 2013 for electric utilities and large industrial facilities, while distributors of transportation, natural gas and other fuels join in 2015. The ARB expects to link with similar trading programs in the four Canadian provinces of British Columbia, Manitoba, Quebec and Ontario on or after 2013. Starting in 2013, the cap starts at about 2 percent below the emissions level forecast for 2012 and declines about 2 percent in 2014. From 2015 to 2020, the cap trajectory declines about 3 percent annually from 2015 to 2020.

Although the program commences on January 1, 2012, compliance and enforcement with the program is delayed until January 1, 2013, with the first auctions scheduled for August and November 2012. At the time the ARB Board adopted the cap-and-trade regulation, the Board

AR0071295

directed staff to address several key outstanding issues as part of a new rulemaking scheduled to take place in 2012 that will ultimately make further refinements to the program before compliance begins. Two of those issues that LADWP will focus on in 2012 include the provisions surrounding resource shuffling and point of regulation for electricity imports. The resource shuffling provision has potential implications for LADWP's coal transition as it relates to Navajo Generating Station if divestiture is not recognized by ARB as an emission reduction. The point of regulation for electricity imports was changed by ARB staff from the entity that owns the power being imported to California to the entity that schedules the power into California. LADWP will continue to work with other utilities and the ARB to better understand the potential implications this may have on reporting of specified electricity imports (high-emitting as zero-emitting electricity) by parties that do not retain ownership of that power.

C.3.4 The City of Los Angeles GREEN LA Plan

On May 15, 2007, Los Angeles Mayor Antonio Villaragosa released the "GREEN LA – An Action Plan to Lead the Nation in Fighting Global Warming" (GREEN LA Plan) that has an overall goal of reducing the GHG emissions by 35 percent below 1990 levels by 2030. This goal exceeds the targets set by both California and the Kyoto Protocol and is the greatest reduction target of any large U.S. city. Key strategies listed in the GREEN LA Plan related to energy and water include the following:

Energy

Green the Power from the Largest Municipal Utility in the United States

- Meet the goal to increase renewable energy from solar, wind, biomass, and geothermal sources to 20 percent by 2010.
- Increase the efficiency of natural gas-fired power plants.
- Increase biogas co-firing of natural gas-fired power plants.

Make Los Angeles a Worldwide Leader In Green Buildings

- Establish a comprehensive set of green building policies to guide and support private sector development designed to reduce carbon dioxide emissions by 80,000 tons by 2012. Approved on April 22, 2008, the Private Sector Green Building Plan makes Los Angeles the largest city in the nation to adopt such a plan.
- Implement other related Green Buildings efforts. For example, (e.g., all City-owned buildings over 7,500 square feet will be required to meet LEED Silver Standards). Other efforts, including the adoption of respective ordinances and updating of applicable building codes, will enable the City of Los Angeles to transform its building stock in both the public and private sector thereby facilitating all buildings to operate in a more energy efficient manner consistent with technological innovations and economic incentives whenever possible.

AR0071296

Transform Los Angeles Into the Model of an Energy Efficient City

- Reduce energy use by all City departments to the maximum extent feasible
- Complete energy efficiency retrofits of all City-owned buildings to meet a 20 percent or more reduction in energy consumption.
- Install the equivalent of 50 "cool roofs" per year by 2010 on new or remodeled City buildings
- Install solar heating for all City-owned swimming pools
- Improve energy efficiency at drinking water treatment and distribution facilities. Maximize energy efficiency of wastewater treatment equipment
- Replace 140,000 conventional street lights with Light emitting diode (LED) green street lights, reducing carbon emissions by 40,500 tons per year and saving the city $10 million annually

Help Angelenos Be "Energy Misers"

- Distribute two compact fluorescent light (CFL) bulbs to each of the 1.2 million households in the City
- Increase the level and types of customer rebates for energy efficient appliances, windows, lighting, and heating and cooling systems.
- Increase the distribution of energy efficient refrigerators to qualified customers
- Create a fund to "acquire" energy savings as a resource from LADWP customers

Water

- Decrease Per Capita Water Use
- Meet all additional demand for water resulting from growth through water conservation and recycling.
- Reduce per capita water consumption by 20 percent.
- Implement the City's innovative water and wastewater integrated resources plan that will increase conservation and maximize use of recycled water, including capture and reuse of storm water.
- Meet city directives and ordinances with respect to water conservation. Monitor technological improvements with respect to equipment, appliances, and engineered systems that would reduce the water consumption of various buildings and related need to adopt relevant ordinances and update municipal codes consistent with cost-effective technology available in the marketplace

C.3.5 LADWP's Efforts To Address Climate Change

Since 1998, LADWP has taken steps to move away from dependence on coal generating resources, including the divestiture of power purchase agreements with Colstrip and Coronado Generating Stations, the shutdown of Mohave Generating Station in December 2005, and the discontinuation of involvement in the development of Unit 3 at Intermountain Generating Station. Table C-1 shows the downward trajectory in LADWP's power generation portfolio CO_2 emissions and CO_2 emissions intensity between 1990 and 2008.

Table C-1. HISTORICAL LADWP POWER GENERATION CO_2 EMISSIONS

Year	Total CO_2 Emissions from Owned & Purchased Generation (metric tons)	Total CO_2 Emissions from Owned & Purchased Generation minus Wholesale Power Sales (metric tons)	Total Owned & Purchased Generation (MWh)	LADWP System CO_2 Intensity Metric (lbs CO_2/MWh)
1990	17,925,410	17,764,874	25,481,532	1,551
2000	18,464,480	16,992,238	28,806,750	1,413
2001	18,086,034	16,663,305	28,032,375	1,422
2002	16,873,841	16,237,832	26,808,569	1,388

Notes:
1. Calculated CO_2 emissions using fuel data and fuel-specific emission factors from the California Registry's reporting protocols.
2. Used source specific data where available, and 1100 lbs CO_2/MWh for unspecified power purchased.

SF6 Emissions

In February 2010, CARB adopted a new regulation to reduce SF6 emissions from gas insulated electrical switchgear as part of the AB 32 program. This new regulation, which is scheduled to take effect starting Jan 1, 2011, imposes a declining limit on a utility's annual average SF6

AR0071298

emissions rate starting at 10 percent in 2011 and decreasing to 1 percent in 2020, as well as new recordkeeping and reporting requirements.

Over the past decade, LADWP has been proactive in reducing SF6 emissions by implementing its own internal program to reduce emissions through equipment replacement, repair, and process improvements. As a result, LADWP's 2008 SF6 emissions rate was slightly under 1 percent. This voluntary effort to reduce SF6 emissions demonstrates LADWP's commitment to environmental stewardship and puts LADWP in a good position to comply with the new emission limits imposed by the SF6 regulation.

LADWP's Historical Accomplishments in Reducing GHG Emissions

In 1995, LADWP signed a Climate Challenge Participation Accord with the U.S. Department of Energy (DOE), voluntarily committing to reduce GHG emissions from power generation to keep LADWP's average CO_2 emissions from 1991 - 2000 below its 1990 baseline. LADWP achieved this goal. In addition, LADWP voluntarily participated in DOE's EIA-1605b "Voluntary Reporting of Greenhouse Gases" program from 1995 – 2005, annually reporting CO_2 emissions from power generation as well as programs to reduce emissions.

In 2000, LADWP set a new goal in its Integrated Resource Plan to reduce GHG emissions five percent below 1990 levels by 2008. LADWP exceeded this goal (actual 2008 power generation portfolio CO_2 emissions were 9.3 percent lower than our 1990 baseline).

In 2002, LADWP became a charter member of the California Climate Action Registry, and has since reported and certified eight annual entity-wide GHG emissions inventories with the Registry.

C.3.6 LADWP Programs and Projects to Reduce CO_2 Emissions

Since 1990, LADWP has undertaken numerous programs to reduce CO_2 emissions. Tables C-2 and C-3 below show the variety of LADWP's emission reduction programs and reductions achieved.

AR0071299

Table C-2. EMISSION REDUCTION PROGRAMS

Years	Program	Description	Cumulative CO_2 Emissions Avoided or Sequestered (short tons)
Renewable Energy			
2004-2008	Renewable Energy	LADWP's goals are to achieve 20% RPS by 2010 and 35% RPS by 2020.	3,521,102
Water Conservation			**3,129,099**
1991-2008	Water Conservation Program	Encourage customers to conserve water with rebates for installing hardware such as ultra-low-flush toilets and low-flow shower heads, a rate structure that rewards conservation, and public education.	Hardware: 1,771,814 Behavior: 1,311,324 3,083,139
1999-2008	High efficiency clothes washers	Rebates for purchase of energy efficient residential & commercial clothes washers.	45,960
Energy Efficiency			**1,738,544**
1999-2008	Refrigerator Replacement	Sale of high efficiency refrigerators at discount prices to multi-family residential units and non-profit organizations that are DWP customers, and removal & recycling of old refrigerators.	27,606
1999-2008	Commercial Lighting	Incentives for small commercial customers to install lighting equipment that exceeds Title 24 standards.	935,781
1999-2008	HVAC Replacement	Incentives for small commercial customers to install HVAC equipment that exceeds Title 24 standards. Expanded to include residential HVAC units from 2000-2002.	236,440
2000-2008	Chiller Replacement	Incentives for businesses and hospitals to install new high-efficiency water or air-cooled chillers that exceed Title 24 standards.	285,894
2002-2008	Consumer Rebate	Rebates to residential customers for purchase & installation of Energy Star appliances, lighting, windows, and HVAC.	105,737
2004-2008	Refrigerator Retirement	Free pick-up and recycling of old spare refrigerators for residential customers.	54,164
2004-2008	CFL Distribution	Free compact florescent light bulbs to residential customers.	42,818
2006-2008	Non-Residential Refrigeration	Rebates for non-residential customers to improve the energy efficiency of refrigeration equipment, reduce energy consumption in cold storage facilities, and install high efficiency refrigerated cases and equipment.	4,142

AR0071300

Table C-2. EMISSION REDUCTION PROGRAMS

Years	Program	Description	Cumulative CO_2 Emissions Avoided or Sequestered (short tons)
(Continued from page C-15)			
2006-2008	Small Business Direct Install	Provide free energy assessments, recommend lighting improvements, and install lighting upgrades to assist small business customers become more energy efficient.	30,001
2007-2008	New Construction	Incentives for building to LEED or CHPS 2006 standards, or for installing equipment from an approved list of energy efficient products.	133
2007-2008	Custom Performance	Incentives for non-residential customers to install energy saving measures, equipment or systems that exceed Title 24 or minimum industry standards such as equipment controls, industrial processes and other innovative energy saving strategies.	15,826
Digester and Landfill gas-to-energy			**1,152,479**
1995-2008	Scattergood	Burn digester gas from Hyperion Wastewater Treatment Plant at Scattergood Generating Station to generate electricity.	1,139,881
2002-2007	Lopez Canyon	Burn landfill gas in micro turbines at Lopez Canyon Landfill to generate electricity.	12,599
Recycling			**159,034**
1998-2008	Recycling Program	Recycling of paper, cardboard, metals and other materials from LADWP facilities.	440,136
Electricity Generation & Distribution System			**61,497**
1999-2008	Solar Power	LADWP's Solar Power Program includes: • Customer systems (net metered) • LADWP and City facilities (grid connected).	61,497
Tree Planting (Urban Forestry)			**195,545**
1998-2008	Cool Schools	Planted 9274 trees (cumulative) at LA Unified School District campuses.	48,187
2001-2008	Trees for a Green LA	Distributed 114,427 trees (cumulative) for planting around customer homes and in community areas.	138,793
2007-2008	Million Trees LA	Distributed 23,958 trees (cumulative) for planting around the City of Los Angeles.	8,565
Miscellaneous			**3,638**
2000-2008	Energy Star Office Equipment	Use of Energy Star office equipment (computers & monitors, printers, copiers and FAX machines).	3,638
Total CO_2 Emissions Avoided / Sequestered (Current Programs)			**6,436,197**

AR0071301

Table C-3. COMPLETED / DISCONTINUED PROGRAMS FOR EMISSION REDUCTION

Years	Program	Description	Cumulative CO_2 Emissions Avoided or Sequestered (short tons)
Energy Efficiency			**175,526**
1999-2001	Neighborhood Bill Reduction Service	Provide free CFLs, clean refrigerator condenser coils, distribute low-flow shower heads & aerators, and check for toilet leaks for residential low income customers.	154,108
1999-2001	Commercial Refrigeration Tune-up	Free audits and tune-ups of refrigeration equipment for small commercial customers.	3,856
2000-2002	HVAC Tune-up	Low cost tune-ups of A/C equipment for commercial and residential customers.	17,510
2005	Efficient Motors	Incentives for commercial & industrial customers to install premium efficiency electric motors.	52
Building Energy Efficiency Retrofits			**101,056**
1999-2004	John Ferraro Building Lighting Retrofit	Eliminated 50% of the light fixtures, replaced the remaining fixtures with energy efficient equipment, and installed automatic lighting controls in LADWP's corporate office building.	89,220
2001-2002	Cool Roofs	Incentives to install Energy Star roofing product on commercial or multi-family residential buildings (state funded).	4,164
2001-2004	Reflective Window Film	Incentives to install reflective film on windows to reduce building solar heat gain and reduce A/C load.	3,848
2004-2005	City Building Retrofit	Retrofit 37 City of LA facilities with energy efficient lighting.	2,604
2006	City Energy Efficiency Loan	Loans to other city departments to implement energy efficiency measures.	1,220
Electricity Generation & Distribution System			**9,266**
1996-2005	Energy Efficient Transformers	1592 Energy Star transformers were purchased in 1995 & installed in LADWP's distribution system.	9,266
Total CO_2 Emissions Avoided (Completed Projects / Discontinued Programs)			**297,610**

AR0071302

Additional actions and changes in LADWP's generation resource mix from 1990 to 2009 include

- Replacement of two steam generators in each of Palo Verde Nuclear Generating Station's (PVNGS) three generating units, to provide for the continued use of the units to the end of their projected 40-year life and possibly through their 20-year extended life. The project began in 2003 and was completed in 2007. The replacement of the steam generators and the turbine rotors resulted in an increase in power output of approximately 210 MWs for PVNGS.
- The seven units of the Castaic Pump Storage Power Plant (Castaic Plant) are currently being rotated out of service for modernization. This multi-phase process, began in 2004 and is expected to continue through 2013. To date, modernization to five units have been completed. The refurbishment is projected to increase the efficiency of the units and add up to 80 MWs of capacity to the Castaic Plant.
- Certain IPP participants have a right under the IPP Excess Power Sales Agreement to recall from LADWP up to 38.2 percent of the capacity of IPP (currently equal to approximately 327 MWs) for defined future summer or winter seasons or both, following no less than 45 days notice and up to 43 MWs of such capacity on a seasonal basis following no less than 90 days notice. Such participants are currently recalling 48 MWs of winter season capacity from LADWP. Future capacity of IPP subject to recall from LADWP under the Excess Power Sales Agreement can vary.
- Recent drought conditions and low lake levels have reduced the LADWP's capacity entitlement at the Hoover Plant from 491 MWs of capacity (calculated based on 25.15 percent of 1,951 MWs of total contingent capacity) to an annual average of approximately 431 MWs (calculated based on 25.16 percent of 1,634 MWs annual average output capability). Future available capacity from Hoover Plant will depend on future drought condition.
- The LADWP Power RPS Policy was established to increase the amount of energy LADWP generates from renewable power sources to 20 percent of its energy sales to retail customers by 2010 and 33 percent renewable energy by 2020. Acquisitions of the renewable energy are based on a competitive bidding process through the issuance of Requests for Proposals. To date, renewable projects in-service or under construction, provide a total of 5,300 gigawatt per hour (GWh) of renewable energy annually.
- The Power Reliability Program (PRP) is a comprehensive, long-term power reliability program developed by LADWP to replace aging infrastructure or make permanent repairs to generation, transmission and distribution infrastructure that has failed during recent outages. Through the program, LADWP plans to accelerate the management and replacement of transformers, poles, underground cables, underground vaults, station transformers, new distribution and receiving stations, and modifications to existing stations. LADWP also plans to install new control, integrated central monitoring and dispatch systems needed to facilitate reliable and secure system operations and modify its staff training programs and increase staffing.

AR0071303

- The LADWP continued its commitment to energy efficiency through numerous programs and services for customers to encourage the installation and use of energy efficient measures and equipment LADWP establish annual efficiency targets reducing total forecasted electricity consumption by 10 percent over the next 10 years. LADWP is on track to meet the requirements established under AB 2021. Since 2000, the LADWP energy efficiency programs have reduced long-term peak period demand and consumption by approximately 271.1 MWs and 894.1 GWh of energy savings. LADWP has budgeted funding for fiscal year 2009-10 to renew and expand its commitment to energy efficiency.
- LADWP offers its customers an opportunity to participate in the Green Power Program. "Green Power" is produced from renewable resources such as wind energy, geothermal, or other renewable resources, rather than conventional generating plants. Over 17,100 LADWP customers participated in the program during 2010. These participants receive approximately 104,000 MWh of renewable energy annually. Since program inception, in 1999, to the end of 2010, 818,768 MWh of renewable energy was procured, making it one of the largest voluntary green pricing programs in the nation.
- Completion of the Pine Tree Wind Project which is a 135 megawatt wind generating facility north of Mohave, California, consisting of 90 wind turbines The project began commercial operation on June 16, 2009.
- Numerous environmental laws and regulations, specifically those relating to air and water quality, affect the LADWP Power System's facilities and operations. LADWP monitors its compliance with laws and regulations and reviews its remediation obligations on an ongoing basis.

C.4 Power Plant Once-Through Cooling Water Systems

Power plants with "once-through cooling" (OTC) systems draw or take in water from coastal/estuarine water, via intake pipes, to cool turbines used to generate electricity. After the water is used for cooling it is discharged to a nearby water body. OTC systems can impact the marine environment.

LADWP has three coastal generating plants that utilize OTC. The new state wide OTC Policy and upcoming 316 b Federal Rule requires minimizing and/or reducing the impacts on marine life.

In order to reduce these impacts, LADWP has already implemented the following:

- In the 1970's LADWP installed a velocity cap (a large disk-shaped structure just upstream of the ocean water intake pipe) at its Scattergood Generating Station to control IM. In 2006, LADWP conducted an effectiveness study on its velocity cap and the results showed that it is 96% effective.

AR0071304

- To date, LADWP has reduced the number of power plant units that utilize OTC from 14 to 9, reducing ocean water use from 1934 MGD to 1571 MGD, an overall reduction of ocean water usage by 17%.

- LADWP has spent over $600 million dollars to replace the older generating units with more efficient generating units (known as "repowering") at its Haynes and Harbor Generating Stations. This has resulted in a reduced use of coastal waters.

To further reduce impacts and completely eliminate OTC, LADWP plans to do the following:

- As a result of the Haynes 5&6 repowering project, reduce the number of OTC units to 7 by 2013. This will decrease ocean water use from 1571 MGD to 1110.2 MGD, an overall reduction of 42%, from 1990 ocean water usage levels.

- As a result of the Scattergood 3 repowering project, further reduce the number of OTC units to 6 by 2015, decreasing ocean water use from 1110.2 MGD to 830.8MGD, an overall reduction of 56% from the original ocean water usage level.

- As a result of the Scattergood 1&2 repowering project, further reduce the number of OTC units to 4 by 2020, decreasing ocean water use from 830.8 MGD to 503.1MGD, an overall reduction of 70% from the original ocean water usage level.

- As a result of the Haynes 1&2 repowering project, further reduce the number of OTC units to 2 by 2024, decreasing ocean water use from 563.3 MGD to 338.7 MGD, an overall reduction of 82%, from the original ocean water usage level.

- By 2020, further reduce of the number of OTC units to 1, decreasing ocean water use from 338.7 MGD to 231 MGD, an overall reduction of 87% from the original ocean water usage level.

- By 2029, final reduction of OTC units to 0, 100% elimination of OTC.

Figure C-5 shows LADWP's reduction in OTC usage from 1990 to 2029.

AR0071305

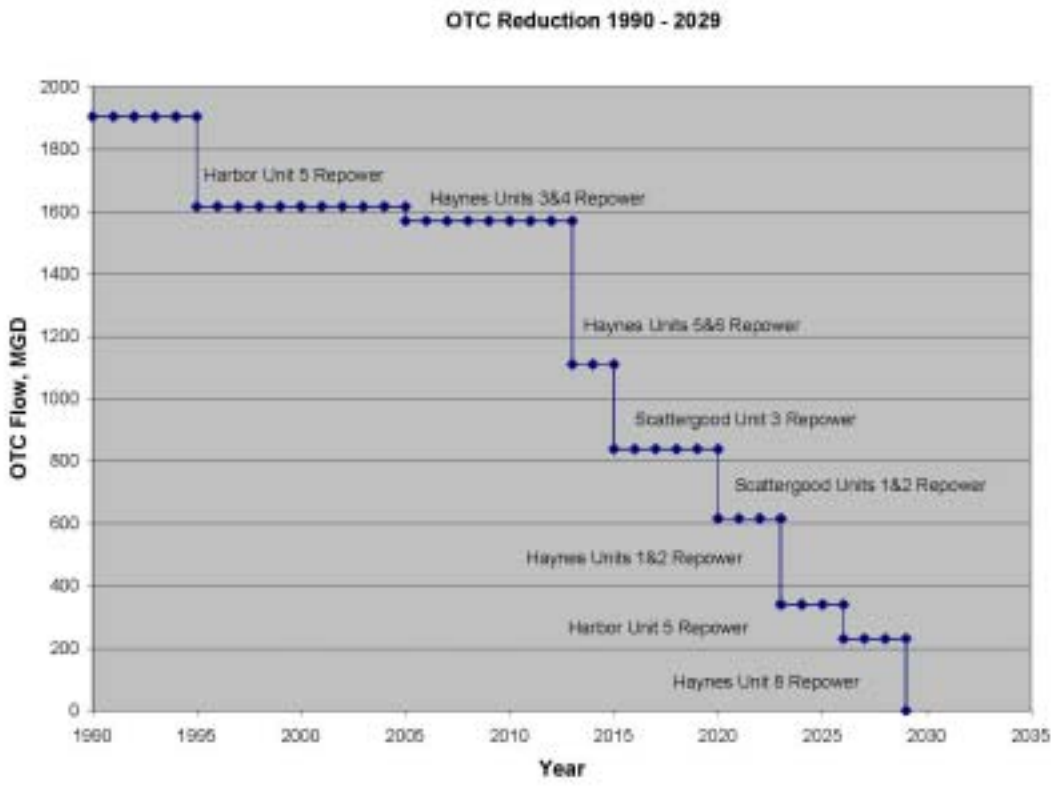

Figure C-5: LADWP OTC reduction from 1990 to 2029.

C.4.1 USEPA 316(b) Requirements for Cooling Water Intake Structures

EPA's Clean Water Act Section 316(b) Phase II Cooling Water Intake Structure Rule (Rule) released in 2004 was subsequently challenged and ultimately heard in both the Second Circuit Court and in the U.S. Supreme Court. The Second Circuit Court issued its decision on January 25, 2007, and determined that the restoration and cost-benefit elements of the original 2004 Rule were unlawful and that other fundamental components of the 2004 Rule, such as the impact reduction performance standards attainable for certain technologies, were to be remanded for further evaluation and demonstration by U.S. EPA. The U.S. Supreme Court was subsequently asked to weigh in on the ability to use the "wholly disproportionate" cost-benefit test in the application of the 316(b) regulations. On April 1, 2009, the Supreme Court affirmed that a cost-benefit analysis can be used by regulatory agencies. While the various challenges proceeded through the court processes, U.S. EPA gave the states permission to continue with implementation and enforcement of the Clean Water Act 316 (b) requirements using "Best Professional Judgment (BPJ) when reauthorizing facility National Pollutant Discharge Elimination System (NPDES) permits.

During this period, LADWP completed the required Characterization Study to identify baseline biological impacts in order to determine an appropriate impingement mortality (IM) and entrainment (E) reduction method. However, when the Rule was remanded to U.S. EPA to

AR0071306

re-study and then re-propose a rule, it essentially placed remanded Rule and the fulfillment of its associated requirements on hold. At that point, LADWP stopped any further work necessary to comply with the suspended Rule and has been awaiting the outcome of U.S. EPA's effort to re-propose a new rule. The UP EPA publicly noticed the new proposed Rule for existing facilities on April 19, 2011 and the comment period ended on August 18, 2011. The UP EPA is targeting the end of 2012 to finalize its Rule. The use of BPJ by permitting authorities is still in effect.

C.4.2 SWRCB 316(b) Requirements for Cooling Water Intake Structures

On June 30, 2009, the SWRCB released its draft Once-Through Cooling Water Policy for public review and comment, with the accompanying Supplemental Environmental Document released on July 14, 2009. Comments were due September 30, 2009. Subsequent policy drafts were issued on November 23, 2009 and March 22, 2010 with corresponding comment periods. The final Policy version was adopted on May 4, 2010 and became effective on October 1, 2010. The adopted Policy has major implications for the coastal power plants making it extremely difficult to continue the use of OTC retrofitted with IM and E impact control technology; making the use of cooling towers the only certain compliance path. The Policy proposes a two-track compliance pathway. Track I requires OTC flows to be reduced commensurate with wet closed cycle cooling (CCC) or a 93 percent flow reduction and essentially requires the installation of cooling towers. If Track I can be demonstrated as "not feasible" a Track II compliance option is available. A Track II compliance pathway requires the biological impacts to be reduced on a unit by unit basis to a level comparable with (i.e., within 10 percent) what would exist with CCC. New consecutive 36-month IM and E baseline studies will be required if a Track II compliance pathway is pursued. Until compliance is achieved, interim measures are required, which include flow reductions when there is no unit load and mitigation measures (commencing five years from the effective date of the policy and continuing until the facility is in full compliance). Lastly, to prevent disruption in the state's electrical power supply during implementation of the Policy, a committee of state energy and resource agencies know as the Statewide Advisory Committee on Cooling Water Intake Structures (SACCWIS) will assist the SWRCB in reviewing the required utility implementation plans and in monitoring the schedules.

LADWP's implementation plan was the first plan to be reviewed by the SWRCB and SACCWIS. As a result, the SWRCB prepared and adopted an Amendment to the Policy on July 19, 2011. This Amendment modified LADWP's compliance schedule on a unit-by-unit basis with the following compliance dates ::12/31/2013 for Haynes Units 5&6; 12/31/2015 for Scattergood Unit 3; 12/31/2024 for Scattergood Units 1&2; 12/31/2029 for Haynes Units 1&2 and 8, and Harbor Unit 5. In addition, the Amendment requires LADWP to submit any additional information requested, by January 1, 2012, by the SACCWIS and submit the information responsive to SACCWIS to the SWRCB by December 31, 2012 in order for the SWRCB to evaluate whether further modifications to the dates are necessary. Furthermore, LADWP must commit to complete elimination of OTC and in the interim conduct a study or studies, singularly or jointly with other facilities, to evaluate new technologies or improve existing technologies to reduce impingement and entrainment. LADWP must submit the results of the study and a proposal to minimize entrainment and impingement to the Chief Deputy Director no later than December 31, 2015, and upon approval of the proposal by the Chief Deputy Director, complete implementation of the

AR0071307

proposal no later than December 31, 2020. LADWP is in the process of commencing these studies and has begun the Haynes Units 5&6 repowering project in order to meet the 2013 deadline. Also, the conceptual planning and design for the Scattergood Unit 3 has commenced in order to meet the 2015 deadline.

C.5 Mercury Emissions

Mercury emissions are an issue for all coal fired power plants. However, the level of such emissions varies widely based on the type of coal burned and the type of emission controls on the plants.

Coal-burning power plants are the largest human-caused source of mercury emissions to the air in the United States, accounting for over 40 percent of all domestic human-caused mercury emissions. The EPA estimates that about 1/4 of U.S. emissions from coal-burning power plants are deposited within the contiguous U.S., and the remainder enters the global cycle.

The IGS in Utah, of which LADWP is the Operating Agent, has one of the lowest mercury emission rates in the country. This is due to the fact that the existing emission control devices, which are designed to reduce sulfur dioxide and particulate matter, have the co-benefit of removing about 96 percent of the mercury from bituminous coal which is burned at IGS.

On March 15, 2005 U.S. EPA promulgated the Clean Air Mercury Rule (CAMR), which established a nationwide cap-and-trade program for mercury emissions. CAMR was designed to reduce mercury emissions by 60 percent between 2010 and 2018. Several legal challenges of the CAMR ensued. As a result, the D.C. Circuit vacated U.S. EPA's Clean Air Mercury Rule on February 18, 2008. On May 3, 2011, EPA proposed NESHAPs for coal- and oil-fired EGUs under Clean Air Act (CAA) section 112(d) and proposed revised NSPS for fossil fuel-fired EGUs under CAA section 111(b). The proposed NESHAP would protect air quality and promote public health by reducing emissions of the hazardous air pollutants (HAP) listed in CAA section 112(b). In addition, these proposed amendments to the NSPS are in response to a voluntary remand of a final rule. EPA was scheduled to finalize its rule by December 2011.

C.6 Coal Combustion Residuals

On May 4, 2010, the U.S. Environmental Protection Agency released pre-publication co-proposals to regulate the management of coal ash from coal-fired power plants.

Coal combustion residuals (CCRs), commonly known as coal ash, are byproducts of the combustion of coal at power plants and are typically disposed of in liquid form at large surface impoundments and in solid form at landfills, most often on the properties of power plants. There are almost 900 landfills and surface impoundments nationwide.

Due to the metal constituents of the CCRs, EPA's co-proposals will establish control measures, such as liners and groundwater monitoring, which would be in place at new landfills to protect groundwater and human health. Existing surface impoundments would also require liners, with incentives to close the impoundments and transition to landfills, which store coal ash in dry form.

AR0071308

The proposed regulations may change the way CCRs are handled and stored at Intermountain Power Plant and Navajo generating station. If implemented, the rules would require the phase-out of wet handling systems and surface impoundments of bottom ash and the subsequent permitting and installation of lining under fly ash landfills. The facilities would have to conduct additional groundwater monitoring, and provide closure and post closure care of the surface impoundments and landfills. For Mohave generating station, the rules, as proposed are expected to have minimal impacts because the facility did not operate any surface impoundment.

AR0071309

Appendix D Renewable Portfolio Standard

D.1 Overview

LADWP has historically maintained that its major objectives concerning integrated resource planning are; (1) providing reliable service to its customers; (2) remaining committed to environmental leadership; and (3) maintaining a competitive price.

Since its 2007 IRP, LADWP has made great strides towards achieving the 2010 goal of increasing its supply of electricity from "eligible" renewable resources to 20 percent, measured by the amount of electric energy sales to retail customers, and has met the 20 percent goal for calendar year 2010.

On April 12, 2011, the California governor signed into law the Senate Bill 2 (1X) which extends the 20 percent target to 2013, and ramps up the target to 25 percent by December 31, 2016 and 33 percent by December 31, 2020.

On December 6, 2011, the LADWP Board approved the Renewables Portfolio Standard Policy and Enforcement Program and is included in Reference D-1 and D-2.

This 2011 IRP documents how LADWP expects to maintain 20 percent renewable energy and describes the process for LADWP's continuing commitment to increase the renewable energy goal to 25 percent by 2016 and 33 percent by 2020. Additionally, LADWP will continue to encourage voluntary contributions from customers to fund renewable resources above the stated Renewable Portfolio Standard (RPS) goal, as part of its Green Power for a Green LA Program (GREEN).

D.2 Renewable Energy Requests for Proposals (RFPs)

To help meet the renewable energy goals for the GREEN Program and the RPS policy, LADWP has issued four major Request for Proposals (RFP) for renewable energy projects: January 2001, June 2004, January 2007, and March 2009. LADWP performed detailed technical and economic analysis of the proposals on a least-cost, best-fit basis. This approach considered factors such as cost, technical feasibility, project status, transmission issues, and environmental impact.

Separately, the Southern California Public Power Authority (SCPPA), of which LADWP is a member, has issued five RFPs for renewable energy projects.

D.2.1 2001 Renewable RFP

In response to the 2001 RFP, a total of 21 projects were proposed. The 120 megawatts (MW) Pine Tree wind project met LADWP's renewable, economic, technical and least-cost, best fit criteria. The Pine Tree wind project is an eighty-turbine wind farm facility located in the

AR0071311

Tehachapi area, and is owned and operated by LADWP. This project was put in-service in June 2009.

The Pine Tree wind farm was expanded with ten new wind turbines that added 15 MW, for a total of 135 MW. The expansion was completed in 2011.

D.2.2 2004 LADWP Renewable RFP and the 2005 SCPPA Renewable RFP

In June 2004, LADWP issued another RFP with the intent of securing an increased portion of its power requirements from renewable resources. The goal of LADWP's 2004 RFP was to obtain about 1,300 gigawatts hours (GWhs) per year of renewable energy per year to meet the then RPS interim goal of 13 percent by 2010. A total of 57 distinct proposals were received, covering nearly all types of renewables, although wind and geothermal represented the largest share of proposed energy. Most of the proposals were from new California projects, with only a few actually located in Los Angeles. The proposals offered a mix of power purchase and ownership options.

To ensure fairness and consistency during the evaluation process of the 2004 RFP, the evaluation team included two independent entities. The team evaluated proposals through a structured process consisting of two phases. The Phase 1 evaluation included completeness and requirements screening, a technical and commercial evaluation, and an economic assessment. Proposals short-listed were then evaluated in greater detail in the Phase 2 evaluation, which included a comparison of Net Levelized Cost (NLC). The NLC of each proposal equals the levelized busbar cost of energy, in units of $/MWh, less the avoided energy and capacity costs, and adding the levelized transmission costs to cover wheeling, losses, transmission upgrades, etc.

In 2005, the Southern California Public Power Agency (SCPPA), of which LADWP is a participant, also issued an RFP for renewable resources.

Five contracts for renewable energy resulting from the 2004 and 2005 RFPs have been entered into, which provide 1,179 GWhs/yr of renewable energy from landfills, small hydro and wind.

D.2.3 2006 SCPPA and 2007 LADWP Renewable RFPs

In 2006 SCPPA issued an RFP for renewable resources, in which LADWP participated.

In January 2007, LADWP issued another RFP with the intent of obtaining approximately 2,200 GWhs of renewable energy per year to meet the RPS goal of 20 percent by 2010. A total of 59 distinct proposals were received, covering wind, solar thermal, solar photovoltaic (PV), geothermal, and biomass renewable technologies. The proposals offered a mix of power purchase and ownership options.

Three contracts for renewable energy resulting from the 2006 and 2007 RFPs have been entered into, which provide 424 GWhs/yr of renewable energy from wind and small hydro projects. Several other proposals that were received are currently being negotiated.

AR0071312

D.2.4 2008 SCPPA and 2009 LADWP Renewable RFPs

In 2008 SCPPA issued an RFP for renewable resources, in which LADWP participated.

In March, 2009, LADWP issued a fourth RFP for Renewable Resources. The intent of this RFP was to obtain a sufficient amount of renewable energy per year to achieve the RPS goals, set by the Mayor, of 20 percent by 2010 and 35 percent by December, 31, 2020.

The 2008 RFP process resulted in two contracts, which provide 834 GWhs/yr of renewable energy from wind resources. Several other proposals that were received are currently being negotiated.

D.2.5 2011 SCPPA RFP

In January 2011, the Southern California Public Power Agency (SCPPA) also issued an RFP for renewable resources, in which LADWP participated. LADWP participated in the evaluations of the RFP proposals. LADWP evaluated proposals through a structured process. The evaluation included a completeness and requirements screening, a technical and commercial evaluation, and an evaluation of deliverability of the product. The evaluation also considered the Net Levelized Cost (NLC) for each proposal. The NLC of each proposal is equal to the levelized busbar cost of energy, in units of $/MWh, less the avoided energy and capacity costs, and adding the delivery cost to LADWP's load. Other factors were also considered, including: compliance with pending State renewable portfolio standard legislation, utility scale project experience, capacity, commercial operation date, and labor issues.

In August 2011, SCPPA issued another RFP for renewable resources. The response deadline is November 30, 2012.

D.3 Renewable Project Strategy

LADWP (and SCPPA) has increased its renewable energy through successful project development and completed agreement negotiations with multiple developers and project entities resulting from the above described RFPs. Existing renewable projects that supply LADWP are geographically diverse; wind energy comes from the ridges of the California Tehachapi Mountains, the north-central hills of Oregon, the southern Washington Columbia River Gorge area, the Milford Valley of Utah, and Southwestern Wyoming. Planning for future renewable energy will continue to emphasize geographic diversity, as well as technology diversity.

The variety of renewable energy projects and technologies facilitates the Power System capability to integrate renewable energy reliably. As described in other sections of the IRP, LADWP will maintain its Balancing Authority responsibility by addressing system issues such as reserve sharing, reserve commitments, system voltage support, spinning reserves, existing and future quick response combustion turbine response units, etc.

This IRP describes several fundamental principles for the RPS progression from the current 20 percent renewable energy to a potentially higher goal of 33 percent by 2020. Issues and principles affecting the future of the RPS plans are discussed below:

AR0071313

D.3.1 Issues

- The "Ramp Rate", i.e., the annual rate of progress from 20 percent to 33 percent renewables, will be subject to several factors. The time frame is 10 years, which would equate to a constant ramp of 1.33 percent per year. However, the projected ramp rate is not a straight line, but rather varies from year to year depending on factors both external and internal to the LADWP. These factors include SB 2 (1X) requirements, LADWP fiscal constraints, renewable energy technology improvement over time, renewable energy pricing, LADWP system integration limits, and transmission constraints, both in the LADWP systems and regionally.

- Steady investment in renewable resources is required to maintain a 20 percent RPS between 2010 and 2012 and to ramp to 33 percent between 2013 and 2020. There are several reasons for this path forward: Between 2010 and 2012, the projects maintaining the 20 percent RPS will become fully integrated into the system; reflecting 2010 economic conditions and allowing time for pricing adjustments and efficiencies of certain renewable industries such as solar PV to reach the marketplace. For budgeting and planning purposes, the assumed RPS implementation strategy is 1 percent annual RPS increases from 2013 thru 2015 and 2 percent from 2016 thru 2020. Of course, all of this strategy is dependent on adequate funding.

- Transmission limitations in several regions are constraining development activities. These constraints are being studied at regional, statewide, and Western Electricity Coordinating Council (WECC) levels and potential federal and state legislative actions will affect transmission availability. Further resource decisions are dependent on transmission availability and cost.

- Greenhouse Gas (GHG) and other climate change regulatory and legislative issues are pending. The eventual cap and trade methodology and market mechanisms that are implemented will influence RPS strategic and tactical decisions.

- Within the overall RPS plan, decisions as to specific projects, technologies, operational strategies, and project financial structures, will be made as the marketplace and regulatory environment change.

D.3.2 Principles

Future renewable projects will be strategically obtained with the following principles.

1. Geographic diversity is important to maintain and enhance power system reliability.

2. The use of existing LADWP assets such as transmission lines, land, and existing generation resources should be maximized.

AR0071314

3. Pursue multi-faceted development with adequate back-up strategies to handle project delays, project failures, reduced generation output, and operation or maintenance impacts.

4. Projects shall be targeted to specifically meet the Power System/Renewables Policy objectives.

5. Flexible RPS goals will be established to address the variable nature of renewable energy while conforming to applicable state and federal requirements

6. Ownership, operation, and maintenance are core objectives to maintain power system reliability and cost stability. The Power System is interested in owning projects that are based on proven technology.

7. Operation and maintenance (O&M) management is a key criterion in clustering renewable projects. Keeping projects in close proximity would reduce O&M costs due to economies of scale and personnel efficiencies.

D.3.3 Balancing Renewable Resources

Several of these principles may be overlapping or even conflicting. For example, clustering of renewable projects would decrease O&M expenditures, but too many projects in an area will not meet the needs for geographic diversity. Also, ownership goals may impact project costs and immediate availability. Obtaining tax credits and/or grants may necessitate the need for developers to own a project for a certain number of years (typically 7-10 years) to capture tax advantages; thereby lowering the ultimate cost to LADWP.

Subject to further studies, given the wind and solar projects coming on-line, limitations on the percentage of intermittent resources may be required. There may be more stringent limitation in certain resource areas, or along certain transmission systems. It is possible that no more than 15-20 percent intermittent energy can be ultimately integrated in the current electric grid. Of the 20 percent renewable energy consumed in 2010, less than $1/5^{th}$ of that amount was of an intermittent type. Most renewable resources are either small hydro or biogas having a predictable energy pattern or wind projects that have their energy output firmed and shaped by outside balancing authorities before delivery to LADWP. The total amount of intermittent energy obtained will not be increased beyond current levels unless studies demonstrate that these resources can be reliably integrated.

Wind, as shown elsewhere in this IRP, is a volatile renewable energy resource. It is recommended that LADWP's wind forecasting tools and meteorological analysis capabilities be enhanced to provide efficient integration of wind energy.

Similar studies will be required for solar projects coming on line in the next few years, and limitations of the percentage of solar will be required. Photovoltaic solar systems can have dramatic voltage changes, resulting from passing cloud cover and/or storms. Large installations of solar PV will likely need to be limited in size within a geographical area, unless it is coupled with solar thermal systems or energy storage systems.

AR0071315

The renewable energy mix of 2010 is shown on Figure D-1

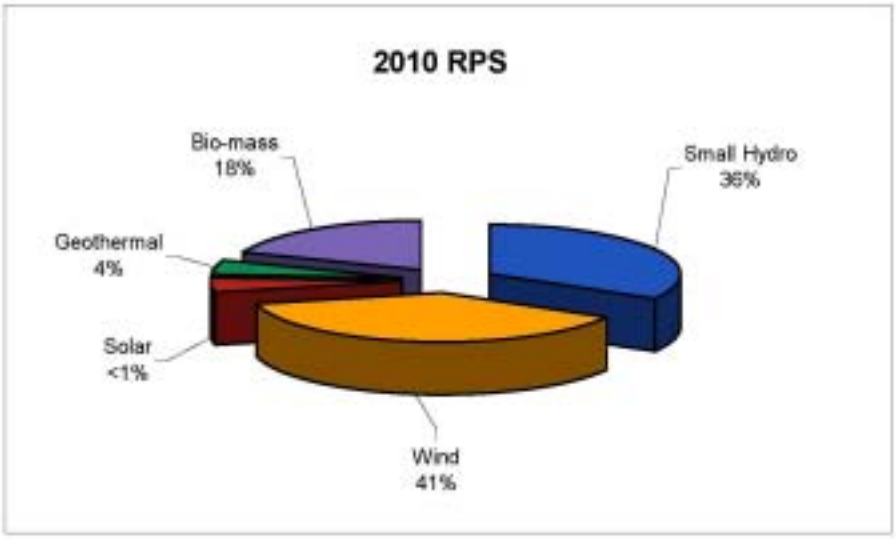

Figure D-1: 2010 Renewable Energy Mix

D.3.4 Impacts of CA Senate Bill SB 2 (1X)

On April 12, 2011, Governor Edmund G. Brown Jr. signed into law the California Renewable Energy Resources Act (herein referred to as "Act" or "SB 2 (1X)"). This Act sets new Renewable Portfolio Standard (RPS) procurement targets, new renewable resource eligibility definitions, and new reporting requirements applicable to Publicly Owned Electric Utilities (POUs). SB 2 (1X) becomes effective December 10, 2011, 90 days after the end of the special session in which it was enacted.

This bill expresses the intent that the amount of electricity generated from eligible renewable energy resources be increased to an amount that equals at least 20% of the total electricity sold to retail customers in California by December 31, 2013, 25% by December 31, 2016 and 33% by December 31, 2020. In addition, this bill requires POU governing boards to adopt a policy with similar goals imposed on IOUs to enforce the RPS Program on its respective utility.

According to the legislation, POU governing boards are directed to adopt "a program for the enforcement of this article" by January 1, 2012. As such, POU governing boards have discretion to interpret the following provisions:

- Procurement Target Goals
- Reasonable Progress to achieve such goals
- Procurement Requirements
- Rules to apply excess procurement for future compliance periods
- Conditions that allow for delaying timely compliance
- Cost limitations for procurement expenditures.

AR0071316

Resources obtained in compliance with SB 2 (1X) must meet the following criteria:

Category (aka "Buckets")	Percentage of RPS Target
1. Either: Have a first point of interconnection with a California balancing authority, have a first point of interconnection with distribution facilities used to serve end users within a California balancing authority area, or are scheduled from the eligible renewable energy resource into a California balancing authority without substituting electricity from another source [PUC Section 399.16(b)(1)(A)]. Or, have an agreement to dynamically transfer electricity to a California balancing authority. [PUC Section 399.16(b)(1)(B)]	**Compliance Period 1 (2011-2013):** 50% of RPS minimum from this category. **Compliance Period 2 (2014-2016):** 65% of RPS minimum from this category. **Compliance Period 3 (2017 to 2020):** 75% of RPS minimum from this category. **Post – 2020** 75% of RPS minimum from this category.
2. Firmed and shaped eligible renewable energy resource electricity products providing incremental electricity and scheduled into a California balancing authority. [PUC Section 399.16(b)(2)]	Shall be calculated as the remainder of resources which are not in either Category 1 or Category 3.
3. Eligible renewable energy resource electricity products or any fraction of the electricity generated, including unbundled RECs that do not qualify under Bucket 1 or 2. [PUC Section 399.16(b)(3)]	**Compliance Period 1 (2011-2013):** 25% of RPS maximum from this category. **Compliance Period 2 (2014-2016):** 15% of RPS maximum from this category. **Compliance Period 3 (2017 to 2020):** 10% of RPS maximum from this category. **Post – 2020** 10% of RPS minimum from this category.

The regulations promulgating this legislation by the CEC over POUs have not yet been finalized.

D.3.5 Renewable Energy Credits

The Public Utilities Code Section 399.12 (h) defines a Renewable Energy Credit (REC) as "a certificate of proof, issued through the accounting system established by the California Energy Commission…that one unit of electricity was generated and delivered by an eligible renewable energy resource." RECs include all renewable and environmental attributes, including avoided greenhouse-gas (GHG) attributes, associated with the production of electricity from the eligible renewable energy resource.

The primary method of renewable energy resource procurement will be through the development and acquisition of physical generation assets and energy purchase contracts, in which LADWP will acquire the "renewable energy credit" (REC) from the renewable resource "bundled" with the associated energy.

AR0071317

In order for RPS compliance targets to be managed effectively, LADWP may buy, sell, or trade RECs without the associated energy (unbundled). This procurement approach will be limited by the percentage requirements established by PUC Section 399.16(b)(3), and as described in the City of Los Angeles Department of Water and Power Renewable Portfolio Standard Policy and Enforcement Program, as amended on December 2011.

AR0071318

D.4 Transmission of Renewable Energy

California and many of the western states contain a variety of resources (wind, solar, geothermal, and other "eligible" resources previously defined in the RPS Policy) that can be developed to ultimately generate electricity. However, the current transmission system was not primarily designed with these natural resources in mind.

Even with the substantial existing transmission system owned by LADWP, and the other transmissions systems in California, there is only a limited amount of transmission lines to many of the potential renewable resource locations. In order to gain access to these sources of renewable energy, LADWP is planning on building additional transmission lines and expanding the capabilities of several existing lines, and utilizing transmission lines as part of renewable purchase power agreements. These projects include:

1. Barren Ridge Renewable Transmission Project (BRRTP) - Transmission access and transmission line upgrades are needed to accommodate proposed wind projects in the Tehachapi area and solar thermal projects in the Mojave Desert, which total nearly 1,000 MW. The initial project was the construction of the Barren Ridge substation which supports the 135 MW Pine Tree Wind project. This substation interconnects with LADWP's existing 230 kV Inyo-Rinaldi transmission line (which was built to gain access to the renewable hydro-generated energy from LADWP's aqueduct system in the Owens Valley). The Inyo-Rinaldi transmission capacity needs to be increased in order to accommodate additional renewable energy projects. A full Environmental Impact Report (EIR) process is currently underway on this project.
2. Related to the BRRTP project, the potential Owens Valley Solar projects may require further upgrades to the Inyo-Barren Ridge segment of this transmission line and a generation tie-line into the project area. Depending on ultimate solar build-out in the Owens Valley, additional new transmission may be required.
3. The joint Southern California Edison/Imperial Irrigation District upgrade of Path 42 is critical for delivery of renewable generation from the IID area into the California ISO. Upgrading Path 42 requires improvements to facilities under the control of SCE and the California ISO as well as facilities under IID control. The IID upgrades consist of replacing the 220 kV circuits between the Coachella Valley Substation and the Mirage Substation with bundled circuits, two conductors per circuit. The IID portion of the upgrades would increase the capacity of IID's portion of the path by around 800 MW and could be completed by the end of 2011. The total renewable potential for the California ISO/IID Path 42 upgrades is approximately 1,400 MW.

AR0071319

Figure D-2: Renewable Transmission Paths and Potential Resources, 2010 - 2030

AR0071320

D.5 Funding the RPS

For LADWP to develop a responsible and prudent renewable energy policy, it must balance environmental objectives such as fuel diversity, energy efficiency and clean air against its core responsibility to provide and distribute safe, reliable, and low-cost energy to its customers. That means developing a RPS that ensures LADWP's continued financial integrity and striving to mitigate the financial impact on retail customers.

The financial impact of meeting a 33 percent RPS goal will vary depending on the mix of resource types and associated costs. Generally, renewable energy costs more than traditional energy sources such as natural gas and coal. However, a diversified energy portfolio, including a larger mix of renewables, may also reduce the risk of price spikes due to fuel supply shortages.

Estimated RPS revenue requirements to comply with SB 2 (1X) compliance targets of 25 percent renewable in 2016 and 33 percent in 2020 are shown in Figure D-3. Revenues required for an additional 4000 GWh annually for 2020 and beyond will require increasing annual renewable portfolio costs from 400 million to 950 million over the next 9 years.

During the early years of the RPS program, low cost, small hydro resources and biogas comprised the bulk of the portfolio with relatively higher cost wind energy being recently introduced over the last several years. Going forward, higher cost resources such as wind, solar, and geothermal must be used to comply with RPS standards as other lower cost alternatives have been largely exhausted. As can be seen in Figure D-4, contracts for renewable projects totaling 1,250 GWh or 28 percent of the renewable energy supply will expire over the next 4 years and will need to be replaced with higher cost renewable resources. Maintaining the current 20 percent RPS will require additional revenue to compensate for these higher cost replacement resources.

AR0071321

Figur D-4. LADWP RPS supply and goals for 2011-2020.

D.6 Other LADWP Renewable Projects

LADWP has several additional projects that are in various stages of development. LADWP also has short-listed additional renewable energy projects that have been offered in response to past LADWP's Request for Proposal (RFPs) or SCPPA RFPs. These short-listed projects and other proposals from upcoming RFP's will be used to select future projects, subject to the criteria enumerated within this section.

The eligibility of wind, solar, and geothermal projects to count toward renewable energy targets is well understood. LADWP has also procured biogas and is considering the use of certain types of biomass. Energy generated from this category is RPS-eligible.

AR0071323

D.6.1 Biogas

The current California Energy Commission (CEC) Overall Program Guidebook of January, 2011 defines biogas as "a gas derived from RPS-eligible fuel including biomass, digester gas, and/or landfill gas". CEC is currently working on a new Guidebook to comply with the SB 2 (1X) RPS requirements to further define eligible sources of Biogas.

Biogas or digester gas is typically derived from the anaerobic digestion of agricultural or animal waste and biomass is typically defined as any organic material not derived from fossil fuels, including agricultural crops, agricultural wastes and residues, waste pallets, crates, dunnage, manufacturing, construction wood wastes, landscape and right-of-way tree trimmings, mill residues that result from milling lumber, rangeland maintenance residues, biosolids, sludge derived from organic matter, and wood and wood waste from timbering operations.

In keeping with capturing the intent of the California legislature to increase use of renewable fuels, the LADWP amended its RPS policy when the CEC issued its third edition of the Guidebook in January 2008. Language from the CEC Guidebook states, "RPS-eligible biogas (gas derived from RPS-eligible fuel such as biomass or digester gas) injected into a natural gas transportation pipeline system and delivered into California for use in an RPS-certified multi-fuel facility may result in the generation of RPS-eligible electricity." The CEC also considers landfill gas (LFG) - gas produced by the breakdown of organic matter in a landfill - a renewable fuel.

The LADWP's gas-fired generating units capable of burning a mixture of biogas and conventional natural gas fall under the CEC multi-fuel designation. The CEC Guidebook states, "…only the renewable portion of generation will count as RPS eligible, and only when the Energy Commission approves a method to measure the renewable portion."

Pursuant to the CEC Guidebook, the LADWP calculates the amount of RPS-eligible electricity produced at its gas-fired generating units by multiplying the total generation of the facility by the ratio of the quantity of biogas used to the quantity of total gas used by the facility. Both the energy generated and the quantity of gas used must be measured on a monthly basis.

The LADWP currently produces RPS-eligible energy derived from biogas/biomass. Digester gas produced at the Hyperion Wastewater Treatment facility is piped to the adjacent Scattergood Generating Station, where it is used to produce RPS-eligible energy. Additionally, the LADWP procures biogas/biomass-derived renewable energy via gas-fired microturbines located at several landfills throughout Los Angeles.

The LADWP currently holds short-term contracts with developers to purchase LFG. Under these contracts, the LADWP obtains LFG from several landfill sites located outside California. LFG produced by the landfills is scrubbed and filtered to pipeline grade and injected into the interstate natural gas pipeline system for delivery to the LADWP's most efficient gas-fired generating units.

D.6.2 Municipal Solid Waste

- The current CEC criteria sets forth several conditions for RPS-eligibility of municipal solid waste (MSW) conversion facilities: The facility uses a two-step process to create energy whereby in the first step (gasification conversion) a non-combustion thermal process that consumes no excess oxygen is used to convert MSW into a clean burning fuel, and then in the second step this clean burning fuel is used to generate electricity.

AR0071324

- The facility is located in-state or satisfies certain out-of-state requirements.
- The technology produces no discharges of air contaminants or emissions, including greenhouse gases as defined in Section 42801.1 of the Health and Safety Code.
- The technology produces no discharges to surface or groundwaters of the state.
- The technology produces no hazardous wastes.
- As much as possible, the technology removes all recyclable materials and marketable green waste compostable materials from the solid waste stream before the conversion process.

The facility certifies that any local agency sending solid waste to the facility diverted at least 30 percent of all solid waste it collects through solid waste reduction, recycling, and composting.

The LADWP currently does not procure energy from any MSW combustion or conversion facilities, but may consider projects that meet all CEC criteria.

D.7 Power Content Label

In 1997, Senate Bill 1305 was approved, which required Energy Service Providers (ESP) to report to their customers information about the resources that are used to generate the energy that they sell. A form, called the Power Content Label, would be used for this purpose, which would also provide a common reporting method to be used by all ESPs.

In addition, the 2002 Senate Bill 1078 established California's Renewable Portfolio Standard (RPS) which included both a requirement for electric utilities to report annually to their customers the resource mix used to serve its customers by fuel type, and to report annually to its customers the expenditures of public goods funds used for public purpose programs. The report should contain the contribution of each type of renewable energy resource with separate categories for those fuels considered eligible renewable energy resources, and the total percentage of eligible renewable resources that are used to serve the customers' energy needs.

LADWP's 2010 Power Content Label is shown in Table D-1. As LADWP has two separate renewable programs, the RPS policy and GREEN, both of these programs are reported on the Power Content Label.

AR0071325

Table D-1: LADWP's 2010 Power Content Label

POWER CONTENT LABEL Annual Report of Actual Electricity Purchases for LADWP Calendar Year 2010			
ENERGY RESOURCES	LADWP Power ACTUAL MIX	LADWP Green Power ACTUAL MIX	2010 CA POWER MIX** (for comparison)
Eligible Renewable * **	**20%**	**100%**	**14%**
– Biomass & waste	4%	59%	2%
– Geothermal	1%	0%	5%
– Small hydroelectric	7%	41%	2%
– Solar	0%	0%	0%
– Wind	8%	0%	5%
Coal	39%	0%	7%
Large Hydroelectric	3%	0%	11%
Natural Gas	22%	0%	42%
Nuclear	11%	0%	14%
Other	0%	0%	0%
Unspecified sources of power*	**5%**	**0%**	**12%**
TOTAL	**100%**	**100%**	**100%**

* "Unspecified sources of power" means electricity from transactions that are not traceable to specific generation sources.

** Percentages are estimated annually by the California Energy Commission based on the electricity sold to California consumers during the previous year.

*** This is in accordance with Los Angeles City Council's action on 10-5-04 for File No. 03-2688 (RPS)

For specific information about this electricity product, contact LADWP at 1-800-DIAL-DWP. For general information about the Power Content Label, contact the California Energy Commission at 1-808-555-7794 or www.energy.ca.gov/consumer.

AR0071326

Reference D-1 – LADWP Renewables Portfolio Standard Policy and Enforcement Program Amended December 2011 - Board Resolution:

WHEREAS in August 2000, the Board of Water and Power Commissioners (Board) approved a resolution that authorized the Los Angeles Department of Water and Power (LADWP) to adopt an Integrated Resource Plan that established a goal of meeting 50 percent of projected load growth through a combination of Demand-Side-Management, Distributed Generation, and Renewable Resources; and

WHEREAS in 2002, the California Legislature passed Senate Bill 1078 that established the California Renewables Portfolio Standard (RPS), and a goal for all investor-owned utilities to increase their use of renewable resources by at least 1 percent per year, until 20 percent of their retail sales were procured from renewables by 2017; and

WHEREAS publicly-owned utilities like LADWP were exempt from California Senate Bill 1078, however they were encouraged to establish renewable resource goals consistent with the intent of the California Legislature; and

WHEREAS on June 29, 2004, the Los Angeles City Council adopted a LADWP RPS Framework and requested that the Board establish a RPS Policy, including achieving "20 percent renewable energy by 2017" and "incorporating this RPS into all future energy system planning"; and

WHEREAS on October 15, 2004, the Los Angeles City Council adopted a resolution approving the inclusion of existing LADWP hydroelectric generation units greater than 30 megawatts in size, excluding the Hoover hydroelectric plant, as part of the City's RPS list of eligible resources; and

WHEREAS on June 29, 2005, the Los Angeles City Council approved LADWP's Renewables Portfolio Standard Policy, which was designed to increase the amount of energy LADWP generated from renewable power sources to 20 percent of its energy sales to retail customers by 2017, with an interim goal of 13 percent by 2010; and

WHEREAS in December of 2005, the Board recommended that LADWP accelerate the RPS goal to obtain 20 percent renewables by 2010, which recommendation included updating LADWP's Integrated Resource Plan to include this goal, proceeding with the negotiation and contract development for renewable resources proposed and selected in LADWP's 2004 RPS and Southern California Public Power Authority 2005 RPS, supporting the cost of accelerating the RPS, and maintaining the financial integrity of LADWP's Power System during times of natural gas price volatility; and

WHEREAS on April 11, 2007, the Board amended LADWP's RPS Policy by advancing the date of the goal that required 20 percent of energy sales to retail customers be

AR0071327

generated from renewable resources to December 31, 2010, and by establishing renewable energy procurement ownership targets; and

WHEREAS, on May 20, 2008, the Board approved an amended RPS Policy which included an additional RPS goal that required 35 percent of energy sales to retail customers be generated from renewable resources by December 31, 2020, expanded the list of eligible renewable resources, and provided new energy delivery criteria; and

WHEREAS, the California Renewable Energy Resources Act will become effective on December 10, 2011, and requires the governing board of a local publicly owned electric utility, such as LADWP, to adopt a program for enforcement, in accordance with Public Utilities Code Section 399.30(e), by January 1, 2012;

NOW, THEREFORE BE IT RESOLVED that the Board of Water and Power Commissioners of the City of Los Angeles hereby adopts the Renewables Portfolio Standard Policy and Enforcement Program, Amended December 2011, approved as to form and legality by the City Attorney, and on file with the Secretary of the Board;

I HEREBY CERTIFY that the foregoing is a full, true, and correct copy of a resolution adopted by the Board of Water and Power Commissioners of the City of Los Angeles at its meeting held

Secretary

AR0071328

Reference D-2 – LADWP Renewables Portfolio Standard Policy and Enforcement Program Amended December 2011:

City of Los Angeles Department of Water and Power
Renewables Portfolio Standard Policy
and
Enforcement Program
Amended December 2011

1. Purpose:

On April 12, 2011, Governor Jerry Brown signed into law the California Renewable Energy Resources Act (herein referred to as "Act" or "SB 2 (1X)"). This Act sets new Renewable Portfolio Standard (RPS) procurement targets, new renewable resource eligibility definitions, and new reporting requirements applicable to local Publicly Owned Electric Utilities (POUs). It is anticipated that SB 2 (1X) becomes effective on December 10, 2011, ninety days after the end of the special legislative session (1X) in which it was enacted.

This RPS Renewables Portfolio Standard Policy and Enforcement Program (RPS Policy) as amended, represents the continued commitment by the Los Angeles Department of Water and Power (LADWP) to renewable energy resources. It is being adopted in accordance with the newly added Section 399.30 (e) of the Public Utilities Code (PUC), requiring the governing boards of POUs to adopt "a program for enforcement of this article" on or before January 1, 2012.

The SB 2 (1X) also requires the California Energy Commission (CEC) to "adopt regulations specifying procedures for enforcement of this article", which include a public process under which the CEC may issue a notice of violation and correction against a POU for failure to comply. The CEC is further required to refer violations of its regulations to the California Air Resources Board which may impose penalties to enforce the Act consistent with California Assembly Bill 32, (AB32 - California Global Warming Solutions Act of 2006).

It is the intent of LADWP to comply with the provisions of the Act, and with applicable enforcement regulations adopted by the CEC pursuant to the Act. It is also the intent of LADWP to update this RPS Policy, as necessary, after the CEC adopts regulations specifying procedures for enforcement.

The Board of Water and Power Commissioners of the City of Los Angeles (Board) retains its jurisdiction to enforce the RPS Policy in accordance with PUC Section 399.30 (e).

2. Background:

In 2002, California Senate Bill 1078 (SB 1078) added Sections 387, 390.1 and 399.25, and Article 16 (commencing with Section 399.11) to Chapter 2.3 of Part I of Division 1 of

AR0071329

the PUC, establishing a 20 percent RPS for California investor-owned electric utilities. SB 1078 provided that each governing board of a local POU be responsible for implementing and enforcing a RPS that recognizes the intent of the Legislature to encourage renewable resources and the goal of environmental improvement, while taking into consideration the effect of the standard on rates, reliability, and financial resources.

On June 29, 2004, the Los Angeles City Council passed Resolution 03-2064-S1 requesting that the Board adopt an RPS Policy of 20 percent renewable energy by 2017 setting applicable milestones to achieve this goal, and incorporate this RPS into a future Integrated Resource Plan (IRP).

On May 23, 2005, the Board adopted a LADWP RPS Policy that established the goal of increasing the amount of energy LADWP generates from renewable power sources to 20 percent of its energy sales to retail customers by 2017, with an interim goal of 13 percent by 2010. On June 29, 2005, the Los Angeles City Council approved the LADWP RPS Policy.

On April 11, 2007, the Board amended the LADWP RPS Policy by accelerating the goal of requiring that 20 percent of energy sales to retail customers be generated from renewable resources by December 31, 2010. In addition, the amended policy established a "Renewable Resource Surcharge" and also established renewable energy procurement ownership targets.

The Board subsequently approved a RPS Policy, as amended April 2008, which included an additional RPS goal of requiring that 35 percent of energy sales to retail customers be generated from renewable resources by December 31, 2020, expanded the list of eligible renewable resources, and provided new energy delivery criteria.

In 2010, LADWP achieved its RPS goal of 20 percent.

3. RPS Compliance Targets

To promote stable electricity prices, protect public health, improve environmental quality, provide sustainable economic development, create new employment opportunities, reduce reliance on imported fuels, and ensure compliance with applicable state law, the following RPS compliance targets are hereby adopted:

1. For the period of January 1, 2011 to December 31, 2013, LADWP will procure sufficient electricity products from eligible renewable energy resources to achieve an average of 20 percent of retail sales during such period.
2. LADWP will increase its procurement of electricity products from eligible renewable energy resources to achieve 25 percent of retail sales by December 31, 2016, based on an average percentage of retail sales calculations for the period of January 1, 2013 to December 31, 2016.

AR0071330

3. LADWP will increase its procurement of electricity products from eligible renewable energy resources to achieve 33 percent of retail sales by December 31, 2020, based on an average percentage of retail sales calculations for the period of January 1, 2020 to December 31, 2020.
4. For each calendar year after 2020, LADWP will procure sufficient electricity products from eligible renewable energy resources to achieve a minimum 33 percent of retail sales based on an average percentage of retail sales calculations for the period of January 1 to December 31 in each such calendar year.

The LADWP will continue to encourage voluntary contributions from customers to fund renewable energy resources in addition to the stated RPS compliance targets, in accordance with its Green Power for a Green L.A. Program or any successor program.

4. Eligible Renewable Energy Resources:

Prior to the enactment of SB 2 (1X), the LADWP RPS Policy defined the following technologies as "eligible renewable resources": "biodiesel using biomass; conduit hydroelectric (hydroelectric facilities such as an existing pipe, ditch, flume, siphon, tunnel, canal, or other manmade conduit that is operated to distribute water for a beneficial use); digester gas; fuel cells using renewable fuels; geothermal; hydroelectric incremental generation from efficiency improvements; landfill gas; municipal solid waste; ocean thermal, ocean wave, and tidal current technologies; renewable derived biogas (meeting the heat content and quality requirements to qualify as pipeline-grade gas) injected into a natural gas pipeline for use in renewable facility; multi-fuel facilities using renewable fuels (only the generation resulting from renewable fuels will be eligible); small hydro 30 Mega Watts (MW) or less, and the Los Angeles Aqueduct hydro power plants; solar photovoltaic, solar thermal electric; wind; and other renewables that may be defined later."

All renewable energy resources approved by the Board as part of its renewables portfolio in accordance with applicable law and previous versions of this RPS Policy including without limitation those on Appendix A, will continue to be eligible renewable energy resources. These renewable energy resources will count in full towards LADWP's RPS targets adopted in section 3 under this updated RPS Policy.

For RPS resources procured after the effective date of SB 2 (1X), "eligible renewable energy resource" means a generation facility that meets eligibility criteria under applicable law, including a "Renewable Electrical Generation Facility" as defined in Section 25741 (a) of the Public Resources Code and "Eligible Renewable Energy Resource" as defined in PUC Sections 399.12 (e) and 399.12.5.

5. Long-Term Resource and Procurement Plan

The LADWP will integrate the RPS Policy into its long-term resource planning process and the RPS Policy will not compromise LADWP's IRP objectives of service reliability.

AR0071331

competitive electric rates and environmental leadership. Future IRPs will incorporate and expand upon RPS compliance targets, and further define plans for procuring eligible renewable energy resources by technology type and geographic diversity.

Each year, the Board adopts an annual fiscal year budget, including a Fuel and Purchased Power Budget (FPP), which defines the specific expenditures for renewable energy resources. The annual fiscal year budget, including the FPP, will comprise the LADWP Renewable Energy Resources Procurement Plan, as required under SB 2 (1X).

6. Procurement of Eligible Renewable Energy Resources:

The LADWP will procure eligible renewable energy resources based on a competitive method and least-cost, best-fit evaluations. Furthermore, preference will be given to projects that are located within the City of Los Angeles or on City-owned property and are to be owned and operated by LADWP to further support LADWP's economic development and system reliability objectives.

Notwithstanding the foregoing, LADWP will also procure eligible renewable energy resources through programs such as a Distributed Generation Feed-in-Tariff, Senate Bill 1 (SB1) Customer Net Metered Solar PV, other local renewable energy programs, or similar procurement processes. These transactions will be made in as cost-effective a manner as is feasible in each respective instance, with pricing that reflects applicable legal requirements and market conditions, prevailing policy, and competitive methods. Short-term renewable energy transactions will be needed as well, on a limited basis, to manage LADWP's RPS eligible renewable energy resources portfolio effectively based on prevailing wholesale practices.

Before December 31, 2010, LADWP pursued its 20 percent RPS goal in a manner which resulted in a minimum of 40 percent renewable energy generation ownership that LADWP developed or that LADWP procured through contracts with providers of renewable energy. Further, with respect to the foregoing contracts with providers, such contracts provided for LADWP ownership or an option to own, either directly or indirectly (including through joint powers authorities).

On or after January 1, 2011, a minimum of 75 percent of all new eligible renewable energy resources procured by LADWP will either be owned or procured by the LADWP through an option-to-own, either directly or indirectly (including through joint powers authorities) until at least half of the total amount of eligible renewable energy resources, by Megawatt-hour (MWh), is supplied by eligible renewable energy resources owned or optioned either directly or indirectly (including through joint powers authorities) by LADWP.

The first priority for LADWP will be to pursue outright ownership opportunities, and the second priority will be consideration of procuring option-to-own, cost-based renewable energy resources. In comparing outright ownership to "option-to-own," option-to-own

AR0071332

projects must show clear economic benefits such as pass-through of Federal or State tax credits or incentives which could not otherwise be obtained, or the need to evaluate new technology. The option-to-own will be exercisable with the minimum terms necessary to obtain and pass those tax credits and/or incentives to LADWP and/or upon a reasonable amount of time to evaluate the operation of the new technology.

7. Portfolio Content Categories

As required by SB 2 (1X), eligible renewable energy resources procured on or after June 1, 2010, will be in accordance with PUC Sections 399.16 (b) and (c). Section 399.16 (b) defines eligible renewable energy resources in three distinct portfolio content categories, commonly known as "buckets". LADWP will ensure that the procurement of its eligible renewable energy resources on or after
June 1, 2010 will meet the specific percentage requirements set out in Section 399.16 (c) for each bucket in each compliance period.

These buckets and percentage requirements are summarized in Table 1 below

Table 1: Procurement Content Categories and Percentage Requirements

	Category (aka "Buckets")	Percentage of RPS Target
4	Either: Have a first point of interconnection with a California balancing authority, have a first point of interconnection with distribution facilities used to serve end users within a California balancing authority area, or are scheduled from the eligible renewable energy resource into a California balancing authority without substituting electricity from another source [PUC Section 399.16(b)(1)(A)] Or, have an agreement to dynamically transfer electricity to a California balancing authority [PUC Section 399.16(b)(1)(B)]	**Compliance Period 1 (2011-2013):** 50% of RPS minimum from this category **Compliance Period 2 (2014-2016):** 65% of RPS minimum from this category **Compliance Period 3 (2017 to 2020):** 75% of RPS minimum from this category **Post 2020:** 75% of RPS minimum from this category.
5.	Firmed and shaped eligible renewable energy resource electricity products providing incremental electricity and scheduled into a California balancing authority [PUC Section 399.16(b)(2)]	Shall be calculated as the remainder of resources which are not in either Category 1 or Category 3.
6.	Eligible renewable energy resource electricity products, or any fraction of the electricity generated, including unbundled RECs, that do not qualify under Bucket 1 or 2. [PUC Section 399.16(b)(3)]	**Compliance Period 1 (2011-2013):** 25% of RPS maximum from this category **Compliance Period 2 (2014-2016):**

AR0071333

	15% of RPS maximum from this category. **Compliance Period 3 (2017 to 2020):** 10% of RPS maximum from this category **Post 2020:** 10% of RPS maximum from this category

The LADWP will define the specific scheduling methods, including firming services, as needed, to maintain transmission system reliability and compliance with these procurement content categories and specified percentage requirements.

Subject to the provisions of PUC Section 399.16 (d), renewable electricity products procured prior to June 1, 2010, are exempt from these portfolio content categories and will continue to count in full toward LADWP's RPS compliance targets.

8. System Rate Impact.

The LADWP may not make any major financial commitment to procure renewable resources prior to evaluating the rate impact and any potential adverse financial impact on the City transfer.

9. Compliance Considerations:

In accordance with this RPS Policy, the Board will review the annual fiscal year budget and Renewable Energy Resources Procurement Plan, and will ensure that reasonable progress is being made towards compliance with the RPS compliance targets.

Reasonable progress may include activities that further the development and procurement of eligible renewable energy resources. Such activities may include, but are not limited to, real estate purchases for future project development, project planning and environmental permitting for either renewable energy projects or transmission in support of renewable energy projects, and other engineering, planning, budgeting, contracting and regulatory compliance activities.

In accordance with PUC Section 399.30 (d) (2), under exceptional circumstances the Board may adopt conditions that allow for delaying timely compliance with the RPS compliance targets, consistent with PUC Section 399.15 (b). Such conditions may include permitting, interconnection or environmental delays; transmission constraints; resource availability; or operational limitations.

In accordance with PUC Section 399.30 (d) (3), under exceptional circumstances the Board may adopt cost limitations for procurement expenditures consistent with PUC Sections 399.15 (c) and 399.15 (d).

AR0071334

In accordance with PUC Section 399.30 (d) (1), under exceptional circumstances the Board may adopt rules permitting LADWP to apply excess procurement in one compliance period to subsequent compliance periods in the same manner as allowed for retail sellers pursuant to PUC Section 399.13

10. Reporting and Notice Requirements:

The LADWP will provide a monthly RPS Progress Report to the Board of Commissioners. Additionally an annual report will be provided to its customers and the CEC containing all information required to be reported pursuant to SB 2 (1X), SB 1078 SB 107 and related regulations

Per PUC Section 399.30 (e) the Board will adopt the program for enforcement at a publicly noticed Board meeting offering all interested parties an opportunity to comment. No less than 30 days' notice shall be given to the public of any meeting held for purposes of adopting the program. No less than 10 days' notice shall be given to the public before any meeting is held to make a substantive change to the program.

Per PUC Section 399.30 (f), LADWP will post notice whenever the Board will deliberate in public on its Renewable Energy Resources Procurement Plan. LADWP will either notify the CEC of the date, time, and location of the meeting in order to enable the CEC to post the information on its Internet Web site, or provide the CEC with the uniform resource locator (URL) that links to this information. In addition, upon distribution to the Board of information related to LADWP's renewable energy resources procurement status and future plans, for the Board's consideration at a noticed public meeting, LADWP shall make that information available to the public and shall provide the CEC with an electronic copy of the documents for posting on the CEC's Internet Web site, or provide the Uniform Resource Locator (URL) that links to the documents or information regarding other manners of access to the documents.

Per PUC Section 399.30 (g), LADWP shall annually submit to the CEC documentation regarding eligible renewable energy resources procurement contracts that it executed during the prior year

Per PUC Section 399.30 (l), LADWP shall report, on an annual basis, information on: (1) expenditure of public goods funds for eligible renewable energy resources development, (2) the resource mix used to serve its retail customers by energy source, and (3) status in implementing the RPS and progress toward attaining the RPS

LADWP will continue to provide a Power Content Label Report to its customers as required by SB 1305 (1997) and AB 162 (2009), and an annual report of the total expenditure for eligible renewable energy resources funded by voluntary customer contributions.

AR0071335

11 Use of Renewable Energy Credits

The primary method of renewable energy resource procurement will be through the development and acquisition of physical generation assets and energy purchase contracts where the "Renewable Energy Credit" (REC) is "bundled" with the associated energy. PUC Section 399.12 (h) provides the REC definition.

In order for RPS compliance targets to be managed effectively, LADWP may buy, sell or trade RECs without the associated energy (unbundled). This procurement approach will be limited by the percentage requirements established by PUC Section 399.16 (b) (3), and as described in section 7 above.

Appendix E Power Reliability Program

E.1 Overview

This Appendix describes LADWP's existing power reliability programs, which has provided high quality service to customers for more than 90 years. Recommendations are then presented for programs and actions to ensure high reliability in the future. Finally, statistical information is provided on the progress of the Power Reliability Program (PRP).

E.2 Historic Reliability of LADWP System

Reliable electric power has been a cornerstone objective of LADWP since it began offering municipal electricity in 1917. Historically, LADWP's Power System reliability has consistently placed in the top quartile of the electric utility industry, and it is LADWP's goal to continue this into the foreseeable future. However, as a result of aging electrical distribution infrastructure, there are significant challenges for LADWP to continue to maintain these reliability goals.

The City of Los Angeles (City) was founded in 1781 and incorporated in 1850. Since then, Los Angeles has grown to the Nation's second largest City with a population of almost 4 million residents. Historically, most of this growth occurred between 1920 when there were roughly 580,000 residents and 1970 when the City had grown to over 2.8 million residents. This incredible growth of 2.2 million residents (roughly 56 percent of today's population) coincided with the mass electrification of homes and businesses throughout the country and specifically the City. During this time, LADWP installed tremendous amounts of electrical infrastructure to ensure that these growing numbers of new homes and businesses were supplied with reliable electric service. Figure E-1 shows the number of electrical distribution poles categorized by age, and demonstrates that the installation of these poles (and the related electrical distribution infrastructure) was directly related to the historical population growth.

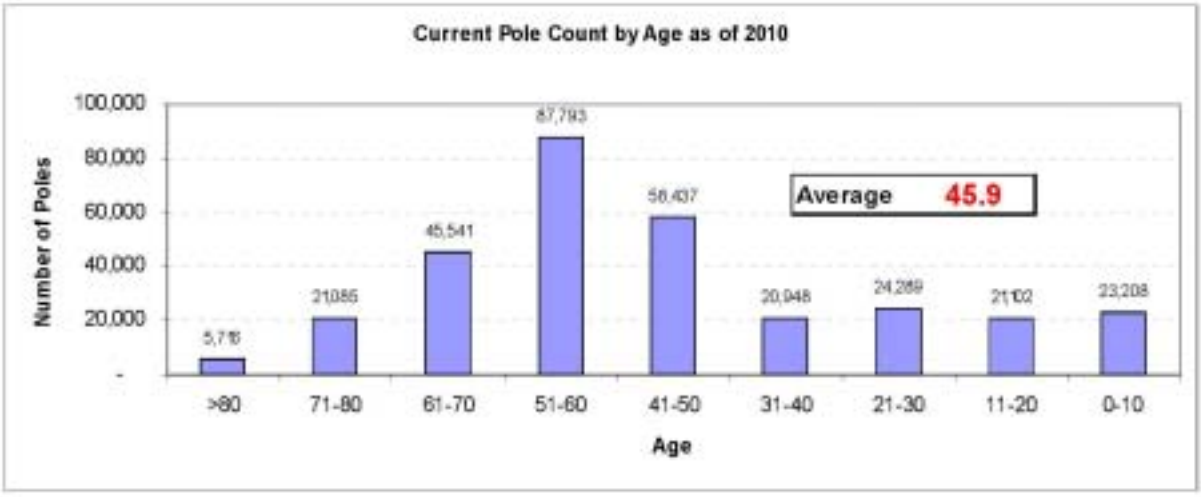

Figure E-1. Pole count by year range installed.

AR0071339

As a testimony to the initial design and installation of this electrical infrastructure, it has reliably served the residents of the City over the last 40 to 70 years. However, data now shows that reliability is beginning to deteriorate. In the past few years, outage rates have increased, including several high profile outages, demonstrating that this equipment is at the end of its service life. As more of the infrastructure ages and there is related performance deterioration, it will create a significant backlog of deferred maintenance and require increased levels of reliability-enhancing capital work. Existing staffing and funding levels will not be sufficient to replace the infrastructure that is needed to maintain the reliability that LADWP customers have come to expect.

E.3 Recommendations to Improve System Reliability

System reliability can be measured in terms of the key SAIDI and SAIFI performance indicators, defined below:

- SAIFI – System Average Interruption Frequency Index -Total number of sustained customer interruptions divided by the total number of customers, expressed in interruptions per customer per year.
- SAIDI – System Average Interruption Duration Index -Total minutes of sustained customer interruption divided by the total number of customers, expressed in minutes per customer per year.

Power System staff and independent industry experts have reviewed the overall system and have developed the following set of initial recommendations to improve reliability. These are summarized in the following subsections.

E.3.1 Operations and Maintenance (O&M) Programs

- Abnormal Circuits and Open Circuits: Abnormal Circuits and Open Circuits are cables that have been temporarily repaired and not in an as designed condition. These temporary repairs were made in the interest of restoring service in a timely manner rather than making permanent repairs, which were planned later. However, because temporary repairs are increasing, more staff is needed to make permanent repairs. Expanding Distribution Construction and Maintenance (DC&M) crews and proceeding with the Cable Replacement program will facilitate timely permanent restoration.
- Station Equipment Maintenance: The current maintenance practice is generally reactive to failures, not proactive and/or preventative. There is a large backlog of maintenance jobs. Maintenance practices should be modified, increasing maintenance frequency and adjusting staffing as appropriate.
- Overhead Transmission Maintenance: There is substantial deferred maintenance and a large volume of new capital work. Maintenance frequency should be increased and staffing adjusted as required.

Figure E-2 shows the SAIDI per Calendar year, both achieved to date and projected, and the impact of the ongoing PRP to reduce the SAIDI to the long term goal of 60 minutes by 2015.

AR0071340

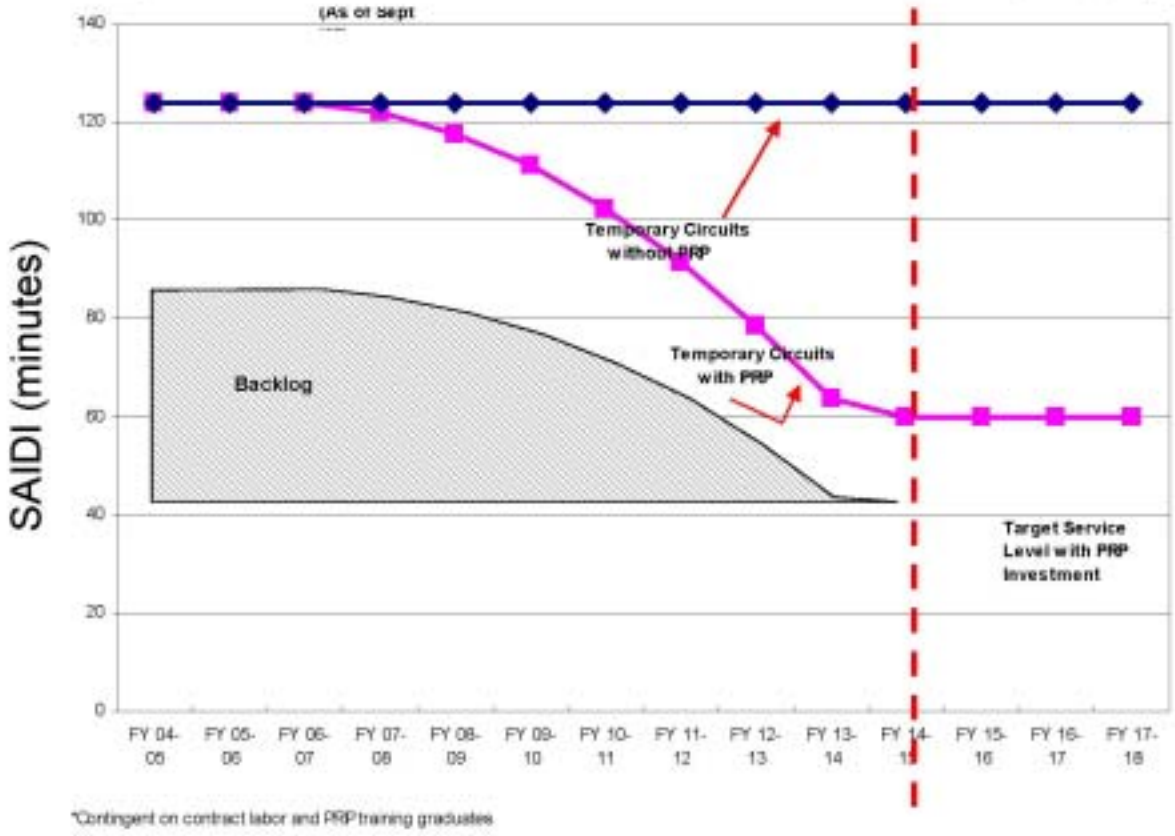

Figure E-2. Temporary circuit restoration and worst performing circuits and stations.

E.3.2 Capital Projects:

- Pole Replacement: The number of poles replaced annually should be increased with the goal of achieving an overall replacement cycle of 60 years.
- Cable Replacement: The amount of underground cable replacements should be increased from 40 miles per year to 60 miles, representing a 75-year replacement cycle. LADWP's Underground Transmission section is also planning to replace one 138-kV underground line per year.
- Distribution Transformers: A transformer management program is required to closely monitor transformer loading. Priority based transformer replacements take into account various factors such as loading, number of customers, age, and neighborhood conditions.
- Load Growth: Construction of new lines and stations to support load growth is a very important infrastructure improvement. Construction resources should be increased to support the timely installation of new facilities. Limited engineering staffing is restricting sufficient numbers of work packages for load growth, maintenance, and construction jobs. A 58,000 labor-hour backlog exists for various records, and approximately 60,000 as-built drawings from the Integrated Resource Plan require processing.

AR0071341

- Deteriorated Vaults & Obsolete Equipment: Over 900 substructures require repair. Much of this work is deferred due to lack of resources. Various obsolete equipment has been identified as needing replacement. Necessary resources and funding should be provided.
- Station Transformers: There are 846 main transformer banks in Distribution, Receiving and Switching stations, some over 60 years old. We are currently changing 2 transformer banks per year. Increased funding is recommended to replace this aging equipment.
- Reliability Engineering Work Group: LADWP should establish this group and develop work processes for structured analysis of failure rates, outage rates, and testing data as input to prioritize the maintenance basis and capital jobs for transmission and delivery (T&D) reliability.
- Generation Reliability Engineering: Staffing should be increased in select generation engineering groups to improve analysis and evaluation of generation unit performance and other reliability related programs and projects.

E.3.3 Distribution Infrastructure Undergrounding Program

- In addition to aesthetic considerations, undergrounding overhead lines has a reliability benefit of reducing the frequency of outages to almost half that of overhead. Currently, LADWP is converting undergrounds at approximately 6 miles per year.

E.3.4 Funding and Resources

The recommendations above are based on the initial observations of the Power System staff and industry experts. As these programs are implemented, prioritizations and/or resources will be directed to the programs that will result in the maximum amount of increased reliability. LADWP's equipment was installed with significant resources over a long period of time; the program to replace the infrastructure will also require a long-term commitment.

In order to ensure that this program is implemented with the maximum impact on reliability and in the most efficient manner possible, LADWP has established a Power Reliability Oversight Committee. This committee conducts quarterly reviews of all facets of the reliability program and makes changes as needed to improve its effectiveness. This includes a review of percent completion of milestones, cost metrics, and impacts that the program is having on reliability metrics.

AR0071342

E.4 Current Power Reliability Program

As discussed in Section E.1, the PRP provides a blueprint for ensuring continued reliable energy service for future generations of Los Angeles residents. LADWP implemented the PRP through a two-pronged approach—rebuilding infrastructure and providing proactive maintenance—and will invest more than $1 billion in the program over the next 5 to 15 years. The program is funded through a power reliability surcharge. Figure E-3 shows the historic and future planned PRP expenditures.

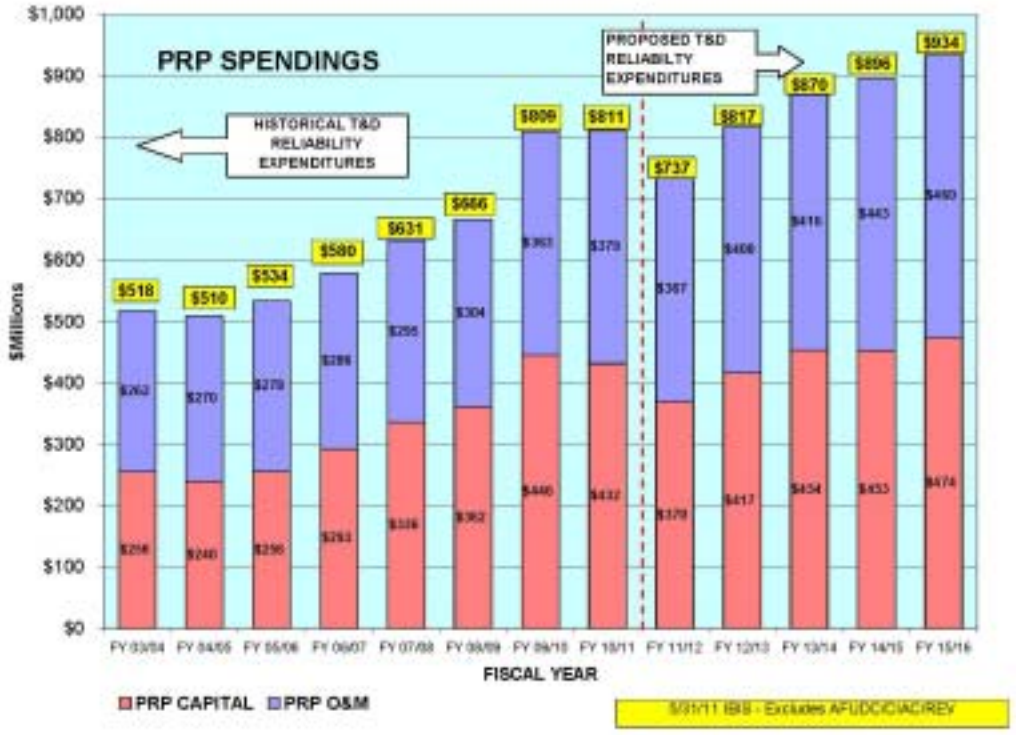

Figure E-3. PRP Expenditures.

The goals of the program include: 1) mitigating problem circuits and stations based on the types of outages specific to the facility, 2) implementing proactive maintenance and capital improvements that take into account system load growth and the inspections and routine maintenance that must take place to identify problems before they occur, and 3) establishing replacement cycles for facilities that are in alignment with the equipment's life cycle.

***The tables and* figures** below detail the progress of LADWP's Power Reliability Program. Figure E-4 and Tables E-1 and E-2 present the reliability achieved in terms of the SAIDI and SAIFI performance indicators, as compared to California's major investor-owned utilities.

Appendix F Generation Resources

F.1 Overview

LADWP's generation resources are presented in this Appendix. Resources that are not wholly owned by LADWP are available either as long-term power purchase agreements or as entitlement rights resulting from undivided ownership interests in facilities that are jointly-owned with other utilities. Most of these additional resources are available through LADWP's participation in the Southern California Public Power Authority (SCPPA). Each project participant with respect to jointly-owned units is responsible for providing its share of construction, capital, operating, and maintenance costs.

F.2 Resources

Generation resources for LADWP are comprised of the following five categories:

- In-Basin Thermal Generation
- Coal Fired Thermal Generation
- Nuclear-Fueled Thermal Generation
- Large Hydroelectric Generation
- Renewable Resources and Distributed Generation

F.2.1 In-Basin Thermal Generation

LADWP is the sole owner and operator of four electric generating stations in the Los Angeles Basin (the "Los Angeles Basin Stations"), with a combined net maximum generating capability of 3,415 megawatts (MWs) and a combined net dependable generating capability of 3,337 MWs. Natural gas and digester gas are used as fuel for the Los Angeles Basin Stations. Low-sulfur, low-ash residual distillate is used for emergency back-up fuel for some of the stations.

LADWP's natural gas-fueled generating plant capabilities are shown in Table F-1.

AR0071349

Table F-1. NATURAL GAS GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Capability (kW)	Net Dependable Capability (kW)
Harbor	1	1995	100,400	82,000	461,000[2]
	2	1995	100,400	82,000	
	5	1995	75,000	65,000	
	10	2002	60,500	47,400

	14	2002	60,500	47,400	
Haynes	1	1962	230,000	222,000	1,525,000[3]
	2	1963	230,000	222,000	
	5	1966	343,000	292,000	
	6	1967	343,000	243,000	
	7	1970	2,000	1,599	
	8	2005	264,350	250,000	
	9	2005	182,750	162,500	
	10	2005	182,750	162,500	
Scattergood	1	1958	163,200	183,000	796,000
	2	1959	163,200	184,000	
	3	1974	496,800	450,000	
Valley	5	2001	60,500	43,000	556,000[4]
	6	2003	182,750	159,000	
	7	2003	182,750	159,000	
	8	2003	264,350	215,000	
Total				3,414,599	3,337,000

Notes:

1. COD refers to Commercial Operation Date.
2. Harbor Generating Station Net Dependable Plant Capability is 461 MW, reflecting Units 1 and 2 reduced performance during hot-weather conditions.
3. Haynes Generating Station Net Dependable Capability is 1,525 MW reflecting 8, 9, and 10 reduced performances during hot weather conditions; and Unit 7 used for auxiliary power only. Unit 5 Net Maximum Unit Capability was decreased to 292 MW to reflect LP hot-reheat piping derating. Unit 6 Net Dependable Unit Capability is 238 MW reflecting 243 MW transformer derating during hot weather conditions. Unit 4 was decommissioned in November 2003 and Unit 3 was decommissioned in September 2004.
4. Valley Generation Station Net Dependable Capability limited to 556 MW reflecting reduced performance during hot weather conditions.

Haynes Generating Station

The largest of the Los Angeles Basin Stations is the Haynes Generating Station, located in the City of Long Beach, California . The Haynes Station currently consists of eight generating units (Unit 7 is used for auxiliary power only) with a combined net maximum capability of 1,556 MWs and a net dependable capability of 1,525 MWs. This station includes a 575 MW

AR0071350

combined-cycle generating unit installed in February 2005. The combined-cycle generating unit includes two combustion turbines and a common steam turbine. The combustion turbines can each operate with the steam turbine independently or together in a two on one configuration (and are counted by LADWP as three generating units). LADWP plans to repower unit 5 and 6 with simple-cycle gas turbine units by December 2012.

Valley Generating Station

The Valley Generating Station is located in the San Fernando Valley. The Valley Station began its repowering in 2001 with a simple-cycle, 60.5 MW gas–turbine generator. Repowering was completed in 2004 with the installation of a combined-cycle generating unit consisting of two gas turbines with heat recovery steam generators, which supplies one steam turbine with 576 MWs of maximum capability. The total net dependable capacity for the Valley Station is 556 MWs.

Harbor Generating Station

The Harbor Generating Station is located in Wilmington, California. The Harbor Station was repowered in 1995 with a combined-cycle generating unit (counted as three units). Five additional peaking combustion turbines were installed in 2002 for a total of eight generating units. These activities resulted in the Harbor Station's net maximum capability of 466 MWs and a net dependable capability of 461 MWs.

Scattergood Generating Station

The Scattergood Station is located in Playa del Rey, California and is comprised of three steam generating units with a net maximum capability of 817 MWs from natural gas and a net dependable capability of 796 MWs from natural gas. Units 1 and 2 also burn digester gas from the adjacent Hyperion Wastewater Treatment Plant.

F.2.2. Coal-Fired Thermal Generation

LADWP's coal generating capacity comes from the Navajo Generating Station and the Intermountain Generating Station (IGS). IGS is also referred to as the Intermountain Power Project (IPP). Coal generating resources are summarized in Table F-2.

AR0071351

Table F-2: COAL GENERATING RESOURCE

Plant Name	Unit	COD[1]	Nameplate (kW)	Net Max Capability (LADWP kW)	Net Dependable Capability (LADWP kW)	LADWP Expiration	LADWP Share
Intermountain	1 2	1986 1987	820,000 820,000	401,553 401,553	401,553 401,553	15Jun2027	44.617%

Navajo	1 2 3	1974 1974 1975	803,000 803,000 803,000	159,000 159,000 159,000	477,000[3]	31Dec2019	21.2%
Total				1,679,000	1,524,000		

Notes:

1. COD refers to Commercial Operation Date.
2. IPP's Net Capacity available maybe less than 1202 MW due to Excess Power Recall. The LADWP entitlement is 44.617% direct ownership plus a 4% purchase from Utah Power & Light Company, plus 86.281% of up to 21.057% of muni's and co-op's recallable entitlement which can vary. The nominal net Maximum Unit Capability and Net Dependable of both Units 1 and 2 is 900 MW.
3. LADWP's contract entitlement is 21.2% of Navajo's total net generation.

Intermountain Power Project (IPP)

General. The IPP consists of: (a) a two-unit coal-fired, steam-electric generating plant located near Delta, Utah, with net rating of 1,800 MWs and a switchyard located near Delta, Utah; (b) a rail car service center located in Springville, Utah; (c) certain water rights and coal supplies; and (d) certain transmission facilities consisting primarily of the Southern Transmission System. Pursuant to a Construction Management and Operating Agreement between the Intermountain Power Authority (IPA) and LADWP, IPA appointed LADWP as project manager and operating agent responsible for, among other things, administering, operating and maintaining IPP.

Power Contracts. Power is provided to LADWP under three separate agreements.

- Pursuant to a Power Sales Contract with IPA (the "IPP Contract") and a Lay-Off Power Purchase Contract with Utah Power & Light Company ("UP&L") and IPA, LADWP is entitled to 44.617 percent of the capacity of the IPP (currently equal to 803 MWs). The IPP Contract terminates in 2027 and may be renewed by LADWP under certain circumstances, subject, in addition, to legal and regulatory mandates.

- Pursuant to a Power Purchase Agreement with UP&L, LADWP purchases capacity and energy equivalent to the capacity and energy made available to UP&L pursuant

AR0071352

to its 4 percent entitlement in the IPP (currently equal to approximately 72 MWs) until 2027, subject to certain renewal rights, which are dependant upon certain factors including the renewal of the IPP Contract.

- LADWP also has available additional capacity in the IPP through an excess power sales agreement with certain other IPP participants (the "IPP Excess Power Sales Agreement"). Under the IPP Excess Power Sales Agreement, LADWP is entitled to a maximum 18.168 percent of the capacity of IPP (equal to approximately 327 MWs). However, this amount varies as portions of it may be recalled by other participants. Of the maximum possible 327 MW allowed under this Agreement, approximately 172 MW is the current entitlement amount.

Fuel Supply: IPA sold its 50 percent undivided interest in the Crandall Canyon Mine in Emery County, Utah and 50 percent undivided interest in the West Ridge Mine in Carbon County, Utah, in 2010. As part of the sale, a continued long term contract for fuel from the West Ridge Mine for IPP was agreed to at about 20 percent of the annual 6,000,000 ton coal requirement. LADWP, in its role as Operating Agent, manages all fuel supply contracts on behalf of IPA, including several long-term coal supply agreements that can provide in excess of 60 percent of the coal requirements for the IPP. Spot market and opportunity purchases provide the balance of the fuel requirements for the facility. Additional information regarding IPP's fuel procurement strategy is found in Appendix H.

Over the past several years, the IPP units have had several substantial modifications, including cooling tower additions, high pressure turbine replacements, boiler capacity additions, distributed control system replacement, scrubber outlet modifications and rebuilds, and induced draft fan drive replacement. These modifications have decreased emissions and increased plant efficiency. They have also increased the plant's capacity by 110 MW, resulting in a 68 MW increase in capacity for LADWP.

Navajo Generating Station

The Navajo Generating Station (NGS) is located near the City of Page, Arizona. Salt River Project (SRP) is the operating agent for the Navajo Station. The Navajo Station is a coal-fired electric generating station and consists of three units with a combined capacity of 2,250 MWs. LADWP's entitlement of the Navajo Generating Station capability is 21.2 percent. On March 23, 1976, LADWP, Arizona Public Service Company (APS), Nevada Power Company (NPC), SRP, Tucson Electric Power Company (TEP), and the U.S. Department of Interior executed the Navajo Project Co-Tenancy Agreement effecting the co-owners' participation and the operation and maintenance of the Navajo Project for as long as the land lease with the Navajo Nation is in effect until December 31, 2019 and throughout the lease extension thereafter. Negotiations are currently under way between the Navajo Nation and SRP, on behalf of the NGS participant owners, to renew the terms of the lease and all rights of way (ROWs) and grants related to the NGS site, transmission and railroad until December 31, 2044.

The station's SO_2 scrubbers, which were installed in 1999, continue to operate in full compliance with federal regulations for SO_2. The plant-wide compliance number ranges around 0.60 pounds per million BTU relative to an emission limit of 0.10 pounds per million BTU.

AR0071353

NGS also completed its Low NO_x burner Separated Overfire Air (SOFA) retrofit project in late March 2011 with the completion of the Unit 1 major overhaul. The Low NO_x/SOFA installation on all three units' boilers has contributed to a successful reduction of NO_x emissions by 40%, representing an annual NO_x emissions reduction of 14,000 tons/year.

Stringent NO_x emissions control standards currently being considered by the federal government for the pending Regional Haze Best Available Retrofit Technology (BART) ruling may require Navajo Generating Station to install Selective Catalytic Reduction (SCR) systems which carry a capital cost of approximately $550 million (or $117 million for LADWP). Should the new regulations require the installation of baghouses in addition to the SCRs, the combined capital cost of both SCRs and baghouses would amount to $1.13 billion (or $240 million for LADWP). The installation of these SCRs and baghouses could begin as early as 2017 and as late as 2029.

In March 2011, the Environmental Protection Agency (EPA) released another proposed rule called the Utility Maximum Achievable Control Technology (MACT) that sets the national emissions standards for hazardous air pollutants (HAP) for electric generating units (EGUs). This rule calls for compliance of monitoring systems for Hg, particulate matter, and SO_2 for HCl, hourly data collection, quarterly submission of emissions data, and new work practice standards for dioxins, furans, and other organic HAPs that would require regular "tune ups" of boilers to optimize combustion. These MACT modifications are estimated at $148.5 million (or $31.5 million for LADWP).

The EPA also proposed federal regulations governing the disposal of coal ash and other coal combustion byproducts (CCBs) under the Resource Conservation and Recovery Act (RCRA). Under this rule, CCBs may be classified as either RCRA Subtitle C hazardous waste or RCRA Subtitle D non-hazardous waste. The regulation of CCBs under RCRA Subtitle C would impose staggering compliance costs on the power industry, including NGS. An unfavorable ruling would jeopardize fly ash sales, trigger significant capital improvement to minimize environmental releases of coal ash and other byproducts, involve additional manpower to manage new programs, and require additional monitoring of the ash disposal landfill. Such coal ash disposal initiatives could amount to approximately $10 million (or $2.1 million for LADWP).

AR0071354

F.2.3. Nuclear-Fueled Thermal Generation

LADWP's nuclear-fueled generating plant capabilities are shown in Table F-3.

Table F-3. NUCLEAR GENERATING RESOURCES

Plant Name	Unit	COD[1]	License Expiration	Nameplate (kW)	Net Max Capability (LADWP kW)	Net Dependable Capability (LADWP kW)	LADWP Share[2]
LADWP Direct Ownership Interest:							
Palo Verde	1 2 3	1986 1986 1988	2045 2046 2047	1,413,000 1,413,000 1,413,000	75,981 76,152 76,038	74,727 74,898 74,784	5.7%
LADWP Entitlement Interest Through SCPPA:							
Palo Verde	1 2 3	1986 1986 1988	2045 2046 2047	1,413,000 1,413,000 1,413,000	52,787 52,906 52,826	51,916 52,034 51,955	3.96% (SCPPA)
Total					386,690	380,314	

Notes:
1. COD refers to Commercial Operation Date.
2. LADWP's contract entitlement is 9.66 percent of generation comprised of 5.7 percent direct ownership in Palo Verde and another 67 percent power purchase of SCPPA's 5.91 percent ownership of Palo Verde.

Palo Verde Nuclear Generating Station (PVNGS) is located approximately 50 miles west of Phoenix, Arizona. PVNGS consists of three nuclear electric generating units (numbered 1, 2 and 3), with a design electrical rating of 1,333 MW (Unit 1), 1,336 MW (Unit 2) and 1,334 MW (Unit 3) and a dependable capacity of 1,311 MW (Unit 1), 1,314 MW (Unit 2) and 1,312 MW (Unit 3). PVNGS's combined design capacity is 4,003 MW, and its combined dependable capacity is 3,937 MW. All three units have been operating under 40-year Full-Power Operating Licenses from the Nuclear Regulatory Commission (NRC) expiring in 2025, 2026, and 2027, respectively. In April 2011, the NRC approved Palo Verde's application to extend the units' operating licenses to 20 years beyond the original term, allowing Unit 1 to operate through 2045, Unit 2 through 2046, and Unit 3 through 2047. APS is the operating agent for PVNGS. For the fiscal year ended June 30, 2011, PVNGS provided over 3.1 million megawatt-hours ("MWhs") of energy to the Power System. LADWP has a 5.7 percent direct ownership interest in the PVNGS (approximately 224 MW of dependable capacity). LADWP also has a 67.0 percent generation entitlement interest in the 5.91 percent ownership share of PVNGS that belongs to SCPPA through its "take-or-pay" power contract with SCPPA (totaling approximately 156 MWs of dependable capacity), a joint powers authority in which LADWP participates, so that LADWP has a total interest of approximately 380 MW of dependable capacity from PVNGS. Co-owners of PVNGS include APS; the SRP Agricultural Improvement and Power District, a political subdivision of the state of Arizona, and the Salt River Valley Water Users' Association, a

AR0071355

corporation (together, the "Salt River Project"); Edison; El Paso Electric Company; Public Service Company of New Mexico; SCPPA, and LADWP.

The aftermath of the Fukushima earthquake and tsunami prompted the U.S. nuclear industry to form a task force under the direction of Palo Verde's Chief Nuclear Officer to take immediate actions in ensuring the reliability of all U.S. nuclear plants. Palo Verde itself has established a task force to evaluate the plant's safety and emergency preparedness. An initial assessment of the plant systems, safety policies, and emergency procedures revealed significant differences between Palo Verde and Fukushima. Palo Verde's low-seismic location, robust pressurized water reactor design, redundant safety features, ample effluent water supply, and multiple back-up power sources make a similar catastrophe in Arizona highly improbable. Despite the seemingly substantial advantages, Palo Verde, in conjunction with other nuclear agencies, is continuously working to make sure that the plant is adequately prepared to meet beyond design basis events, respond to extended loss of power situations, and mitigate potential fire and flood events. While evaluations are still in progress, among the initial recommendations are plans to accelerate fuel removal from the spent fuel pools and possibly purchase a standby diesel generator as reinforcement to the existing back-up power sources.

F.2.4 Large Hydroelectric Generation

LADWP's large hydroelectric facilities include the Castaic Pumped Storage Power Plant and an entitlement portion of the Hoover Power Plant. LADWP's hydroelectric plant capabilities are shown in Table F-4.

AR0071356

Table F-4. LARGE HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Capability (LADWP kW)	Net Dependable Capability (LADWP kW)	LADWP Expiration	LADWP Share
Castaic[2]	1 2 3 4 5 6 7	1973 1974 1976 1977 1977 1978 1972	212,500 265,000 265,000 265,000 265,000 265,000 56,000	240,000 265,000 265,000 265,000 265,000 265,000 55,000	1,175,000	Owned Asset	100%
Hoover[3]		1936	2,079,000	491,000	436,000	30Sep2017	15.4229%
Total				1,763,000	1,611,000		

Notes:

1. Commercial Operation Date.
2. Castaic Power Plant is re-rated at 1,175 MW. Castaic Power Plant Units 2, 4, 5, 6 modernizations were completed September 2004, June 2006, July 2008, and December 2005 respectively. Unit 3 modernization was completed in June 2009.
3. LADWP's entitlement is 25.16% of the plant's contingent capability of 1,951 MW (or 491 MW). The reduced entitlement is due to lower lake levels resulting from the western drought, which causes plant capability to vary constantly. The current Hoover net plant capability as of July 28, 2011 is 1732 MW.

AR0071357

Castaic Pump Storage Power Plant.

The Castaic Pump Storage Power Plant (the "Castaic Plant") is located near Castaic, California. The Castaic Plant is LADWP's largest source of hydroelectric capacity and consists of seven units with a net dependable capacity of 1,175 MWs. The Castaic Plant provides peaking and reserve capacity for LADWP's load requirements.

Hoover Power Plant.

General. The Hoover Power Plant (the "Hoover Plant") is located on the Arizona-Nevada border approximately 25 miles east of Las Vegas, Nevada and is part of the Hoover Dam facility, which was completed in 1935 and controls the flow of the Colorado River. The Hoover Plant consists of 17 generating units and two service generating units with a total installed capacity of 2,080 MWs. LADWP has a power purchase agreement with the United States Department of Energy Western Area Power Administration ("Western") for 491 MWs of capacity (calculated based on 25.16 percent of 1,951 MWs of total contingent capacity) and energy from the Hoover Plant through September 2017. The facility is owned and operated by the United States Bureau of Reclamation.

Drought Conditions. Due to recent drought conditions and low lake levels, LADWP's capacity entitlement at the Hoover Plant was reduced to an annual average of approximately 436 MWs (calculated based on 25.16 percent of 1,732 MW output capability as of July 28, 2011).

F.2.5 Renewable Resources and Distributed Generation

LADWP's Renewable Resources and Distributed Generation consists of

- Eligible renewable small hydro resources as shown in Tables F-5, F-6 and F-7.
- Wind resources as shown in Table F-8.
- Other resources and distributed generation as shown in Table F-9.

AR0071358

Table F-5. OWENS VALLEY SMALL HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Unit Capability (LADWP kW)	Net Max Plant Capability (LADWP kW)	Net Dependable Capability (LADWP kW)
Haiwee[3]	1 2	1927 1927	2,800 2,800	3,600 3,600	4,200	0
Cottonwood[3]	1 2	1908 1909	750 750	1,200 1,200	1,900	400
Division Creek	1	1909	600	680	680	400
Big Pine[4]	1	1925	3,200	3,050	3,050	400
Pleasant Valley[5]	1	1958	3,200	2,700	2,700	0
Total					12,530	1,200[2]

Note:

1. Commercial Operation Date.
2. Owens Valley combined Net Dependable Plant Capability is 1.2 MW based on 20-years of historical data. 1.2 MW consists of 0 MW from Haiwee and Pleasant Valley and 0.4 MW each from Cottonwood, Division Creek and Big Pine.
3. Haiwee maximum unit capability is 3.6 MW each when feed is taken from North Haiwee Reservoir. Cottonwood Power Plant Units 1 and 2 were re-wound to higher Net Maximum Unit Capability of 1.2 MW.
4. Big Pine Net Maximum Unit Capability is limited to maximum flow through penstock.
5. Pleasant Valley Power Plant output is limited to Division of Safety of Dams (DOSD) reservoir level restriction.

AR0071359

Table F-6. OWENS GORGE SMALL HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Unit Capability (kW)	Net Max Plant Capability (kW)	Net Dependable Capability (kW)
Upper Gorge	1	1953	37,500	37,500	37,500	36,500
Middle Gorge	1	1952	37,500	37,500	37,500	36,500
Control Gorge	1	1952	37,500	37,500	37,500	36,500
Total[2]					112,500	109,500

Notes:

1. Commercial Operation Date.
2. Owens Gorge Net Dependable Plant Capability was decreased to 109.5 MW to reflect re-watering flow.

The Owens Gorge and Owens Valley Hydroelectric generating units (the "Owens Gorge and Owens Valley Hydroelectric Generation") are located along the Owens Valley in the Eastern High Sierra. The Owens Gorge and Owens Valley Hydroelectric Generation are a network of hydroelectric plants which use water resources of the Los Angeles Aqueduct and three creeks along the Eastern Sierras. The water flow fluctuates from year to year; as a result, water flow may be reduced from seasonal norms from time to time.

San Francisquito Canyon and at the Los Angeles and Franklin Reservoirs. LADWP also owns and operates 12 units located north of the City along the Los Angeles Aqueduct in San Francisquito Canyon and at the Los Angeles and Franklin Reservoirs. The net aggregate dependable plant capability of these smaller units is 24 MWs under average water conditions. Table F-7 summarizes these 12 units.

AR0071360

Table F-7. AQUEDUCT SMALL HYDROELECTRIC GENERATING RESOURCES

Plant Name	Unit	COD[1]	Generator Nameplate (kW)	Net Max Unit Capability (kW)	Net Max Plant Capability (kW)	Net Dependable Capability (kW)
Foothill (PP4)	1	1971	11,000	9,900	9,900	2,900
Franklin (PP5)	1	1921	2,000	2,000	2,000	400

Sawtelle (PP6)	1	1986	640	650	650	130
Total[3]					83,050	24,230

Note:

1. Commercial Operation Date.
2. San Francisquito Power Plant Unit 1 has been out of service since 1996. The plant's Unit 2 stator heating limits capacity to 8 MW during hot weather condition. The plant's Unit 3 has a new generator with refurbished turbine as of the end of 2006. The contract specification is 18 MW output, but the unit was tested to only 16 MW due to low water flow and restricted downstream capacity. Assumed maximum actual output is 18 MW.
3. Aqueduct combined Net Dependable Plant Capability reflects low water availability during winter.

Notes for Tables F-8 and F-9:

Tables include LADWP's renewables and distributed generating sources from LADWP-owned and contracted projects. This table is based on data from the January 2010 RPS Master Project List and contract sources

[1] The full-load continuous rating of a generator unit under specified conditions as designated by the manufacturer.

[2] Maximum Plant Capability reflects water flow limits at hydro plants; or sum of each unit at renewable plants.

[3] Net Dependable Plant Capability reflects the amount of generating capability that can depend on during the peak demand hours of a day. Dependable capacity of a renewable technology plant is estimated by applying a Dependable Capacity Factor (DCF) to the plant nameplate capacity.

AR0071362

Appendix G Distributed Generation

G.1 Overview

Distributed Generation (DG) is a concept of installing and operating small-scale electric generators, typically less than 20 megawatts MW, at or near an electrical load and interconnected to the electric utility distribution system. The most common technologies used today for DG are turbines and internal combustion engines (ICEs). However, new technologies including fuel cells, microturbines, and solar PVs are now being developed. The promise of DG is to provide electricity to customers at a reduced cost and more efficiently than the traditional utility central generating plant with transmission and distribution wire losses. Other benefits that DG could potentially provide, depending on the technology, include reduced emissions, utilization of waste heat, improved power quality and reliability and deferral of transmission or distribution upgrades.

DG can be customer installed or utility installed. The benefits for customer installed DG include waste heat recovery, backup power and power quality. The benefits for utility installed DG include generation, transmission and distribution infrastructure deferral, and reduction of delivery losses.

This Appendix describes DG on the grid, ICE technologies, fuel cells, and PV technologies.

G.2 Distributed Generation on the Grid

The introduction of competition into the electric marketplace has driven the development of new electrical generation technologies. Most technologies being developed for DG applications are more costly than traditional generating resources. However, it is anticipated that, with advances in the technologies and a greater demand for DG, costs will decrease, and more systems will be installed.

LADWP currently has approximately 350 MW of customer installed DG on its electrical grid, producing approximately 1,700 Gigawatt hours (GWh) annually, most of which is consumed on-site, although some (approximately 40 MWh/h) is exported back to LADWP. Most of the customer installed DG (approximately 300 MW) is made up of 20 MW or larger natural gas combustion engines. The amount of customer DG installed in the future will depend on several factors including reliability, cost of the technologies, and natural gas and electricity prices. With stable electricity prices and high natural gas prices, customer generation becomes less attractive. Additionally, as of November 30, 2011, more than 4,500 LADWP customers have installed over 41 MW of solar PV energy systems with the help of LADWP's Solar Incentive Program.

LADWP has installed more than 1 MW of solar PV energy systems on LADWP and City of Los Angeles (City) facilities to generate clean, renewable energy for the LADWP grid. LADWP has also installed various other DG technologies for demonstration purposes to understand the

AR0071363

operating issues and benefits associated with various equipment and to promote the development of new clean, efficient technologies. Future DG installations for demonstration purposes will showcase new technologies and should add approximately 1 MW in capacity every three years. These projects will be funded with Public Benefits funds, described in Section 2 of the IRP.

Utility installed DG may also play a role in meeting capacity needs in the future that have very low energy production requirements (low capacity factors). It is estimated that approximately 1 MW of DG will be installed annually beginning in 2010. Tables G-1 and G-2 provide projections of DG and Solar PV capacity and energy. The projections are summarized in Table G-3.

Table G-1. PROJECTED DISTRIBUTED GENERATION CAPACITY AND ENERGY - CUMULATIVE

Calendar Year		2006	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017

Row Notes

1 See Table G-1. The October 2006 Load Forecast incorporates existing Customer DG. Future years are converted to annualized values.

2 See Table G-1. Converted to annualized values

3 See Table G-2. 10 MW of existing Customer PV is deducted. Future years are converted to annualized values.

4 See Table G-2. 1 MW of existing LADWP PV is deducted. Future years are converted to annualized values.

PV funding continues through 2011. This IRP assumes a continuation of the program for future years.

The October 2006 Load Forecast incorporates the existing 10 MW Customer PV and 1 MW LADWP PV

5 The values are negative as they act to add load.

G.3 Internal Combustion Engines

ICEs include reciprocating engines and combustion turbines. Improvements have been seen recently in the emissions and efficiencies of reciprocating engines and combustion turbines. Combustion turbines have typically been in the multi-MW size, but recently small-scale combustion turbines, or microturbines, have been developed.

Microturbines are machines ranging in size from 28 kilowatts (kW) to 500 kW, which include a compressor, combustor, turbine, alternator, recouperator, and generator. They have the potential to be located on sites that have space limitations to produce power. The advantages of microturbines are that there are a small number of moving parts, are compact in size, are lightweight, and can utilize waste fuels.

LADWP has installed nearly 2 MW of microturbines, the first of which was located at LADWP's Main Street Center in 1999. Additional microturbines have been installed at LADWP facilities and the Lopez Canyon landfill.

AR0071365

G.4 Fuel Cells

A fuel cell combines hydrogen and oxygen to produce electricity through an electrochemical process. Besides electricity, fuel cells produce water and heat. If the oxygen source is air, then small amounts of NO_X may also be emitted. Fuel cells produce energy at relatively higher efficiencies and emit far fewer air pollutants than combustion technologies. Fuel-cell power plants are now becoming commercially available for use by electric power producers, industrial facilities, and large commercial buildings. Smaller systems for residential, small commercial buildings and transportation applications are expected to be commercially available in the near future. The pricing for these products is expected to become competitive due to several factors:

- A fuel cell is a fairly simple technology with reasonably priced components.
- Significant recent investments in the technology are accelerating the development of fuel cells, and costs are decreasing.
- Integrating fuel processing and power conditioning equipment can be a significant cost with regard to fuel cells, but reductions are likely as more fuel cells are manufactured and installed.

Under a pilot project, LADWP installed a total of four 200-250 kW fuel cell power plants in various locations in Los Angeles that have provided considerable experience and data. Three of the fuel cell plants have accomplished the task and the fuel cells have been removed from service. The fourth plant is being evaluated for viability of continued operation.

G.5 Photovoltaics

Solar energy is converted to electricity using two power technologies: PV systems and solar thermal power systems. PV systems convert sunlight directly into electricity. PV systems are modular, portable, highly reliable, and have low environmental impact, making them ideal for power applications of all sizes. Several large PV systems capable of powering hundreds of homes are now connected to utility grids throughout the United States. Many utilities are installing these systems on the rooftops of schools and their customers are installing them on the rooftops of their houses. LADWP has recently seen the popularity of local customer owned solar generation skyrocket due to the combination of utility paid incentives and recent federal tax law changes, as well as declining solar equipment costs.

A typical 4 kW alternating current (AC) residential rooftop solar power system produces 6,600 kW-hours per year. Presently, LADWP has installed about 1.3 MW of PV at LADWP facilities and other City facilities. LADWP incentives have supported the installation of over 41 MW on its customers' properties, as of November 30, 2011. In 2006 state legislation SB1 required all utilities to offer incentives to customers to install solar energy systems through 2016. LADWP's solar incentive program has been developed with a goal of encouraging the installation of 280 MW of customer installed solar PV systems by 2016 with a budget of $313 million over 10 years, however because of LADWP's lower electric rates, a higher incentive amount has been offered which will reduce the expected amount of customer installed solar to approximately 125MW. An additional 150MW of distributed solar is expected to be installed through a new feed-in tariff program.

AR0071366

The energy generation characteristics of a typical PV installation are that the output peaks around 1:00 p.m., and that 90 percent of a solar PV system's energy is produced from 10:00 a.m. to 4:00 p.m. during a typical summer day in California. Another point worth noting is that a solar PV system can be designed to coincide more closely to the system load profile by altering the module's orientation. While this will increase the energy produced during the peak load of the utility, it will result in an overall lower amount of energy produced for the day. Cloud cover also affects the energy output of a solar photovoltaic installation. The type of clouds will either raise or lower the output of the PV system. Darker rain clouds will lower PV output, but a light marine layer may actually produce more energy than the nameplate rating of the modules due to light reflecting off of the modules, back to the atmosphere, and then back to the modules. This does not happen often but does cause design issues that must be taken into account.

G.6. Combined Heat and Power (CHP) Program

Combined heat and power (CHP) systems, or also known as thermal cogeneration, simply capture and utilize excess heat generated during the production of electric power. CHP systems offer economic, environmental and reliability-related advantages compared to power generation facilities that produce only electricity. Distributed power generation systems, which are frequently located near thermal loads, are particularly well suited for CHP applications.

Currently CHP installed in the LADWP Power System consists primarily of cogeneration projects of industrial and commercial customers. This totaled to approximately 265 MWs nameplate capacity operating in the LADWP's service area. Some cogeneration projects sell excess energy to the LADWP under interconnection agreements.

Current barriers to the expansion of CHP can be attributed to:

- Natural gas price volatility in recent years has caused uncertainty in the economic feasibility of CHP projects.
- Diminishing industrial customer base in recent years has reduced CHP developable potential.
- Reliability and economic issues made small systems infeasible.
- Added cost from utility replacement reserve requirements.
- Uncertain Green House Gas emissions add costs to CHP electric generation.
- Air quality sitting restriction for new carbon-based CHP electric generation.

LADWP is developing CHP target goals to incorporate CHP generation in its future resource mix. LADWP is currently considering development of the following self-owned CHP projects:

- Terminal Island Renewable Energy Project is a fuel cell plant to produce 4 MW of electricity and process heat using methane gas.

AR0071367

- Los Angeles Bureau of Sanitation Alternative Technologies Projects to convert waste to heat

To encourage customer-developed CHP, shift demand from electric grid, and provide accurate price signals to customer, LADWP is currently offering a Standard Energy Credit (SEC) to its customers for excess energy they sell to LADWP. The SEC is based on LADWP marginal generation cost, and is updated and posted monthly. In the future, for renewable CHP, LADWP will provide a renewable premium based on the energy market plus the SEC. For non-renewable CHP, LADWP will continue to purchase CHP excess energy at the SEC.

Current Net Metering Incentives offered to customers require

- Customer must purchase electric services from LADWP to be eligible for interconnection
- Customer submits completed Standard Offer Agreement for interconnection and qualification for the CG Rate
- Customers pay for all costs associated with time of use metering, interconnection, and safe grid-parallel operation of the generation facilities
- For cogeneration facilities greater than one megawatt, the customer is required to install remote monitoring equipment for LADWP
- Customer maintains adequate insurance on generating facilities
- Excess power reimbursements are made to the customer at end of billing period at the CG Rate
- The interconnection agreement has a three year term and requires approval by the General Manager initially and for renewal and extension

Inclusion of the CHP goals under the IRP process will help communicate CHP program information and facilitate stakeholder feedback.

AR0071368

Appendix H Fuel Procurement Issues

H.1 Overview

This Appendix presents issues and strategies related to LADWP procurement of both natural gas and coal.

H.2 Natural Gas

LADWP generates about 22 percent of energy from natural gas-fired generation. Or, in other words, almost one-fourth of LADWP's energy generation is exposed to the risks of gas price volatility. This percentage will increase in the future as coal is removed from LADWP's resource portfolio, and with the integration of additional variable energy resources. Figure H-1 below graphically illustrates the daily natural gas spot market price (including delivery charges to LADWP's gas plants) and the large price fluctuations from the year 2002 to 2006.

Figure H- 1. Natural gas daily spot prices.

As is shown on Figure H-1, the natural gas market has been very volatile with extreme variations of prices. Since gas currently plays such an important role in LADWP's generation portfolio, it is paramount that the impact of gas price volatility to the resource plan be mitigated.

To minimize LADWP's exposure to natural gas price volatility, LADWP has implemented a variety of actions since the 2000 IRP, which include:

AR0071369

1. Created a financial risk management program to mitigate natural gas price spikes and a comprehensive gas procurement strategy to support renewable generation and long term financial goals.
2. Established executive controls over energy risk management and natural gas hedging activities by creating an Executive Risk Policy Committee to provide clearance for all major hedging decisions.
3. LADWP obtained approval from the Los Angeles City Council to delegate its award authority to LADWP's General Manager for approving limited term and price gas procurement contracts. LADWP also approved pro forma NAESB (North American Energy Standards Board) contracts for use in procuring natural gas.
4. LADWP has participated with SCPPA in purchasing an active gas reserve in the Pinedale anticline area of Wyoming. This reserve is currently producing approximately 25,000 million British thermal units (MMBtu)/day, of which LADWP receives approximately 83 percent of the project.
5. LADWP has also replaced approximately 1,100 megawatts (MW) of electrical generation with combined cycle technology. This technology is much more efficient in generating electricity than the generating units that were replaced, resulting in a 30 percent to 40 percent decreased usage of natural gas to generate the same amount of electricity.
6. As a result of implementing the greater use of renewable energy, LADWP's usage of natural gas and coal will be reduced considerably. A general discussion on natural gas pricing issues is provided in the following subsections.

H.2.1 Natural Gas Pricing Issues

Gas delivered to the burnertip for electric generation in California is comprised of three elements: 1) commodity costs; 2) interstate transportation; and 3) intrastate transportation. Other concerns include regulatory/legal issues, gas price volatility, support for renewables and gas supply issues.

Commodity Costs

Natural gas for electric generation is produced primarily outside California in areas known as basins, such as the Green River Basin near Opal, Wyoming; the San Juan Basin near San Juan, New Mexico; and the Permian Basin in west Texas. Gas produced from individual wells is gathered by small pipeline systems and delivered into a gas plant that processes the raw gas into pipeline quality gas for delivery to markets. Prior to the 1980s, this pipeline gas was sold as a bundled product by various interstate pipelines to distribution companies in the individual states, such as the Southern California Gas Company (SoCal) and the Pacific Gas & Electric Company (PG&E). Eventually interstate gas rates were restructured so that interstate pipelines became transport-only businesses with the gas marketing function spun off to the market via unregulated affiliates or independent marketers.

Intensified exploration in non-traditional producing areas of the country, chiefly the so called shale gas, has produced a surplus of gas, which has contained prices recently and will continue to do so in the foreseeable future. The development of Liquefied Natural Gas (LNG) import terminals in the United States has been delayed by a number of factors, including regulatory requirements,

AR0071370

environmental issues, safety concerns, and economic uncertainty. Development of resources known to exist in the United States offshore continental shelf, especially in view of the blowout of a deep underwater well near the coast of Louisiana, continues to experience similar issues.

Interstate Transportation

The interstate pipeline companies that formally sold bundled gas along with their transportation services have now focused primarily on the transportation of gas from producing basins to interconnections with the individual state's local distribution companies. The jurisdiction for the regulation of these companies falls under the authority of the Federal Energy Regulatory Commission (FERC). California is currently served by seven interstate pipelines although only four are actually directly connected to supply basins. The other three redistribute gas from other interstates. Volatility in gas prices into California has arisen because of various supply-related issues, variations in liquidity stemming from fewer suppliers in the aftermath of the market adjustment following 2000-2001, financial trading of commodities by funds, and weather-related events throughout the country. Limited price discovery has also added an element of uncertainty in gas transactions. Additional pipeline capacity to California is readily available through expansions of existing pipelines and interruptible capacity. LADWP has firm capacity on the Kern River pipeline approximately equal to its forecasted average gas requirement although there is a certain amount of uncertainty in this forecast depending upon the degree of implementation of renewables.

Intrastate Transportation

SoCal is the sole provider of intrastate gas transportation services in Southern California. These services consist primarily of delivering gas from the interconnections with interstate pipelines near the California border, but also include storage, balancing, wheeling, parking, and loaning of gas. Ever since May 1988, SoCal has been relieved of its obligation to serve the so-called non-core customers, those who are able to make their own arrangements for procuring their own gas. All electric generators such as LADWP are deemed non-core or transport-only customers. The rate charged by SoCal for this transportation only service is regulated by the California Public Utilities Commission (CPUC). This rate is the lowest for any customer class (outside of any special negotiated rate) because it provides the minimum service and provides as close to cost-of-service pricing as possible. LADWP's active participation in SoCal's rate cases at the CPUC was instrumental in achieving this distinction.

Additional services relating to the delivery of gas are available from SoCal, but the rates are subject to negotiation and, usually, CPUC approval. Generally speaking, these services are of more value to marketers than to municipal generators, but in any case add to the cost of delivered gas.

One issue that has emerged from the recent price volatility in Southern California is whether or not SoCal has the ability to accept all the gas that will be filling the expanded interstates over the next few years. The CPUC has addressed this issue in a recent proceeding into the adequacy of SoCal's system to serve the expected load on its system. So far no conclusions can be made but SoCal is confident that they have the problem in hand because of their recent completion of various system upgrades increasing takeaway capacity by approximately 21 percent. SoCal has been able

AR0071371

to settle rate allocation issues to allow its intrastate transmission system to accommodate the delivery of LNG Gas supplies into its system

Regulatory Legal Issues

Several issues at the CPUC and FERC also impact pricing. SoCal revised its rates on October 2008 to accommodate the delivery of LNG into California, through the implementation of what is known as the Firm Access Rights (FAR) decision. Implementation of FAR has affected the role of transportation pricing and the distribution of receipt point allocations for deliveries into the California market. The FAR program has been renewed for another three years under the name Basic Transportation Service (BTS). The Department has obtained BTS rights that match with its firm Kern River Interstate capacity. Another issue regarding the SoCal system, is the Wobbe Index. The Wobbe Index relates to the energy content of the natural gas delivered into SoCal's system which affects operating characteristics of gas turbines and emission levels. The Wobbe Index has risen to prominence due to environmental concerns which may substantially affect SoCal's service to electric generators. The CPUC has already allowed SoCal to set sufficiently high limits on the Wobbe Index for gas coming into its system. This will chiefly benefit LNG sourced gas although there is a challenge being mounted by the South Coast Air Quality Management District (SCAQMD). The SCAQMD has adopted a new rule, Rule 433, which proposes to monitor the effects of any increase in the Wobbe Index and could be interpreted as an attempt to regulate the distribution of natural gas. It is anticipated that the CPUC will oppose this initiative, and at this point in time, SoCal has filed a lawsuit to set aside Rule 433.

The FERC is presently preparing new tariff sheets for the Kern River pipeline in which LADWP has a substantial interest. Kern River had applied for a significant rate increase, but lost after a long proceeding at the FERC. The rate case was settled by most of the interested parties and refunds were distributed. Subsequently, one party that did not settle was able to halt the settlement pending further review by the FERC. The distribution of refunds stands until the FERC resolves the issue.

Gas Price Volatility

During the winter 2000-2001 gas prices were highly volatile. This was somewhat repeated in milder form briefly in early 2003 and the second half of 2005. For the most part, extreme volatility has subsided with prices remaining at substantially lower levels than in previous years due to the recession. Forward pricing indicates that gas prices will move relatively sideways with a slight bias upward, in part due to the competing effects of the economy and increased supplies of shale gas. The industry has endeavored to reduce volatility through a massive effort of injecting gas into storage for winter use, thereby eliminating the perception of a huge overhang of expected gas purchases during the winter heating season.

AR0071372

Gas Supply Issues

- New drilling techniques make it possible to extract natural gas from deep shale rock formations. The advances mean the United States has more abundant natural gas resources than previously believed. Gas advocates say it could significantly alter the future U.S. energy market.
- Horizontal drilling ($1.06-$1.34 /thousand cubic feet (Mcf)) vs. vertical drilling ($1.71 Mcf): horizontal wells open up much larger area of the resource-bearing formation.
- Hydraulic Fracturing (or fracking): Injecting a mixture of water and sand at high pressure to create multiple fractures throughout the rock, liberating trapped gas.
- Combination of the Horizontal drilling and fracking.
- With more drilling experience, U.S natural gas reserves are likely to rise dramatically in the next few years. At current level of demand, U.S. has about 90 years of proven and potential supply.
- Preliminary estimates suggest that shale gas resources around the world could be equivalent to or even greater than current proven natural gas reserves.

H.2.2 Natural Gas Procurement Strategy

LADWP retained the services of PriceWaterhouse Coopers (PwC) in 2003 to assess, validate, and verify LADWP's current gas procurement strategy. Their report assessed the current strategy, suggested changes and enhancements to that strategy, and prepared a preliminary plan and timetable for implementing the changes.

As a result of PwC's review of gas operations, LADWP decided to adopt a program of protecting its gas costs from price volatility through financial hedging. The appropriate authority was sought and received by the City Council to employ financial hedges for up to ten years and physical hedges for up to five years, and to limit spending for this effort to no more than $15 million per year.

In addition, an Executive Risk Policy Committee was formed with senior management as members to provide oversight over the energy risk management activities of LADWP, including natural gas. Several actions have taken place.

First, LADWP's Financial Services Organization (FSO) negotiated individual ISDA (International Swaps and Derivatives Association) agreements with potential counterparties for the swaps to hedge gas prices. Fiscal Year 03-04 was the first complete year for using financial hedging to cap gas prices over a portion of forecasted gas requirements.

Second, LADWP obtained approval of two ordinances from the Council authorizing the Board of Water and Power Commissioners to delegate its award authority to the General Manager for approving gas procurement contracts. Subsequently the Board approved two separate pro forma NAESB (North American Energy Standards Board) contracts for use in procuring natural gas for up to one year, and for up to five years in duration. A number of the one-year NAESB

AR0071373

agreements are now being used to buy gas. Five year strips of gas for physical risk management purposes were completed in late 2008 using the 5-Year NAESB authority. In addition, in mid 2009 the 5-Yr NAESB was used to obtain strips of biogas which contributes to the LADWP's Renewable Portfolio Standard goal.

Third, LADWP participated through SCPPA in a Request for Proposal (RFP) process soliciting proposals for a term supply of natural gas for 30 years for up to an average of 27,500 MMBtu/Day. The agreements were negotiated but the deal was never completed because difficulties with the economy greatly reduced the anticipated discount offered under the prepay.

Fourth, LADWP has participated with the SCPPA in purchasing an active gas reserve in the Pinedale anticline area of Wyoming. Savings from this purchase have totaled approximately $48,000,000 for the four years of ownership. Further production is indicated by virtue of the fact that neighboring production has been approved for drilling on 10-acre spacing, up from the current 20-acre spacing, by the Wyoming Division of Oil, Gas and Conservation. Other production adjacent to the SCPPA properties has already shown promise although development depends upon a number of environmental challenges.

PwC noted that LADWP's previous gas procurement strategy was highly dependent on spot market purchases and lacked the flexibility necessary to appropriately manage the price risk involved in gas buying, trading, and transportation activities. They argued at the time that price risk was a critical issue because gas was playing an increasingly important role in LADWP's future due to increased reliance on natural gas-fired generation. (Note that the 2006 IRP had recommended repowering four natural gas fired generating stations and adding six gas-fired simple cycle combustion turbines to make up for a sale of a portion of LADWP's interest in the coal-fired Mohave plant, to replace units that were over 40 years old, and to meet anticipated load growth). Additionally, the increased use of renewables, such as wind farms and solar projects, may require higher levels of reserve margins because of their variable and intermittent nature, with the higher reserve margins being provided by gas-fired generation. Also, gas price volatility and constraints on the SoCal intrastate transportation system required LADWP to place more importance on gas supply management.

Implementation Actions
LADWP has adopted strategies to reduce exposure to daily gas price swings, by the use of monthly spot purchases, implementation of index based financial swaps, physical term purchases, and ownership of gas reserves. Monthly spot purchases look to first of the month indexes and reducing the volumes subject to floating daily prices. The reserve acquisition will reduce overall costs through amortization of the purchase price for the reserve. Additional administrative procedures were put in place to further strengthen deal tracking and audit trails.

An important initiative was put into play to obtain delegated authority from the City Council to allow LADWP management to execute SoCal's Master Service Contracts. This contract allows the LADWP to take advantage of additional services offered by SoCal such as storage, parking, loaning and wheeling. The initiative was completed in early 2008.

Additional Actions To Be Considered

AR0071374

With respect to transportation and storage options, LADWP will need to evaluate its options in view of the aggressive schedule adopted by the Board of Commissioners in meeting its goals for implementation of renewable technologies for generation and elimination of coal-fired generation. The successful completion of both these goals will significantly impact the need for natural gas generation. To this end, LADWP has begun to develop standardized methods for evaluating capacity projects. Factors to consider in evaluating options including:

- Cost of being short gas supply
- The amount of fuel carried in inventory for emergencies
- The type of fuel carried in inventory for emergencies
- Cost of alternatives
- Demand Side Management (DSM)
- Spot power purchases
- Alternative generation costs
- Service interruptions
- Political and budget impacts
- Cost of being over-contracted for off-peak periods
- Cost of new capacity (initial capital and demand and charges)
- Value of excess capacity sold on short term basis

These factors are applied to the contracting options that range from meeting baseload requirements to meeting peak requirements.

SoCal is LADWP's only available intrastate transportation supplier by virtue of its authorized franchise. Since SoCal provides 100 percent firm full requirements service, LADWP's transportation need is met. Storage is being developed by others. In the meantime, LADWP may participate in SoCal's auction to acquire an appropriate amount of inventory space, injection rights, and withdrawal capacity on a year to year basis. Storage is most effective contiguous to load centers. However, the most geologically effective sites in the greater Los Angeles area have already been developed by SoCal Storage service. Storage is primarily useful for minor load balancing and, to some extent, hedging. Given the robustness of SoCal's distribution system in particular, and the interstate transportation system in general, storage is not necessary for emergency backup supply for power generation.

AR0071375

H.2.3 Proposed Actions

LADWP proposes to take the following actions to provide additional flexibility in implementing its natural gas procurement strategy:

- Increase the long-term natural gas hedging price cap. LADWP's authority for purchasing financial swaps for long-term natural gas is currently limited to $10.00 per MMBtu.
- Increase the short-term physical natural gas purchase price cap. LADWP's authority for purchasing short-term natural gas is currently limited to a rolling twelve months at $20.00 per MMBtu.
- Obtain delegated authority to execute SoCal's Master Services Contracts (MSC) along with the attachments for ancillary services as soon as the new MSC is published by SoCal after approval of its 2009 BCAP Phase II settlement.
- Increase the term limitation for its short-term power purchases. LADWP's authority for purchasing short-term power is currently limited to a rolling eighteen months from date of execution. And likewise increase to eighteen months the 1-year gas NAESB contracts for short term gas purchases.
- Seek authority to enter into long-term power purchase hedging contracts. LADWP is currently not authorized to enter into such arrangements.

In summary, LADWP has attempted to mitigate the impacts of volatile natural gas supplies and prices by acquiring a natural gas field, utilizing financial hedging contracts, and repowering over 1,000 MW of electrical generation with more efficient combined cycle technology.

H.2.4 Liquefied Natural Gas

LADWP has been carefully monitoring for years the development of LNG throughout the country, and in particular the many projects aimed at California. Generally, LADWP has been supportive of the concept but has not taken an active role in any proposed project. LADWP supports making additional supplies available to the market in California for reliability and cost reasons. This will be especially true as more states implement environmental regulations that will limit the amount of electricity produced from coal resources and shift much of the energy production to natural gas.

Currently there are no active LNG projects in California though several have been planned. Environmental issues and price containment from non-conventional shale gas have made project development a challenge.

AR0071376

H.3 Coal Procurement Strategy for the Intermountain Generating Station

H.3.1 Intermountain Generating Station

The Intermountain Power Agency (IPA) owns the Intermountain Generating Station (IGS). LADWP receives part of the power from IGS under a power purchase agreement with IPA that currently runs through 2027. LADWP is additionally under contract with IPA to oversee the operations of IGS and is known in that role as the Operating Agent. One of LADWP's duties as the Operating Agent is to arrange for the procurement of coal or coal assets, including any transportation services needed to get the procured coal to IGS. All contracts for coal procurement or coal asset ownership are done under the name of IPA. Management approval for coal procurement or coal asset ownership is given by the Intermountain Power Project Coordinating Committee (IPPCC), which is made up of IGS power purchasers (including LADWP), and the IPA Board of Directors (which does not include LADWP). Future coal procurement and coal asset ownership and related strategic development are therefore, done at the discretion and approval of the IPPCC and IPA Board of Directors on behalf of the power purchasers and owners of IGS.

H.3.2 Coal Supply – A Role for the Operating Agent

In its role as Operating Agent, LADWP administers, on behalf of IPA, a diversified portfolio of coal supply contracts that should by design hedge IGS power purchasers against escalating coal prices. The portfolio contains a combination of long-term, mid-term, and short-term coal supply contracts, which are either market price-based, fixed price-based, or cost of production price-based.

H.3.3 Coal Portfolio

The current coal procurement portfolio mix is as follows:

Long-term fixed pricing (with contracts beyond 2013):	60 percent
Short-term market pricing (spot market purchases):	40 percent

In all, the Operating Agent procures about six million tons of coal per year for IGS based on current capacity factors. At present, IPA has in place coal contracts which can supply all of the coal needs of IGS through 2013, with a significant portion of the coal needs beginning 2014 also already in place.

Historically, the vast majority of coal procured for IGS has come from Utah sources. The procurement of coal in the near- and far-term will likely be done in a similar manner as described above, with the percentages of the pricing methodologies in the portfolio mix being determined with pricing and security of supply in mind. While Utah coal is expected to remain a key part of the IGS coal supply for the next 20 years, Utah sources of coal are diminishing. Thus, it is prudent for to the Operating Agent (with IPPCC and IPA Board of Directors guidance and approval) to seek out sources from new Utah mines and from other Rocky Mountain states. For

AR0071377

several years the Operating Agent has procured short-term contract coal from more than a half dozen sources in Colorado and Wyoming. This will have to be done to a greater extent in the future. Since travel time using IPA-owned unit-trains increases while traveling greater distances to the out-of-state sources, the Operating Agent has already made arrangements to lengthen IPA's unit-trains, obtain additional railcar capacity, and expand IPA's railcar operation and maintenance facility.

H.4 Alternative Fuels for Basin Generation

Although there will be ample supplies and delivery capacity for natural gas to power all Basin generation for the foreseeable future, there is some concern that that LADWP will become too dependent on a single fuel. As a consequence, a great deal of thought has been put into identifying potential backup supplies in the event of an emergency.

Among those considered are liquefied natural gas and ultra-low sulfur (CARB) diesel. Both fuels present unique storage, handling, operational, and/or environmental problems. Both are deemed too expensive to implement.

The greatest disaster that could possibly affect the LADWP's ability to generate electrical energy for native load would be a massive earthquake such as the Northridge Earthquake that afflicted Los Angeles in 1994. During that event, due to transmission line problems, the entire power system in Los Angeles was islanded and all available basin generation was put on line. No power was brought in from the Pacific Intertie and minimal power from Palo Verde, Navajo, Mohave or Intermountain power was available. Natural gas demand for power increased by 200,000 MMBtu/Day and was provided by a minority supplier in a timely fashion. This situation persisted for over two weeks until field crews could repair damage to transmission lines. No power plants were damaged as a result of the quake, but some were temporarily taken off line until the situation stabilized. All generation was eventually brought on line within a few hours of the quake. If the quake were much more severe, damage to the power plants' turbines would have necessitated them to be taken off line. The gas delivery system, both SoCal's distribution system as well as the interstate transmission systems, were not harmed by the Northridge quake. Characteristically, gas pipelines are imbedded in sand-filled trenches that allow the pipes to move about when the earth shifts, thereby reducing the possibility of breaking. Major transmission lines bring gas from the East and cross the San Andreas Fault, which move all the time, but rarely cause delivery outages. Thus it would appear that the gas delivery infrastructure is more robust than the power plants that depend on it.

We can conclude from this that although it might seem desirable to maintain some type of backup supply of fuel for in-Basin power plants, the existing natural gas supply system is likely both adequate and reliable enough to withstand a major disruption event.

AR0071378

Appendix I Transmission System

I.1 Transmission Resources

LADWP is one of only a handful of electric utilities that own and operate a system with both alternating current (AC) and direct current (DC) transmission lines. The typical utility is exclusively an AC system with a shorter geographical reach than the LADWP network. LADWP employs its DC lines to import bulk power across state lines from markets and plants in Utah/Wyoming, Washington and Oregon. To lower transmission losses, AC/DC conversion equipment is utilized to interconnect its long distance DC lines with the AC system. Table I-1 lists LADWP's transmission resources.

Table I-1. BREAKDOWN OF TRANSMISSION RESOURCES

Voltage Class	AC/DC	Circuit-Miles
Out-of-Basin		
±500kV	DC	1,068
500kV	AC	1,069
345kV	AC	189
287kV	AC	350
230kV	AC	353
Out-of-Basin Circuit-Miles		3,029 (81%)
In-Basin		
230kV	AC	521
138kV	AC	153
115kV	AC	44
In-Basin Circuit-Miles		718 (19%)
Total Circuit-Miles		**3,747 (100%)**

As Table I-1 shows, the majority of LADWP's transmission assets are located outside of the Los Angeles Basin. Originally constructed to supply lower cost electricity to its customers and thereby maintain lower electricity rates, these assets are vitally important to LADWP's attainment of its 33% RPS goal by 2020. Excess transmission capacity is sold on a non-discriminatory basis in a wholesale market under an open-access transmission tariff largely conforming to FERC Order 890.

AR0071379

A one-line diagram of the key bulk power transmission lines is shown in Figure I-1. The transmission capabilities of the different systems are summarized in Table I-2.

Table I-2. IMPORT CAPABILITY OF TRANSMISSION RESOURCES

Transmission System	Transfer Rating (MW)	LADWP Share (MW)
East-to-LA Basin	4,000	3,566
West-or-River	10,623	3,373
East-of-River	9,300	1,109
Pacific DC Intertie @ NOB	2,990	1,196
Owens Valley Transmission	450	450
Intermountain	2,400	1,428

AR0071380

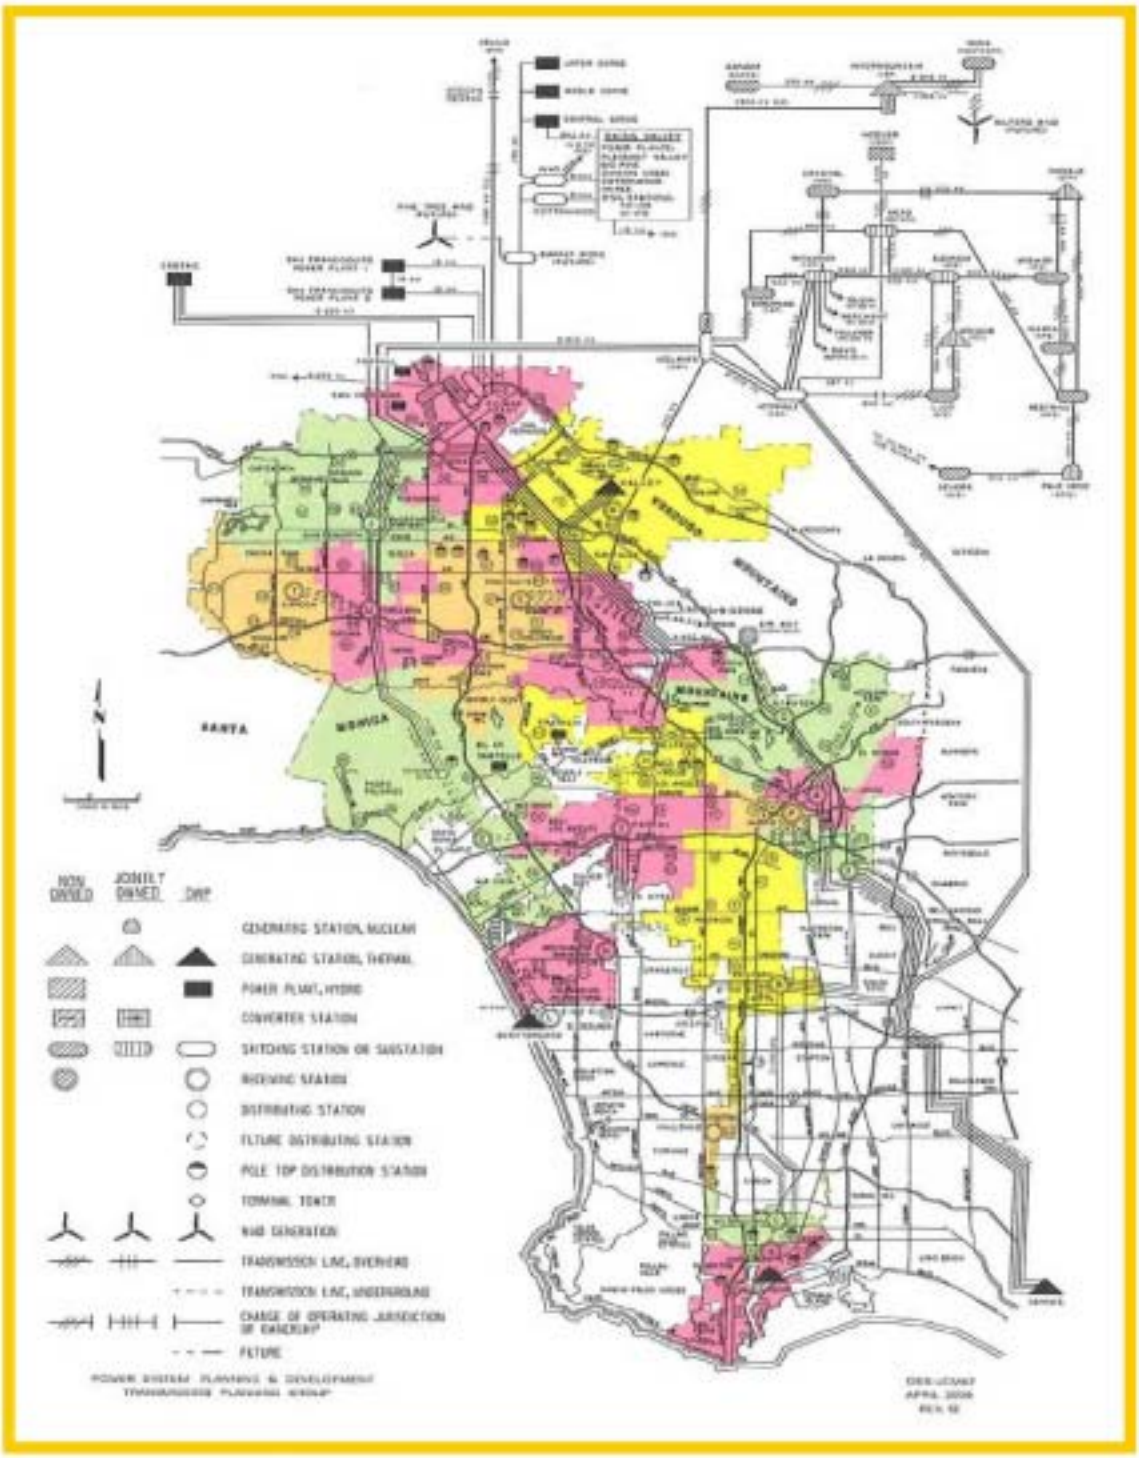

Figure I-1. LADWP Power System diagram.

AR0071381

I.2 Basin Transmission System

LADWP's basin transmission network is comprised of overhead and underground lines ranging from 115kV to 230kV; 4 switching stations that tie together multiple Transmission System circuits; and 20 receiving stations that serve as gateways to the distribution system and as tie points for basin power plants.

Because LADWP serves a metropolis, system reinforcements, additions, and improvements are often challenging; construction in crowded thoroughfares inconveniences so very many people. Compounding this challenge is the very real need to invest in an aging transmission infrastructure, parts of which date back to 1916. LADWP continues to explore and exercise feasible options to increase the utility of its resources, including dynamically rating critical belt-line segments. Even so, it is clear that long-term investments must be made in the near-term. According to the Ten-Year Transmission Assessment released in November 2010, LADWP's transmission system is capable of handling expected system peak loads for the next four years when supported by approved remedial actions to address vulnerable, critical double contingencies.

Further, the annual Ten-Year Transmission Assessments have consistently identified the need to install Scattergood-Olympic –230kV Line 1 for many years now. With each passing year, the urgency becomes more apparent so that now even remedial actions have limited benefit. For this reason, LADWP is moving forward with the installation. With construction slated to begin in 2012, the new 15-mile long Scattergood-Olympic 230kV Line 1 in the Westside should be in-service before Summer 2015. Information on this project is available at the following website: http://www.ladwp.com/ladwp/cms/ladwp013744.jsp.

I.3 East-to-LA Basin Transmission System

The East-to-LA Basin System (see Table I-3) transmits power into the Los Angeles Basin from distant resources in Utah and the Desert Southwest. The Adelanto Station receives power from the Intermountain DC corridor. The Victorville Station is similarly joined to the task of receiving power from the West-of-River System.

Table I-3. EAST TO LA BASIN TRANSMISSION SYSTEM

Victorville-Century Lines 1&2 Victorville-Rinaldi Adelanto-Toluca Adelanto-Rinaldi	287 500 500 500	4,000	100	100

AR0071382

I.4 West-of-the-River System

LADWP's West of River (WOR) system transmits power from the McCullough/Marketplace area to the Adelanto/Victorville area along WECC's WOR (Path 46). Path 46 facilitates transportation of electricity from Navajo Generating Station (Page, Arizona) and Palo Verde Generating Station (Wintersburg, Arizona) to Southern Nevada and Southern California. Until the 1580 MW Mohave Generating Station was shut down in 2005, the Mohave-Lugo 500kV line primarily interconnected that station to the WECC power grid. Since 2006, LADWP has been selling available capacity in the wholesale markets via OASIS. The Palo Verde-Devers 500kV line, of which LADWP has contractual rights to 468MW, is common to both the West-of-River System and the East-of-River System. Both systems are also related in that the capacity ratings are seasonally adjusted according to the Southern California Import Transmission (SCIT) Operating Nomogram.

The WOR system is summarized on Table I-4 and shown on Figure I-2.

AR0071383

Table I-4. WOR TRANSMISSION SYSTEM

	Transmission Line	Voltage Class (kV)	Allocation (MW)	LADWP Entitlement (MW)

AR0071384

I.5 East-of-the-River (EOR) System

LADWP's East of the River (EOR) system transmits power from the north-central and central areas of Arizona to the McCullough/Marketplace/Mead area along the WECC EOR (Path 49). Path 49 facilitates transportation of electricity from Navajo Generating Station (Page, Arizona) and Palo Verde Generating Station (Wintersburg, Arizona) to Southern Nevada and Southern California. The Palo Verde-Devers 500kV line, of which LADWP currently has contractual rights to 468MW, is common to both the West-of-River System and the East-of-River System. Both systems are also related in that the capacity ratings are seasonally adjusted according to the Southern California Import Transmission (SCIT) Operating Nomogram.

The EOR system is summarized on table I-5 and shown on Figure I-3.

AR0071385

Table I-5. EOR TRANSMISSION SYSTEM

Transmission Line	Voltage Class (kV)	Allocation (MW)	LADWP Entitlement (MW)

AR0071386

I.6 Owens Valley Transmission Line

Essentially a segmented single line, the Owens Valley System is becoming increasingly important as a corridor to import renewable resources that support LADWP's RPS goals. Developers have proposed interconnecting renewable resource projects totaling more than 2950MW. These projects have been placed in the interconnection queue but require the construction of LADWP's Barren Ridge Renewable Transmission Project, described in Section 2.4.8 of this IRP.

The Owens Valley transmission system is summarized on Table I-6 and shown on Figure I-4.

Table I-6: Owens Valley Transmission System

Transmission Line	Voltage Class (kV)	Approximated Allocation (MW)	LADWP Expiration	LADWP Entitlement (MW)

AR0071387

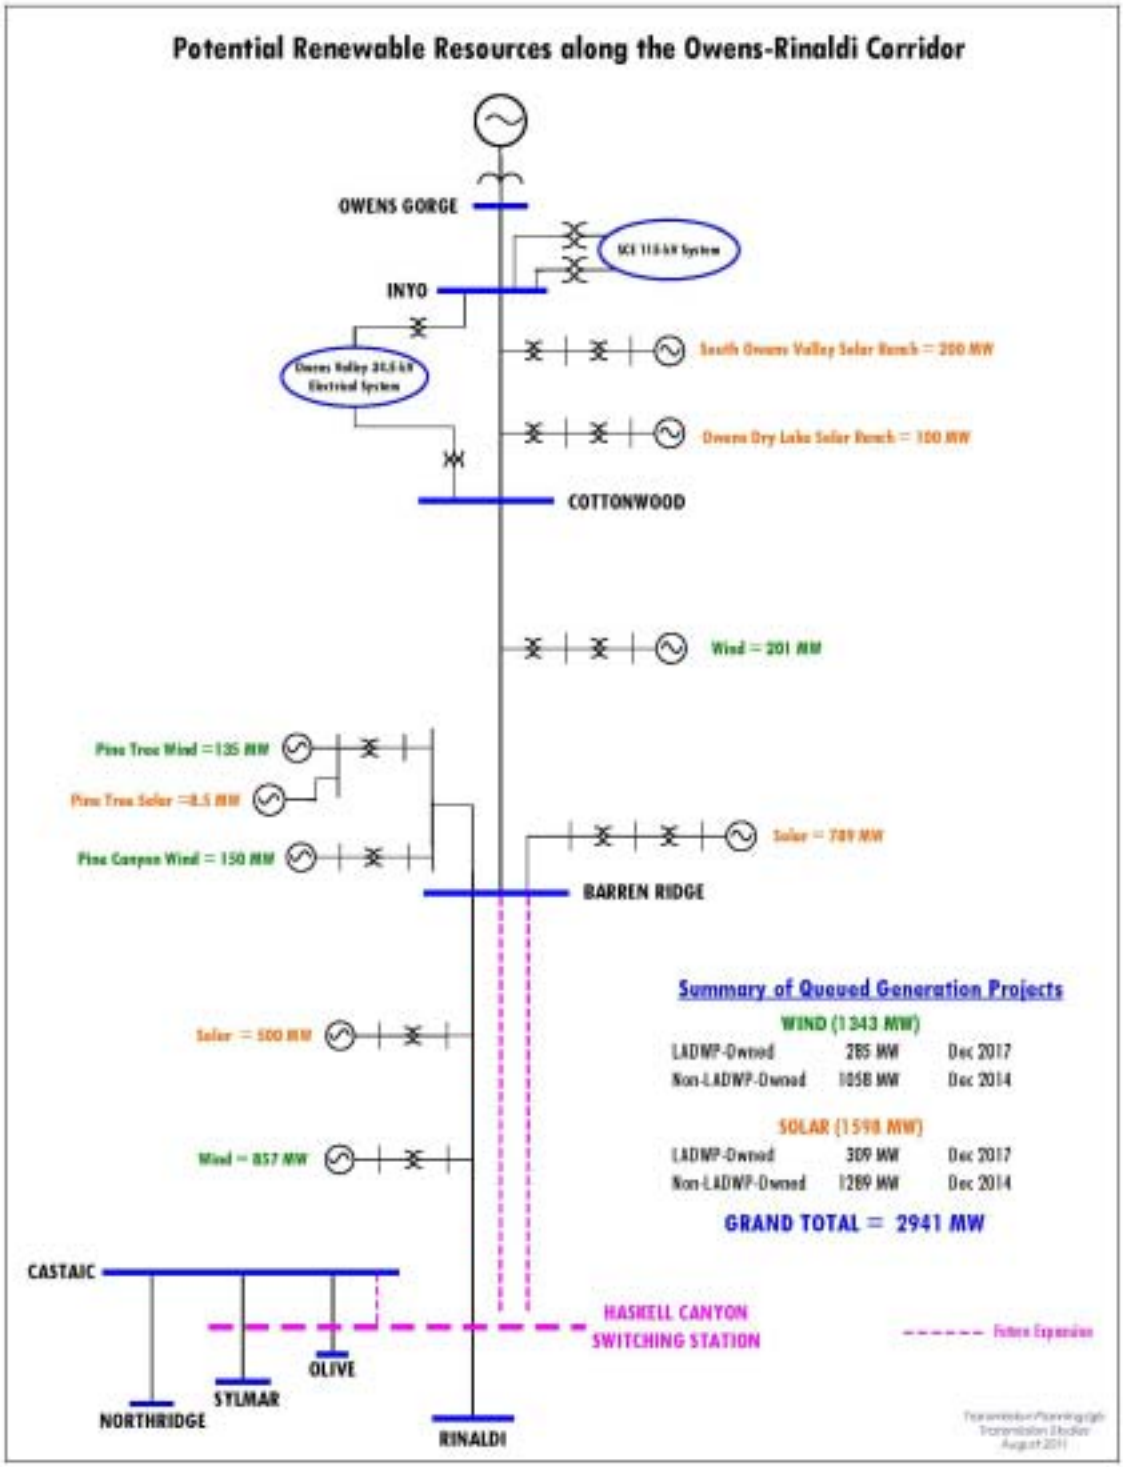

Figure I-4. Owens Valley transmission resources.

AR0071388

I.7 Intermountain System

The Intermountain System is comprised of three WECC paths operated by LADWP on behalf of the Intermountain Power Authority:

- WECC Path 27, the 488-mile Intermountain Power Project DC Line, was upgraded from 1920MW to 2400MW in May 2011. The increased capacity has been accommodating transmission of wind energy from Utah (see Table I-7 and Figure I-5).
- WECC Path 28, the 50-mile Intermountain-Mona 345kV line ties Pacificorp to LADWP's Balancing Authority Area (see Table I-8 and Figure I-6).
- WECC Path 29, the 144-mile Intermountain-Gonder 230kV line ties NV Energy to LADWP's Balancing Authority Area (see Table I-9 and Figure I-7).

AR0071389

Table I-7. WECC PATH 27

AR0071392

I.8 Pacific DC Intertie System

Also known as WECC Path 65, the Pacific DC Intertie is a ±500kV DC line stretching from the Pacific Northwest to the Los Angeles Basin. This corridor provides the means for LADWP to import wind energy and hydroelectricity created from spring runoffs. For the Pacific Northwest, it provides access to low cost generation resources during cold winter months. As described in 2.4.8 of this IRP, research into the various technological options to increase the capacity of the Pacific DC Intertie is being conducted.

AR0071394

Appendix J Integration of Intermittent Energy From Renewable Resources

J.1 General Integration Principles

One of the main responsibilities of power system operators is to maintain the balance between the total aggregate electrical demand of the system's customers and the amount of energy generated to meet that demand on an instantaneous basis. Conventional electrical generation technologies, such as nuclear, coal, natural gas and large hydro are controlled and dispatched by the power system operators throughout the day to maintain this instantaneous balance between demand and generation.

However, some renewable resources generate energy according to nature in a variable and intermittent manner, and the energy from these renewable resources is generally neither controllable nor dispatchable by power system operators. For example, solar resources generally only produce energy when the sun is up, and wind resources only produce energy when the wind is blowing. Such renewable resources are often referred to as variable and intermittent renewable generation technologies.

It is anticipated that the amounts of energy generated from solar and wind resources will be substantial and increasing. The percentage of solar and wind resources compared to the total capability of a utility's power system may also be defined as "percent penetration." Percent penetration can be measured either by a capacity or energy method. Either measurement method is important, since a utility may use this information to determine the maximum amount of intermittent resources that a power system can absorb without impairing the utility's ability to reliably maintain the required instantaneous balance between demand and generation.

Because power system operators cannot control or dispatch the production of energy from most renewable resources, the remainder of the power system must be controlled and dispatched to accommodate both the changes in renewable energy production and the changes in customer demand. In general, with the addition of increasing amounts of renewable resources, the conventional resources of a power system must become more flexible in their ability to increase and decrease the amount of energy generated to successfully and reliably integrate new renewable generation.

J.2 Findings of System Integration Studies

In the last several years, LADWP has been increasing its efforts to acquire renewable resources. In 2009, 14 percent of energy sold to its customers was generated from renewable energy resources, 20 percent was generated in 2010, and 33% is mandated in 2020. With the much higher percentage of renewables coming on line, a variety of modifications will need to be made to the Power System to successfully and reliably integrate these higher penetrations of renewable resources. In preparation, LADWP has conducted preliminary studies on integrating renewable resources, and has also reviewed many renewable resource integration studies published over the last several years.

AR0071395

These studies have some common observations and recommendations regarding the integration of intermittent renewable resources into power system generation portfolios. Some common observations of these studies include the following:

1) Larger power systems with robust transmission systems have a greater ability to integrate intermittent wind and solar resources.

2) Individual wind farms tend to have a high variability in the amount of energy produced (see Figure J-1).

3) Wind energy production impacts regulation (minute to minute variability), load following (hourly variability), and unit commitment decisions (day ahead flexibility). See Figure J-2.

4) Wind is usually categorized primarily as an energy resource. The dependable capacity value of a wind farm to the power system is much lower than the rated capacity of the wind turbines.

5) There is a financial cost to integrate intermittent wind and solar renewable projects into existing power systems, and this cost increases with increasing amounts of intermittent renewable resources.

6) Wind energy production patterns are not usually aligned with daily load patterns. Wind production tends to be greatest in the evenings when the daily load is at its minimum.

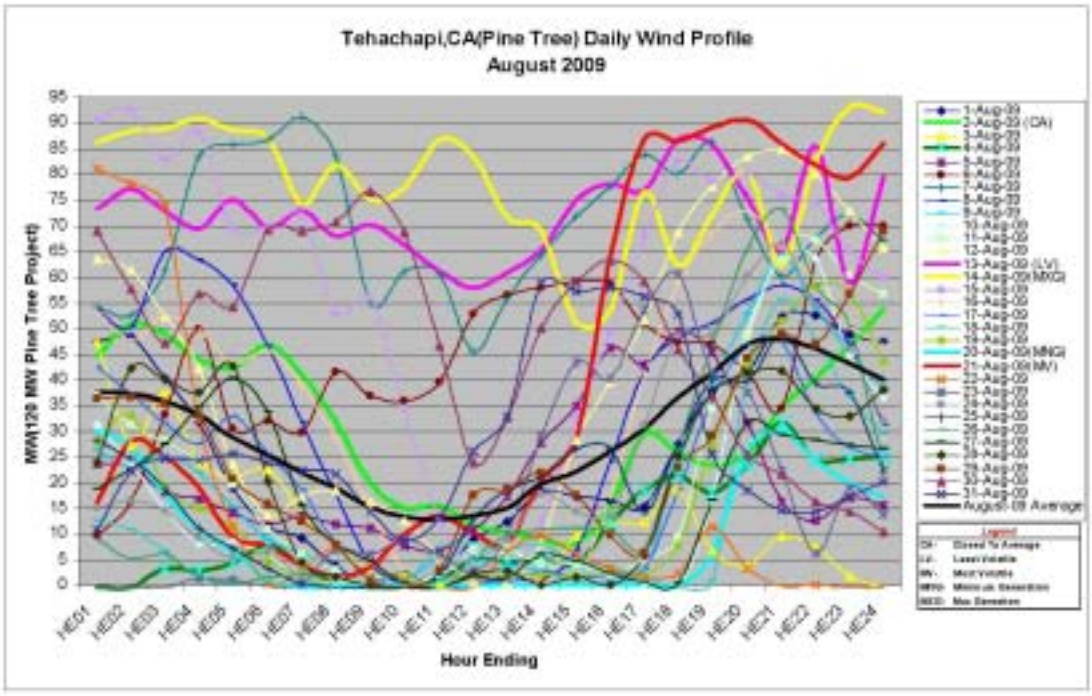

Figure J-1. Wind farm daily wind profiles.

AR0071396

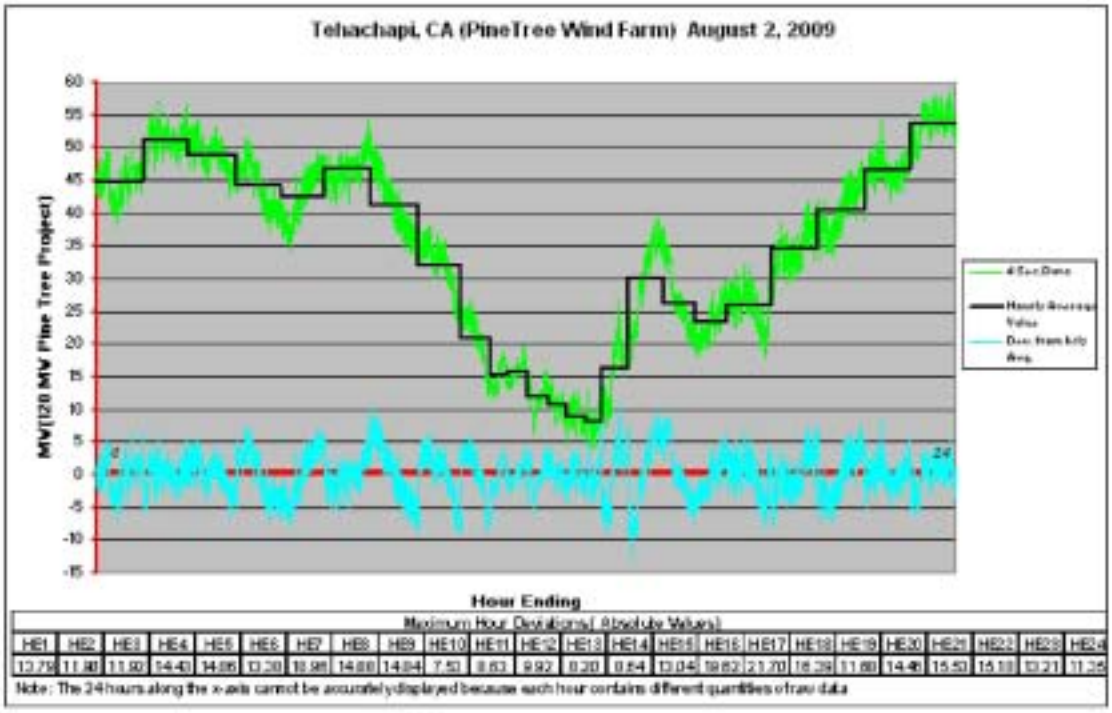

Figure J-2. Wind farm impact on load following capability.

7) High wind energy production during low power system energy demand hours in many cases represents the greatest challenges for power system operations.

8) Average daily and monthly wind energy production profiles are not representative of actual hourly production, due to the high variability in hourly energy production (see Figure J-1).

9) Solar energy production patterns are more closely aligned with daily load patterns than with wind energy production patterns (see Figure J-3).

10) Energy generated from Solar PV technology is highly sensitive to cloud cover. These PV systems can experience variations in output of $\pm$ 50 percent in 30 to 90 seconds, and $\pm$ 70 percent in five to 10 minutes. When a single large sized PV facility experiences these rapid changes in output, the Power System must also be able to react just as quickly with other generation resources to accommodate such rapid changes. The capabilities of a power system's dispatchable resources will limit the size of a single PV facility.

11) In the current energy market, the energy from renewable resource generation will tend to displace the marginal resource, which is typically natural gas. However, if future financial burdens are applied to carbon fuels such as coal, and coal becomes the marginal resource, then coal energy may be displaced by renewable resources.

AR0071397

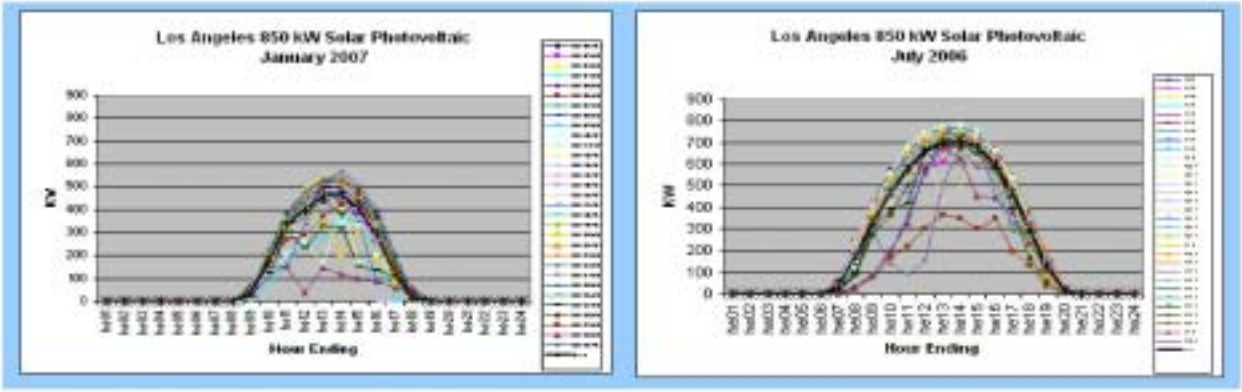

Figure J-3. Solar photovoltaic comparisons.

Some common recommendations from these studies include the following:

1) Successful integration of intermittent renewable resources requires an investment in transmission and generation resources, changes in power system operations and practices, and cooperation among power system operators and energy providers.

2) New generation should be able to operate flexibly, meaning it should be able to start and stop quickly and to cycle on and off many times throughout the year. It should also be able to ramp (change the amount of energy it produces) quickly, and operate at low generation levels.

3) State-of-the-art forecasting, particularly for wind resources, needs to be made available to power system operators.

4) Wind production equipment needs to have "grid friendly" features, including low voltage ride through, voltage control, and reactive power control.

5) Wind energy production must be curtailable by power system operators if wind production negatively affects power system reliability. The power system operators also must have the ability to set power ramp rates for wind projects if needed to ensure power system reliability.

6) Natural gas fired combustion turbines and pump-storage hydro plants are good complements to integrating intermittent renewable resources into existing power systems. Additionally, pump-storage hydro plants with variable speed pumping capability provide even more flexibility to a power system. Other energy storage devices described in Appendix K may also assist in integrating intermittent renewable resources.

7) Customer load shifting programs work well in integrating intermittent renewable resources.

Further studies, planning and system modeling will be needed as additional renewable resources come on-line to assure power system reliability.

AR0071398

Appendix K Energy Storage

K.1 Overview

This Appendix provides a review of the general requirements of grid-scale energy storage systems (ESSs) and ESS technologies. A proposed ESS demonstration project is described, and a summary of Demonstration Program benefits is provided.

K.2 Requirements of Grid-Scale Energy Storage Systems

LADWP plans to meet its 33 percent renewable generation goal by acquiring and self-developing eligible renewable resources including wind and solar. Because wind and solar are intermittent resources by nature, integrating them into the power system is a major challenge. One method of integrating these intermittent generating resources will be large-scale ESSs. The LADWP currently has electrical storage capacity of 1175 megawatts (MW) of pumped storage at the Castaic Lake Hydroelectric Pumped Storage Plant. The plan is to augment this with large-scale battery-based and/or compressed air energy storage when feasible. The ESSs used in the system should be cost effective and provide economical benefit to LADWP.

The ESS power and energy requirements vary widely with the particular grid support application (Figure K-1). Power quality applications require ESSs with high power capability and short storage capacity, while grid support systems require high power output and medium storage capability. Grid-connected renewable energy generation requires large-scale energy storage and large power capability.

AR0071399

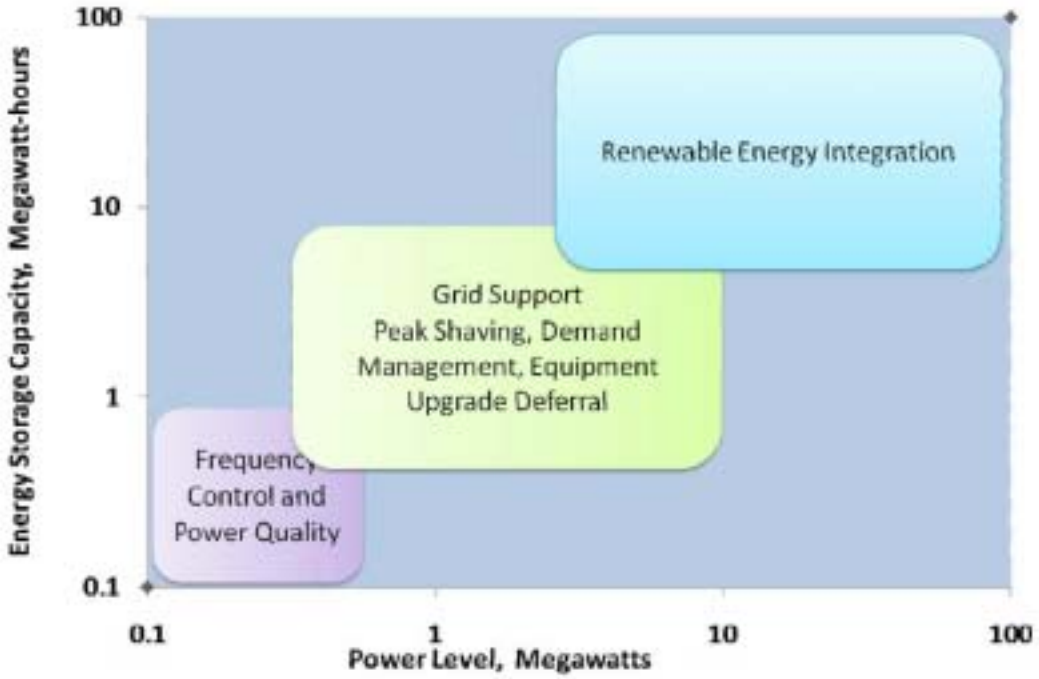

Figure K-1. Requirements of grid-scale ESS.

Electrical ESSs are critical for the integration of intermittent renewable energy sources, load shifting, and improving the stability and reliability of the electricity grid. Such electrical ESSs must be capable of storing hundreds of megawatt-hours (MWhs) and operating without significant degradation for 15-20 years at a cost comparable to today's power plants.

K.3 Energy Storage System Technologies

LADWP is presently in the process of assessing various advanced electrical energy storage technologies to meet its renewable energy program goals. The technologies that look promising for grid-scale energy storage are rechargeable batteries, compressed-air energy storage (CAES), pumped hydro-storage, flywheels energy storage (FES), and supercapacitors. Table K-1 summarizes the salient characteristics of the various energy storage technology options. Among these options, CAES and pumped hydroelectric systems are the technologies most suited for storing large quantities of electrical energy for long periods of time. Rechargeable batteries can support applications requiring a few minutes to a few hours of energy storage. However, hybrid ESSs consisting of rechargeable batteries and other electrical storage systems are likely to meet a wide range of requirements.

AR0071400

Table K-1. COMPARISON OF VARIOUS ESS TECHNOLOGIES

Electrical Storage Technology	Power	Energy Storage Capacity	Duration of Discharge	Advantages	Challenges / Issues
Lead Acid	< 1 MW	0.1 kWh - 1 MWh	1 - 5 hours	low cost, mature technology	limited cycle life low energy density
Lithium-Ion	< 2 MW	0.1 kWh - 10 MWh	1 - 8 hours	high energy density, high power density	high cost, safety in large systems, life,
Sodium Sulfur	< 40 MW	< 250 MWh	1 - 24 hours	high energy density, modest power density	high temperature operation, cost, safety of large systems, life
Redox Flow	< 5 MW	< 15 MWh	1 - 24 hours	long life, safe, easily scalable, medium cost	low energy density, low power density
Compressed Air	25 MW - 3000 MW	1 GWh	1 - 24 hours	high capacity, low cost	special site requirements
Pumped Hydro	100 MW - 4000 MW	15 GWh	4 - 24 hours	mature, high capacity, low cost	special site requirements
Flywheels	< 1 MW	< 10 MWh	< 1 hour	high power density	low energy density, high cost
Supercapacitors	< 1 MW	< 100 kWh	< 1 minute	high power density, long life, high efficiency	low energy density, high cost
Superconducting Magnetic Storage	< 10 MW	< 1 MWh	< 30 minutes	high power density, high efficiency	high cost

K.3.1 Rechargeable Batteries

Rechargeable batteries, upon being charged, convert electrical energy into chemical energy within reactant materials. The chemical energy can be returned as electrical energy upon discharge of the batteries. The rechargeable batteries being considered for the grid support applications described in this appendix are Lithium-Ion Batteries, Sodium-Sulfur (NaS) Batteries, and Redox Flow Batteries.

Lithium-Ion Batteries

Figure K-2. Lithium-ion batteries.

The basic chemistry of these batteries is the same as that of the batteries used in cell phones, laptops, and other portable electronic devices. Large batteries can be fabricated using the same chemistry to provide ESSs for the grid. These batteries consist of carbon-based anode materials and lithiated metal oxide (metals such as cobalt, nickel, and manganese) cathode materials along with an organic electrolyte. Other material choices include lithium titanate for the anode and lithium iron phosphate for the cathode. The cells are sealed to prevent exposure of the battery chemistry to moisture and

AR0071401

oxygen. These batteries offer specific energy values as high as 200 watt hour per kilogram (Wh/kg) and 400 watt hour per liter (Wh/L). They are three to six times lighter than lead acid batteries for the equivalent capacity and allow for fast charging and discharging. Operational life of about five years has been demonstrated. Further research is currently being done to improve battery-life characteristics for automotive applications. Cost and safety are the key challenges for widespread deployment of these types of batteries. Lithium iron phosphate and lithium titanate are particularly attractive for automotive applications because of their lower cost and higher abuse tolerance, albeit at a moderate reduction in energy density to 100 Wh/kg. AES Energy Storage is current installing a 32 MW lithium-ion storage system to regulate the 100-MW Laurel Mountain Wind Farm in West Virginia. Similarly, A123 Systems and AES have jointly deployed a 2 MW system (see Figure K-2). The current cost for lithium-ion batteries is between $650-$1000/kWh and $400-$2000/kW. Current costs of lithium-ion batteries are coming down because of ongoing developments in the automotive industry and are expected to reach $250/kwh by 2020.

Sodium-Sulfur Battery

This type of battery was developed prior to lithium ion batteries and uses metallic sodium and elemental sulfur. A sodium-ion conductive ceramic separates both electrodes. Redox and Lithium-Ion batteries can operate at ambient temperatures, but NaS batteries must operate at about 450°C and must be maintained at this high temperature by appropriate thermal insulation. Repeated heating and cooling cycles will reduce the life of NaS batteries. Since NaS batteries consist of reactive materials maintained at high-temperatures, engineering measures are required to ensure safe operations. Notwithstanding these challenges, large-scale NaS battery installations have been demonstrated worldwide, with the largest installed unit being 34 MW, 245 MWh for a wind power stabilization application in Northern Japan by NGK Insulators Inc. (see Figure K-3). Thus far in the U.S., about 40 MWs have been deployed for grid support and integration with wind energy systems. General Electric USA has recently announced its intention to develop and manufacture NaS batteries for renewable energy system integration. The projected cost of large-scale NaS batteries is $450/kW and $400/kWh.

Figure K-3. Sodium-sulfur batteries.

AR0071402

Redox Flow Batteries

In a redox flow battery (see Figure K-4), the chemicals produced in the cell stack during electrical charging are pumped out of the cell stack and stored as a solution in tanks. The solutions are then re-circulated through the cell stack when the energy needs to be regenerated. Since large amounts of energy can be stored as solutions in tanks, the redox flow battery concept is particularly suitable for large-scale energy storage applications. The Vanadium Redox Battery (VRB) is one of the best known examples of a redox flow battery that has been scaled up to MWh sizes; systems with the power level of 2 MW and storage capacity of 12 MWh have been demonstrated. Many units based on VRB technology are in operation worldwide. Some of the flow battery systems have been in operation for over 30 years with minimal maintenance. The life cycle emission from these batteries is less than 25 percent of that of lead-acid batteries. The capital cost for these batteries is in the range of $1000/kW and $300/kWh. With a 15-year life span, the amortized cost of this system is comparable to that of lead acid batteries.

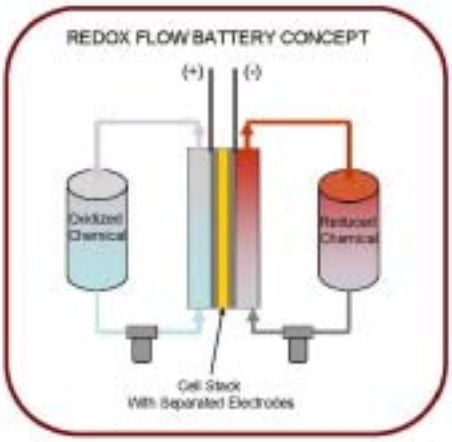

Figure K-4. Redox flow batteries.

K.3.2 Compressed Air Energy Storage

CAES systems compress large masses of air during periods of low energy demand (off-peak) and then expand the air in turbogenerators to produce power during periods of peak demand. Heating the compressed air before sending it through the turbogenerator results in a three-fold increase in the power that could otherwise be generated without the heater. Compressed air stores mechanical energy that can be released very rapidly. However, the stored energy density of CAES systems is relatively small compared to liquid fuel (gasoline, diesel). Currently, about 80-85 percent of the mechanical work for compressing the air is lost as waste heat during the compression. New air compressor devices that recover the heat generated will substantially increase the efficiency.

K.3.3 Pumped Hydroelectric Storage

Pumped Hydroelectric Storage (PHS) is one of the most widely used ESS technologies. The PHS system involves pumping water from a lower reservoir to a higher reservoir when electricity is available (generally at night) and then flowing water down through hydroelectric generators to produce electricity when additional power capacity is needed (typically at midday during periods of peak demand). PHS systems require a particular geographical topology where reservoirs can be situated at different elevations and where sufficient water is available. PHS systems constitute 3-4 percent of the current worldwide power generation capacity. The typical size of these PHS systems is around 1000 MW, and the storage capacity can exceed thousands of MWhs based on the size of the reservoirs and the hydroelectric generator assets involved. The round-trip efficiency of these systems usually exceeds 70 percent. Installation costs of these systems tend to be high because of the geographical siting requirements. System cost is estimated to be $4000/kW and $200/kWh.

AR0071403

K.3.4 Flywheel Energy Storage

FES systems work by using an electric motor to accelerate a rotor (flywheel) to a very high speed, maintaining the energy in the system as rotational energy using very low-friction bearings and engaging an electric generator to convert the rotational energy back to electricity by decelerating the flywheel. FES technology is a good fit for managing relatively limited amounts of electricity for short periods of time and is being considered as a strong contender for frequency control of the grid. Beacon Power Corporation has developed a flywheel system for frequency control of the grid and is currently testing several installations of prototype equipment.

K.3.5 Supercapacitor Energy Storage

Supercapacitor Energy Storage (SES) and Ultracapacitor Energy Storage (UES) systems are targeted to fill the gap between capacitors and batteries. These devices can deliver large amounts of power for short periods of time and can be used to dampen the in-rush current noise caused by the start-up and shut down of large motors and generators in large power system facilities. However, these devices are not likely to be good candidates for large-scale energy storage.

K.3.6 Superconducting Magnetic Energy Storage

Superconducting Magnetic Energy Storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil, which has been cryogenically cooled to a temperature below its superconducting critical temperature. SMES technology is highly efficient, but manufacture of actual commercial equipment has been hard to achieve. This technology appears to be too immature for large scale commercialization.

K.4 Potential LADWP Barren Ridge ESS Integration Pilot Project

K.4.1 Background

The proposed Barren Ridge ESS Integration Pilot Project was formulated to demonstrate the benefits of energy systems to effectively utilize the energy generated by wind farms and effectively integrate it with the power grid.

Integrating renewable power systems from wind and solar generated power into the electric grid presents several challenges. These renewable power systems are by nature somewhat unpredictable and intermittent. Thus, the amount of electrical energy they produce varies over time and depends heavily upon a variety of random factors mostly tied to local weather conditions. Small wind power systems can be managed without an ESS, but large wind power systems (at rated capacities somewhere around 10 percent of a grid's capacity) are not grid manageable without an ESS. The is because even moderate fluctuations in wind speed could result in excessive fluctuations in grid-fed wind-generated electricity and hence force grid managers to disconnect wind generated power from the grid just when the potential energy yield is greatest.

AR0071404

Installing large ESSs as part of a wind power system architecture will reduce the power fluctuation problem and will produce frequency-clean, voltage/current controlled, and uninterruptable power into the grid. Several studies have indicated that ESS integration with renewable energy resource power generators will enable clean and controlled delivery of more than 92 percent of the available generated power, while greatly reducing or eliminating the need for back-up fossil fuel power plants.

K.4.2 System Description

The overall system concept for the Barren Ridge ESS Integration Pilot Project is schematically shown on Figure K-5. The energy generated from the Pine Tree Wind Power Project (PTWPP) will be diverted into the ESS at the Barren Ridge Switching Station (BRSS) in California. Additional energy storage will be available at the pumped hydro storage at Castaic Lake. All the power control system equipment will be located at the BRSS.

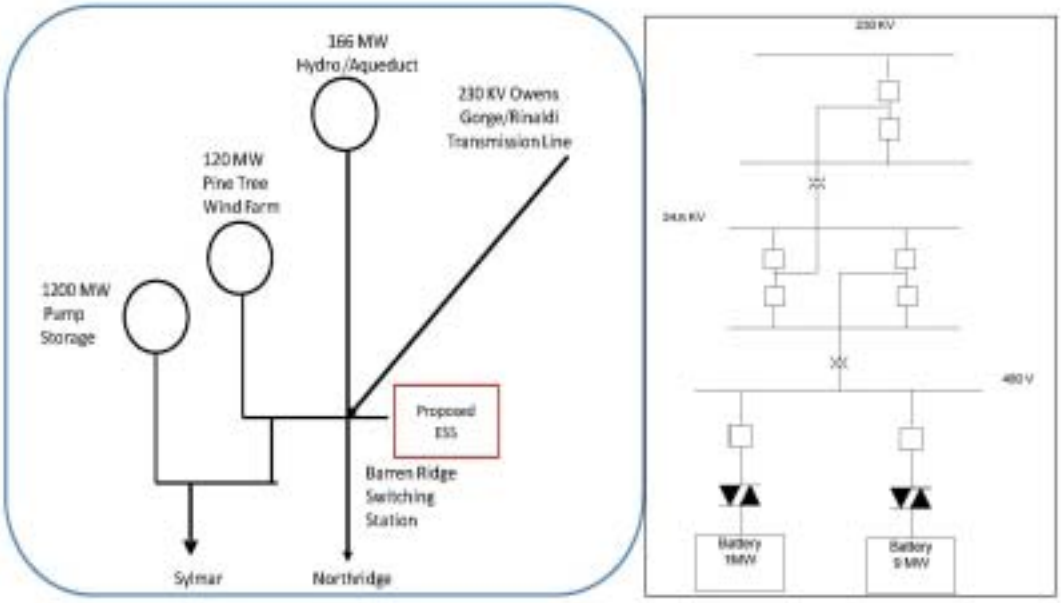

Figure K-5. System concept for Barren Ridge ESS Integration Pilot Project.

K.4.3 Project Site and Assets

The BRSS site was selected because the required assets for this demonstration project, namely, the wind farm generated power and its associated high voltage alternating current transmission lines, are available. Further, the auxiliary PHS facility is linked by other transmission lines to the BRSS.

The LADWP's PTWPP is the largest municipally-owned wind power farm in the U.S. and is located about 12 miles north of Mohave, CA. The PTWPP is sited on 8000 acres of rough terrain and consists of 90, 1.5 MW wind turbines to provide a rated wind power capacity of 135 MW.

A new 8.25-mile transmission line routes power from the PTWPP to the BRSS, where power is tied into the high voltage (230 kV) north-south transmission line that feeds Los Angeles.

AR0071405

The LADWP could conceptually install about 75 miles of new 230 kilovolt (kV) conductors on both existing and new north-south transmission towers to a new Haskell Switching Station (HSS). The conductors would carry the wind and solar generated power between the BRSS and the HSS, which is linked to the Castaic Lake plant at Elderberry Forebay (462 m above sea level).

K.4.4 ESS

Integration of very large-scale wind and solar farms into the grid requires a low-cost, long life ESS capable of storing hundreds of MWh of electrical energy. The hybrid ESS described here combines a moderate amount of battery storage capacity with a large PHS capacity. This hybrid ESS concept is ideally suited for this application and enables the maximum dispatchability (or usability) of all generated renewable power so that the generated renewable power is not wasted.

Further, the battery storage system can be designed with adequate capacity to provide the necessary reserves for serving both frequency response and spinning reserve requirements, while also serving to dampen out the power quality fluctuations inherent in wind and solar power generators. The battery ESS can also provide ramp control as non-spinning reserves ramp up to capacity. The large PHS ESS will satisfy the needed utility load-shifting requirement by pumping water to a higher elevation during off-peak periods and generating power through the hydroelectric generators during peaking periods. Three primary battery ESS candidates being considered for this demonstration are: redox flow batteries, large-capacity lithium ion batteries, and NaS batteries.

Based on the intermittency and variability of wind-generated power, the ESS that will firm up the wind farm output from the PTWPP should be sized to have a power output of at least 80MW and a storage capacity of 560 MWh. This will be in addition to the pumped hydro storage capability at Castaic Lake. Initial design studies and demonstration of the overall design will be conducted at the 10 MW level. LADWP will then use the lessons learned to scale the system up to 80 MW.

AR0071406

Table K-2: KEY CHALLENGES OF BATTERY SYSTEMS

Vanadium Redox Battery	Lithium Ion Battery	Sodium-Sulfur Battery
High cost of vanadium Negative environmental impact of using large quantities of a biologically active heavy metal such as vanadium Low-efficiency Low to Moderate power density Loss of efficiency by cross diffusion of constituents, Low storage capacity of solutions	Operational safety of large-scale batteries Degradation after 2000 cycles on deep discharge which translates to about 3-4 years of operation. High cost of materials to achieve high-energy density.	High temperature operation of the battery (400°C) adds to cost, maintenance and safety Rapid degradation of sealing elements when subjected to thermal cycling. Degradation of battery over 1000 cycles High cost arising from materials and manufacturing methods.

Advanced Lithium-Ion Batteries

Many of the safety features provided in small 18650 size cells, such as PRTs and CIDs, are not incorporated into large capacity Li-ion cells. One approach to improve the safety of Li-ion cells is to adopt the use of electrode materials that are inherently safer and still offer the high energy densities provided by lithium-ion technology. To this end, the demonstration project will scale up and implement new electrolytes and cathode materials under development at JPL.

Currently utilized electrolyte formulations, which are composed of organic alkyl carbonates, are highly flammable; there is a strong desire to reduce the inherent flammability of the electrolyte itself. This can be accomplished by the incorporation of flame retardant additives, such as phosphates, phosphites, and phosphonates, and/or the use of non-flammable electrolyte solvents, such as halogenated carbonates and esters. At JPL, development work has been focused upon both approaches, with the intent of developing safer electrolyte solutions for "human rated" aerospace applications.

Advanced Redox Flow Battery

An advanced redox flow battery that operates on iodate/iodide redox coupling has been under development and can potentially offer a superior system for large-scale energy storage compared to the vanadium redox battery. The key improvements achieved by this new concept over the state-of-art vanadium redox battereis are shown in Table K-3. A schematic of an iodide/iodate redox battery with the reactions occuring at either electrode is presented on Figure K-7.

AR0071407

Table K-3: COMPARISON OF SOA AND ADVANCED REDOX BATTERIES

Parameter	Vanadium Redox Battery (State of the Art)	Iodide-Iodate Redox Battery (Advanced Concept)
Environmental Impact	Uses biologically active heavy metal	Uses iodide No heavy metals. Environmentally friendly
Energy Density	25 - 30 Wh/liter	> 50 Wh/liter
Energy losses through membrane	Yes. Cationic reactants diffuse through membrane	No. Anionic reactants cannot diffuse through membrane
Projected Life	10 - 15 years	> 15 years

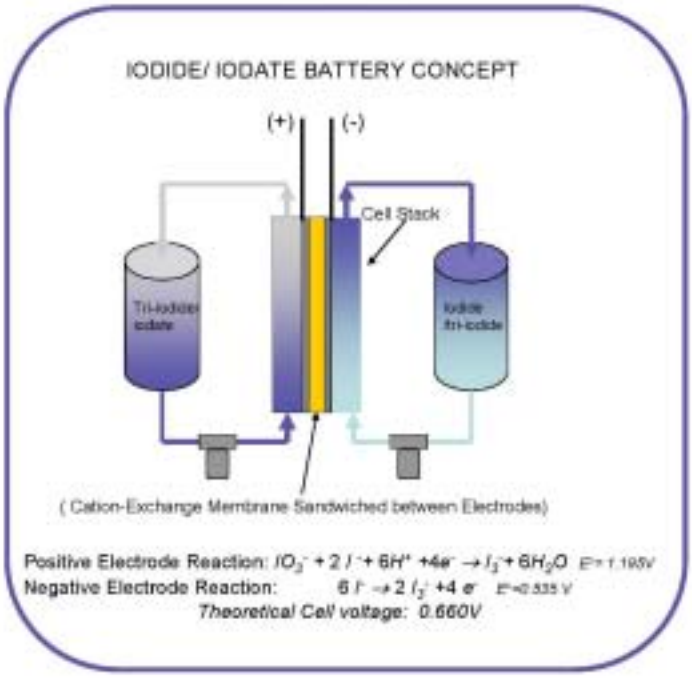

Figure K-7: Schematic of iodide/iodate redox battery.

AR0071408

K-5 Benefits

Quantifiably advances in ESS technologies, and implementation will result in several benefits as shown on Table K-4.

Table K-4. BENEFITS OF ENERGY STORAGE SYSTEMS

LADWP Approach	Benefits	Metrics
Use Battery Energy Storage to supply energy when the generation dips from the wind or solar generators during peak demand periods or demand increases	Lower electricity cost	Lowering peak demand needed from expensive combustion turbine generators with wind and solar generation
Use Battery Energy Storage to supply energy when the generation dips from the wind or solar generators or during system disturbances	Reduced power interruptions and increase reliability	Fewer and Shorter outages
Use Battery Energy Storage to supply energy when the generation dips from the wind or solar generators or during system disturbances	Reduced costs from better power quality	Fewer momentary outages
		Fewer severe sags and swells
		Lower harmonic distortion
Use Battery storage energy from green power reduces CO2 Emissions	Reduced damages as a result of lower GHG/carbon emissions	Percentage of green power relative to total power generated.
Increase of battery storage from green power to reduce need for oil or gas		Percentage of green power relative to total power generated
Reduce reliance on non renewable resources	Greater energy security from reduced oil consumption	Percentage of green energy utilized

AR0071414

1 Introduction

1.1 Purpose of this document

The Los Angeles Department of Water and Power (LADWP) Smart Grid Deployment Plan represents a roadmap to address the anticipated future needs of the people of the City of Los Angeles. By meeting the requirements of both SB 17 and Title XIII, LADWP's Smart Grid Deployment Plan outlines the coordinated and integrated approach in implementing new technologies while maintaining or improving safety and reliability.

1.2 Smart Grid Initiative Background

Smart Grid is a national policy that grew as a response to The Energy Policy Act of 2005, which called for advanced metering. It, however, has been insufficient to achieve the desired goals of energy conservation, migration to renewable energy, and reduction of CO2 emissions from power plants. The federal Energy Independence and Security Act of 2007 called for the implementation of Smart Grid systems as a "Policy of the United States". The new Energy Independence and Security Act of 2007 authorizes $100 M each year from 2008 through 2012 to be divided between five Smart Grid demonstration projects throughout the nation. The Department of Energy is required to report within one year on the status of Smart Grid deployments and identify any regulatory or government obstacles.

Additionally, utility executives and regulators have become increasingly concerned about multiple issues that can only be addressed through an enterprise wide Smart Grid solution. The four main concerns are:

(a) Cost and uncertainty about New Generation and Transmission

(b) Environmental impacts ("Green House" gases emitted from fossil fuel power plants and proposed right-of-ways for transmission lines crossing through pristine forests, deserts and wild life areas to service urban areas) such as those proposed in AB 32, the *California Global Warming Solutions Act, 2006*.

(c) Increasing requirements for the use of Renewable and Distributed Generation (Wind, Solar, Geothermal, Hydro, and Biomass)

(d) Demographics: aging workforce

Regulated utilities in California are now responding to regulatory direction to submit plans for large-scale AMI and Smart Grid initiatives with full delineation of costs and benefits. This regulatory initiative is an aggressive step, seeking to promote customer awareness of peak load periods, and response to peak-sensitive pricing. The Smart

AR0071415

Grid deployments and the associated utility customer features are proceeding through out the State of California.

1.3 Smart Grid Definition

The Los Angeles Department of Water and Power maintains that the definition of a smart grid is a system which facilitates the integration of advanced technologies in existing networks to improve system performance, power flow control, and reliability. Such a system is characterized by the following:

(a) Increased use of cost-effective digital information and control technology to improve reliability, security, and efficiency of the electric grid.

(b) Dynamic optimization of grid operations and resources, with cost-effective full cyber security.

(c) Deployment and integration of cost-effective distributed resources and generation, including renewable resources.

(d) Development and incorporation of cost-effective demand response, demand-side resources, and energy-efficiency resources.

(e) Deployment of cost-effective smart technologies, including real time, automated, interactive technologies that optimize the physical operation of appliances and consumer devices for metering, communications concerning grid operations and status, and distribution automation.

(f) Integration of cost-effective smart appliances and consumer devices.

(g) Deployment and integration of cost-effective advanced electricity storage and peak-shaving technologies, including plug-in electric and hybrid electric vehicles, and thermal-storage air-conditioning.

(h) Provide consumers with timely information and control options.

AR0071416

(i) Develop standards for communication and interoperability of appliances and equipment connected to the electric grid, including the infrastructure serving the grid.

(j) Identification and lowering of unreasonable or unnecessary barriers to adoption of smart grid technologies, practices, and services.

1.4 Stakeholders

1.4.1 Customer

LADWP ratepayers are the Customers and will realize the monetary, social, and environmental benefits of the plan.

AR0071417

2 LADWP Smart Grid Initiatives

2.1 Smart Grid Objectives

Currently, the Department is involved in two strategic initiatives related to Smart Grid. The first is the Smart Grid Regional Demonstration Project and the second is the Smart Grid Investment Program.

The Smart Grid Regional Demonstration Project began in December of 2009, when LADWP was awarded 60.2 million dollars grant from the Department of Energy for the American Reinvestment and Recovery Act for Smart Grid Demonstrations. As a result of the award, LADWP is managing a consortium of Los Angeles metropolitan area research institutions with established energy and technology transfer programs. Together, the team is carrying out a regionally unique demonstration by using innovative technology test beds located at LADWP's partner university campuses and technology transfer laboratories to prove the viability of the demonstration technology. Additional research is being conducted to explore options for informed, enabled customers based on historical usage and pricing data. This research uses a multi-tiered rate approach to address the diversity of customer demands by exploring time-varying and time-of-use products for the end consumer. The regional demonstration project includes four interrelated project initiatives, which will be incorporated into the long term investment program:

(a) A fully integrated demonstration of Smart Grid operation and technology as applied to Demand Response.

(b) A comprehensive portfolio of research empoying a unique test bed structure to identify historical usage and consumer adoption obstacles essential for succesful adoption of Smart Grid Technologies and improved energy usage patterns.

(c) Demonstration of next generation cyber security technologies using the Regional Project as the driving source of specific system architecture and models.

(d) The integration of electric vehicles into the LADWP managed grid, addressing solutions to overcome both technical and social impediments.

The Smart Grid investment plan is a 10-year project that incorporates 11 strategic initiatives.

2.1.1 Links with the Department's Strategic Objectives

The Smart Grid Implementation Plan continues to align LADWP's efforts to implement the technology with the goal of increasing LADWP's Power System monitoring,

AR0071418

control and reliability while decreasing operating costs and gaining significant efficiencies.

2.2 LADWP Smart Grid Initiatives in Progress

"Smart Grid" is a term used to describe a variety of advanced information-based utility improvements. Smart Grid is a major enabler for many existing and potentially new Demand Side Resource programs. Smart Grid is a national policy evolving from the Energy Policy Act of 2005. Smart Grid refers to intelligent data gathering and advanced two-way digital communication capabilities overlaid on electric distribution networks to provide real-time data that enhances the utility's ability to optimize energy use. Smart Grid technologies can turn every point in the existing network—including every meter, switch and transformer—into a potential information source, able to feed performance data back to the utility instantly. Smart Grid Technologies will provide utilities with the information required to implement real-time, self-monitoring networks that are predictive rather than reactive to instantaneous system disruptions. It can enable the utility and consumer to make decisions to optimize the use of energy, improve reliability, and reduce the consumption of fossil fuels.

Section 8360 of the Senate Bill 17 defines the policy that governs the way utilities modernize transmission and distribution systems. LADWP's eleven Smart Grid Initiatives are designed to be collectively compliant with SB17. The following is the list of the initiatives:

(a) Renewable Integration

(b) Transmission Automation Initiative

(c) Substation Automation Initiative

(d) Distribution Automation Initiative

(e) AMI Metering Initiative

(f) Demand Response Initiative

(g) Communications Initiative

(h) Cyber Security Initiative

(i) System and Data Integration Initiative

(j) Feed-In Tariff Initiative

(k) Solar Incentives Program

AR0071419

2.3 Renewable Integration

LADWP has a comprehensive Integrated Resource Plan where new Wind, Solar, and Geothermal Power Plants, as well as Energy Storage, and Electric Vehicles will be incorporated into the power generation mix. Currently, the ECS/Historian Servers have been installed at Pine Tree Generation Station, and there are plans to install more of these servers at each of the power plants. These servers allow for real-time monitoring and control of renewable sources, which will be equipped with automation equipment in order to facilitate peak shaving activities and to better support the adoption and utilization of renewables.

2.4 Transmission Automation Initiative

For years, LADWP has worked in substations to meter the transmission lines and record Phasor Measurement Units (PMU). These measurements are used to determine the health of the Electrical System. LADWP will install PMUS, and upgrade Tie-Line Meters to improve measurement, provide backup metering at Tie Points, collect dynamic reads, and reroute power. The real-time data provided by PMU will be used for predicting instability in the transmission system and undertaking preventive actions.

2.5 Substation Automation Initiative

For the past five years, LADWP has implemented a comprehensive program to install a new Power System Substation Automation System (SAS) from the Energy Control Center to the Substations, transmission, and Generation Stations. Currently, 80 of the approximate 200 substations and generation stations have been updated to the new Substation Automation, and a new SCADA system has been implemented. There are approximately 70 more stations in the inventory that will be implemented over the next two to three years. Approximately 840 feeders now have remotely controlled circuit breakers and remote monitoring of megawatt loading of wire/cables. A significant amount of data is already being processed through the SCADA system and is available to the load dispatchers and other personnel on an as needed basis. At the conclusion of this project, the vast majority of feeders at all substations will be observable and controllable from the Energy Control Center.

2.6 Distribution Automation Initiative

There have been several pilot projects for the Distribution Automation relating to devices outside the substation walls (Current's Broadband over Power Line project, Ricochet Spread Spectrum project, and Telemetric Cellular project). These projects were never rolled out as the industry was still being developed and LADWP's decision was to wait until more robust solutions were available. Additionally, some of the pilot programs were never considered industry standard since it was using obsolete

AR0071420

technology. The LADWP is currently evaluating fault indicators, remotely controlled switches and automatic cap banks. These devices can be used for dynamic optimization of the distribution system.

2.7 AMI Metering Initiative

LADWP has been progressing over the past few years with the AMI Metering Initiative.

- As of 6/01/11, the LADWP has installed 162,200 AMR meters
  - Residential Meters (F meters) – 85,000 (using RF Technology and one way communication providing billing information for walk or drive by meter reading)
  - Small Commercial Demand Meters (FM meters) – 68,000 (using RF Technology and one way communication providing billing information)
  - Large Commercial Wireless Meters (A meters) – 9,000 (using Cellular Technology and two way communication providing billing information and load profile information)
- AMR meters represent approximately 10.6% of the total meters in the system but over 45% of the power revenue

Wireless meter reading and real-time pricing are available for 9,000 Large Commercial Customers with demand greater than 200kW. The newest AMI meters have the capability of short range connectivity. This feature will be used by the Home Area Network devices that display various real-time energy consumption data to the customers.

2.8 Demand Response Initiative

LADWP has had a Demand Response (DR) rate for years for large industrial users. Currently, there are 30 Megawatts of interruptible load, but very rarely has this been used because LADWP has had a philosophy to cover all its loads. This pilot program is also voluntary in that when a load reduction is required, the customer has the option to not participate and pay for the higher cost of energy. Currently, the LADWP is planning to develop a formal demand response program that will allow the Department to reduce generation cost and distribution system strain during peak consumption periods.

2.9 Communications Initiative

The component that pulls all of the initiatives together is the common communication network. Over the past ten years, thousands of miles of fiber optic cable has been installed in over 72 substations as part of a fiber optic broadband infrastructure. The plan is for all substations to have fiber optic connections within the next two years.

AR0071421

LADWP evaluates different communication protocols that can be used for the real-time control and observation of deployed automation equipment.

2.10 Cyber Security Initiative

The implementation of Smart Grid will involve a wide deployment of smart remotely controlled network capable devices. These devices can be potential points of cyber attack due to network connectivity. This is why NERC and FERC have developed strict procedures and guidelines that require utilities to treat any critical cyber asset (CCA) with great attention. The breach of CCA can result in critical damage to the power distribution system.

Due to the importance of Cyber Security, the Smart Grid will need to better understand and improve the cyber security, and more importantly, three key items will be developed:

- Grid Resilience: this effort will show how the Smart Grid can operate resiliently against physical and cyber attack.
- Operational Effectiveness: this effort will demonstrate a complete cyber security testing approach for components and installed systems.
- Redefinition of Security Perimeter: this effort will demonstrate new cyber security measures that address the expansion of this perimeter by Smart Grid technologies to the meter in residential and commercial sites.

2.11 System and Data Integration Initiative

Significant progress has been made in the Power System in implementing the best of breed systems (see **Figure 2.11-1** Power System Technology Architecture). These systems are the backbone of the business and information processes in the Power System. Additionally, significant integration between these and the corporate systems is in place.

In particular, OSIsoft's Pi Historian is a fast real time data processing system that has been purchased and installed by LADWP. The next Pi Historian initiative is to use it as a central repository for all of LADWP's real-time data and to allow access to the appropriate users of the data throughout the utility. LADWP has currently installed the Pi Historian in two locations (ECC and JFB) with a tag count of 20,000 data points. There are three pilot Pi Historian applications running at this time: 1) door/gate alarm; 2) Operation logger; and 3) Power System Dashboard real time data. Five user groups (Reliability, Planning, Station Operators, Grid Operations, and Meter) are also currently developing new applications.

In addition, LADWP is working on integrating the Meter Data Management System (MDMS), Outage Management System (OMS), and Customer Information System

AR0071422

(CIS) with various Web services. These services will be designed to provide accurate and timely information to customers regarding their consumption, billing, any pending outages and restoration statuses. The customers will have the option to adjust their accounts to set up their profile and notification preferences.

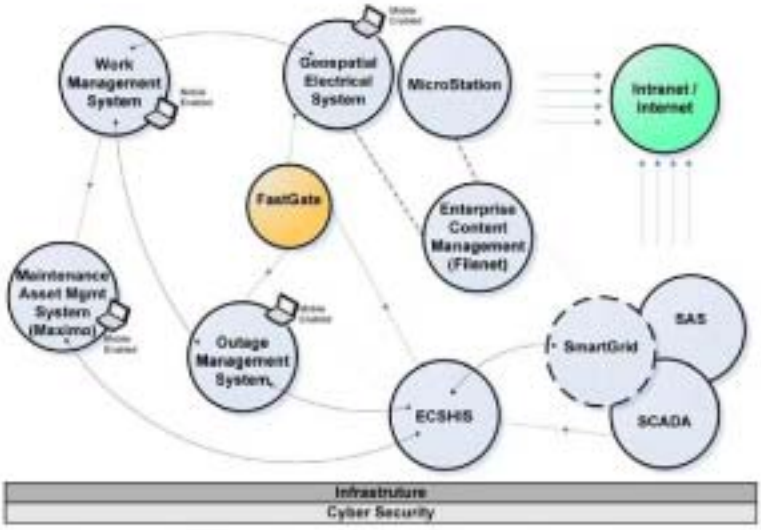

Figure 2.11-1 Power System Technology Architecture

2.12 Feed-In Tariff Initiative (FiT)

FiT seeks to purchase energy from small and medium-scale renewable energy projects (from 30 kilowatts up to one megawatt in AC capacity) within the service territory of LADWP under a long-term Standard Offer Power Purchase Agreements (SOPPA). The SOPPA terms are standard for all participants, can be up to 20 years in duration, and participants will be paid the bid base price of energy plus Time-of-Delivery (TOD) multipliers. FIT is a distributed generation (DG) program designed for the local Los Angeles market, and gives LADWP customers the opportunity to sell energy to LADWP from using their property as the DG site.

2.13 Solar Incentive Program (SIP)

The LADWP Solar Photovoltaic Incentive Program provides financial incentives to LADWP customers who purchase and install their own solar power systems. LADWP currently also provides an additional incentive payment for systems using PV modules manufactured in the City of Los Angeles.

LADWP currently provides a Los Angeles Manufacturing Credit (LAMC) for qualifying photovoltaic equipment manufactured in Los Angeles as approved by the LADWP guidelines. The goal of the LAMC is to promote local economic development through

AR0071423

manufacturing and job creation within the City of Los Angeles and to reduce costs through increased volume and competition.

3 Proposed Deployment Plan

The overall scope of the Smart Grid Deployment Plan includes the following three overlapping phases:

3.1 Implement a short term plan (one year horizon)

This plan includes the following coordinated activities:

- Create a Smart Grid System Architecture (**Table 3.1-1** ***SG Architecture (Phase 1) Schedule*** & **Table 3.1-2 SG Architecture (Phase 2) Schedule**)
- Create a Comprehensive Business Plan/Case (**Table 3.1-3 SG Business Plan Schedule**)
- Integration of Various Information Systems
- Participate in Standard Development
- Creation of a Multi Disciplinary matrix team

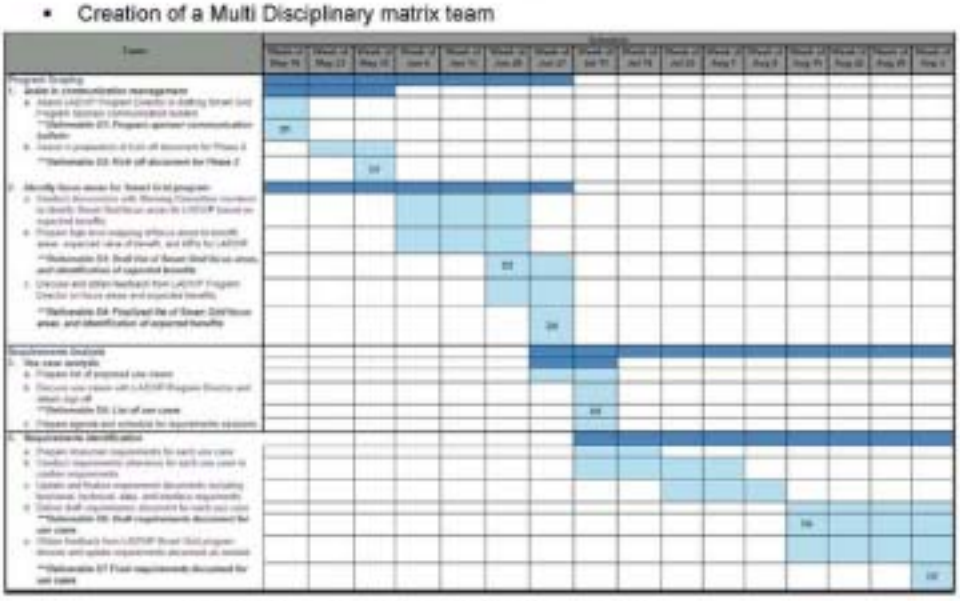

Table 3.1-1 SG Architecture (Phase 1) Schedule

AR0071424

Table 3.1-2 *SG Architecture (Phase 2) Schedule*

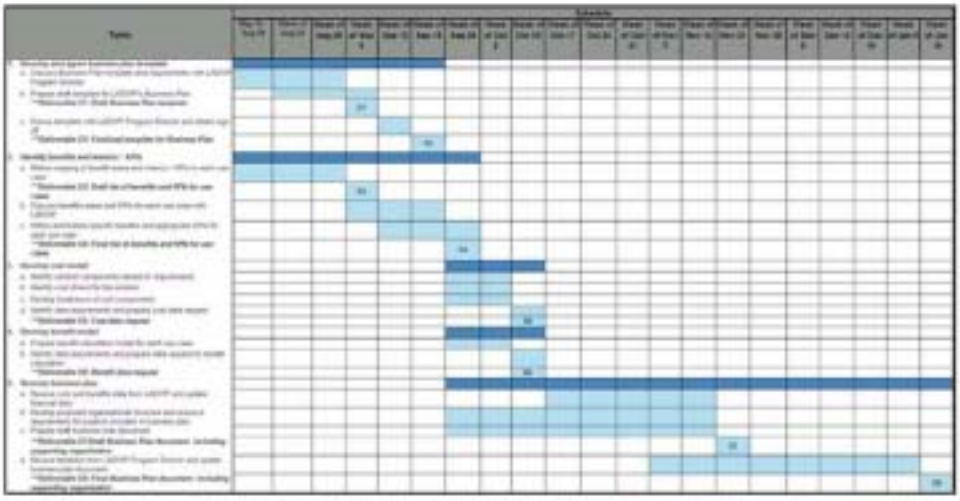

Table 3.1-3 *SG Business Plan Schedule*

3.2 Implement a mid term plan (up to five years horizon)

This plan includes the following coordinated activities:

- Complete and implement LADWP's ARRA Smart Grid Regional Demonstration Project, which focuses on Customer and Behavioral Studies, Cyber Security, Demand Response, and Electric Vehicles.

AR0071425

Figure 3.2-1 *Smart Grid Regional Demonstration Project Schedule* below shows the implementation schedule of the Smart Grid Regional Demonstration Project.

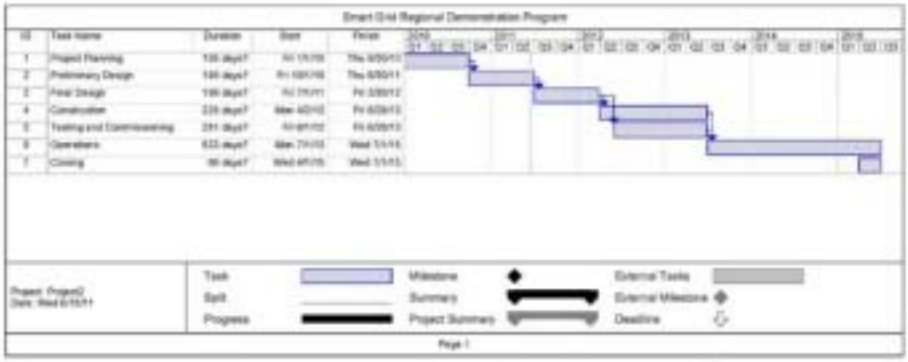

Figure 3.2-1 Smart Grid Regional Demonstration Project Schedule

- Implement the balance of the SAS project to automate all generation, substation, and transmission with the SCADA system. **Table 3.2-1** *Substation Automation Project Installation Progress Schedule* below shows the overall schedule of activities to implement the SAS project.

Table 3.2-1 Substation Automation Project Installation Progress Schedule

- Implement the balance of the projects at ECC to use all of the features and upgrades of the SAS and other systems with the new technology. **Figure 3.2-2** ***ECC Plans to be Implemented*** below shows the activities and systems to be implemented.

Figure 3.2-2 ECC Plans to be Implemented

- Implement the balance of the projects at ETC to use all of the features and upgrades of the Smart Grid systems with the new technology. **Figure 3.2-3** ***ETC Plan and Enhancements*** below shows the various activities to be implemented.

AR0071427

Figure 3.2-3 ETC Plan and Enhancements

- Implement a new CIS and Supply Chain System

The effort must be made to implement a new CIS, and a new Supply Chain Corporate System. These systems will be able to manage the new information and transaction of a Smart Grid system.

Other activities to be implemented during this phase are as follows:

- Implement the balance of the electric model with the GIS system and engineering design tools
- Create and advertise Multiple RFPs as needed to start the implementation of the Smart Grid components
- Create Multiple contracts as needed to bring the vendors on-board

3.3 Implement the full Smart Grid Features (up to 10 years)

Implement all the remaining features indicated in this plan in various phases based on the requirements and needs identified, and with the dynamics of the utility and technology environment. The phases of this significant program could include two large pilot periods where various telecommunication technologies will be tested while Smart Grid technology will be utilized to cover overhead, underground, single family residences, multi-family residences, and medium and large customers in a couple of neighborhoods. The final phase would be the full city wide implementation assuming the data and results from the pilot programs are satisfactory.

AR0071428

The full functionality of the Smart Grid could include all of the following aspects:

(a) Outage Notifications

(b) Transformer Monitoring

(c) Capacitor Controls

(d) Line Switch Controls

(e) Automatic Meter Reading

(f) Load Control of residential and commercial devices (DSM Program)

(g) Video Surveillance via Smart Grid

(h) Fault Management

(i) Transformer Deterioration

(j) Transformer Overloading

(k) Current Monitoring

(l) Cable Management

(m) Surge Protection

(n) Lighting Controls

(o) Weather

(p) Municipal Applications

(q) Other applications as they become available.

Other features could include:

- Installation of Smart Grid equipment in the City of Los Angeles Facilities
- Installation of Smart Grid equipment and potentially replacement all of the water meters
- Access to broadband capabilities (Internet access, VoIP, video) for City of Los Angeles Municipality
- Access to City of Los Angeles Municipal information via broadband connections

AR0071429

- Set up an internal LADWP organization to maintain and operate the Smart Grid equipment
- Maintain, install, and operate the Smart Grid equipment through the following organization and service components:

  1. Services
  2. Customer response center
  3. Network Operation Center (NOC)

3.4 Related Projects

The following projects are related to the Smart Grid as follows:

1. Substation Automation System: Extension and upgrade of the remaining Switching, Receiving, and Distribution Systems
2. Telecommunications system: Extension and upgrade of the telecommunications to support the Power System operations through the implementation of a fiber optic broadband network.
3. Subtransmission and distribution switches: Automation of subtransmission and distribution switches, implementing line monitoring, line switch control, and 4.8 kV line capacitor bank control.
4. Fault and outage detectors: Installation of remotely monitored fault and outage detectors which would provide a means to locate faults and outages on selected 4.8 kV distribution lines.
5. Operating orders, procedures, and processes: Re-engineering of operating orders and processes as required for monitoring and controlling changes of the Power System.

3.5 Constraints

The following are potential constraints:

- Budget/Cost
- Regulatory environment which may limit Smart Grid installations
- Internal Resources
- Political environment (City/State/Federal)

AR0071430

3.6 Urgency

The timing of LADWP's Smart Grid Deployment coincides with the initiatives by other major U.S. utilities. Additionally, the Department of Energy is encouraging utilities to invest in Smart Grid by offering grants and the regulatory environment seems to support Smart Grid as an alternative to the existing utility practice.

3.7 Procurement Process

The Smart Grid Plan will utilize the procurement process as follows:

(a) Determination of requirements

(b) Preparation of RFP(s)

(c) Vendor(s) Selection

(d) Preparation of Agreements

(e) Initial Implementation – Phase 1

(f) Phase 1 Evaluation

(g) Multi-phase Implementation over the next 10 years.

4 Critical Milestones

4.1 Schedules and Critical Milestones

The Smart Grid Plan assumes a 1-year, 5-year, and 10-year implementation.

4.1.1

4.1.2 Critical Milestones

Table 4.1.2-1 Critical Milestones illustrates the critical milestones:

Milestone or Event	Significance
Smart Grid Business/Project Plan and Architecture Presentation	Get concurrence from Management
Setup of Smart Grid Project Committee	Establish Project Committee
Preparation of Smart Grid Project Requirements	Establish project requirements
Advertise Request for Proposals	Request for Proposals
Vendors Selection	Selection of qualified bidder
Board Approval	Contract approval by LADWP Board of Commissioners

AR0071431

City Council Approval	Contract approval by City of Los Angeles
Contracts Award	Execution of contract award
Implementation Phase 1	Implement Smart Grid Phase 1 (Pilot Programs)
Evaluation of Phase 1	To continue Full Implementation
Begin full deployment	Implement city wide

Table 4.1.2-1 Critical Milestones

AR0071432

5 Budget

Smart Grid equipment costs are expected to continue to drop due to technology advances and significant market changes, **Table 4.1-1** Budget Estimates for various Systems given below is our best estimate for various alternatives at this point. As RFPs are produced and responses are received, we will have a better idea as to the cost of these types of systems and process.

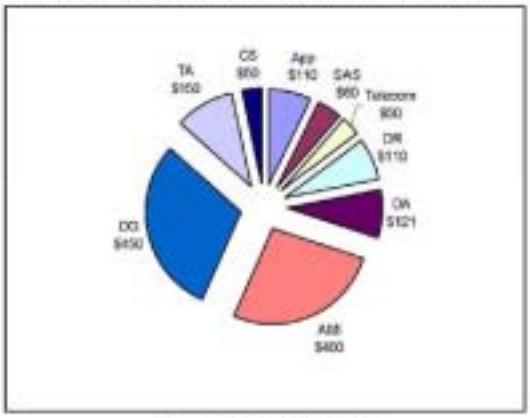

Figure 4.1-1 P2P Cost Graph

AR0071434

6 Impacts

6.1 Internal

The Smart Grid equipment will impact several areas within LADWP. **Table 6.1-1** Potential Impacts within LADWP shows some potential impacts on these organizations:

Area within LADWP	Nature of impact
Meter Reading	Automated method reading of electric meters
Control System Operations	may gain capability to control devices at all levels
Customer Service	Establish direct communications with customer
Electric Trouble Dispatch	Will process trouble calls using Smart Grid information
Engineering Design	Power network design process (OH/UG)
Distribution Line Crews	Maintain and operate new Smart Grid equipment
ITS	Provides support of Smart Grid network equipment
Water Meters	Automated method of reading water meters

Table 6.1-1 Potential Impacts within LADWP

Area within the department	Nature of impact
Energy Control Center	Will use SAS for real-time data instead of current RTU
Electric Trouble Center	Will use real-time data
Plant Control System Operations	Will use real-time data access and archived data
Substation Operations	Selected station status information will be available
Substation Maintenance	Will access intelligent relay settings and logs without having to connect directly to the devices
ITS	Provides support of ECS WAN network.
Power Systems Operation and Maintenance	Provides support of SAS application software and hardware
Engineering	Will use archived data

Table 6.1-2 Potential Impacts within department

AR0071435

6.2 External

Table 6.2-1 Potential Impacts external to LADWP shows some potential impacts on organizations that are external to LADWP:

Area external to LADWP	Nature of impact
City of Los Angeles	Gain fiber optic broadband infrastructure
Broadband Companies	May perceive competition from LADWP and receive services.
Gas Utility	Opportunities to collaborate with LADWP
State of California (CPUC)	May encourage Smart Grid installation at Los Angeles

Table 6.2-1 Potential Impacts external to LADWP

7 Smart Grid Business Plan & Evaluation Strategy

A Smart Grid business plan will be developed in conjunction with the roadmap and architecture development activities which will include cost-benefit analysis of projects for implementation of the functionality identified in the Smart Grid architecture and roadmap. The business plan documentation will outline the project description; costs associated with the implementation; and expected benefits. The financial analysis will be based on estimated benefits and costs information and will be updated throughout the course of the implementation of the projects as the actual cost data become available. The business plan development process will include an assessment to identify the benefit areas and develop an estimate of actual quantifiable benefits expected from investment into particular Smart Grid area. The benefits resulting from LADWP's Smart Grid investments could be in various areas including but not limited to better customer service, reduced operational costs, higher operational efficiency, and achievement of environmental goals. The benefit estimation will be developed using LADWP KPIs and other relevant metrics. The business plan will also include a cost model to estimate the implementation costs of each project. The cost estimates will be based on assumptions of the technology and implementation choices, and will be updated during implementation of the projects with actual costs and implementation plans.

8 Smart Grid Safety

Smart Grid Deployment Plan requires specific installation, maintenance, and operation procedures, which LADWP personnel will need training on. Additionally, the Smart Grid equipment will require compliance and resolution of issues relating to the following state regulations:

(a) California Public Utilities Commission - General Order 128 – Construction of underground electric supply and communication systems.

AR0071436

(b) California Public Utilities Commission - General Order 95 – Overhead electric line construction.

(c) California Public Utilities Commission - General Order 165 – Inspection Cycles for electric distribution facilities

(d) The Smart Grid vendors and utilities are currently handling all of these issues with success.

9 Smart Grid Operational issues

LADWP intends to own and operate the Smart Grid equipment. The ownership entails the support and ability to operate the Smart Grid network by LADWP personnel.

The following are potential operational issues:

- 24/7 operational support of the Smart Grid equipment
- Training of Crews for the operation and maintenance of the Smart Grid equipment
- 24/7 operational support of the telecommunications and fiber optic broadband infrastructure access

10 Smart Grid Performance Measurement

The critical success factors essential for plan success are as shown in **Table 10-1** Critical Success Factors:

Critical Success Factors	Measurement method
Plan Buy-in from LADWP Board	LADWP Board Approval
Plan Buy-in from City	City Council approval
Appropriate plan budget	Budget approval
Smart Grid Technical Feasibility	Market proven Smart Grid technology
Secure staffing resources	Appropriate resource leveling based on project scope
Regulatory Support for Smart Grid	City, State legislative approvals for Smart Grid implementation

Table 10-1 Critical Success Factors

AR0071437

11 Smart Grid Product Benefits Realization

The benefits will be measured as shown in **Table 11-1** Benefits:

Potential Benefits	Measurement method
Municipal fiber optic broadband Capability	No. of City of Los Angeles Broadband users
Smart Grid enabled Automated meter reading	No. of automated meter reads
Customer Energy Management Programs	No. of devices under Direct load control
Improved reliability	No. of Utility applications in service
Additional Revenue Sources	Capitalize on revenue generating opportunities

Table 11-1 Benefits

AR0071438

12 Conclusion

The Los Angeles Department of Water and Power is dedicated to integrating new technologies to improve system performance, power flow control, safety and reliability. By maintaining a high level of commitment and service for the City of Los Angeles, LADWP is taking the necessary steps to:

(a) Coordinate efforts across multiple stakeholders

(b) Integrate new technologies to supplement the power system

(c) Deliver safe, secure, and efficient electrical service well into Los Angeles's future

LADWP's overall strategic plan is inclusive of the Smart Grid Deployment plan. LADWP's focus is the City of Los Angeles, customer enhancement, utility services, and operations. LADWP looks forward to further collaborate with policymakers, customers, and stakeholders as the process of Smart Grid implementation unfolds.

AR0071440

Appendix M Model Description and Assumptions

M.1 Overview

The study horizon for the model analysis is the 20 year period 2011 through 2030. In performing this modeling, it is necessary to assume certain actions are taken in each of the next 20 years. However, it must be understood that the Integrated Resource Plan (IRP) is an ongoing process. A new IRP is developed every two years. Between each 2-year interval, the most recent IRP is modified if appropriate. The key results from this IRP analysis is the action plan that will be put in place for the next 1 to 5 years. These near-term actions are important recommendations that will enable and support the goals and objectives of the long term plan.

This Appendix presents the Model Analysis and is organized as follows:

- Section M.2, Model Description, provides a description of the model selected by LADWP to simulate the operation of its power system under different futures and with different resource portfolios.
- Section M.3, Renewable Resources Selection Process/Gap Analysis, describes the method used to assess the amount of future renewables required, and the valuation process used in selecting the future renewable resource portfolio.
- Section M.4, Case Options, reviews the key resource distinctions between the 3 case options under consideration.
- Section M.5, Model Inputs and Assumptions, presents the major input parameters that were used in the production cost model runs.

AR0071441

M.2 Model Description

LADWP has chosen a widely used and industry accepted hourly chronological unit commitment and dispatch model to simulate the operation of the LADWP power system under different futures and with different resource portfolios. The model is the Planning & Risk model (PaR) licensed from Ventyx (an Atlanta based software firm). It uses the PROSYM unit commitment and dispatch algorithm.

PROSYM is designed for performing planning and operational studies, and as a result of its chronological structure, accommodates detailed hour-by-hour investigation of the operations of electric utilities. Because of its ability to handle detailed information in a chronological fashion, planning studies performed with PROSYM closely reflect actual operations. PROSYM considers a complex set of operating constraints to simulate the least-cost operation of the utility. This simulation, respecting chronological, operational, and other constraints, is the essence of the model.

This model looks at the LADWP load for each hour and then dispatches LADWP generation supplies on an economic basis (lowest variable cost units first) until the load is met. The model output reflects all the variable costs incurred in meeting the load for each study performed. The fixed costs for the resources are added to the modeled variable costs to develop the total power cost incurred in meeting the load.

The model is also capable of representing certain transmission constraints on a utility system. LADWP load is generally confined to the geographic area of Los Angeles. An IRP would not generally be a replacement for transmission planning activities needed in the service area. However, LADWP does have generation outside of Los Angeles and has transmission rights to other areas of the Western Interconnect. To better represent the constraints and opportunities related to these remote facilities, the modeling topology depicted on Figure M-1 was developed for this IRP.

AR0071442

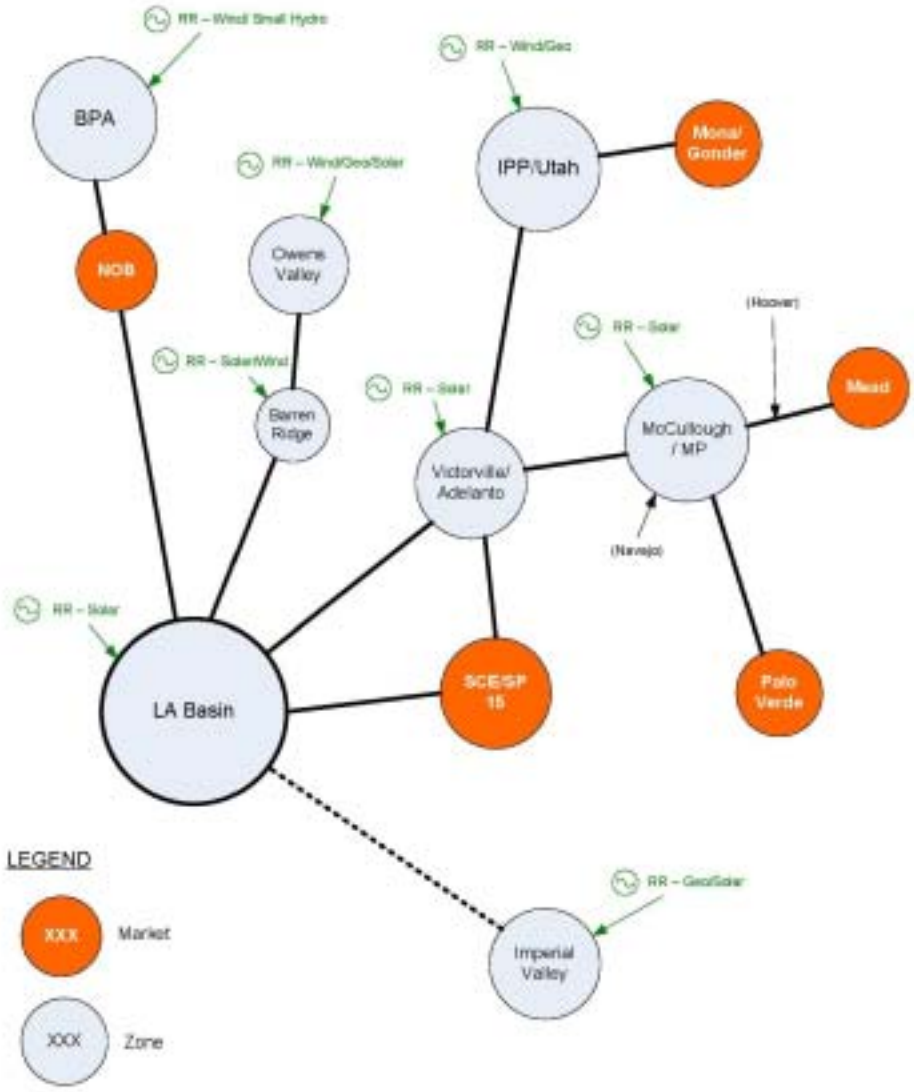

Fig M-1: LADWP Modeling Topology.

On a day-to-day basis, LADWP will buy power in spot markets if such a purchase can be done both without causing a reliability problem and if the price of the spot market power is less than the operating cost of its own power plants. Similarly, on a day-to-day basis, LADWP will sell power in spot markets if the price of power in the spot market is greater than the cost of operating an LADWP resource and the power is not needed to meet LADWP load. In an IRP analysis, it may or may not be desirable to attempt to reflect spot market activity. For this IRP, short term and long term market purchases and sales were included in the overall energy mix. For resource adequacy, some limited Q3 purchases were included to supply short term capacity deficits in future years resulting from coal divestment and load growth.

AR0071443

M.3 Renewable Resources Selection Process/Gap Analysis

The gap analysis in this IRP evaluated both a Resource Adequacy (RA) need as well as a need to meet certain goals for renewables as a percentage of billed energy (renewable need). The RA need compares available generation supplies to the load that needs to be served. For LADWP, this comparison was based on the annual peak load plus a planning reserve margin. In addition to a system wide demonstration of RA, a certain amount of generation needs to be located in the Los Angeles service territory to assure local reliability. Sections 2.4.5, 3.4.1, 4.2.1.4 and 4.3.1 of this report discuss the LADWP approach to RA.

M.3.1 Amount of Renewables Needed

To determine the amount of renewable energy necessary to meet future targets, forecasts were made for the future power demand and the amount of existing renewable capacity available to meet these requirements. The difference between the projected amount required and the amount currently being utilized is the net short that will need to be acquired to meet RPS guidelines. A description of the methodology undertaken to define the future renewable needs is outlined below.

LADWP Renewable Net Short

The net short is the generation target to be met with resources identified in this project. The calculation for the net short was performed using the following equation:

Net Short(GWh) = (Forecasted Energy Sales) x (Annual Renewable Percent Goal) – (Operating Renewable Resources – Under Construction and Pre-construction Renewable Resources - Renewable Energy Purchases)

SB 2 (1X) has established the level of renewables required by 2020 and beyond, and also sets interim targets between now and 2020. These levels and targets represent the *Annual Renewable Percent Goal* parameter in the equation. By incorporating forecasted sales, existing renewable projects, and current and forecasted renewable energy purchases, the net short can be calculated.

M.3.2 Renewable Resources Selection Process

Over the last ten years, LADWP has issued several requests for proposals for renewable energy and gained a thorough understanding of the nature and availability of the different renewable resource technologies. This knowledge was used in developing the renewable portfolio. Additionally, LADWP largely considered renewable resources within the Western Governors' Association's Western Renewable Energy Zones (WREZ). In the WREZ initiative, Qualified Resource Areas were defined as areas of dense, high-quality renewable energy resources, meeting various resource size, quality, environmental, and technical criteria. LADWP screened all resources to ensure they are located near available LADWP transmission infrastructure. Assumptions were made for the cost and performance of each technology used to convert the

AR0071444

renewable resources to electricity. These assumptions were used in calculating the levelized cost of electricity.

A valuation process designed to provide a single ranking value to a resource was then applied. The valuation process is a method to rank the total value of separate renewable resource projects, and accounts for such parameters as transmission costs, integration costs, supply curves, load shapes, the capacity benefit provided by the resource, capital and O&M costs, financial factors and other measures This step is intended to identify resources with the combination of lowest cost and highest value. The valuation approach is similar to the bid evaluation process many utilities use when procuring renewable resources.

After applying the appropriate constraints, resources were selected and added progressively to the renewable resource mix based on lowest rank cost and transmission availability until the net short was mitigated. To assess and rank projects consistently, a method must be developed to measure the economics of all resources on a consistent basis. Renewable technologies all have different characteristics, with different cost requirements and energy delivery patterns. Resource valuation is a way to measure different renewable resources on a comparable basis.

M.3.3 Renewable Generation Cost

The cost of generation is calculated as a levelized cost of energy ("LCOE") at the point at which the project will interconnect to the existing transmission system. The LCOE for a project is the total life-cycle cost of generating electricity at the facility normalized by the total generation from the facility and is calculated in terms of dollars per megawatt hour ($/MWh). LCOE provides a consistent basis for comparing the economics of disparate projects across all technologies and ownership.

For each project or resource class, a pro forma financial analysis was conducted to determine the life-cycle cost. This pro forma model uses input assumptions for key project variables to determine expected revenues, costs, and year-by-year after-tax cash flow over the project life. The pro forma model used is consistent with the model used in CEC's Cost of Generation model, as well as those used in WREZ and California's Renewable Energy Transmission Initiative. It is also very similar to the model used by the CPUC to calculate the Market Price Referent (MPR), with the necessary modifications to make the calculations appropriate for renewable resources, including the modeling of tax incentives, accelerated depreciation, and other incentives.

The analysis included appropriate assumptions for each project. Some assumptions were tailored to be technology specific, such as financing terms and appropriate tax incentives. Other assumptions such as capacity factor and capital cost depended on geography and the available natural resource. Specific costs included in the generation costs were:

- Capital costs
- Generation interconnection costs ("gen-tie")
- Fixed operation and maintenance
- Variable operation and maintenance

AR0071445

- Heat rate (if applicable)
- Fuel costs (if applicable)
- Incentives
- Net plant output
- Capacity factor
- Economic life

M.3.4 Renewable Generation Cost

The integration cost of a project is the indirect operational cost to the transmission system to accommodate the generation from the project into the grid. The addition of substantial amounts of intermittent and as-available renewable resources could result in substantial generation swings on the transmission system, and the grid operator must accommodate these swings by ensuring there is sufficient regulation service, modifications to current daily ramps, additional reserve capacity, and voltage support. Additional integration costs will include wear-and-tear on resources if they are required to repeatedly cycle to adjust for the intermittent resource output.

M.3.5 Renewable Resource Capacity Value

The capacity value of a generating resource is based on its ability to provide dependable and reliable capacity during peak periods when the system requires reliable resources for stable operation. Resources that can provide firm dependable capacity will have a higher capacity value than resources that cannot. In the WREZ model, the ability of a renewable resource to generate power during the top 10 percent of the model's yearly load was used as the capacity credit. LADWP uses a more conservative approach by considering the dependable capacity which varies depending on the resource type and is a fraction of the total available capacity as shown in Table 3-4.

The baseline value of capacity is the cost of the next most likely addition of low-cost capacity, defined as the fixed carrying costs of a simple cycle gas turbine generator. This includes the capital costs, fixed operations and maintenance costs, and other fixed charges associated with the gas turbine generator capacity, expressed as a dollar per kilowatt per year ($/kW-year). The fixed carrying cost assumed in the model is $100/kW-yr. The baseline capacity value does not include variable costs, such as fuel purchases. For new projects, the capacity factor is derived from the projected generation profile for the resource. The formula for calculating capacity value ($/kW-yr) is:

*Capacity Value ($/MWh) = (Dependable Capacity Factor) x (Baseline Capacity Value) / (Project Capacity Factor * 8760/1000)*

AR0071446

M.3.6 Renewable Resource Energy Value

The energy value of a resource assesses the value of its hourly output to the energy markets. Resources that produce more power during high-price, peak demand periods will have a higher energy value than resources that provide power primarily during low demand periods.

The formula for calculation of energy value is:

$$\textit{Energy Value (\$/MWh)} = \Sigma\,[\textit{(Energy Value in Time Period)} \times \textit{(Energy Output in Time Period)}] \,/\, \textit{Total Energy Output}$$

M.3.7 Renewable Energy Portfolio

Utilizing the methodology described in the previous subsections, a best-value portfolio of renewable resources was developed. This portfolio was applied to all case options considered in this IRP. Because regulation mandates the procurement of specific levels of renewables, the quantities are predetermined for compliance periods in accordance with SB 2 (1X). The renewable capacity and energy production schedules shown in Figures M-2 and M-3 were used in all cases including the recommended case (Case 2) and are consistent with the procurement targets established by SB 2 (1X).

M.4 Case Options

Coal divestiture is the key parameter distinguishing the different 2011 IRP strategic cases. Unlike other areas that are constrained by mandated regulatory requirements (such as renewable resources), the decision to divest from coal earlier than legally required is discretionary and thus appropriate for analysis. The 2011 IRP strategic cases are designed to assist policymakers and ratepayers to make informed decisions regarding accelerated coal divestment, particularly with regard to the environmental benefits and resulting resource and electricity rate impacts. Included in Table M-1 is a description of the strategic cases.

Table M-1. Description of strategic cases

Case ID	Description
Case 1 (Base Case)	No Early Coal Divestiture – This case assumes coal resources will be replaced with combined cycle natural gas and renewable resources upon the expiration of coal contracts with no early compliance with SB1368. Maintains the 33 percent standard renewables mix recommended to comply with SB 2 (1X).
Case 2	Navajo Early Replacement Strategy – This case considers early replacement of Navajo on 12/31/2015, or 4 years prior to contract expiration with IPP replacement at the end of contract expiration in 2027. Maintains the recommended 33 percent standard renewables mix to comply with SB 2 (1X).
Case 3	Navajo and IPP Early Replacement Strategy – This case considers early replacement of Navajo on 12/31/2015, 4 years prior to contract expiration, and early replacement of IPP on 12/31/2020 or 7 years prior to contract expiration. Maintains the recommended 33 percent standard renewables mix to comply with SB 2 (1X).
Recommended Case 2010 IRP	33% RPS Balanced Strategy – Primarily used to compare the other strategic cases to the recommended long term strategy described in the 2010 IRP with 33 percent renewable compliance by 2020. Considers early divestiture of Navajo on 1/1/2014 or five years prior to contract expiration and assumes replacement of IPP in 2027.

The displaced energy from early coal divestment is generally replaced with a combination of renewable energy and new gas-fired combined cycle generation. Energy efficiency, demand response, and short term 3rd quarter market purchases are used to primarily satisfy load growth. Table M-2 summarizes the different replacement resources for the different cases and Table M-3 summarizes the costs associated with the replacement resources selected for the recommended case (Case 2).

Each case was modeled using low, medium and high assumptions for gas and coal prices. Results of the model runs were tabulated to compare power costs and GHG emission reduction. See Section 4.3 for a discussion regarding the analysis of the model results for the three cases. The analysis concludes with Case 2 as the recommended case for this 2011 IRP. Additional analysis, including non-generation costs and a rate-impact assessment, are included in Section 5.

NET MAXIMUM AND NET DEPENDABLE SYSTEM CAPABILITY w/ REDG						**8,385,404**	**7,294,224**

Notes:

[1] This table is based on data from Power System Engineering Division January 1, 2011 Generation Rating and Capabilities of Power Sources sheet. This table also include data for the renewables and distributed generating resources owned and contracted by LADWP. The data are from the August 12, 2011 RPS Master Project List and project contracts.

[2] Nameplate capability is the full-load continuous rating of a generating unit under specified conditions as designated by the manufacturer.

[3] Unit can attained Maximum Capability when the weather and equipment are simultaneously at optimal conditions.

[4] Maximum Plant Capability reflects water flow limits at hydro plants; or sum of each unit at in-basin thermal plants; or entitlements from external thermal plants.

[5] Net Dependable Plant Capability reflects year-round outputs adjusted for low generation season. For hydro plants, winter is the low generation season. Thermal plants experience reduced performance during hot weather conditions.

[6] Dependable capacity of renewable technology plants are estimated by applying a Dependable Capacity Factor (DCF) to the plant nameplate capacity. The conservative factor is used until LADWP gains more actual account of operating experience with renewable technologies. DCFs currently used are as follow:

- Digester Gas 1.00
- Geothermal 0.95
- Landfill Gas 0.90
- Municipal Solid Waste Conversion 0.90
- Small Hydroelectric 0.50
- Solar Photovoltaic 0.25
- Solar Thermal 0.25
- Wind 0.10 (projects with firming contracts are rated at firming levels)

Appendix N Public Outreach

N.1 Overview

This section outlines the public outreach that will be carried out as part of the 2010 IRP process to provide information and increase awareness of LADWP's long-term power resource plans.

N.2 Community workshops

A series of regional public workshops are being scheduled in mid-July 2010 throughout Los Angeles.

Workshops will be publicized through newspaper advertisements, press releases, a dedicated Website and social media.

A dedicated, interactive Website, www.LAPowerPlan.org, will be established and will enable visitors to provide comments directly online.

The workshops will be professionally facilitated.

Following the workshops, LADWP will summarize feedback and post frequently asked questions and responses on the Website.

N.3 Public Comments

This section will address comments received during the Public Outreach effort related to the 2010 Integrated Resource Plan.

N.4 Questions and Answers

This section will address questions received during the Public Outreach effort related to the 2010 Integrated Resource Plan. These will be posted on the Website as well as presented to the Board of Water and Power Commissioners.

Report Overview

This report provides a summary of input received through the community outreach program conducted for the Los Angeles Department of Water and Power's (LADWP's) 2010 Power Integrated Resource Plan (IRP). The community outreach program consisted of a series of regional public workshops, a website (www.lapowerplan.org), and an online survey, along with stakeholder meetings, which were intended to inform the public about the 2010 IRP and to solicit feedback.

The kickoff public workshop was held on August 12, 2010, at the LADWP headquarters in downtown Los Angeles. Seven regional workshops were held between September 11, 2010, and September 30, 2010. The regional workshops were held throughout Los Angeles to gather input that reflects the City of Los Angeles' geographic and demographic diversity and to maximize participation opportunities. A website was also created for the 2010 IRP; it included an electronic version of the 2010 IRP and associated documents, promoted the public workshops, and provided an interactive online survey consisting of questions similar to the workshop discussion questions. All the presentation materials from the public workshops were also made available on the website. A series of stakeholder meetings were also held in August through October, 2010, with representatives from business and environmental groups with a specific interest in the 2010 IRP.

This summary is arranged into four sections: Report Overview, Community Outreach Program, Discussion Theme Synthesis, and Exhibits. The information contained in each of the remaining sections is described below:

- Community Outreach Program: Provides an overview of all aspects of the outreach related to the 2010 IRP, including the public workshops, website, stakeholder meetings, and elected/appointed official briefings.

- Discussion Theme Synthesis: Contains a summary of the input contributed during the community outreach program. The input has been synthesized to reflect the breadth and depth of the input received and incorporates reoccurring themes that were expressed by participants.

- Exhibits: Includes the project fact sheet, a transcription of the notes from the public workshops, comment cards submitted at the workshops and through the website, and online survey results, as well as other comments collected as part of the community outreach program.

AR0071465

Community Outreach Program

Purpose

The community outreach program was designed to collect broad input on issues, ideas, and concerns related to the 2010 IRP. Input was collected with the intention of providing guidance to LADWP staff in the formulation of a final long-term strategy, and to inform the LADWP Board of Commissioners prior to adoption of a final document. An overview of the 2010 IRP is provided in Exhibit A, Project Fact Sheet.

Specific objectives of the community outreach program were to:

- Prioritize transparency and inclusiveness in the 2010 IRP process
- Receive feedback and public comments to be incorporated into the Final 2010 IRP document
- Educate and create awareness about the 2010 IRP among stakeholders and community members.
- Communicate strategies for reducing carbon emissions and integrating renewable resources, while meeting forecasted demand, maintaining reliability, and keeping costs as low as possible
- Communicate the potential impact on costs and customer rates for various alternative cases analyzed in the 2010 IRP

To achieve these objects, LADWP developed a multipronged outreach approach to allow community members and stakeholders different opportunities to provide input on the 2010 IRP. Community involvement opportunities were provided through a website, stakeholder meetings, and a series of public workshops. Elected and appointed official briefings were also held to keep local representatives abreast of outreach opportunities and the community's contributions. Input collected through each of these programs is considered of equal importance when considered by LADWP staff.

Public Workshops

The public workshops were held in different locations throughout the city to reflect the geographic and demographic diversity of Los Angeles. Workshops were also held on various days of the week at different times to allow many options for participants to find a convenient workshop schedule.

Workshop Schedule and Location

A kick-off workshop was held in Downtown Los Angeles on August 12, 2010, in the LADWP headquarters. Seven regional workshops were held between September 11, 2010, and September 30, 2010, throughout Los Angeles. Table 1 shows the meeting location and schedule.

Thursday, September 30, 2010
6:30 pm – 8:30 pm
Occidental College
Thorne Hall
1600 Campus Road
Los Angeles, CA 90041

Attendance

Attendance varied between each of the public workshops as shown in Table 2. Most attendees identified themselves as customers of LADWP when they signed in, although individuals were not required to be customers to attend the meetings and provide input. Several attendees also identified themselves as being associated with industry groups or environmental organizations, such as solar developers or the Sierra Club. There were also a number of people who attended multiple meetings.

Table 2: Workshop Attendance by Location

Meeting	Attendees
Downtown	36
East Valley	41
West LA	34
South LA	38
East LA	17
Harbor	19
West Valley	50
Northeast LA	17

Workshop Publicity

LADWP conducted extensive publicity to maximize inclusiveness and diversity among participants. To publicize the workshops, meeting information was detailed on the project website, advertisements were placed in local and regional newspapers, and press releases and Twitter messages were issued. Targeted outreach was also conducted to inform the Council Districts and engage the Neighborhood Councils.

Web, Email, and Social Networking

LADWP placed electronic advertisements on the City Watch Website, which averages between 220,000 and 500,000 hits daily, beginning August 24 and running through the final workshop September 30. LADWP also used Twitter to send messages ("tweets") about the entire workshop series and to promote each individual workshop. Issued Neighborhood Council and stakeholder email blasts, and included the workshop series in customer e-newsletters (*LADWP at Work* and *At Home*), which are emailed to all LADWP residential and commercial customers.

Media

Advertisements that featured the locations and dates of all workshops were placed in community and regional newspapers, including:

- *Daily News*
- *Daily Breeze*
- *L.A. Watts Times*
- *L.A. Sentinel*
- *Korean Daily*
- *Chinese Daily*
- *La Opinion*
- *Philippine Media*
- *Downtown News*
- *Korean Times Daily*
- *Beverly Press Park La Brea News*
- *Torchanon Chronicle*
- *Tolucan Times*
- *L.A. Business Journal*
- *San Fernando Valley Business Journal*
- Wave Independent/Equal Access Media
- Eastern Group Publications

A general news release was issued to announce the first workshop followed by a second release announcing the entire workshop series, emphasizing the desire for public feedback on the 2011 IRP, which includes an invitation to the IRP website to take the online survey. Media advisories were also issued the morning of each workshop.

AR0071468

Additional Outreach

To reach additional members of the public, LADWP distributed flyers at public libraries throughout the city. Flyers announcing the workshops, along with fact sheets, were distributed to all Council District field offices, at the Mayor's Office, and at the Council District 2 National Night Out Finale community event at Valley Plaza Park.

LADWP conducted extensive outreach to engage Neighborhood Councils, including announcements at Neighborhood Council meetings, distribution of flyers, and email blasts, which encouraged Neighborhood Councils and community members to attend the regional workshops. LADWP staff also made announcements about the regional workshops to over 30 Neighborhood Council meetings throughout the city in August and September.

Workshop Format

The community workshops consisted of four main components: (1) a presentation on the 2010 IRP by Michael Webster, LADWP Assistant Director of Power System Planning and Development; (2) small group discussions led by facilitators; (3) report back and workshop wrap up; and (4) written comment cards. Please see Exhibit B for the workshop agenda.

Presentation

The workshop presentation established a foundation for the community to get a better understanding of the 2010 IRP. Important contextual information was presented, which provided a historical overview of LADWP's mission, operations, and vertical approach to service, background and objectives of the IRP, and challenges of balancing the objectives. The presentation also outlined specific strategies for reducing carbon emissions and integrating renewable resources, while meeting forecasted demand, maintaining reliability, and keeping costs as low as possible. A video of the presentation was posted on the project website for all community members to view the presentation outside of the workshops.

Small Group Discussions

After the presentation, participants joined smaller breakout sessions ranging from 10 to 15 people, depending on the number of attendees. Through a guided discussion, the small groups provided a forum for participants to provide input and identify issues, share ideas, and voice concerns related to the 2010 IRP. The small groups were also designated to make the complex and technical information in the IRP more accessible by creating an environment where all attendees felt comfortable asking questions and sharing thoughts about the complex technical information in the long-range plan.

Each group was led by a facilitator and an LADWP staff member familiar with the details of the 2010 IRP. Each of the group discussions began by having the group's LADWP staff member lead attendees through the 2010 IRP Executive Summary, which was distributed to each participant as they entered the meeting. The staff member presented the details for each of the six case options, including the mix of resources, estimated costs, estimated reduction in greenhouse gas emissions, and the potential impact on customer rates. This overview was

AR0071469

followed by a question and answer period. The LADWP staff member answered technical questions and provided clarification on the 2010 IRP.

Following the LADWP staff presentation and the question and answer period, participants were then given the opportunity to share their perspectives related to the 2010 IRP. Participants were eager to express viewpoints on many issues during the group discussion session.

Discussion Questions

The facilitator assisted the group in communicating priorities, issues, and concerns related to the 2010 IRP by asking the following questions:[1]

1. What priorities does LADWP need to consider when making a recommendation on the IRP long-term strategy?

2. How much more per bill are you willing to pay to implement some of the types of concepts in the IRP?
   - 5%?
   - 15%?
   - 25%?
   - 0% (Nothing!)

3. Are there any other comments or ideas you would like LADWP to consider related to the 2010 IRP?

The facilitator maintained a record of the participant responses to each question. After a period of sharing the priorities that were important for consideration in the 2010 IRP as part of the discussion on Question 1, four sticky dots were distributed to each member of the group. Group members were asked to use the dots to identify the priorities, or priority, that were most important to them out of those that were shared among the group. Each dot represented an identification of a priority, and participants were allowed to place multiple dots on a priority to indicate relative importance of a topic over another. The priorities identified by each group were considered in the development of the Discussion Themes.

Exhibit C contains detailed transcriptions of all the notes collected during the discussion group for each public workshop, as well as the results of all the input collected during the dot prioritization exercise.

[1] The following questions were used for the August 17, 2010 morning and evening public workshops: (1) What priorities does LADWP need to consider when making a recommendation on the IRP long-term strategy? (2) How much more per bill are you willing to pay to implement some of the types of concepts in the IRP? (3) Are there any other comments or ideas you would like LADWP to consider related to the 2010 IRP? The following questions were used for the August 18, 2010 workshop: (1) What priorities does LADWP need to consider when making a recommendation on the IRP long-term strategy? (2) How much more per bill are you willing to pay to implement some of the types of concepts in the IRP? (3) Are there any other comments or ideas you would like LADWP to consider related to the 2010 IRP? The following questions were used for the August 19, 2010 workshop: (1) What priorities does LADWP need to consider when making a recommendation on the IRP long-term strategy? (2) How much more per bill are you willing to pay to implement some of the types of concepts in the IRP? (3) Are there any other comments or ideas you would like LADWP to consider related to the 2010 IRP?

AR0071470

Additional Notes on Question 2

After the group members finished with the prioritization exercise, the facilitator asked Question 2. Participants were asked if they were willing to pay 5%, 15%, 25%, or 0% (nothing) more per bill to implement some of the types of concepts in the IRP. Attendees were asked to raise their hands to indicate support for any amount they felt comfortable supporting. Some group members were uncomfortable answering the question and asked to provide comments instead of, or in conjunction with, raising their hand. This question was intended to understand group members' sentiment about costs. There is no statistical significance associated with the informal poll that was taken during each group discussion. Instead, this question is more appropriately understood as feedback from a focus group that identified larger opinions and attitudes of group members that relate to costs, as well as the priority participants placed on renewable energy development.[1]

Report Back and Wrap Up

To allow participants to get a sense of the discussions that occurred in the other groups, participants reconvened as an audience at the conclusion of the breakout session, where a representative from each group recapped his/her group discussion. To accomplish this, a volunteer from each group reported back on the top three priorities that were collectively identified by the group as the topics with the most dots from the prioritization exercise.

The workshops concluded with an explanation of how workshop input and input collected by other outreach programs would be documented into a summary. It was also explained that the summary would be considered by the project team in formulating the 2012 Final IRP that would be presented to the LADWP Board of Commissioners, and posted on the project website.

Written Comment Cards

At the beginning of the meeting, attendees were also provided a comment card with questions that mirrored the small group discussion questions. The comment card provided a medium for detailed written comments to be submitted. The comment cards were collected at the conclusion of the meeting or could be mailed afterwards to LADWP. In addition, participants were invited to submit additional comments through the website or directly to LADWP. All comment cards, letters, and other input received electronically can be found in Exhibit D.

---

[1] For results of the analysis of Question 2, the following statements were made by participants during the breakout discussions:

AR0071471

Website and Online Survey

A project website (www.lapowerplan.org) was created specifically for the 2010 IRP. The website provided access to a complete version of the 2010 IRP and associated technical appendices, as well as a stand-alone version of the Executive Summary, which was formatted to improve readability for the public. A fact sheet about the IRP, which was prepared to convey the complex material in visual and written format, was also made available on the website. The website included a schedule of public workshops, and a section that allowed the public to submit comments and questions about the plan online. Comments submitted through the website can be found in Exhibit D.

In addition, the website contained an online survey that mirrored the questions asked in the public workshops, as well as the comment card distributed during the workshops. Members of the public who were unable to attend a public workshop were given the same opportunity to provide input on the 2010 IRP through the website survey. There were 55 responses to the online survey, all of which can be found in Exhibit E.

Stakeholder Meetings

LADWP conducted meetings targeting specific stakeholders, including business and industry representatives, as well as environmental groups. These meetings were conducted in a similar fashion as the public workshops. Input collected at these meetings is included in the discussion themes found in the next section of this document, and discussion notes can also be found in
Exhibit C.

Business and Industry

LADWP offered presentations for the following business and industry stakeholders:

- Central City Association – meeting on September 21, 2010
- LA Business Council – meeting on September 24, 2010
- Large Commercial Customers – meeting on September 30, 2010
- Valley Industry and Commerce Association – meeting on October 6, 2010

Environmental Groups

Representatives of key environmental groups—including the Sierra Club, National Resources Defense Council, Environment Now and the Green L.A. Coalition—were invited to briefings and contacted directly to attend the kick-off workshop and regional workshops.

Elected/Appointed Officials Briefings

LADWP also met with various elected and appointed officials to provide an overview of the contents of the 2010 IRP and to inform them about the community outreach process. The briefings were intended to inform decision makers about the 2010 IRP and the process, and are not reflected in the discussion themes found in the next section of this document.

AR0071472

- Board of Water and Power Commissioners – Presentation to Board, July 22, 2010
- Briefings were conducted for staffs of City Council members, Mayor's office, Chief Legislative Analyst (CLA), and Chief Administrative Officer (CAO) on August 12, 2010, and September 16, 2010. A follow-up briefing will be scheduled in October
- Neighborhood Council Memorandum of Understanding Oversight Committee briefing August 7, 2010.
- Additional Outreach

  A summary of the first workshop was emailed to Council staff

  An additional IRP summary after the first week of regional workshops was emailed to Council staff

  LADWP requested a special IRP briefing with Council members (Energy & Environment Committee), Mayor, CLA, CAO.

  LADWP requested to have a special IRP outreach meeting with stakeholders selected by Council members

  LADWP requested that the IRP workshop schedule be placed in individual Council community newsletters (it was placed in newsletter of Councilmember Bernard Parks

  A final IRP analysis will be provided to Mayor/Council/CAO/CLA staff

Discussion Theme Synthesis

The public workshops, stakeholder meetings, online survey, and comment cards yielded a significant amount of information from LADWP customers related to the 2010 IRP. This information has been synthesized into a set of discussion themes that reflect the major ideas provided by participants during the community outreach program.

Methodology for Identifying Discussion Themes

During the community outreach program, attendees provided broad input about issues, ideas, and concerns related to the 2010 IRP. The discussion themes provide a synopsis of this input and represent expansive discussion topics for the community outreach program. For a comprehensive understanding of the richness and range of input, the major discussion themes should be reviewed in connection with the transcription of the notes from the small group discussions and stakeholder meetings, the comment cards, and responses to the online survey.

An "initial" series of broad themes was first identified to categorize all of the statements gathered during the public outreach program. Coding strategies were then used to validate and refine the themes.[1] Using Atlas/TI, a computer software program for qualitative data analysis, codes were established for each theme and applied to all of the public input that was collected through the community outreach program. Codes were applied to individual comments and enabled comparison between different comments relating to the same topic. For example, a statement such as "Educate consumers about how to conserve." was ultimately coded as (1) "Energy Efficiency and Conservation" because it was one of many statements provided by workshop participants that related to using less energy or using energy more efficiently, and (2) "Education and Community Outreach" because it relates to efforts by LADWP to inform and engage the community.

After coding all the input, the initial set of themes was refined. A narrative on each theme was also created to provide context and understanding. The narrative is based upon the comments that were tagged with a code relating to specific themes. The comments were reviewed to understand the frequency of certain discussion topics, the breadth of all discussion topics, and the relationships between the topics.

Discussion Themes

The discussion themes listed below are not representative of the city at large, and only encompass input from participants in the public workshops, attendees at the stakeholder meetings, and members of the public who completed the online survey or comment card. All the ideas that were prioritized during the public workshops are included within the discussion themes, however, each theme is considered to be of equal importance, and the themes are not listed in any order of priority.

[1] For more information on the methodologies employed to identify themes, please see Ryan, Gary W., and H. Russell Bernard. 2003. "Techniques to Identify Themes." *Field Methods* 15(1): 85–109.

AR0071474

Emphasize a *Variety* of Energy Sources

Many participants were supportive of the resource strategies presented in the 2010 IRP. Recognizing that over-reliance on a single energy source could lead to instability, attendees advocated for a strategy that integrates a variety of resources. In particular, participants were concerned that natural gas was especially subject to fluctuations in price and relied heavily on delivery pipelines, which could jeopardize reliability. Some attendees expressed a desire to see a wider variety of energy sources beyond wind and solar. Some of the suggested energy sources included:

- Algae
- Biofuels
- Fuel Cells
- Geothermal
- Hydroelectric
- Natural Gas
- Nuclear
- Solid Waste
- Wave

The discussion of these other energy sources varied greatly. Nuclear and geothermal sources were mentioned by various participants. Many attendees indicated that LADWP should stay on the forefront of new advancements, and all viable sources of energy should continually be evaluated as modern technology evolves.

Maximize *Energy Efficiency and Conservation* to Meet Future Energy Needs

Energy efficiency and conservation efforts were strongly supported by participants and were recognized as necessary components in meeting the future energy needs of Los Angeles. Participants expressed that LADWP could use several strategies to encourage customers to use less energy, as well as take steps to make the entire power system (both customer-side and utility-side) more energy efficient.

Many participants recommended that LADWP incorporate additional financial incentives to customers who use less energy. Suggestions included the installation of smart meters to provide information about real-time energy use, enabling customers to make smarter

AR0071475

decisions about how they use power. In addition, some attendees believed that an increase in energy rates would also lead to an overall reduction in energy consumption. Participants also suggested that charging higher prices during peak periods than during off-peak periods could encourage conservation when demand is highest, and could potentially shift energy use to periods with a lower demand.

Participants also emphasized the need for education programs for customers on the importance of conservation and ways to conserve energy. Political and cultural challenges in encouraging energy efficiency and conservation were identified as well.

In addition, many participants recommended that LADWP look for ways to improve the efficiency of the power system as a whole. This included suggestions to improve the efficiency of generating and transmitting energy. Several attendees also commented that technical improvements on the customer-side could lead to more efficient energy use, such as using more energy-efficient appliances. There was support for requirements that newly constructed buildings be designed for energy efficiency and it was suggested that older buildings should be retrofitted. Participants also proposed that LADWP provide/expand energy audits to demonstrate to customers what changes or improvements could be made in homes or businesses to use less energy.

Eliminate Coal from LADWP's Energy Portfolio

Many participants expressed concern over the continued use of coal, recommended its removal from LADWP's energy portfolio, and suggested that it be replaced with renewable energy sources as much as possible. These participants noted that the elimination of coal would reduce greenhouse gas emissions and improve air quality, and some said that replacing coal with natural gas would not be a significant improvement. Other participants believed that the secondary costs of coal were not totally being accounted for, and that impacts to the environment and public health have a cost not always reflected in energy prices.

In addition, there was some discussion of the need to insulate the energy portfolio from anticipated cost increases of coal, such as compliance with new regulatory requirements including a cap and trade program. It was recommended by some attendees that this insulation should be created by the development of renewable sources because the cost of natural gas is also predicted to increase. Furthermore, some participants recognized that the preserve development of renewable sources could stabilize cost increases and avoid potential market-driven/investor-influenced cost spikes.

Finally, some attendees said developing more renewable sources now will allow LADWP to hedge against future uncertain energy market fluctuations and experience lower renewable development prices from early market entry. Other suggestions included increasing the renewable sources in the near-term portfolio while high-yield development sites are still available.

AR0071476

Expand *Local* Solar Generation

There was widespread support for LADWP to expand solar power generation in-basin. However, out-of-basin solar generation was also viewed favorably. Many participants noted that in-basin solar has environmental benefits because of the decreased need for transmission facilities. In addition, some participants felt that distributed, in-basin generation would improve reliability, especially on summer days when both energy demand and solar radiation are typically high. In-basin solar had an additional perceived benefit of creating local jobs and improving the local economy.

Participants suggested that LADWP offer additional incentives to promote small scale, in-basin photovoltaic systems, which could include subsidized loans to offset construction costs and/or feed-in tariff programs. Some attendees suggested that LADWP advance initiatives to install solar panels on roofs throughout Los Angeles, including on public buildings and parking lots.

Some participants expressed frustration over the current billing system related to individual solar systems, and an owner's inability to sell energy back to LADWP for cash. It was suggested that LADWP consider reevaluating this program and the way in which credits are applied.

Avoid Adverse Impacts to Vulnerable Communities

A number of participants expressed concern over the possibility that some communities in the region may experience unequal impacts from implementing particular components of the IRP. Low-income households, seniors, disabled persons, and others on a fixed income were identified as populations that may be impacted financially by potential costs associated with repowering. There was support for LADWP continuing to provide some protection against overly burdensome costs of electricity to customers who are economically disadvantaged. Many participants believed that costs could also be minimized through incentive programs that encourage energy efficiency. Additionally, some participants voiced opinions that communities with a disadvantaged socioeconomic status have historically received more than their fair share of major infrastructure and suggested that equal distribution of facilities throughout the city should be prioritized.

There was also concern on how facilities would impact communities outside of Los Angeles. Some participants questioned if it is ethical [illegible] to allow out-of-basin communities to bear

AR0071477

the environmental impacts of providing power to Los Angeles and expressed a desire to see out-of-basin generation minimized. However, most understood the benefits of out-of-basin generation, such as greater resource diversity and reliability, and recognized continued collaborative relationships with other out of basin utilities.

Clarify Costs of IRP Implementation and *Potential Impacts* to Ratepayers

Nearly all participants felt there was a need to clarify costs of IRP implementation and the potential impacts to ratepayers. Many participants thought that clarifying the different costs associated with generation, transmission, and distribution would provide a more accurate assessment of the overall costs associated with the IRP. Others considered it important to clarify labor and administrative costs of LADWP operations and their relation to the IRP. There was also discussion of the need to demonstrate the relationship between the costs associated with the IRP and LADWP's Strategic Plan.

The relative costs of different energy sources were also of interest to attendees. Many participants were concerned with the externalities associated with the IRP, including the secondary costs of the different case options. Secondary costs of interest to participants include the environmental and public health impacts, which were perceived by many to be costs incurred by the community but not reflected in energy rates. In contrast, other participants suggested that implementing the IRP would create local jobs and provide an economic benefit.

Some participants were adamantly opposed to potential future increases in their energy bills, while others supported an increase with caveats such as the need for improved transparency and accountability, or that additional revenues would be used exclusively for providing more renewable energy and/or getting off coal early. Participants who supported a potential increase often argued that an increase could be offset by reduced energy consumption, which could ultimately lower bills. There was also a desire to avoid any adverse impacts that a potential increase would have on low-income communities and individuals with a fixed income. Many people expressed concern that increasing energy costs would be detrimental to businesses in Los Angeles, especially during the current economic climate.

Reduce Environmental Impacts

Environmental protection was a priority for many participants. Some participants expressed a general concern for the environment, while other participants were interested in specific impacts to wildlife and landscapes, water quality, and aesthetics, as well as the storage of nuclear waste. Many attendees indicated that their concern for the environment extended

AR0071478

beyond air quality and global warming/climate change issues.

The environmental impacts of construction, maintenance, and operation of generation, transmission, and/or distribution facilities were all among the activities that participants were concerned about. It was noted that environmental impacts could be reduced by maximizing existing infrastructure and locating new facilities on already disturbed sites, such as rooftops and brownfields, where possible.

Provide Proactive Leadership and Transparency

Participants saw an opportunity for LADWP to take proactive steps to educate the public about existing LADWP programs and incentives, ways to improve energy efficiency and conservation, and the power system in general. Some participants advocated LADWP to make information easily accessible and clearly identify the decision-making process.

Some participants felt that LADWP needed to lead-by-example with their operations and facilities, invest in research and development, and demonstrate the viability of new technologies. Participants supported LADWP continuing outreach to the public by partnering with existing local groups, schools, and other institutions to disseminate important information, especially related to energy efficiency and conservation. Suggestions were also expressed that clear and accessible information about LADWP's power system be made readily available to the public.

Organizational transparency and accountability were important to participants. Participants emphasized that the planning and facility development process continue to involve the public. There was also support for an independent ratepayer advocate to provide transparency and accountability in LADWP's finances and promote the interest of ratepayers in decisions. Some participants felt that billing statements should explicitly separate water and power costs and provide clear information and education on how bills are calculated. There were also suggestions that a program be established to monitor progress in achieving goals outlined in the IRP.

Exhibits

A – Project Fact Sheet

B – Workshop Agenda

C – Discussion Group Notes

D – Comment Cards

E – Online Survey

Appendix O Abbreviations and Acronyms

O.1 Overview

This appendix presents acronyms for agencies and other entities, facilities and locations, electric industry terms, miscellany, and units of measure.

O.2 Agencies and Other Entities

APS	Arizona Public Service Company
BPA	Bonnerville Power Administration
BOS	Bureau of Sanitation
CAISO	California Independent System Operator
CARB	California Air Resources Board
CEC	California Energy Commission
City	City of Los Angeles
CPUC	California Public Utilities Commission
DOD	U.S. Department of Defense
DOE	U. S. Department of Energy
EPA	U. S. Environmental Protection Agency
EPRI	Electric Power Research Institute
FERC	Federal Energy Regulatory Commission
FSO	LADWP Financial Services Organization
IID	Imperial Irrigation District
IOU	California investor owned utilities
IPA	Intermountain Power Agency
IPCC	Intergovernmental Panel on Climate Change
IPPCC	Intermountain Power Project Coordinating Committee
ISDA	International Swaps and Derivatives Association
JPL	NASA Jet Propulsion Laboratory
LADWP	Los Angeles Department of Water and Power
NAESB	North American Energy Standards Board
NASA	National Aeronautic Space Administration
NERC	North American Electric Reliability Corporation
NPC	Nevada Power Company
NREL	National Renewable Energy Laboratory
PG&E	Pacific Gas and Electric Company
PwC	PriceWaterhouse Coopers
RTO	Regional Transmission Organization
RWQCB	Regional Water Quality Control Board
SCAQMD	South Coast Air Quality Management District
SCE	Southern California Edison
SCPPA	Southern California Public Power Agency
SoCal	Southern California Gas Company
SRP	Salt River Project

AR0071481

SWRCB	State Water Resources Control Board
TEC	Tucson Electric Company
UCLA	University of California at Los Angeles
UCSD	University of California at San Diego
USC	University of Southern California
WAPA	Western Area Power Administration
WECC	Western Electricity Coordinating Council

O.3 Facilities and Locations

BPA	Bonnerville Power Administration
BBRTP	Barren Ridge Renewable Transmission Project
BRSS	Barren Ridge Switching Station
COB	California-Oregon Border
COI	California-Oregon Intertie
EOR	East-of-the-River
HSS	Haskell Switching Station
IGS	Intermountain Generating Station
IPP	Intermountain Power Project
NOB	Nevada-Oregon Border
NTS	Northern Transmission System
PACI	Pacific AC Intertie
PDCI	Pacific High Voltage Direct Current Intertie
PTWPP	Pine Tree Wind Power Project
PVD2	Palo Verde-Devers Line No. 2
PVNGS	Palo Verde Nuclear Generating Station
SHARE	Scattergood-Hyperion Alternative Renewable Energy Project
SRP	Salt River Project
STS	Southern Transmission System
UGPP	Upper Gorge Power Plant
US	United States
WREZ	Western Renewable Energy Zone
WOR	West-of-the-River
WSPP	Western Systems Power Pool

O.4 Electric Industry Terms

A/C	air conditioning
AC	Alternating Current
AEDP	Advanced ESS Demonstration Project
AMI	Advanced Metering Infrastructure
AQMP	Air Quality Management Plan
BACT	Best Available Control Technology
BIGCC	Biomass Integrated Gasification Combined Cycle
BPJ	Best Professional Judgment

AR0071482

CAES	compressed air energy storage
CAMR	Clean Air Mercury Rule
CAP	Climate Action Plan
CCC	closed cycle cooling
CH_4	methane
CHP	combined heat and power
CLEO	Commercial Lighting Efficiency Offer
CNG	compressed natural gas
CLFR	compact linear fresnel reflector
CO_2	carbon dioxide
CSP	concentrating solar thermal power plants
CY	calendar year
DC	Direct Current
DC&M	Distribution Construction and Maintenance
DG	distributed generation
DNI	direct normal insolation
DR	Demand Response
DSM	Demand Side Management
E&L	Environment and Lands
ECAF	Energy Cost Adjustment Factor
EDS	Energy Dissipation Station
EE	Energy Efficiency
EHV	Extra-High Voltage
ESPs	energy service providers
ESS	energy storage system
ETD	Electric Trouble Dispatch
FAR	Firm Access Rights
FES	flywheel energy storage
GHG	greenhouse gas
GHGs	greenhouse gases
GREEN	Green Power for Green LA Program
GWP	global warming potential
HHV	higher heating value
HRSG	heat recovery steam generator
HVAC	heating, ventilating, and air conditioning
ICEs	internal combustion engines
IGCC	integrated gasification combined cycle
IM	impingement mortality
LCOE	levelized cost of energy
LF	Load Factor
LFG	landfill gas
LNG	liquefied natural gas
LPG	propane
LSE	loadserving entities
NaS	sodium-sulfur
NEL	Net Energy for Load

AR0071483

N_2O	nitrous oxide
NO_2	nitrogen dioxide
NOx	oxides of nitrogen
NPDES	National Pollutant Discharge Elimination System
NPHR	net plant heat rate
O&M	operations and maintenance
OASIS	open-access same-time information systems
OATTS	open access transmission tariffs
OTC	once-through cooling
PFCs	perfluorocarbons
PHEV	plug-in hybrid electric vehicle
PHS	pumped-hydro storage
PMU	power measurement units
POUs	publicly-owned electric utilities
PTC	production tax credit
PV	photovoltaic
QRAs	Qualified Resource Areas
RASS	Residential Appliance Saturation Survey
RECLAIM	Regional Clean Air Incentive Market
RETI	Renewable Energy Transmission Initiative
RPS	Renewable Portfolio Standard
RS	receiving station
RTCs	RECLAIM Trading Credits
Rule	Cooling Water Intake Structure Rule
SAIDI	System Average Interruption Duration Index
SAIFI	System Average Interruption Frequency Index
SAS	Substation Automation System
SCADA	supervisory control and data acquisition
SEC	Standard Energy Credit
SES	super capacitor energy storage
SF_6	sulfur hexafluoride
SMES	Superconducting Magnetic Energy Storage
SNCR	selective non-catalytic reduction
SOx	sulfur oxide
T&T	transmission and delivery
UES	ultra capacitor energy storage
VRB	Vanadium Redox Battery
WEC	Wave Energy Converter
XRT	experimental curtailment response contract
ZIA	Zone Identification and Technical Analysis
ZNE	Zero Net Energy

AR0071484

O.5 Miscellany

A	Category of Flow Meter
AB	Assembly Bill
AMR	Automatic Meter reading
CFL	compact fluorescent light
CI	commercial/industrial
CIS	Customer Information System
CS	Customer Service
CSA	Candidate Study Aras
ECC	Energy Control Center
EIR	Environmental Impact Report
F	Category of flow meter
FM	Category of flow meter
GDP	gross domestic product
JFB	John Ferraro Building
LED	light-emitting diode
MFR	multi-family residence
NLC	net levelized cost
OH	overhead
QRAs	Qualified Resource Areas
RF	Radio Frequency
RFP	Request for Proposal
SB	Senate Bill
SBDI	Small Business Direct Install
SFR	single family residence
UG	Underground

O.6 Units of Measure

BTU	British thermal unit
GWh	gigawatt-hour
kV	kilovolt
kW	kilowatts
MMBtu	Million British thermal units
MMT	million metric tons
$MMTCO_2E$	million metric ton CO2 equivalent
MVA	mega volt amperes
MW	megawatt
MWhs	megawatt hours
TWh	terawatt hour

AR0071485

CITY OF LOS ANGELES
DEPARTMENT OF WATER AND POWER

DRAFT 2010 URBAN WATER MANAGEMENT PLAN

JANUARY 14, 2011

The Draft 2010 UWMP is available for review at www.ladwp.com.

Written comments are due by March 15, 2011 to:
LADWP – Water System
111 N. Hope St, Room 1460
Los Angeles, CA 90012
Attn: Simon Hsu
or
simon.hsu@ladwp.com

** The report is not in the final format.

Draft Table of Contents for LADWP 2010 UWMP

Executive Summary ES-1

Chapter 1: Introduction 1-1

Purpose 1-1

UWMP Requirements and Checklist 1-1

Water Supply Action Plan 1-2

Service Area 1-3

Land Use 1-3

Demographics 1-4

Climate 1-7

Water Demand and Supply Overview 1-8

Chapter 2: Water Demands 2-1

Historical Water Use 2-1

Water Use By Sector 2-2

Indoor and Outdoor Use 2-3

Quantification of Historical Water Conservation 2-5

Water Demand Forecast 2-6

Demand Forecast Methodology 2-6

Applying the Methodology 2-7

Water Demand Forecast Results 2-9

Water Demand Forecast with Average Weather Variability 2-10

Low-Income Water Demand Projections 2-11

Chapter 3: Water Conservation 3-1

Water Conservation Goals 3-4

Water Supply Action Plan Conservation Goal 3-4

Water Conservation Act of 2009 3-4

Existing Programs, Practices, and Technology to Achieve Water Conservation 3-6

State Laws and City Ordinances 3-6

Conservation Pricing 3-10

CUWCC Best Management Practices 3-11

LADWP Conservation Programs 3-13

Future Programs, Practices, and Technology to Achieve Water Conservation 3-26

Graywater 3-26

Demand Hardening 3-30

Projected Water Conservation Savings 3-31

Cost & Funding 3-34

Chapter 4: Recycled Water **4-1**

Regulatory Requirements 4-2

Non Potable Reuse Regulations 4-2

Groundwater Replenishment Regulatory Requirements 4-6

Wastewater Treatment Plants 4-7

Donald C. Tillman Water Reclamation Plant 4-8

Los Angeles – Glendale Water Reclamation Plant 4-8

Terminal Island Water Reclamation Plant 4-9

Hyperion Treatment Plant 4-9

Projected Wastewater Volume 4-9

Existing Recycled Water Deliveries 4-10

Harbor Area 4-11

Metro Area 4-12

San Fernando Valley Area 4-13

Westside Area 4-15

Comparison of 2010 Projections Versus Actual Use 4-17

Recycled Water Master Planning Documents 4-18

Near-Term Planned Projects Through 2015 4-20

Non-Potable Reuse Projects to be completed between 2015 - 2025 4-23

Groundwater Replenishment 4-24

Efforts Beyond 50,000 AFY 4-26

Recycled Water Master Plan Cost and Funding 4-27

Stakeholder Process and Agency Coordination 4-28

Recycled Water Quality 4-29

Chapter 5: Los Angeles Aqueduct System 5-1

Historical Deliveries 5-1

Mono Basin and Owens Valley Supplies 5-4

Water Rights 5-5

Environmental Issues and Mitigation 5-5

Mono Basin 5-6

Lower Owens River Project 5-8

Owens Lake Dust Mitigation 5-10

Water Quality 5-12

Projected Deliveries 5-13

Los Angeles Aqueduct Delivery Cost 5-15

Chapter 6: Local Groundwater 6-1

Groundwater Rights 6-1

OLARA Groundwater Basin Adjudication 6-2

Historical Groundwater Production 6-2

San Fernando Basin 6-3

Groundwater Rights 6-3

Water Quality 6-4

Agency Cooperation of SFB Remediation 6-5

SFB Contamination Clean-up Programs 6-6

Sylmar and Eagle Rock Basins 6-8

Groundwater Rights 6-8

Water Quality 6-9
Central Basin 6-9
Groundwater Rights 6-9
Water Quality 6-10
West Coast Basin 6-10
Groundwater Rights 6-10
Water Quality 6-11
Water Quality Goals and Management 6-11
Groundwater Monitoring 6-11
Operating Goals 6-11
Managing Emerging Contaminants of Concern 6-12
Groundwater Pumping Costs 6-13
Groundwater Production Projections 6-14

Chapter 7: Watershed Management **7-1**
Importance of Watershed Management to Groundwater Supplies 7-1
Additional Benefits of Watershed Management 7-3
Stormwater Capture Master Plan 7-5
Tree People – Memorandum of Agreement 7-6
Centralized Stormwater Capture Projects 7-6
Distributed Stormwater Capture 7-10
Watershed Council – Water Augmentation Study 7-10
Integrated Water Resources Plan Analysis 7-13
Distributed Stormwater Capture Projects 7-18
Low Impact Development (LID) and Best Management Practices (BMP's) 7-21
Future Programs 7-21
Integrated Regional Water Management Plan (IRWMP) Program 7-22
Cost Analysis 7-23

Chapter 8: Metropolitan Water District Supplies **8-1**

Supply Sources 8-1

The Colorado River *8-4*

The State Water Project *8-12*

In Basin Storage *8-21*

Groundwater Storage and Water Transfers *8-24*

MWD Supply Reliability and Projected LADWP Purchase 8-27

MWD Rate Structure and LADWP's Purchase Water Costs 8-29

MWD Rate Structure *8-29*

LADWP's Purchase Water Costs *8-30*

Chapter 9: Other Potential Water Supplies **9-1**

Water Transfers and Banking 9-1

LADWP Opportunities *9-2*

MWD Opportunities *9-3*

Seawater Desalination 9-5

Desalination Technology *9-5*

DWR Desalination Efforts *9-6*

MWD Desalination Efforts *9-7*

LADWP Seawater Desalination Efforts *9-8*

Potential Water Supply Yield and Cost 9-9

Chapter 10: Integrated Resources Planning **10-1**

City of Los Angeles Integrated Water Resources Plan 10-1

Description and Purpose *10-1*

Integrated Watershed Approach *10-2*

Stakeholder Involvement *10-2*

IRP Alternatives *10-2*

Implementation Status *10-3*

Agency Coordination 10-7

IRP Implications for LADWP's Urban Water Management Plan 10-7

Greater Los Angeles Integrated Regional Water Management Plan (IRWMP) 10-7

Description and Purpose 10-7

Stakeholder Involvement 10-9

Recommended Projects 10-9

Implications of IRWMP for LADWP's Urban Water Management Plan 10-12

MWD's Integrated Resources Plan 10-13

MWD IRP 2004 Update 10-13

MWD IRP 2010 Update 10-14

Stakeholder Participation 10-15

Agency Coordination 10-15

IRP Implications for LADWP's Urban Water Management Plan 10-16

Chapter 11: Water Supply Reliability and Financial Integrity **11-1**

Unit Cost and Funding of Supplies 11-1

Unit Cost Summary of Supplies 11-1

Funding of Supplies 11-2

Reliability Assessment Under Different Hydrologic Conditions 11-3

Los Angeles Aqueducts 11-3

Groundwater 11-3

Conservation 11-3

Recycled Water 11-4

Water Transfers 11-4

MWD Imported Supplies 11-4

Potential Supplies 11-5

Service Area Reliability Assessment 11-6

Water Shortage Contingency Plan 11-15

Stages of Action 10632 (a) 11-15

Driest Three-Year Supply – 10632 (b) 11-16

Catastrophic Supply Interruption Plan 10632 (c) 11-18

Mandatory Water Use Prohibitions 10632 (d) 11-18

Consumption Reduction Methods during Water Shortages 10632 (e) 11-19

Penalties for Excessive Use (Non-Compliance to Prohibited Use) 10632 (f) 11-20

Analysis and Effects on Revenues and Expenditures of Reduced Sales During Shortages – 10632 (g) 11-21

Water Shortage Contingency Resolution or Ordinance – 10632 (h) 11-21

Methodology to Determine Actual Water Use Reductions During Shortages – 10632 (i) 11-23

Water Supply Assessments 11-24

Chapter 12: Climate Change **12-1**

Potential Impacts of Climate Change on Water Service Reliability 12-1

Local Impacts 12-2

Los Angeles Aqueduct Impacts 12-4

State Water Project Impacts 12-8

Colorado River Aqueduct Impacts 12-9

Water and Energy Nexus 12-9

State Water Project Supplies 12-10

Colorado River Aqueduct Supplies 12-11

Los Angeles Aqueduct Supplies 12-12

Local Groundwater Supplies 12-12

Recycled Water Supplies 12-12

Treatment Energy 12-13

Distribution Energy 12-14

Carbon Footprint 12-16

Climate Change Adaption and Mitigation 12-18

LADWP Adaption and Mitigation 12-18

MWD Adaption and Mitigation 12-19

Executive Summary

Executive summary will be included following public review.

Presentation at February 2011 public workshops provides an overview of the Urban Water Management Plan findings.

DRAFT

AR0071496

AR0071497

DRAFT Chapter One
Introduction

1.0 Overview

The availability of water has significantly contributed towards the tremendous growth and development of the City of Los Angeles (City). Since 1902, when the City's population was approximately 102,000, the Los Angeles Department of Water and Power (LADWP) has supported the City's transformation into the nation's second largest city with over 4 million residents, encompassing a 464 square mile area, and comprising the world's sixteenth largest economy. The largest municipal utility in the nation, LADWP was established in 1902 to deliver safe and reliable water and electricity supplies at an affordable price to the residents and businesses of Los Angeles.

With increasing demands for additional water supplies, LADWP along with all other water agencies in Southern California, are faced with the challenge of providing a reliable water supply for a growing population. LADWP will meet the City's water needs through the following actions:

- Pursue cost-effective water conservation, stormwater capture and recycling projects to increase supply reliability.
- Ensure continued reliability of the City's supplemental water supplies from the Metropolitan Water District of Southern California (MWD) through active representation of City interests on the MWD Board
- Protect existing groundwater supplies from contamination and provide treatment to optimize their use
- Maintain the operational integrity of the Los Angeles Aqueduct and in-City water distribution systems
- Meet or exceed all Federal and State standards for drinking water quality

1.1 Purpose

The LADWP 2010 Urban Water Management Plan (UWMP) serves two purposes: (1) achieving compliance with requirements of California's Urban Water Management Planning Act (Act); and (2) serving as a master plan for water supply and resources management consistent with the City's goals and policy objectives.

1.1.1 UWMP Requirements and Checklist

This 2010 Urban Water Management Plan (UWMP) complies with Sections 10610 and 10657 of the California Water Code, Urban Water Management Planning Act (Act), and details how LADWP plans to meet all of the City's customer water needs. The Act became effective on January 1, 1984 and requires that every urban water supplier that provides municipal and industrial water to more than 3,000 customers (or supplies more than 3,000 acre-feet per year) prepare and adopt an Urban Water Management Plan, in accordance with prescribed requirements, every five years. Appendix A contains the Act.

The Act was originally developed due to concerns for potential water supply shortages throughout the State. Therefore, it required information that focused primarily on water supply reliability and water use efficiency measures. Since its original passage in 1983, there have been several amendments added, the most recent adopted in 2009. Some of the recent amendments include: providing assessment of present and proposed future demands to achieve per capita water use reductions by 20 percent by 2020, projecting water use for low-income single family and multi-family residential housing, and the addition of "indirect potable reuse" to the list of recycled water uses. A copy of the 2010 UWMP Act requirements is

AR0071498

provided in Appendix B. A checklist of the Urban Water Management Plan cross-referencing Act requirements to applicable pages in this UWMP is provided in Appendix C.

With the passage of Senate Bills 610 and 221 in 2001, Urban Water Management Plans took on even more importance. SB 610 and 221 require that counties and cities consider the availability of adequate water supplies for certain new large developments. These statutes require written verification of sufficient water supply to serve these new developments, and Urban Water Management Plans are identified as key source documents for this verification. Based on this statute the LADWP prepares individual Water Supply Assessments for these new large developments.

LADWP's 2010 Urban Water Management Plan is not only designed to meet the current requirements of the Act, but also serves as the City's master plan for water supply and resource management. The UWMP is not only intended for officials in Sacramento, but also helps guide policy makers in the City and the Metropolitan Water District of Southern California (MWD), as well as providing information to the citizens of Los Angeles. The UWMP provides the basic policy principles that guide LADWP's decision-making process to secure a sustainable water supply for Los Angeles.

1.1.2 Water Supply Action Plan

LADWP has a long history of working to ensure that its customers have enough water. These efforts go back to the early 20th century with the building of the Los Angeles Aqueduct. Investments in water rights, aqueducts, reservoirs, conservation and more recently recycled water and stormwater capture have allowed Angelinos to enjoy a water supply that they can rely on. Sound planning and timely investments in water have played a critical role in meeting the water needs of the City despite the fact that Southern California is a semi-arid region

In May of 2008, LADWP's Water Supply Action Plan (Plan), "Securing L.A.'s Water Supply", was released to address a number of critical water supply reliability issues. These water supply issues included: (1) the lowest snowpack on record in the Eastern Sierras in 2007, where Los Angeles historically received the greatest share of its water supply; (2) the driest year on record in 2007 for the Los Angeles basin; (3) anticipated regional water allocations by MWD in response to reductions in imported water available from the San Francisco Bay Delta due to drought and regulatory restrictions; (4) local groundwater contamination in the San Fernando basin, restricting the ability to fully utilize this local resource; (5) Los Angeles Aqueduct delivery reductions due to environmental mitigation and enhancements in the Owen's Valley and Mono Lake Basins, representing nearly one-half of historic water supplies from the Eastern Sierra watershed; and (6) uncertain climate change impacts which threaten traditional water supply sources.

The convergence of these critical issues has far-reaching implications for the City of Los Angeles' water supply that requires long-range planning to sustain a reliable supply of water to meet current and future demand. The Plan was a blueprint for creating sustainable water resources to serve the future needs of the City, and outlined responsible water management and long-term planning. By 2028, the Plan envisioned a six-fold increase in recycled water supplies to a total of 50,000 AFY. Similarly, by 2030, an increase of 50,000 AFY was planned for conservation. As described in the Plan, this aggressive approach included: investments in state-of-the-art technology; a combination of rebates and incentives; efficient clothes washers, and urinals; and long-term measures such as expansion of water recycling and remediating contaminated groundwater supplies. A multi-faceted approach to developing a locally sustainable water supply was developed incorporating the following key short-term and long-term strategies:

DRAFT

AR0071499

Short-Term Conservation Strategies

- Enforcing prohibited uses of water
- Expanding prohibited uses of water
- Extending outreach efforts
- Encouraging regional conservation measures

Long-Term Strategies

- Increasing water conservation through reduction of outdoor water use and new technology
- Maximizing water recycling
- Enhancing stormwater capture
- Accelerating groundwater basin clean-up
- Expanding groundwater storage
- Green Building Initiatives (added subsequent to the release of the Plan)

As an integral part of the UWMP, the Water Supply Action Plan is incorporated into the associated chapters of the UWMP. The UWMP outlines how the strategies contained in the Water Supply Action Plan will be implemented and how these strategies will increase the reliability of LADWP's water supplies through 2035.

1.2 Service Area

In order to properly plan for water supply, it is important to understand the factors that influence water demands over time. These factors include land use, demographics, and climate.

1.2.1 Land Use

The City of Los Angeles is comprised of approximately 302,165 acres. Residential development constitutes over 51percent of the total land use within the City. Within the residential land use category, single-family residential is the largest at approximately 121,500 acres or 40 percent of the total land use within the City. Multi-family residential is approximately 34,000 acres or 11 percent of the total land use within the City. Open space/parks is the second largest land use within the City occupying approximately 13 percent of the total land use. Commercial and manufacturing land uses combined account for approximately 18 percent of total. Commercial land uses are inclusive of public facilities, such as libraries, public schools, and other government facilities. Exhibit 1A provides a breakdown of the land uses within the City of Los Angeles. The "Other" category includes specific plans, transportation, freeways, rights of way, and other miscellaneous uses that are not zoned.

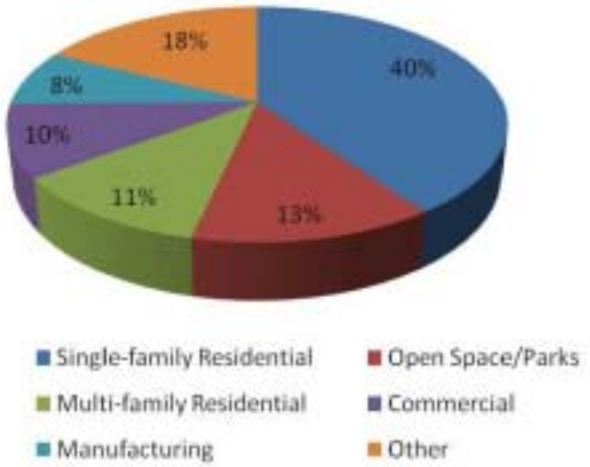
City of Los Angeles Land Uses



Land Use Type	Acres
Single-family Residential	121,470
Open Space/Parks	40,263
Multi-family Residential	34,189
Commercial	30,083
Manufacturing	23,353
Other	52,806
Total	302,165

Source: Data aggregated from City of Los Angeles, Department of City Planning, November, 2009

1.2.2 Demographics

With over 4 million people residing in the LADWP service area, it is slightly larger than the legal boundary of the City of Los Angeles. LADWP provides water service to portions of West Hollywood, Culver City, Universal City, and small parts of the County of Los Angeles.

The population within LADWP's service area increased from 2.97 million in 1980 to 4.1 million in 2009, representing an average annual growth rate of 1.3 percent. The total number of housing units increased from 1.10 million in 1980 to 1.38 million in 2009, representing an average annual growth rate of 0.9 percent. During this time, average household size increased from 2.7 persons in 1980 to 2.9 persons in 2009. Employment grew by about 1.0 percent annually from 1980 to 1990, but declined from 1990 to 2000 as a result of an economic recession that started in 1991. Another decline began in 2008 reflecting the recent economic recession. Overall, employment increased by about 0.3 percent annually from 1990 to 2009. Exhibit 1B summarizes the historical demographics for the LADWP service area.

AR0071501

Exhibit 1B
Historical Demographics for LADWP Service Area

	Population	Housing	Employment
1980	2,970,000	1,100,000	1,692,000
1990	3,501,602	1,243,022	1,813,615
2000	3,732,579	1,290,440	1,773,895
2009	4,051,438	1,376,013	1,812,926

Demographic projections were obtained for the LADWP service area from the MWD utilizing a land-use based planning tool that allocates projected demographic data from the Southern California Association of Governments (SCAG) into water service areas for their member agencies. MWD's demographic projections use data reported in SCAG's 2008 Regional Transportation Plan (RTP). Exhibit 1C summarizes these demographic projections for the LADWP service area.

LADWP's service area population is expected to continue to grow over the next 25 years at a rate of 0.4 percent annually. While this is substantially less than the historical 1.3 percent annual growth rate from 1980 to 2009, it will still lead to approximately 367,300 new residents over the next 25 years. According to SCAG's 2008 RTP, housing is expected to grow faster than population over the next 25 years at 0.7 percent annual growth versus 0.4 percent annual growth for population, and it is anticipated that household size will continue to decline over the projection period.

The 2008 RTP projects that by 2035 the average household size will decrease to 2.65 persons per household. Throughout the projection period, multi-family housing units are expected to increase at slightly less than twice the rate of single-family housing units (0.93 percent annual growth vs. 0.47 percent annual growth).

Employment is expected to increase by 0.4 percent annually throughout the projection period. This growth is primarily driven by the current and long-term opportunities available from the economic base within the five-county metropolitan region of Southern California. The economic base is wide-ranging and includes services, wholesale and retail trade, manufacturing, government, financial service industries, transportation, utilities, construction, education, and tourism. Over the 25 year

AR0071502

forecast period, industrial growth is expected to decline and experience a subtle annual negative growth of -0.4 percent, while commercial employment is expected to increase by about 0.5 percent annually.

Exhibit 1C
Demographic Projections for LADWP Service Area

Demographic	2010	2015	2020	2025	2030	2035
Population	4,100,260	4,172,760	4,250,861	4,326,012	4,398,408	4,467,560
Housing						
Single-Family	627,395	646,067	665,261	678,956	691,703	701,101
Multi-Family	764,402	804,013	846,257	880,580	914,125	942,846
Total Housing	1,391,797	1,450,080	1,511,518	1,559,536	1,605,828	1,643,947
Persons per Household	2.88	2.81	2.75	2.71	2.67	2.65
Employment						
Commercial	1,674,032	1,724,106	1,754,998	1,790,798	1,828,765	1,865,156
Industrial	163,382	157,652	155,012	152,426	150,009	147,508
Total Employment	1,837,415	1,881,758	1,910,010	1,943,224	1,978,773	2,012,664

Source: SCAG Regional Transportation Plan (2008), modified using MWD's land use planning to represent LADWP's service area.

The SCAG demographic projections for population, households, and employment included in their 2008 RTP, and presented in LADWP's 2010 UWMP, vary from what was presented in LADWP's 2005 UWMP. The demographic projections in the 2005 UWMP were based on SCAG's 2004 RTP. The current 2008 projections incorporate the latest population, households, and employment data from multiple local, state and federal agencies. Projected 2008 RTP data reflect adjustments in future population growth related to declining fertility, mortality, labor force participation, and household headship rates; leveling in net migration; fluctuating net domestic migration in response to economic cycles; and an employment shift from the manufacturing sector to the service sector. The SCAG 2008 RTP was adopted in May 2008 prior to the recent recession beginning in 2008. Additionally, MWD has further adjusted the service area boundaries based on LADWP input. Exhibit 1D shows the differences between the SCAG demographic projections for the RTP in 2004 and 2008.

For the forecast year 2030 population was projected to be 4.30 million under the SCAG 2004 RTP and 4.40 million under the 2008 RTP, a difference of about 100,000. Housing was projected to be 1.60 million in 2030 under SCAG 2004 RTP and slightly more under the SCAG 2008 RTP at 1.61 million. Employment was forecast to be less in 2030 under the newest RTP. It is projected to be 2.20 million under the SCAG 2004 RTP versus 1.98 million with the 2008 RTP. It is important to recognize that projected total employment under both the 2004 RTP and 2008 RTP continue to increase from 2010 to 2035. The 2008 RTP simply projects a lower *rate* of increase than does the 2004 RTP. Conversely, the *rate* at which the population increases is expected to be higher with the 2008 RTP as compared with the 2004 RTP.

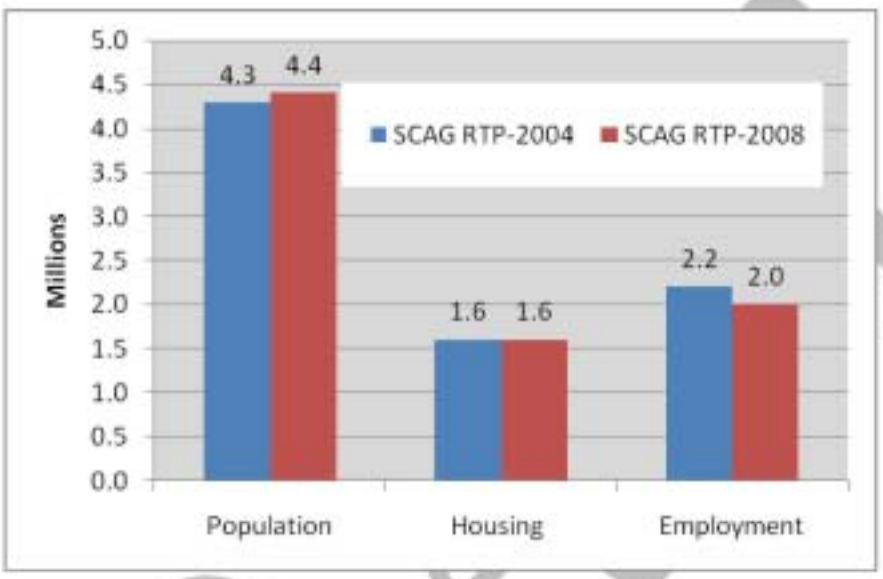
Comparison of SCAG Demographic Projections for LADWP Service Area Between 2004 and 2008 RTP Forecasts for Year 2030



1.2.3 Climate

Weather in Los Angeles is considered mild, which is a major attribute that attracts businesses, residents, and tourists to the City. The City experiences a sizable and popular portion of sunshine throughout the year. Because of its relative dryness, Los Angeles' climate has been characterized as Mediterranean. Exhibit 1E provides a summary of average monthly rainfall, maximum temperatures, and evapotranspiration readings.

The City's average monthly maximum temperature is 76 degrees Fahrenheit based on the period of 1990-2010. This is based on data from the Los Angeles Downtown weather station. The standard annual average evapotranspiration rate (ETo) for the Los Angeles area is 50.29 inches per year. ETo measures the loss of water to the atmosphere by evaporation from soil and plant surfaces and transpiration from plants. ETo serves as an indicator of how much water plants need for healthy growth. Total precipitation averages 14.8 inches per year, with over 90 percent of the total amount typically falling during the period of November through April.

1.2.4 Water Demand and Supply Overview

Primary sources of water for the LADWP service area are the Los Angeles Aqueducts (LAA), local groundwater, and imported supplemental water purchased from MWD. An additional fourth source, recycled water, is increasingly becoming a larger source in the overall supply portfolio. Two of the supply sources, LAA and water purchased from MWD, are classified as imported as they are obtained from outside LADWP's service area. Groundwater is local and is obtained within the service area. Historical supply sources are increasingly under multiple constraints including potential impacts of climate change, groundwater contamination, and reallocation of water for environmental concerns. To mitigate these impacts on supply sources, LADWP is modifying its water supply portfolio through conservation, water recycling, and stormwater capture.

The primary water supply sources are vital to maintaining LADWP's water system reliability. Pressure on one resource, such as little snowfall in the eastern Sierra Nevada Mountains, will result in an increased reliance on another resource, such as MWD. Supplies available from each source are determined using various computer models in an attempt to balance total projected supplies with projected demands. Exhibit 1F illustrates historical water supplies from 1980 to 2010. As a result of supply shortages, overall demands decreased by over 124,000 AFY in 2009-10 as compared to 2006-07. In 2009-10, approximately 36 percent of the water supply was from the LAA, 14 percent from local groundwater, 48 percent from MWD, and 1 percent from recycled water. From 2005-06 to 2009-10, the five–year average of the water supply portfolio was divided into the following percentages: 36 percent LAA, 11 percent local groundwater, 52 percent MWD, and less than 1 percent recycled water. The imported water (LAA water plus MWD water) supplied on average approximately 88 percent of demands.

AR0071506

Chapter Two
Water Demand

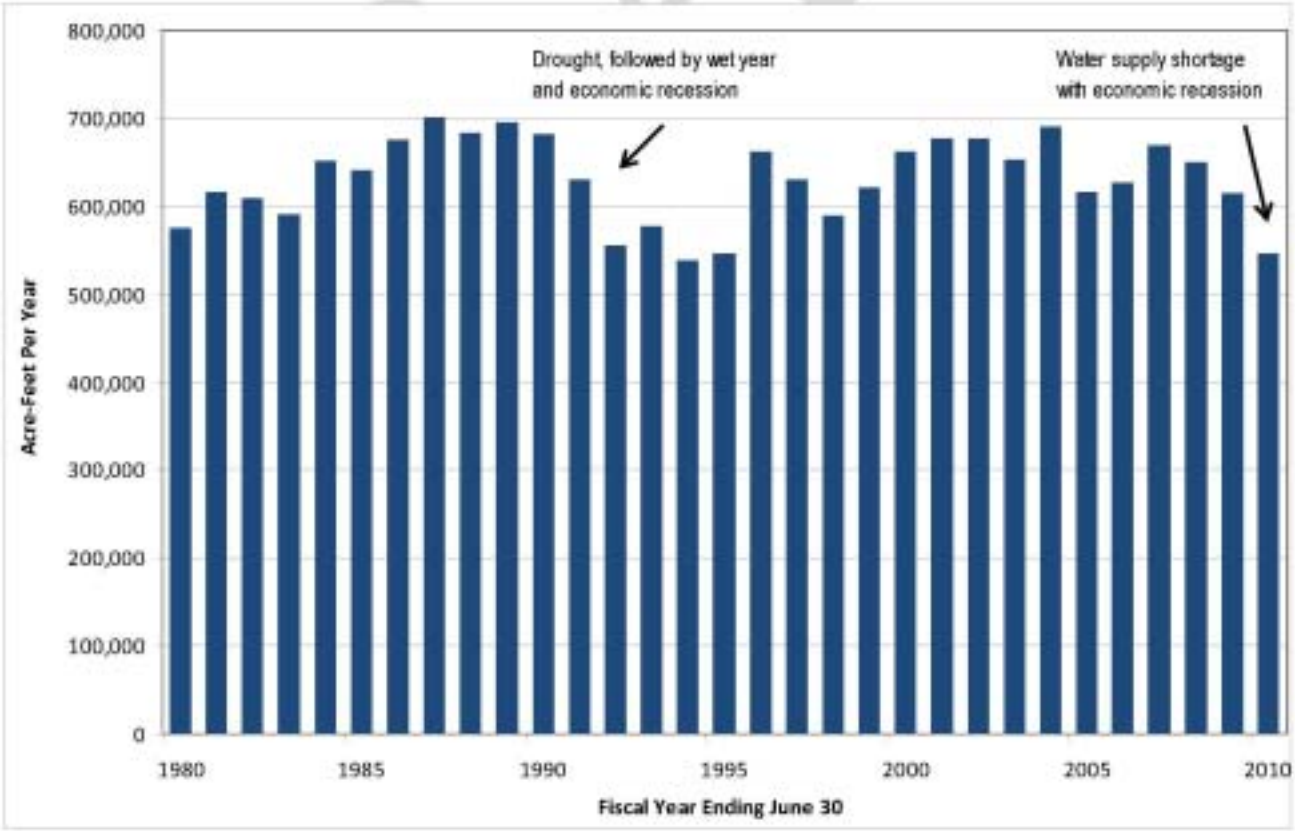
2.0 Overview

In order to properly plan for water supply, it is important to understand water demands and the factors that influence demands over time. LADWP maintains historical water use data separated into the following categories: single-family residential, multifamily residential, commercial, industrial, government, and non-revenue water. This categorization of demands allows better evaluation of trends in water use over time and more precise targeting of water conservation measures.

2.1 Historical Water Use

Exhibit 2A presents the historical water demand for LADWP. As seen in this exhibit, total water demand varies from year to year and is influenced by a number of factors such as population growth, weather, water conservation, drought, and economic activity. In 1991 mandatory conservation imposed on LADWP's customers in response to a six year drought resulted in water use dropping by 8 percent. An economic recession and wet weather in 1992 caused water use to continue to decrease another 12 percent. In 2009 a 3-year water supply shortage coinciding with an economic recession required LADWP to impose mandatory conservation. In 2010 mandatory conservation continued and the economic recession became more severe. This resulted in 2009-10 water use decreasing by 19 percent from 2006-07 levels.

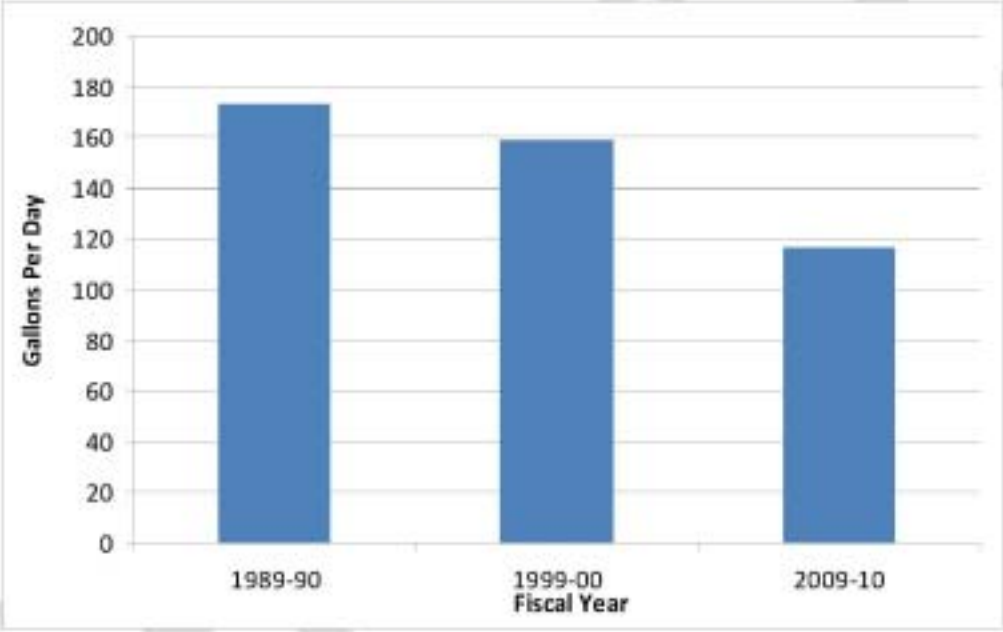
Exhibit 2A
Historical Total Water Demand in LADWP's Service Area



AR0071508

Prior to 1990, population growth in Los Angeles was a good indicator of total demands. From 1980 to 1990, population in the City grew at 1.7 percent annually. Water demands during this same ten year period also grew at 1.7 percent annually. However, after 1991, LADWP began implementing water conservation measures which prevented water demands from returning to pre-1990 levels. Average water demands in the last five years from 2004-05 to 2009-10 are about the same as they were in 1980-81 despite the fact that over 1.1 million additional people now live in Los Angeles. This is evidenced by examining per person (or per capita) water use since 1980 (see Exhibit 2B). In 1989-90, per capita water use was 173 gallons per day (gpd). By 1999-00, per capita water use fell to 159 gpd (or a 10 percent reduction from 1990). In 2009-10, per capita water use is estimated to be 117 gpd – but it is important to note that mandatory conservation and a severe economic recession were occurring at this time.

Exhibit 2B
Historical Per Capita Water Use in LADWP's Service Area



Water Use by Sector

Exhibit 2C shows the breakdown in average total water use between LADWP's major billing categories and non-revenue water in five-year interval for the past 25 years. Non-revenue water, which is the difference between total water use and billed water use, includes water for fire fighting, reservoir evaporation, mainline flushing, system losses, and theft. Single-family residential water use comprises the largest category of demand in LADWP's service area, representing about 36 percent of the total. Multifamily residential water use is the next largest category of demand, representing about 29 percent of the total. Industrial use is the smallest category, representing only 4 percent of the total demand. Although total water use has varied substantially from year to year, the breakdown between the major billing categories of use has not.

Non-revenue water has significantly decreased in recent years. Historically, non-revenue water has averaged 7 percent of total water demand. Since 2005, non-revenue water levels have averaged 5 percent. This may be attributed to a number of steps that LADWP has taken to improve its water system. In 2001, LADWP began replacing its large and intermediate meters. Work was focused on improving accuracy of the meters as well as their strategic placement. In fiscal year 2007-08, an

AR0071509

accelerated mainline replacement program was launched to repair and replace deteriorating pipelines. In addition, work to replace smaller customer meters was finally completed in fiscal year 2009-10 which also contributes to water loss control. Furthermore, LADWP's ongoing program to remove or cover large open-air reservoirs reduces water loss due to evaporation and infiltration.

Exhibit 2C

Indoor and Outdoor Water Use

In order to assess the potential for water use efficiency and target conservation programs, it is important to characterize water use in terms of indoor and outdoor demands. As with most water utilities, LADWP does not have separate irrigation meters for most of its customers. Only a small fraction of LADWP's customers, mostly parks and golf course, have designated irrigation meters. Therefore, measuring indoor vs. outdoor water demands involves the use of other data and assumptions.

There are two methods that LADWP uses to estimate total outdoor water use: (1) estimation of supplemental water needed for landscape irrigation in accordance with the California Model Water Efficient Landscape Ordinance; and (2) comparing wastewater flows to total water consumption. The first method uses the following formula to estimate the water needed to supplement outdoor landscape irrigation beyond the effect of natural precipitation:

$$LW = (Eto - Eppt) \times 0.62 \times A \times ETAF$$

Where:
LW = Estimated total supplemental water needed for landscape irrigation;
Eto = Reference evapotranspiration for the City of Los Angeles;
Eppt = Effective precipitation (25% of monthly precipitation);
0.62 = Conversion factor to gallons;
A = Total greenscape area; and
ETAF = Et adjustment factor

In 2007, an infrared analysis of the City was conducted as part of the City's Million Trees Program to determine tree canopy and landscape coverage. The infrared analysis methodology used two types of remotely sensed data, infrared imagery and aerial imagery, to determine the total greenscape areas within the City. Results of this effort indicated there is approximately 83,699 acres of greenscape area in Los Angeles. The ETAF (or Et adjustment factor) of 0.8 for the City was derived from types of plants to be irrigated and an assumed irrigation efficiency. It is consistent with the ETAF for non-rehabilitated landscapes as defined in the California Model Water Efficient Landscape Ordinance. The 2004-2007 average total water demand was selected as the basis for calculating outdoor water use percentage. This period was considered to be about average in terms of weather for Los Angeles and had no water restriction implemented by the City. Using the formula described previously, the supplemental water for outdoor landscaping in the City was estimated to be 249,000 AFY. During

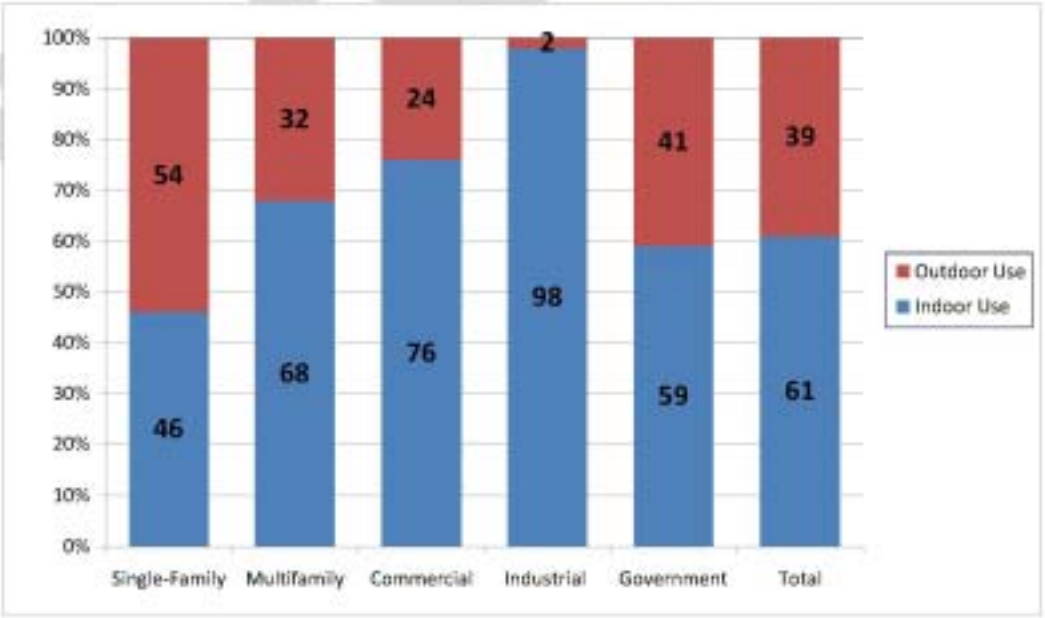
AR0071510

this same period, total water demand averaged 647,000 AFY. Therefore, the City's total outdoor water use represents approximately 39 percent of the total demand.

Comparing wastewater flows to total water consumption is another useful method to assess overall outdoor water use. Since wastewater flow represents indoor water use that flows into the sanitary sewer system, the difference between total water consumption and wastewater flows represents outdoor water use. However, groundwater infiltration and wet weather runoff may enter sanitary sewer systems through cracks and/or leaks in the sanitary sewer pipes or manholes and results in overestimation of the indoor water use. To reduce their impact, only summer months were used to estimate average monthly wastewater attributable to indoor water use. In Los Angeles, the summer months typically have little or no measurable rainfall. Using the same pre-water restriction period of 2004-2007 selected in the first method, the average monthly wastewater flow (only the months of June through September) yields approximately 365 million gallons per day (MGD) or 403,000 AFY of estimated indoor water use. Subtracting this estimated indoor water use from the total water consumption of 647,000 AFY results in an estimated total outdoor demand of 244,000 AFY or 38 percent, which is similar to the 39 percent obtained with the landscape irrigation method. Therefore, two entirely different methods produced very similar results in estimating the total outdoor water use for the City.

To obtain an estimate of indoor vs. outdoor water use for each major billing category, a minimum-month method was used. Monthly water use for single-family, multifamily, commercial, industrial and government was obtained for 2004-2007. The water use in the minimum month, usually one of the cool/wet winter months, is assumed to be mostly indoor use. The difference between any month and the minimum month is all attributed to outdoor water use. But based on the two prior methods, a certain amount of outdoor water use occurs even in the minimum month for some customers. Estimates of the outdoor water use that occurs in the minimum month were developed for each major billing category. Then the outdoor use of each major billing category was summed up to compare with the total outdoor water use obtained from the previous two methods. Exhibit 2D presents the estimated indoor and outdoor water use for the City using all three methods.

Exhibit 2D
Indoor vs. Outdoor Water Use in LADWP's Service Area

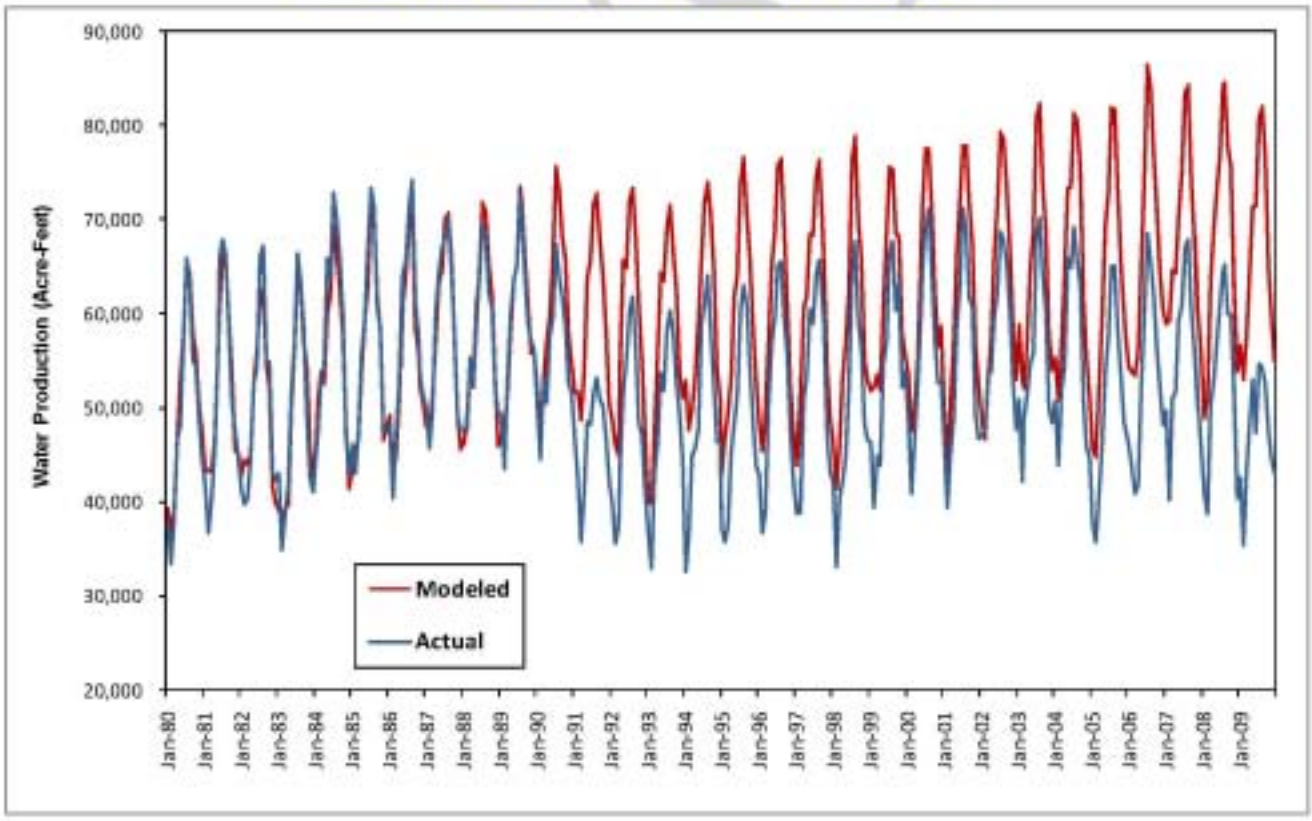


AR0071511

2.2 Quantification of Historical Water Conservation

LADWP has invested hundreds of millions of dollars in water conservation since 1990. These conservation investments include various active programs such as high efficiency toilet rebates, commercial/industrial water audits, education and public outreach and much more. During periods of water shortage, public education and outreach is especially important and has contributed to significant reductions in water use. In an effort to quantify its water conservation efforts, LADWP developed a statistical Conservation Model that correlates total monthly water use in the City with population, weather, the presence of mandatory water conservation, and economic recessions. The model can be used to predict what the water demand would be under actual weather conditions, population growth and economy; but without active or drought water conservation in place. This modeled water consumption without conservation is then compared to actual water consumption—with the difference being attributed to water conservation. In order to assess the model's accuracy, the model is used to "back cast" the period 1980 to 1990 when conservation was not implemented. In this case, the modeled water consumption should be very close to the actual water consumption. After 1990, it is expected that the modeled water consumption will be greater than actual water consumption as LADWP has implemented increasing levels of water conservation measures. Exhibit 2E presents modeled and actual monthly water consumption from 1980 to 2009. As seen, the Conservation Model is performing as expected. The modeled water consumption (red line) is nearly identical to the actual water consumption (blue line) up until 1990. After 1990, the modeled water consumption is greater than actual water consumption.

Exhibit 2E
Modeled vs. Actual Monthly Water Consumption for LADWP



AR0071512

Exhibit 2F summarizes the annual estimated water conservation using the Conservation Model. During periods of water shortage, even when mandatory water conservation is not in place, there is more conservation occurring due to extensive public education and outreach. Water conservation in 2009 represents the highest levels of conservation so far, which reflects a combination of active conservation programs, heightened public education and outreach, and mandatory conservation measures.

2.3 Water Demand Forecast

Demand Forecast Methodology

LADWP has developed a water demand forecast for each of its major categories of demand. This allows the City to better understand trends in water use and target conservation programs. The methodology used for the demand forecast is called a modified unit use approach. The following steps are used in this approach:

AR0071513

Step 1: Estimate baseline per unit water use – take each billed category of water demand (e.g., single-family, industrial, etc.) for a base (or starting) period and divide by associated demographic driver (e.g., number of single-family homes or number of industrial employees). This yields for instance, a baseline of 359 gallons used each day in a single-family residence.

Step 2: Modify the estimated baseline per unit water use to account for future changes in the following socioeconomic variables: price of water, personal income, family size, economy, drought conservation effect, and passive water conservation (which accounts for efficiencies in water use from state and local plumbing codes and ordinances).

Step 3: Multiply modified per unit water use for each category in Step 2 by the associated projected demographic drivers (see Exhibit 2G) in order to obtain projected water demands by billed category that does not include active water conservation (which is defined as conservation that LADWP incentives through rebates and programs).

Exhibit 2G
Projected Demographic Drivers
(Based on MWD allocated 2008 SCAG forecast data with corrected service area boundary, 5-17-2010)

Fiscal Year Ending	Single-Family (# Homes)	Multi-Family (# Homes)	Commercial/ Government (# Employees)	Industrial (# Employees)	Landscaping (# of MF Homes)	NRW* (%)
2010	627,395	764,402	1,674,032	163,382	764,402	6.9%
2015	646,067	804,013	1,724,106	157,652	804,013	6.9%
2020	665,261	846,257	1,754,998	155,012	846,257	6.9%
2025	678,956	880,580	1,790,798	152,426	880,580	6.9%
2030	691,703	914,125	1,828,765	150,009	914,125	6.9%
2035	701,101	942,846	1,865,156	147,508	942,846	6.9%

* Calculated from difference between historical production and billing data

Step 4: Estimate non-revenue water (the difference between total water consumption and billed water use) by applying a non-revenue water use factor, and add non-revenue water to the billed category water demands in Step 3 in order to get a forecast of total water consumption without active water conservation.

Step 5: Subtract future projections of active water conservation from the total water consumption in Step 4 in order to determine the water demand forecast that is fully inclusive of both passive and active water conservation.

Applying the Methodology

In Step 1 of this method, historical water demands for single-family, multifamily, commercial/government, and industrial were averaged from 2005 to 2008 to determine the baseline. This period was used because on average, it represented normal weather conditions, and it was before mandatory water use restrictions that occurred in 2009 and 2010. For each of these categories, the water demand was divided by a demographic driver that could be projected into the future. The result of this calculation is a water demand expressed as a unit use water rate. Exhibit 2H presents this unit use calculation for the baseline.

AR0071514

Exhibit 2H
Baseline Unit Use Water Rates (2005-2008)

Demand Category	Average Water Demand (AFY)	Average Demographic Driver *	Average Unit Use Rate (gallons/day/driver)
Single-Family	244,407	607,301 (homes)	359
Multifamily	184,428	734,461 (homes)	224
Commercial/Gov	153,199	1,631,896 (employees)	84
Industrial	23,613	160,328 (employees)	132

* Source: California Department of Finance and Employment Development Department

Step 2 in the methodology involves modifying these baseline unit use rates to account for changes in the following socioeconomic variables: price of water, personal income, family size, economy, drought conservation effect and passive water conservation. MWD has developed an econometric water demand model as part of its 2010 Integrated Water Resources Plan that is able to account for the impact that personal income, family size and price of water have on water demands. For each of these factors, a statistical coefficient or elasticity was estimated from MWD's Econometric Water Demand. The elasticity is generally interpreted as a percent change in water use resulting from a percent change in the socioeconomic variable. For example, a price elasticity of -0.131 would imply that a 10 percent increase in the real price of water would result in a 1.24 percent decrease in water demand (e.g. $1.24\% = 1-(1+10\%)^{-0.131}$). The following elasticities used in MWD's econometric water demand model were also used for LADWP's water demand forecast:

	Price of Water	Income	Family Size
Single-Family	-0.131	+0.270	+0.550
Multifamily	-0.109	+0.310	+0.450
Commercial/Government	-0.107		
Industrial	-0.107		

Source: MWD 2010 Integrated Water Resources Plan Update Appendix A.1 Demand Forecast

The price elasticities reflect a reduction of approximately 1/3 from those tabulated in MWD's 2010 IRP. However, MWD's 2010 IRP Appendix A.1 states that consumers respond to price increase by installing water-conserving fixtures and appliances. As more water efficient fixtures are installed, the impact of changing water-using behavior through rates is reduced. This is known as "demand hardening". Reducing the price elasticity is to avoid double-counting conservation savings and to account for demand hardening.

Exhibit 2I presents the modified per unit water use over time that incorporates future real increases in the price of water, personal income, and projected changes in family size. Also incorporated are the residual drought conservation effect from the significant public education and mandatory water restrictions that occurred during the drought period of 2009 through 2010, and the effect of passive conservation due to mandated efficiencies from plumbing codes and ordinances.

AR0071515

Exhibit 2I
Baseline Unit Use Water Rates (2005-2008)

	Baseline	2015	2020	2025	2030	2035
Single-Family (per home)	359	317	325	328	333	331
Multifamily (per home)	224	200	205	208	211	210
Commercial (per employee)	84	74	76	77	77	77
Industrial (per employee)	132	116	119	120	121	120

Water Demand Forecast Results

Steps 3, 4, and 5 involve applying the modified per unit water use factors shown in Exhibit 2J to the projected demographics for LADWP (see Chapter 1), then adding non-revenue water, and subtracting projected active water conservation (that is summarized in Chapter 3). The result of these steps is the water demand forecast for each of the major categories of demand.

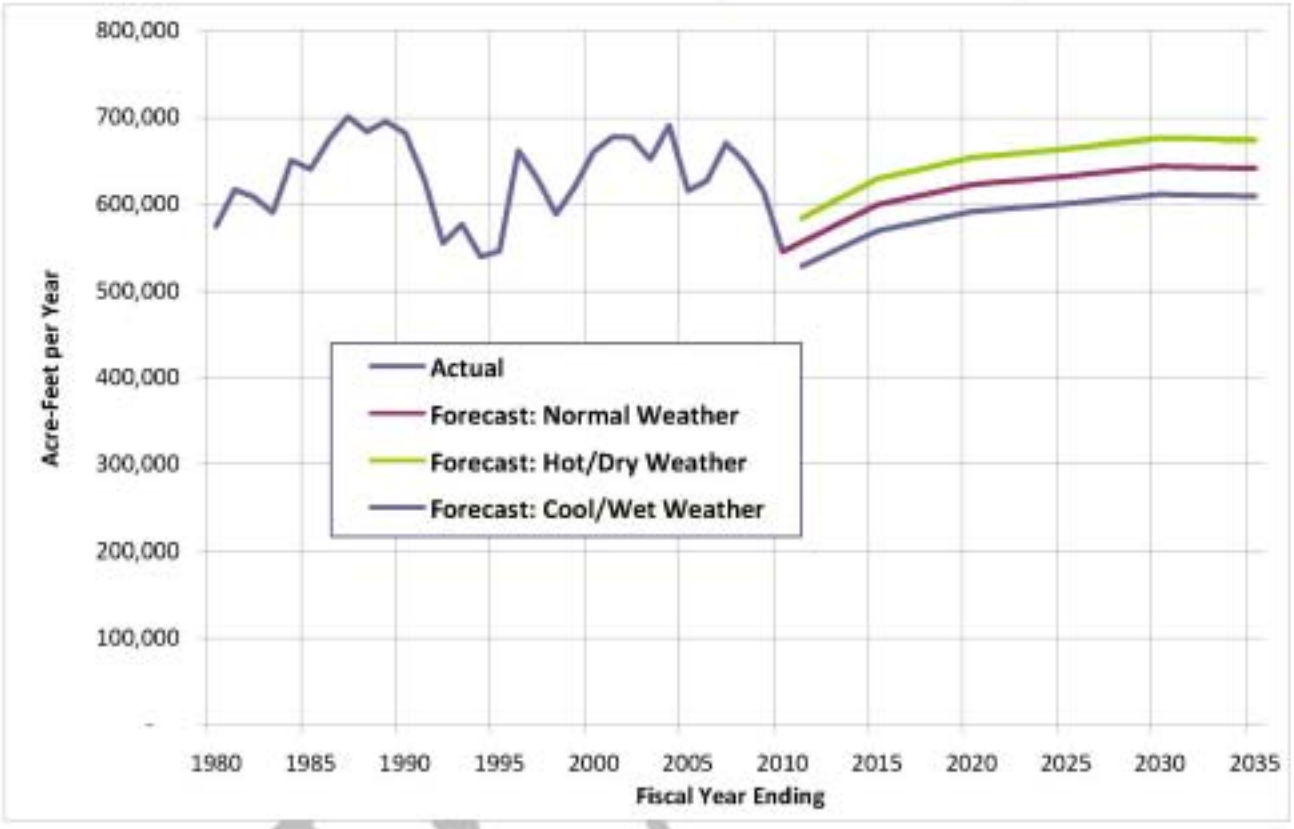
Water Demand Forecast with Average Weather Variability

Using the weather coefficients from the statistical water conservation model (see Exhibit 2E), annual weather adjustment factors can be derived to determine the range in forecasted water demands due to historical weather variability. This is accomplished by projecting water demands assuming long-term normal weather, and then comparing this normal-weather demand to actual demands. After adjusting for economy and drought conditions, projected water demands can vary by approximately ± 5 percent in any given year due to average historical weather variability. Meaning that water demands under cool/wet weather conditions could be as much as 5 percent lower than normal demands on average; while water demands under hot/dry weather conditions can be as much as 5 percent higher than normal demands on average. Exhibit 2K presents LADWP's historical and forecasted total water demands with both passive and active conservation, under the full range of historical weather variability.

AR0071517

Exhibit 2K
Water Demand Forecast with Average Weather Variability



Low-Income Water Demand Projections

The requirements for the 2010 UWMP call for projections of water demands for low-income customers. For rate relief purposes, LADWP maintains records of low-income water customers. For the fiscal year 2009 - 2010, approximately 6.6 percent of the total number of single-family homes in the City was classified as low-income. On average, these customers used about 20 percent less water per household than overall single-family customers. To forecast low-income single-family water demand, the 6.6 percent ratio of low-income to total single-family homes was applied to the total projection of single-family homes for a projection of low-income single-family homes. The system wide per unit water use for single-family homes was reduced by 20 percent and multiplied by the projection of low-income single-family homes.

Because the water services of LADWP's multifamily residential customers are mostly not individually metered—meaning a multifamily water account can represent 2 or even 100 homes—a different approach was used. LADWP's power system does individually meter multifamily homes and also classifies homes as low-income for rate relief purposes. Therefore, the ratio of current low-income to total multifamily homes in the City was applied to the total projection of multifamily homes in order to get a projection of low-income multifamily homes. For the fiscal year 2009 – 2010, approximately 16.3 percent of the total number of multifamily homes in the City was classified as low-income. Assuming that low-income multifamily homes also use 20 percent less water than overall multifamily homes, an adjusted per unit water use for multifamily homes was multiplied by the projection of low-income multifamily homes. Exhibit 2L presents the water demand forecast for low-income residential water customers.

AR0071518

Exhibit 2L
Water Demand Forecast for Low-Income Residential Customers

Low-Income Single-Family Customers	2015	2020	2025	2030	2035

* Assumes same percent conservation as system for single-family and multifamily homes.

DRAFT

DRAFT Chapter Three
Water Conservation

3.0 Overview

Multiple factors are increasingly restricting LADWP's traditional water supply sources. The City of Los Angeles has long recognized water conservation as one of multiple methodologies to reduce demands and improve overall water supply reliability. In May of 2008, LADWP's Water Supply Action Plan (Plan), "Securing L.A.'s Water Supply", was released in response to factors impacting LADWP's major water supply sources beginning in 2007. This plan calls for reducing potable water demands by an additional 50,000 AFY by 2030 through conservation, with multiple conservation strategies to increase the sustainability of LADWP's water supply.

Los Angeles has historically taken a leadership role in managing its demand for water. Los Angeles consistently ranks among the lowest in per person water consumption when compared to California's largest cities. This significant accomplishment has resulted from the City's sustained implementation of effective water conservation programs since the 1980s.

One of LADWP's most effective conservation tools is its customers. During past droughts and water shortages, residents and businesses have aggressively implemented conservation to achieve demand reductions. During FY 09/10, water use was below 1979 water use levels thanks to extraordinary conservation efforts by LADWP customers. Specifically, water use in FY 09/10 was almost 20% lower than water use in FY 06/07 with single-family residential water use 25% lower, multi-family water use 11% lower, commercial water use 16% lower, industrial water use 15% lower, and governmental water use 33% lower.

LADWP has continually invested in water conservation programs and measures targeting cost-effective reductions in water use. Looking forward, LADWP plans to continue to make investments in conservation programs and expand its focus on landscape water use efficiency and conservation opportunities in the commercial/industrial/institutional (CII) customer sectors. LADWP's conservation planning process includes working with other City departments to ensure that mutual needs are addressed and goals are achieved (e.g., landscape water use efficiency and dry weather runoff reduction).

The civic culture of water conservation in Los Angeles began with the installation of water meters on all services in the early 1900's. At that time, this foundational conservation measure resulted in a 30 percent reduction in water use. Throughout the recurrence of periodic water shortages, LADWP customers have demonstrated the necessary concern and responsiveness. When faced with significant supply shortages, City residents have responded with unprecedented reductions in their water use. Los Angeles was one of the cities in southern California to invoke mandatory water rationing during the 1976 through 1977 drought. While severe, the two-year drought resulted in only a temporary reduction in water use, as a subsequent series of wet years erased memories of the water shortage experienced during the brief drought period. However, it was the drought that followed the 1978 through 1986 wet cycle that would prove to be the turning point in Los Angeles' water use awareness.

The drought of 1987-1992 left a permanent imprint on Los Angeles water customers. In response to this drought, LADWP expanded a voluntary water conservation program in 1990. Prompted by an extensive public awareness program and education campaign, LADWP customers responded not only with water saving practices but also by installing conservation measures in their homes and businesses. Devices such as low-flow showerheads and ultra-low-flush (ULF) toilets replaced existing non-water saving devices. These hardware changes, coupled with more responsible use habits, have significantly reduced the amount of imported water that the City would have to otherwise buy as the City's population and commerce has

AR0071520

continued to grow. In response to the current water shortage conditions the City has reinitiated its extensive public awareness campaigns in addition to campaigns launched by MWD to encourage water saving practices and installation of conservation devices in homes and businesses.

With the recent water supply shortage and reduced deliveries of imported water from MWD, residential customers have repeated conservation levels exceeding 20 percent in the period between 2007 and 2010 as a result of mandatory conservation. During the current water supply shortage, the City has updated its Emergency Water Conservation Plan Ordinance with enforceable water waste provisions and implemented mandatory outdoor watering restrictions. In addition, the City has implemented water shortage year rates reducing Tier 1 water allotments for customers by 15%. Since July 2007, 63 billion gallons of water were saved through conservation. As a direct result of conservation, imported water purchases from MWD are 23% below baseline allocations for fiscal year 2009/2010. In response to recently enacted State laws, LADWP has developed new water conservation goals which aim to reach approximately 64,000 AFY in hardware conservation savings by 2035.

Conservation has had a tremendous impact on Los Angeles' water use patterns and has become a permanent element of LADWP's water management philosophy. Water usage in the City in 2010 was less than it was in 1979 despite an increase in population of over 1,000,000 people (see Exhibit 3A). Exhibit 3B shows historical conservation savings from fiscal year 1990/1991 through 2009/2010 based on installation of distributed conservation devices and rebates/incentives claimed as well as conservation achieved through customers' behavior and lifestyle changes to use water more responsibly. Cumulative yearly savings for the period total 223,593 AFY.

1998/1999	2,721	67,948	39,666	107,614
1999/2000	3,038	70,986	-4,406	66,580
2000/2001	3,565	74,552	-2,038	72,513
2001/2002	2,263	76,814	16,688	93,502
2002/2003	2,507	79,321	10,405	89,726
2003/2004	3,047	82,368	14,999	97,366
2004/2005	3,124	85,492	48,932	134,423
2005/2006	3,030	88,522	63,664	152,186
2006/2007	2,197	90,719	77,982	168,701
2007/2008	782	91,501	65,587	157,088
2008/2009	3,127	94,628	106,307	200,935
2009/2010	4,269	98,897	124,696	223,593

1. Negative non-hardware savings are due to overestimation in hardware savings due to years with extreme wet weather conditions.

Conservation benefits the City by improving water supply reliability and reducing embedded energy use for water treatment and pumping. Conserving customers see a tangible benefit as well through monetary savings on their water bill. Another ancillary benefit of conserving water is that the need for costly sewer facility expansions is deferred by reducing wastewater discharge into the sewer collection and treatment systems, thus increasing the lifespan of current sewer infrastructure. Water conservation also has the added benefits of reducing greenhouse gas emissions and energy use associated with delivering water supplies to and within the LADWP service area. In the end, the primary beneficiaries of conservation are the water customers and the environment from where the sources of supply originates. Furthermore, increased conservation will result in decreased dry weather runoff which will decrease the amount of pollutants flowing into the rivers and oceans.

Los Angeles has been implementing permanent conservation since the 1980's. In 1988, the City adopted a plumbing retrofit ordinance to mandate the installation of conservation devices in all properties and to require water-efficient landscaping in new construction. The ordinance was amended in 1998, requiring the installation of ULF toilets and water saving showerheads in single-family and multi-family residences prior to resale. A new ordinance adopted in 2009, the Water Efficiency Requirements ordinance, establishes water efficiency requirements for new developments and renovations of existing buildings by requiring

AR0071522

installation of high efficiency plumbing fixtures in all residential and commercial buildings. LADWP's past water conservation programs have assisted customers affected by the ordinances by offering free ULF toilets and showerheads, free installation of ULF toilets, showerheads and faucet aerators, as well as rebates for ULF toilets purchased and installed. Current water conservation programs co-sponsored by MWD through the SoCal Water$mart Program for residential customers and the Save Water Save a Buck Program for CII customers continue to assist customers in complying with ordinances and reducing overall water demands.

3.1 Water Conservation Goals

Water conservation reduces demand that typically rises over time with growth in population and commerce. By mitigating those increases in demand, water supply reliability is improved while costs are reduced. In the early 1990s, City residents responded with conservation levels exceeding 20 percent due to increasingly drier conditions and mandatory conservation. As normal water supply conditions returned and with continuation of LADWP's conservation program, conservation levels stabilized at approximately 15 percent. With the recent drought and reduced deliveries of imported water from MWD, residential customers have repeated conservation levels exceeding 20 percent in the period between 2007 and 2010 as a result of mandatory conservation. Since July 2007, 63 billion gallons of water were saved through conservation. As a direct result of conservation, imported water purchases from MWD are 23% below baseline allocations for fiscal year 2009/2010. In response to the goals provided in the Plan and recently enacted State laws, LADWP has developed water conservation goals.

3.1.1 Water Supply Action Plan Conservation Goal

To continue increased conservation levels once mandatory outdoor watering restrictions are lifted, LADWP has set a water conservation goal in the Water Supply Action Plan of reducing potable water demands by an additional 50,000 AFY by 2030. This conservation level will further lessen the City's reliance on imported water while providing a drought-proof resource that is not subject to weather conditions. This aggressive approach includes multiple strategies: investments in state-of-the-art technology; a combination of rebates and incentives promoting installation of weather-based irrigation controllers (WBICs), efficient clothes washers and urinals; expansion and enforcement of prohibited water use; reductions in outdoor water use; extending education and outreach efforts; and encouraging regional conservation.

LADWP's commitment to conservation is a proven multi-faceted approach that includes tiered water pricing, education and awareness, financial incentives for the installation of a variety of conservation measures, free water saving showerheads, Technical Assistance Program (TAP) incentives for business and industry, and large landscape irrigation efficiency programs. Conservation is a key component of LADWP's water resource planning efforts and will continue to be implemented over the long term.

3.1.2 Water Conservation Act of 2009

The Water Conservation Act of 2009, Senate Billx7-7, requires water agencies to reduce per capita water use by 20% by 2020 (20x2020). This includes increasing recycled water use to offset potable water use. Water suppliers are required to set a water use target for 2020 and an interim target for 2015 using one of four methods. The 2020 urban water use target may be updated in a supplier's 2015 UWMP. Failure to meet adopted targets will result in the ineligibility of a water supplier to receive water grants or loans administered by the State unless one of two exceptions is met. Exception one states a water supplier may be eligible if they have submitted a schedule, financing plan, and budget to DWR for approval to achieve the per capita water use reductions. Exception two states a water supplier may be eligible if an entire water service area qualifies as a disadvantaged community.

DRAFT

AR0071523

Four methodologies are stipulated for calculating the water use target. Three of the methods are listed in Water Code § 10608.20(a)(1). The fourth method was developed by DWR. The four methodologies are:

- Method 1 - Eighty percent of the water supplier's baseline per capita water use
- Method 2 – Per capita daily water use estimated using the sum of performance standards applied to indoor residential use; landscape area water use, and commercial, industrial, and institutional uses
- Method 3 – Ninety-five percent of the applicable state hydrologic region target as stated in the state's *draft 20x2020 Water Conservation Plan.*
- Method 4 – Description to be added at end of 2010 once developed by DWR

In 2015, urban retail water suppliers will be required to report interim compliance followed by actual compliance in 2020. Interim compliance is halfway between the baseline water use and 2020 target. Baseline, target, and compliance-year water use estimates are required to be reported in gallons per capita per day (gpcd).

For consistent application of the Act, DWR produced *Methodologies for Calculating Baseline and Compliance Urban Water Per Capita Use* in October 2010. Following requirements provided in the document, LADWP has calculated baseline per capita water use, an urban use target for 2020, and an interim water use target for 2015. Reporting compliance daily per capita water use is not required until the 2015 UWMP cycle as it compares the interim target to actual water use in 2015. Exhibit 3C presents results of the calculations. Calculations and technical bases for the calculations are presented in Appendix X.

Baseline per capita water use is 154 gpcd using a ten-year average ending between December 31, 2004 and December 31, 2009 and 146 gpcd using a five-year average ending between December 31, 2007 and December 31, 2009.

LADWP has adopted Method 3 to set its 2015 interim and 2020 water use targets. Method 3 requires setting the 2020 water use target to 95% of the applicable State hydrologic region target as provided in the *State's Draft 20x2020 Water Conservation Plan.* LADWP is within State hydrologic region 4, the South Coast region. LADWP was required to further adjust the calculated 2020 target to achieve a minimum reduction in water use. The gpcd at 95% of the hydrologic region was 142 gpcd and using 95% of the five-year average base daily per capita water use was equal to 138 gpcd. Therefore, LADWP was required to set the 2020 target at the smaller of the two resultant values. LADWP's interim 2015 target is 146 gpcd and the 2020 target is 138 gpcd.

DRAFT

AR0071524

Exhibit 3C
20x2020 Base and Target Data

20x2020 Required Data	Gallons Per Capita Per Day (GPCD)
Base Per Capita Daily Water Use	
10-Year Average[1]	154
5-Year Average[2]	146
2020 Target Using Method 3[3]	
95% of Hydrologic Region Target (149 gpcd)	142
95% OF Base Daily Capita Water Use 5-Year Average (146 gpcd)	138
Actual 2020 Target	**138**
2015 Interim Target	146

1. Ten-year average based on calendar year ending between 12/31/04 and 12/31/10.

2. Five-year average based on calendar year ending between 12/31/07 and 12/31/10.

3. Methodology requires smaller of two results to be actual water use target to satisfy minimum water use target.

3.2 Existing Programs, Practices, and Technology to Achieve Water Conservation

LADWP has developed aggressive water conservation programs to address recently enacted State laws and to meet its goal of achieving an additional 50,000 AFY conservation by 2030. LADWP uses multiple programs, practices, and technologies in conjunction with enactment of ordinances to achieve its current water conservation levels throughout its service area and customer classes.

3.2.1 State Laws and City Ordinances

State Laws

In addition to the Water Conservation Act of 2009 multiple legislative bills have been enacted in the past few years requiring water agencies to enact measures to increase water conservation, establishing new plumbing standards, and linking grants and loans to implementation of best management practices (BMPs).

The Water Conservation in Landscaping Act of 2006, Assembly Bill 1881, reduces outdoor water waste through improvements in irrigation efficiency and selection of plants requiring less water. The Act required an update to the existing Model Water Efficient Landscape Ordinance and adoption by location agencies or an equivalent ordinance no later than January 1, 2010. If any agency failed to adopt the ordinance or its equivalent then the ordinance was automatically adopted by statute. The ordinance requires development of water budgets for landscaping, reduces erosion and irrigation related runoff, utilization of recycled water if available, irrigation audits, requirements for landscape and irrigation design, and scheduling of irrigation based on localized climate for new construction and redevelopment projects.

In 2009, Assembly Bill 1465, Urban Water Management Planning, was approved to include language in the UWMP Act that deem water suppliers that are members of the California Urban Water Conservation Council (CUWCC) and comply with the "Memorandum of Understanding Regarding Urban Water Conservation in California," dated December 10, 2008, as it may be

DRAFT

amended, to be in compliance with the requirement to describe the supplier's water demand management measures in its urban water management plan. A more detailed discussion of the CUWCC and BMP compliance is provided in Section 3.2.3.

Assembly Bill 1420 links state funding for water management by urban water suppliers to implementation of water conservation measures. Urban water suppliers are required to be in compliance with the CUWCC MOU to be eligible for water management grants or loans. Senate Bill X7-7 further clarifies the grant funding conditions required by AB 1420 are repealed on July 1, 2016 and replaced with eligibility determined by compliance with 20x2020 targets.

In the recent years there has been a lot of regulations approved increasing the water use efficiency requirements of plumbing devices, specifically, Assembly Bill 715 (2007), Senate Bill 407 (2009), and the CALGreen Building Standards. AB 716 requires that all toilet and urinal fixtures sold through retail or installed in existing and new residential and commercial building meet the high efficiency standards by January 1, 2014. SB 407 does not address the sale of plumbing fixtures but adds a requirement that beginning in January 1, 2017 all residential and commercial property sales must disclose all non-efficient plumbing fixtures. CALGreen has an effective date of January 1, 2011 and requires use of water efficient plumbing fixtures for all new construction and renovations of residential and commercial properties.

City Ordinances

Los Angeles has utilized ordinances as a tool to reduce water waste since 1988, beginning with the adoption of its first version of a plumbing retrofit ordinance. The ordinance mandated installation of conservation devices in all existing residential and commercial properties and installation of water-efficient landscaping in all new construction. Toilets were required to use less than 3.5 gallons per flush (gpf), urinals less than 1.5 gpf, and showerheads less than 2.5 gallons per minute (gpm). Customers with three acres or more of turf were required to reduce water consumption by 10 percent from 1986 levels or face a 100 percent surcharge on their water bills.

In 1998 the ordinance was amended, requiring the installation of ULF toilets and water saving showerheads in single-family and multi-family residences prior to the close of escrow. This progressive requirement is implemented with the help of local real estate professionals. LADWP has explored the expansion of the City's Retrofit on Resale Ordinance to include nonresidential properties

Los Angeles further increased its water efficiency mandates in 2009 with adoption of the Water Efficiency Requirements ordinance. This ordinance establishes water efficiency requirements for new developments and renovations of existing buildings by requiring installation of high efficiency plumbing fixtures in all residential and commercial buildings. Exhibit 3D summarizes the minimum requirements for new construction and replacement of fixtures in existing buildings.

DRAFT

AR0071526

Exhibit 3D
Water Efficiency Requirements Ordinance Summary

Device	Requirement
High Efficiency Toilets	1.28 gallons per flush
Urinals	0.125 gallons per flush
Faucets	
Indoor Faucets (Maximum)	2.2 gallons per minute
Private Lavatory Faucets	1.5 gallons per minute
Public Use Lavatory Faucets[1]	0.5 gallons per minute
Showerheads	2 gallons per minute
Dishwashers	
Commercial Dishwashers	varies by type between 0.62 and 1.16 maximum gallons per rack
Domestic Dishwashers	5.8 gallons per cycle
Cooling Towers	5.5 cycles of concentration
Single-Pass Cooling Systems	Prohibited[2]

1. Metering faucets shall not deliver more than 0.25 gallons per cycle.

2. Single pass cooling systems are prohibited unless installed for health and safety purposes that cannot otherwise safely operate.

In an effort to lead by example, LADWP has been retrofitting all its facilities with high efficiency plumbing fixtures since before the effective dates of the ordinance. As of early June 2010, LADWP is 57 percent complete in upgrading its 600 buildings to high efficiency faucets, toilets, urinals, showers, flexible hose connectors, angle valves, as well as correcting leaks and removing existing water damage.

In May 1996, the City's Landscape Ordinance (No. 170,978) became effective with an overarching goal to improve the efficient use of outdoor water. This ordinance was recently amended in 2009 to comply with the previously discussed Water Conservation in Landscaping Act of 2006 and the Model Water Efficient Landscape Ordinance.

LADWP first adopted an Emergency Water Conservation Plan ordinance in the early 1990's in response to drought conditions. Subsequently in the current water shortage LADWP has adopted two amendments expanding prohibited uses, increasing penalties for violating the ordinance, and modifying water conservation requirements. Five phases of water conservation are incorporated into the plan with prohibitions and water conservation measures steadily increasing by phase. Regardless of water supply availability, at a minimum Phase I conservation requirements are in effect unless a more stringent phase is in effect. In response to the ongoing drought conditions, LADWP implemented Phase III restrictions on June 1, 2009, allowing outdoor irrigation only two days per week. Upon the recent ordinance amendment, Phase II implementation began on August 25, 2010 which allows outdoor watering three days per week. Exhibit 3E summarizes the five phases as defined in the latest amendment approved in August 2010.

AR0071527

Exhibit 3E
Emergency Water Conservation Plan Ordinance Restrictions by Phase

Phase	Restrictions
I	No use of a water hose to wash paved surfaces
	No use of water to clean, fill, or maintain levels in decorative fountains, ponds, lakes or similar structures used for aesthetic purposes unless a recirculating system is used
	No drinking water shall be served unless expressly requested in restaurants, hotels, cafes, cafeterias, or other public places where food is sold, served, or offered for sale
	No leaks from any pipes or fixtures on a customer's premises; failure or refusal to fix leak in a timely manner shall subject the customer penalties for a prohibited use of water
	No washing vehicles with a hose if the hose does not have a self-closing water shut-off device attached or the hose is allowed to run continuously while washing a vehicle
	No irrigation during rain
	No irrigation between 9am and 4pm, except for public and private golf courses and professional sports fields to maintain play areas and event schedules. System testing and repair is allowed if signage is displayed.
	All irrigation of landscape with potable water using spray head and bubblers shall be limited to no more than ten minutes per water day per station. All irrigation of landscape with potable water using standard rotors and multi-stream rotary heads shall be limited to no more than 15 minutes per cycle and up to 2 cycles per water day per station. Exempt from these restrictions are irrigation systems using very low-flow drip-type irrigation when no emitter produces more than 4 gallons of water per hour and micro-sprinklers using less than 14 gallons per hour. This restriction does not apply to Schedule F water customers or water service that has been granted the General Provision M rate adjustment under the City's Water Rate Ordinance, subject to the customer having complied with best management practices for irrigation approved by LADWP.
	No watering or irrigation of any lawn, landscape, or other vegetated area shall occur in a manner that causes or allows excess or continuous water flow or runoff onto an adjoining sidewalk, driveway, street, gutter, or ditch
	No installation of single-pass cooling systems shall be permitted in buildings requesting new water service.
	No installation of non-recirculating systems shall be permitted in new conveyor car wash and new commercial laundry systems.
	Operators of hotels and motels shall provide guests with the option of choosing not to have towels and linens laundered daily.
	No large landscape areas shall have irrigation systems without rain sensors that shut off the irrigation systems.
II	All prohibited uses in Phase 1 shall apply, except as provided.
	No landscape irrigation shall be permitted on any day other than Monday, Wednesday, or Friday for odd-numbered street address and Tuesday, Thursday, or Sunday for even-numbered street addresses. If a street address ends in 1/2 or any fraction it shall conform to the permitted uses for the last whole number in the address. For non-conserving nozzles (spray head sprinklers and bubblers) watering times shall be limited to no more than 8 minutes per watering day per station for a total of 24 minutes per week. For conserving nozzles (standard rotors and multi-stream rotary heads watering times shall be limited to no more than 15 minutes per cycle and up to two cycles per watering day per station for a total of 90 minutes per week.
	Irrigation of sports fields may deviate from non-watering days to maintain play areas and accommodate event schedules with written notice from LADWP. However, a customer must reduce overall monthly water use by LADWP's Board of Water and Power Commissioners adopted degree of shortage plus an additional 5% from the customer baseline water usage within 30 days.

DRAFT

AR0071528

	If written notice is received from LADWP, large landscape areas may deviate from the non-watering days if the following requirements are met: 1) approved weather-based irrigation controllers registered with LADWP 2) Must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus and additional 5% from the customer baseline within 30 days 3) Must use recycled water if available
	These restrictions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase II, except between the hours of 9am and 4pm.
III	All prohibited uses in Phases I and II shall apply, except as provided.
	No landscape irrigation shall be permitted on any day other than Monday for odd-numbered street address and Tuesday for even-numbered street addresses. If a street address ends in 1/2 or any fraction it shall conform to the permitted use for the last whole number in the address.
	No washing of vehicles allowed except at commercial car washes.
	No filling of residential swimming pools and spas with potable water.
	Irrigation of sports fields may deviate from non-watering days and be granted one additional watering days for a total of two watering days with written notice from LADWP. However, a customer reduce overall monthly water use by LADWP's Board of Water and Power Commissioners adopted degree of shortage plus an additional 10% from the customer baseline water usage within 30 days.
	If written notice is received from LADWP, large landscape areas may deviate from the non-watering days and be granted one extra day of watering for a total of 2 watering days if the following requirements are met: 1) approved weather-based irrigation controllers registered with LADWP 2) Must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus and additional 10% from the customer baseline within 30 days 3) Must use recycled water if available
	These restrictions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase III, except between the hours of 9am and 4pm.
IV	All prohibited uses in Phases I, II, and III shall apply, except as provided.
	No landscape irrigation is allowed.
V	All prohibited uses in Phases I, II, III, and IV shall apply, except as provided.
	The LADWP Board of Water and Power Commissioners is authorized to implement additional water prohibitions based on the water supply situation.

Specific procedures for determining the initiation of a phase and termination of a phase are provided in the Emergency Water Conservation Plan Ordinance. Phases are initiated through recommendations provided by LADWP to the Mayor and City Council (Council).

3.2.2 Conservation Pricing

In 1993, Los Angeles restructured its water rates to provide customers with a clear financial signal to use water more efficiently. It was the first time in LADWP's history that an ascending tiered rate structure was used. This conservation-based rate structure remains in use and applies a lower first tier rate for water used within a specified allotment, and a higher second tier rate for every billing unit (748 gallons) that exceeds the first tier allotment. A unique feature of the rate structure is that the first tier allotment considers factors that influence individual residential customer's water use patterns (i.e. lot size, climate zone, and family size).

The goals of LADWP's two-tiered water rate structure are to:

- Use price as a signal to encourage the efficient use of water

AR0071529

- Provide basic water needs at an affordable price
- Provide equity among customers
- Use price to stabilize water use during a shortage
- Generate adequate revenue for maintaining and upgrading the water system

In a period where increasing demands and reductions in water supply are becoming more commonplace, a rate structure that provides appropriate signals to encourage efficient water use has become a necessity for many areas, including Los Angeles.

The substantial investments required for water quality improvements, security, and supply development have significantly raised the cost of delivering water. As rates increase, water agencies have noticed a change in use patterns. Because there is a known correlation between price and use, agencies use rates to encourage conservation activities and to postpone the need to construct new facilities or purchase even larger quantities of imported water.

LADWP's tiered rate structure, first implemented in 1993 with assistance from a broad-based group of stakeholders, applies a lower tier block rate for responsible water use within a specified amount of water, and a much higher rate for every billing unit above this block. The higher block rate reflects the "marginal cost," or the projected cost for additional water that would be required to meet these needs.

To further emphasize the conservation message, water charges are based solely on water used. This eliminates the inclusion of fixed charges. There are automatic adjustments triggered when a water shortage exists. In June 2009 shortage year rates went into effect reducing first tier allotments for all customers by 15%. These adjustments are based on the actual water use patterns that occurred during the 1991 period of mandatory water rationing. The purpose of these adjustments is to use price to encourage additional conservation and to provide LADWP with the revenue necessary to operate the system efficiently during a shortage.

3.2.3 CUWCC Best Management Practices

The CUWCC is the voice of urban water conservation in California, and LADWP has been active in the CUWCC since its inception in 1991. Instrumental in the development of the MOU, LADWP was also one of the original signatories. The MOU identifies BMPs as proven conservation measures as determined by the CUWCC. The most recent amendment to the MOU was adopted on June 9, 2010 updating compliance alternatives with the adopted BMPs. A water agency can now comply with the MOU through one of three methodologies: BMP compliance, accomplishing water conservation through a set of measures equal or greater than the water savings provided by the BMPs (Flex Track Menu), or accomplishing water conservation goals as measured in gpcd. All Group One (water suppliers) signatories to the MOU are committed to implement the BMPs.

Over the last 19 years, LADWP has played a significant role in the governance and policy making at the CUWCC, holding a seat on the Board of Directors, Strategic Planning Committee, By-Laws Committee, Research and Evaluation Committee, CII Committee, co-chair of the Membership Committee, and chair of the Group 1 Representation Selection Committee. LADWP also has been actively involved in all of the revisions that the MOU has undergone to date.

AR0071530

One of the obligations as a signatory to the MOU is to submit a Best Management Practices Retail Water Agency Report to the CUWCC. Previously submitted annually, this report is now submitted biennially and details progress in implementing the foundational and programmatic BMPs as currently specified in the MOU. LADWP actively implements the BMPs and the CUWCC BMP reports are available for review through the internet by accessing CUWCC's website at www.cuwcc.org.

In the early 1990s, the State Water Resources Control Board identified urban water conservation as a major means for resolving problems in the Bay-Delta. Large water agencies, including LADWP, actively participated in work groups to develop conservation strategies. The result of this effort is in the aforementioned MOU.

The MOU commits signatory water suppliers to develop comprehensive conservation programs using sound economic criteria and to consider water conservation on an equal footing with other water management options. The MOU established the CUWCC to monitor implementation of the BMPs and to maintain the list of BMPs.

A BMP is defined as:

(a) An established and generally accepted practice among water suppliers resulting in more efficient use or conservation of water.

(b) A practice for which sufficient data are available from existing water conservation projects to indicate that significant conservation or conservation-related benefits can be achieved; that the practice is technically and economically reasonable and not environmentally or socially unacceptable; and that the practice is not otherwise unreasonable for most water suppliers to carry out.

LADWP implements all of the BMP requirements in the MOU except for wholesale agency assistance programs, which applies only to wholesale water agencies. Foundational BMPs are considered as essential BMPs for any water utility and are ongoing practices not subject to time limitations. Programmatic BMPs are minimal activities required to be completed by each utility within the timeframe of the implementation schedules provide in the MOU. A listing of the BMPs is shown in Exhibit 3F.

DRAFT

AR0071531

Exhibit 3F
CUWCC BMPs and Implementation Status

Category	Sub-category	Practices	Status
		Foundational	
Utility Operations	Operations Practices	Maintain the position of a trained conservation coordinator	Implemented
		Prevent water waste – enact, enforce or support legislation, regulations, and ordinances	Implemented
		Wholesale agency assistance programs	Not applicable
	Water Loss Control	Conduct Standard Water Audit and Water Balance	Implemented
		Measure performance using AWWA software	Implemented
		Locate and Repair all leaks and breaks	Implemented
	Metering with Commodity Rates	100% of existing unmetered accounts to be metered and billed by volume of use	Implemented
	Conservation Pricing	Maintain a water conserving retail rate structure	Implemented
Education	Public Information Programs	Maintain active public information program to promote and educate customers about water conservation	Implemented
	School Education Programs	Maintain active program to educate students about water conservation and efficient water use	Implemented
		Programmatic	
Residential		Residential Assistance – provide leak detection assistance	Implemented
		Landscape Water Surveys for single family residential accounts	Implemented
		High efficiency clothes washer incentive program	Implemented
		WaterSense Specification (WSS) for toilets	Implemented
Commercial/ Industrial/ Institutional (CII)		Implement unique conservation programs to meet annual water savings goals for CII customers	Implemented
Landscape		Implement Large Landscape custom programs	Implemented
		Offer technical assistance and surveys upon request	Implemented
		Implement and maintain incentive program(s) for irrigation equipment retrofits	Implemented

3.2.3 LADWP Conservation Programs

LADWP develops cost effective programs to achieve multiple goals of cost-effective demand reduction, customer service, environmental responsibility, and compliance with CUWCC BMPs. Conservation potential is considered in determining program approach and duration. Some types of conservation programs result in savings that are more easily measured than others. LADWP's programs include traditional demand-side management measures, as well as infrastructure improvement programs that contribute to water waste reductions. Demand-side management programs, like the rebate programs for water-saving toilets and high-efficiency washing machines, produce results that are measurable. Public information, education, and other general conservation awareness programs are intended to alter customers' behavioral patterns on water use and thus, are more difficult to quantify. It is such behavioral change in water use, however, that the City can point to as the primary reason for significant reduction in water consumption during drought periods. Combined with LADWP's conservation pricing

AR0071532

structure discussed in Section 3.2.2, these programs increase system reliability and efficiency and will provide a secondary benefit of reducing runoff.

Specific conservation programs (past and present) associated with these categories are broken down in Exhibit 3G, and are fully discussed below. Appendix XX contains the latest biennial reports provided to the CUWCC.

Exhibit 3G

Awareness/Support Measures

Awareness/support measures can be active or passive. Active components include full metering of water use, assessment of volumetric sewer charges, and a conservation rate structure. Passive components typically include providing educational materials for schools, community and customer presentations, maintaining a conservation hotline, and a wide range of information distributed through customer bills, advertising in public venues, LADWP's website, and direct mail. Passive awareness/support measures provide the foundation for the conservation movement to build upon by raising water use awareness, water conservation program visibility, and encouraging community involvement.

In 2008, LADWP entered into an MOU with the Los Angeles Unified School District to further improve our water conservation outreach program. In fiscal year 2009/2010 LADWP budgeted approximately $500,000 in funding for educational programs within area schools. Programs included:

AR0071534

- Los Angeles Times in Education – provided newspapers to 50,000 students in grades 4-12 and lesson packages for teachers on supply sources and conservation
- "Thirsty City" Live Performances – Play presented to more than 4,300 students introducing students to water supply sources, water supply challenges, and conservation
- Renewable Energy and Conservation Curriculum – 660 teachers were trained in an extensive model conservation program reaching approximately 50,000 6th grade students
- Renewable Energy and Conservation Center – Funding was provided for a science teacher position to set up and establish a Renewable Energy and Conservation Center with students to be bused to center for hands-on lessons focusing on conservation and renewable energy
- Outdoor Education Multi-Day Environmental Experiences – Approximately 700 students in 20 classes in grades 4-12 attended two or three days of outdoor education experiences focusing on environmental measures, including lessons on energy and water
- Eastern Sierra Institute – Training of 25 teachers over three days about the environment and geology of the Eastern Sierra
- Teacher Fellowships – Ten math and science teachers from middle and high schools served in fellowships at LADWP for six weeks during the fall and summer of 2008 working in multiple offices with the intent of developing classroom lessons based on the experiences.
- Infrastructure Academy – 40 students from the Infrastructure Academy completed water conservation audits at 120 schools, including fixture counts, analysis of toilet makes and models, and analysis of irrigation controllers and field conditions

Included within the short-term strategies of the City of Los Angeles' Water Supply Action Plan is a strategy to increase water conservation in the City through an aggressive $2.3 million conservation education campaign. LADWP Public Affairs Office implemented a media campaign that included radio, TV, and newspaper advertisements, billboards, outreach to Neighborhood Councils; and marketing of City rebates for water-efficiency.

Another aspect of awareness/support is that of advocacy. LADWP has been instrumental in the development of more stringent standards for toilets (e.g. Supplementary Purchase Specification for ULF toilets) that are in use within the City as well as by other water agencies in California and other areas. LADWP also assisted in the adoption of higher residential clothes washer efficiency standards by the California Energy Commission. Recognizing the importance of this activity, LADWP actively participates in advocating local and statewide conservation research and planning.

Residential Category

Multiple residential conservation programs were first developed and launched by LADWP during the drought of 1987 through 1992. In 1990, the ULF Toilet Rebate Program was initiated, followed two years later by the ULF Toilet Distribution Program. In 2003, a well-received free installation service component was added to the ULF Toilet Distribution Program that included

AR0071535

free water-saving showerheads, faucet aerators and replacement toilet flapper valves. Today distribution of free faucet aerators and showerheads continues for all single-family, multi-family, and commercial customers.

In 2008 MWD initiated the region-wide SoCal Water$mart Program for residential water conservation replacing previous LADWP rebate programs and rebate programs offered by individual water service providers throughout the MWD service area. This program sponsored by MWD sets uniform rebate requirements across the MWD service area and provides a clearinghouse for processing rebates for all MWD member agency customers. Local agencies have the option of supplementing baseline rebate amounts to their customers through the program. LADWP has increased baseline rebates for several of the qualifying products. Eligible customers include residential customers residing in single-family and multi-family homes, even if multi-family residents do not receive a water bill.

Although the SoCal Water$mart Program has discontinued rebates for high efficiency toilets (HET), LADWP continues to provide local funding for rebates for its customers of $100 per HET which has proven to be highly successful with over 1900 units installed in fiscal year 09/10 which equates to over 80 AFY savings.

Prior to the SoCal Water$mart Program, LADWP was assisted by community-based organizations (CBOs) to reach the milestone of more than 1.27 million toilets installed through December 31, 2006. CBOs were integral to LADWP's success, reaching into the communities they serve to convey the conservation message and directly undertake conservation activities. Benefits of this approach accrued to community participants through reduced water bills, to the CBOs through employment opportunities and revenues earned, and to the City through significant water savings achieved. Prior to its discontinuation, the program was funded at more than $7 million annually. The toilets replaced through the program continue to produce estimated water savings of more than 20,600 AFY today.

LADWP initiated a High Efficiency Washer Rebate Program in 1998 promoting the purchase and installation of high efficiency washing machines saving both water and energy. As of January 2009, rebates have been paid for more than 66,100 machines purchased and installed throughout the City. The program's minimum efficiency requirements for rebate eligibility were increased in January 1, 2004, resulting in the promotion of higher efficiency models. Initial co-funding of the program was provided by the City's Department of Public Works Bureau of Sanitation, and by the Southern California Gas Company.

In February of 2009 the High Efficiency Washer Rebate Program transferred from LADWP to the SoCal Water$mart Program with co-funding provided by MWD. Since the inception of the SoCal Water$mart Program and through June 2010, over 11,800 rebates for washing machines were issued to LADWP customers with a total annual savings of 368 AFY. Generally rebates are $300 per washing machine with a water factor (a measure of efficiency) of 4.0 or less. As of April 22, 2010 an additional $100 rebate was available for a limited time through the California Cash for Appliances program for a total rebate of $400 per washing machine.

A sprinklerhead rotating nozzle retrofit rebate of $8 per nozzle is available through the SoCal Water$mart Program for a minimum of 25 nozzles. Replacing standard sprinkler heads with rotating nozzles can use up to 20% less water. Rotating nozzles are able to distribute water in a water-efficient manner more uniformly across a landscape than standard sprinklers. Spray from rotating nozzles is less likely to result in misting conditions, misdirection from winds, and reduces runoff onto pervious surfaces thus reducing dry-weather runoff. Between March 2009 and June 2010 2,878 rotating nozzle rebates were issued to LADWP customers saving approximately 12.7 AFY.

AR0071536

Rebates for installation of weather-based irrigation controllers are also available through the SoCal Water $mart Program. Rebates amounts are $200 per controller for landscape areas of less than one acre and $25 per station for landscape areas greater than one acre. Weather-based irrigation controllers provide customized irrigation schedules based on local site conditions and in response to weather changes. These smart controllers receive weather updates to automatically adjust the schedule and amount of water applied. Between March 2009 and June 2010 81 LADWP customers received rebates for installation of the controllers saving approximately 6.2 AFY.

Initially a synthetic turf rebate program was offered through the SoCal Water$mart Program, but has been discontinued as of June 1, 2010. The program provided rebates of $1.00 per square foot. Approximately 316,547 square feet of synthetic turf was installed by LADWP customers between February 2009 and June 2010 saving approximately 44.3 AFY.

LADWP through the SoCal Water$mart program is offering turf removal rebates of $1 per square foot up to $2,000 per residence. Not all MWD member agencies are participating in the turf removal program and participating agencies have additional requirements beyond MWD's requirements. Areas targeted for turf removal must currently be turf irrigated with potable water for a minimum of one year. All replacement materials must be permeable and either hand watered or irrigated with drip irrigation. A minimum of 250 square feet must be converted to be eligible for a rebate. No invasive plants are permitted and all exposed soil must be covered with mulch. Synthetic turf is an acceptable replacement if it is not used in right of ways or parkways. Applicants are required to maintain the converted area for ten years. The program commenced in December 2009, and as of fiscal year 09/10, over 280,000 square feet of turf area has been converted saving over 39 AFY. In conjunction with the turf removal program, LADWP is conducting a drip system pilot program and is offering free residential drip starter kits.

Water-saving showerheads and faucet aerators remain available to LADWP customers, free of charge, upon request. Approximately 12,124 showerheads and 14,792 faucet aerators were distributed between July 2007 and June 2010 saving approximately 241 AFY. During past droughts, more than 1.5 million water conservation retrofit kits were distributed throughout Los Angeles; the kits included one-gallon toilet displacement bags, low-flow showerheads, and toilet leak detection tablets.

As part of past programs promoting residential water conservation measures, students conducted home water surveys through a resource efficiency education program implemented by LADWP in Los Angeles area high schools. Additionally, local community based organizations visited many Los Angeles residences throughout the year, assessing water conservation opportunities in the home and installing applicable measures to immediately capture water savings.

Another element of LADWP's past efforts was a toilet flapper valve replacement pilot program. Although long-term water savings from ULF toilets are predicated on timely replacement of leaking toilet flapper valves with appropriate replacement units, findings from the pilot program indicate a small incidence of leaking flapper valves in toilets rebated or distributed by LADWP. However, toilet leak testing and flapper valve replacement was added to the past ULF Toilet Distribution Program's installation service component for toilets not replaced through the program.

Commercial/Industrial/Institutional Category

This category represents some of the largest volume water users in LADWP's customer base, and represents a great deal of conservation potential. LADWP, in partnership with MWD, developed and has implemented a commercial rebate program, Save Water Save a Buck Program, designed specifically for customers in the CII sector and multi-family residences with five

AR0071537

or more units represented by a homeowners association. In the CII sector, the program provides rebates for water saving plumbing fixtures, food service equipment, and landscaping equipment. Within the multi-family sector the program provides rebates for high efficiency washers, high efficiency toilets, and landscape equipment. In addition, packaged water use efficiency solutions are being developed for specific business sectors. Efforts are also underway to better promote the financial incentives available that make water conservation retrofits more cost effective for business and industry. LADWP takes full advantage of regional programs offered through MWD for the CII sector and for many product rebates, provides supplemental funding to boost the base rebate provided by MWD.

The Save Water Save a Buck Program was launched in 2001 to provide menu-based rebates for water conserving measures applicable to many types of CII facilities. Categories of products eligible for rebates, rebate amounts, number of rebates for the LADWP service area, and estimated savings are provided in Exhibit 3H for the period July 2007 through June 2010. During the period, an estimated annual savings of 6,585 AFY, inclusive of LADWP inhouse programs and the Technical Assistance Program (TAP). The program design provides for ease of participation and has been well-received by LADWP customers. The program has been so successful that the SoCal Water$mart Program for residential customers was modeled after it.

DRAFT

AR0071538

Exhibit 3H
CII Conservation Programs and Savings July 2007 through June 2010

Device Type	Rebate Amount Retrofit	Devices Installed	Estimated Annual Savings (AFY)
Save Water Save a Buck Program			
Current Programs			
High Efficiency Toilets (1.28 gpf or less)	$150 each ($50 new construction)	58,432	2,408.6
Zero and Ultra Low Water Urinals	$500 each ($250 new construction)	6,063	630.9
Cooling Tower pH Conductivity Controller	$3000 each	41	79.7
Cooling Tower Conductivity Controller	$625 each	57	36.7
Air Cooled Ice Machine	$300 each	0	0.0
Connectionless Food Steamer	$600 compartment	23	5.8
Dry Vacuum Pump (maximum 2.0 horsepower)	$125 per 0.5 horsepower	8	0.7
Water Broom	$150 each	73	11.2
Weather Based Irrigation Controller	$50 per station	391	127.1
Central Computer Irrigation Controller	$50 per station	0	0.0
Rotating Nozzles for Pop-up Spray Heads (25 minimum)	$8 each	22,534	99.1
High Efficiency Spray Nozzles for Large Rotary Sprinklers	$13 per head	8,558	308.1
Past Programs			
High Efficiency Coin Clothes Washer	-	1,738	186.8
Pre-Rinse Sprayhead	-	5	0.8
Steam Sterilizer Retrofit	-	6	7.8
X-Ray Processor Recirculation System	-	1	3.2
Synthetic Turf (square feet)[1]	-	15,177	2.1
Subtotal Save a Buck Program	-		**3,908.7**
LADWP Inhouse Programs			
Commercial Showerheads	-	5,180	85.3
Commercial Faucet Aerators	-	20,844	96.5
Water Brooms	-	262	40.2
CII Landscape Program Turf Removal[2]	-	1,251,043	95.6
Technical Assistance Program[3]	-	-	2358.4
Subtotal LADPW Inhouse	-		**2676.0**
Total CII	-		**6584.8**

1. Synthetic Turf rebates as of June 1, 2010 are available through LADWPs Technical Assistance Program.

2. Rebate amount varies and is determined during pre-approval process.

3. Rebates for Technical Assistance Program are $1.75 per 1,000 gallons saved over a two year period with a cap not to exceed the actual cost of the project. Devices installed vary per project.

DRAFT

AR0071539

LADWP created the Technical Assistance Program (TAP) in 1992 to provide custom-type incentives for retrofitting water-intensive equipment. Different from the Save Water Save a Buck Program, the TAP encourages site-specific projects and TAP incentives are based on a given project's water savings. Financial incentives up to $250,000 are available for products demonstrating water savings. Incentives are calculated at the rate of $1.75 per 1,000 gallons saved over a two-year period with a cap not to exceed the actual cost of the installed product. Projects must save a minimum of 150,000 gallons over a two-year period and operate for a minimum of five years. Eligible customers are CII or multi-family residential customers. Past TAP projects include cooling tower controller upgrades and x-ray processor recirculation systems. The estimated unit cost for TAP overall is about $228 per acre-foot saved with an annual savings of 2,358.4 AFY based on projects installed between July 2007 and programs until June 2010.

Similar to the residential turf removal program, LADWP has a turf removal program for commercial properties. This program started in September 2009 and the rebate is $1.00 per square foot of turf with the total project rebate amount as defined in the pre-approval letter provided by LADWP. Areas targeted for conversion must have live healthy turf irrigated with potable water (recycled water is ineligible) via automatic sprinkler valves when a project approval letter is provided by LADWP. Converted areas must contain enough plants to create at least 30% landscape coverage at maturity. Converted areas may not contain turf or synthetic turf (synthetic turf rebates are available through the TAP). All replacement materials must be permeable and plants must be drought tolerant or California native plants. A minimum of 250 square feet must be converted to be eligible for a rebate. No invasive plants are permitted and all exposed soil must be covered with three inches of mulch. If an irrigation system is used it must be a low flow drip or bubbler system. Applicants are required to maintain the converted area for 15 years.

Water-saving showerheads and faucet aerators are available to LADWP commercial customers, free of charge, upon request. Bathroom faucet aerators are provided in 1.5, 1.0, or 0.5 gallons per minute (gpm), kitchen faucet aerators are provided in 1.5 gpm, and showerheads are provided in 2.0 gpm. Approximately 5,180 showerheads and 20,844 faucet aerators were distributed between July 2007 and June 2010 saving approximately 181.8 AFY combined. LADWP additionally offers an inhouse water broom program in addition to the rebates offered through the Save Water Save a Buck Program.

Landscape Category

Recognizing that a substantial amount of water is used outdoors for irrigation, LADWP continues to invest in landscape irrigation efficiency programs and projects. In addition to the previously discussed landscape ordinances (Section 3.21.), LADWP has sponsored free training courses specifically targeting the City's large turf customers to help these customers comply with the landscape ordinance. To further assist this group, LADWP developed a guidebook, "Improving Irrigation Performance" to demonstrate ways for enhancing existing irrigation systems.

LADWP has also sponsored conservation and garden expos to highlight various aspects of efficient outdoor water use and planting practices, and emphasizing native, drought-tolerant plants. Funding was provided for three demonstration gardens to showcase the use of drought-tolerant plants and flowers, including the landmark Lummis Home in Highland Park. Lawn watering guides were mailed to all single-family and duplex residences. Planting guides for native and drought-tolerant plants are also available upon request. Additionally, to demonstrate the beauty and appeal of a water-conserving landscape, LADWP's John Ferraro Building facility (below) has a drought-tolerant garden that is open to visitors year-round.

AR0071540

In addition to the Residential and Commercial Landscape Incentive Programs for turf removal, other types of landscape irrigation improvement projects are also funded through the TAP, with incentives calculated on the basis of a project's water savings. LADWP staff includes certified landscape auditors, and large landscape audits are available upon request.

LADWP is also investigating new programs using data obtained through pilot program efforts. A pilot program was conducted to determine the effectiveness of weather based irrigation controllers in large landscape applications. On the basis of the pilot program results showing water savings, financial incentives are available to LADWP customers for the purchase and installation of weather based irrigation controllers through the SoCal Water$mart and Save Water Save a Buck Programs. Additional efforts are being undertaken to make available a landscape irrigation education program for homeowner associations and other large landscape customers. This program would focus on common green areas in multi-unit complexes to improve irrigation efficiency, including irrigation system maintenance and repair, and plant selection.

LADWP has been implementing an internal program to retrofit outdoor landscaping at department-owned facilities to California-friendly and native plantings with efficient irrigation systems. Additionally, a joint effort between the Department of Recreation and Parks and LADWP is targeting public parks through the City Park Irrigation Efficiency Program. City parks with inefficient irrigation systems, leaks, and runoff problems are identified and upgraded with water efficient distribution systems and sprinkler heads, installation of smart irrigation controllers, and planting of California-friendly landscaping. Since the program began in 2007, seven parks have been completed and 4 new weather stations have been installed. An additional benefit of this program is the educational, trade training, and employment opportunity given to the youth of Los Angeles.

There is also potential for the use of non-potable water for irrigation, which can help extend the utility of the City's traditional water supplies. Through increased stormwater capture, groundwater recharge with captured storm and irrigation runoff, and recycled water, imported surface water and local groundwater used for landscape irrigation can be conserved. The potential to use such non-potable water supplies is further discussed in the Recycled Water and Watershed Management chapters (Chapters 4 and 7 respectively).

New Low Impact Development (LID) projects implemented within the City and innovative work by non-profit organizations demonstrate pioneering ways to conserve water for landscapes. As discussed in Chapter 7, LADWP's Watershed Management Group is proactively developing programs in conjunction with other departments to highlight water conservation through LID and implementing stormwater Best Management Practices (BMPs). A local non-profit, TreePeople, has partnered with various City departments, including LADWP on a number of stormwater capture projects.

For over a decade, TreePeople has demonstrated that rainwater is a viable local water resource. The Open Charter Elementary School Stormwater Project is one of several sustainable stormwater management systems that TreePeople installed in Los Angeles. Other examples include: the Center for Community Forestry which harvests rainwater from its entire hardscape into a 216,000 gallon underground cistern for landscape irrigation use; a retrofitted single family residential home in South Los Angeles that captures a 100 year storm event on site; a 7,600 square foot subsurface stormwater infiltration gallery on the Broadous Elementary School campus in Pacoima. Most recently, TreePeople partnered with the Los Angeles and San Gabriel Rivers Watershed Council, LADWP, and other state and federal agencies to retrofit an entire residential block on Elmer Avenue in Sun Valley. This project now intercepts stormwater from 40 acres upstream and infiltrates it back to the aquifer while also demonstrating effective distributed stormwater BMPs on residential homes.

AR0071541

In partnership with the Los Angeles County Department of Public Works, TreePeople was instrumental in developing the Sun Valley Watershed Management Plan: an alternative stormwater management plan that prioritizes green infrastructure and multi-benefit stormwater capture projects instead of stormdrains. Many projects have been completed, and more are scheduled for construction. These activities create the foundation that will lead to further landscape water conservation and stormwater capture to enhance the City's limited water supplies.

DRAFT

AR0071542

CASE STUDY:
Los Angeles River Revitalization and the North Atwater Park Project

Background

The Los Angeles (LA) River flows 51 miles through some of the most diverse communities in Southern California—its first 32 miles are within the City of LA. The River has a year-round low flow due to contributions from upstream wastewater treatment plants, urban runoff, groundwater inflow, and natural springs, but can become a torrent of racing flows during the rainy season. The River is almost entirely concrete-lined except for a few reaches. Although the design of the River has served its flood control purpose, the River holds far greater potential to serve as a focal point for environmental restoration, economic growth, community revitalization, and recreation.

Realizing that the River should stand as a symbol of pride for the City of LA and its residents and that it should be a landmark for the public to enjoy and admire, the LA City Council established the Ad Hoc Committee on the River in 2002 and adopted the LA River Revitalization Master Plan (LARRMP) in 2007 (www.lariver.org). Led by the City's Bureau of Engineering and funded by the LA Department of Water and Power, the LARRMP was created through a collaboration of elected officials, city departments and agencies, residents, multi-disciplinary experts, and a wide variety of private and non-profit environmental and recreational groups as the 25-to-50 year blueprint for transforming the City of LA's stretch of the River into an extensive network of parks, walkways, bike paths, and diverse land uses that will ensure the growth and sustainability of healthy communities.

Key Features

In October 2010, the City celebrated the groundbreaking of the North Atwater Park Expansion and Creek Restoration project as the first project to emerge from the LARRMP, which is expected to be open to the public by December 2011. The project was undertaken in connection with the settlement of two Clean Water Act enforcement action, Santa Monica Baykeeper v. City of Los Angeles and United States, and State of California ex. Rel. California Regional Water Quality Control Board, Los Angeles Region v. City of Los Angeles and also funded in part by Proposition 50 through the California Resources Agency to improve River Parkways and the Integrated Resources Water Management. The project will use both structural and natural solutions to restore a degraded creek that is a tributary of the River while also expanding River-adjacent parkland with multiple recreational, wildlife habitat, and water quality benefits. The project will add nearly 3 acres to an existing 5-acre City park, connecting it to the River, where visitors will enjoy watching a wide variety of bird species that presently live in that soft-bottomed stretch of the River, framed by stunning views of Griffith Park in the distance. Some of the project's highlights include:

Outdoor Classroom

The project will encourage young children to explore nature via an educational gathering space near the LA River. This "outdoor classroom" will feature a nature-based art area for independent and guided activities—designed particularly for local students to learn about nature, native plants, and the opportunities and challenges associated with revitalizing the LA River.

Native Demonstration Garden

The park's central focus will be a demonstration garden, which will contain a variety of native plants that are used throughout the park, with interpretive displays to educate visitors about the plant species' characteristics, care, and relationship to water conservation. The park will only include native plants because they are considered "drought-tolerant" given their abilities to thrive in Southern California's climate, requiring much less water than other plants. The park's landscape design aims to set an example in the use of such plants, but also to educate the public on the merits of embracing native vegetation as an important component of solving the region's water crisis.

Creek Restoration

North Atwater Creek currently conveys polluted runoff to the River from an upstream stormdrain system that receives flow from a 40-acre urban area. The Creek will be restored and landscaped with native plants to prevent erosion and to naturally filter stormwater before it is discharged to the River, featuring a 1000-foot-long meandering streambed sustained by intermittent street runoff flows. Water quality improvements will include installation of a device at the entrance of the creek to intercept and capture trash and bacteria and special treatment of flows from adjacent equestrian facilities.

AR0071543

Accommodating Visitors

While the park's landscape design capitalizes on the opportunity to educate visitors about the many connections between urban life, nature, and water, its structural features do also. For example, the parking lot will be transformed by installing a gravel bioswale along the borders and replacing existing parking spaces with permeable surfaces. These changes will not only address surface water contamination, but also allow stormwater to infiltrate so that it will assist with groundwater augmentation.

Summary

The North Atwater Park project will utilize innovative Low Impact Development (LID) and Best Management Practice (BMP) technologies to simultaneously achieve a variety of benefits, including responsible water conservation, improved water quality, expanded wildlife habitat connectivity, co-located multi-generational recreation, and public education.

The park's goals recognize that, while it is important to transform the existing park into a beautiful, scenic landmark and natural resource, it is equally important to educate the public about the huge potential such achievements have in encouraging wiser water use practices. Fundamentally, the park is about water—respecting LA's water supply and celebrating the River—by simultaneously improving the survivability of our wildlife and human habitat. North Atwater Park is an example of what can happen when public agencies and residents tackle complicated problems with creative planning and successful collaboration.

"The LA River cause is reaching more and more people every day. We are incredibly encouraged by the USEPA's July 2010 decision regarding the River's federal protection status and particularly because of the context in which it was announced—President Obama's America's Great Outdoors initiative is exactly the kind of support we need now and the visit of so many distinguished Administration officials to the River reinforces the belief that the River is important to millions of people here and across the country."

Carol Armstrong, Ph.D., Environmental Supervisor, Project Manager, LA River Project Office

"The City's commitment to LA River revitalization has only gained in momentum over the years and we have now reached an important crossroads for answering the big questions—such as how to capture and reuse storm flows, how to expand our recycled water uses, how to ensure we have enough water to maintain critical wildlife habitat, and how much flood capacity can we add? The River is central to each and every one of the answers."

Larry Hsu, P.E., Senior Civil Engineer, Project Manager, LA River Project Office

AR0071544

System Maintenance Category

Maintaining system infrastructure reduces water waste and allows for greater water accountability. Infrastructure maintenance is a high priority for LADWP. On-going programs such as pipeline replacement, pipeline corrosion control, and meter replacement preserve the operational integrity of City water facilities, and aims to reduce unaccounted water losses.

In recent years, the LADWP has ramped up its pipeline replacement program from 70,000 LF annually to 130,000 LF annually. LADWP has also made significant progress in replacing and/or retrofitting water meters through its meter replacement program that started in 1988. As a result of extended flow or usage, the moving parts in a water meter can wear down and begin to under-register the actual water consumption. The meter replacement program has been valuable in ensuring the accuracy of the approximately 700,000 meters within the City. Recently, all of the large-sized meters (3-in and larger) in the system were replaced as part of a Large Meter Replacement Program, and the LADWP is also replacing 35,000 small meters annually.

3.3 Future Programs, Practices, and Technology to Achieve Water Conservation

LADWP, on its own, and in cooperation with other agencies continues to investigate future programs, practices, and technology to improve water conservation.

3.3.1 Graywater

As defined by State regulations, graywater is untreated household wastewater which has not come into contact with toilet waste or unhealthy bodily wastes. It includes water sources from bathtubs, showers, bathroom wash basins, and water from clothes washing machines and laundry tubs. It specifically excludes water from kitchen sinks and dishwashers. Graywater is a drought-proof source of supply for subsurface landscape irrigation. Graywater regulations do not allow for its application using spray irrigation. Graywater is also not allowed to pond or runoff, discharge to or reach a storm drain system or surface water body, and is not permitted for irrigation of root crops or edible food crops that are directly in contact with the surrounding soil.

The Graywater Systems for Single Family Residences Act of 1992 legally incorporated the use of graywater as part of the California Plumbing Code. In September 1994, the City approved an ordinance that permitted the installation of graywater systems in residential homes. However, installing graywater systems under the Act was costly in terms of both installation and maintenance. To address the current water shortage and reduce water demands, emergency graywater regulations added Chapter 16A (Part I) "Nonpotable Water Reuse Systems" to the 2007 California Plumbing Code. These regulations were approved by California Building Standards Commission in 2009 and became effective on August 4, 2009. Further revisions were made to the regulations and the regulations became permanent on January 12, 2010 with an effective date of January 20, 2010. These new code changes allow the use of certain types of untreated graywater systems as long as specific health requirements are met as defined by the authority having jurisdiction. The ordinance can be acquired from the City of Los Angeles Department of Building and Safety (LADBS) website at the following link.

http://ladbs.org/LADBSWeb/LADBS_Forms/InformationBulletins/IB-P-PC2008-012Graywater.pdf

Graywater systems in residential buildings are regulated by LADBS. LADBS requires a plumbing permit prior to construction, reconstruction, installation, relocation, or alteration of any graywater systems, treated or untreated. As of fiscal year 2009-10,

DRAFT

LADWP does not offer any rebates or incentives for graywater systems, but continues to assess the potential for this water conservation technology.

Untreated Graywater Systems

Untreated graywater systems are systems where graywater is collected from non-toilet and non-kitchen sources and is utilized without treatment, for uses such as landscape irrigation. According to a 1999 study prepared by the Soap and Detergent Association, the average untreated graywater system in the US uses 6.3 gallons per day. In a 2010 White Paper prepared by Bahman Sheikh, for the WateReuse Association, Water Environment Federation, and American Water Works Association the potential for graywater generation in 2030, adjusted for conservation devices, is estimated at approximately 75.5 gallons per household per day. Potentially 50 percent of indoor potable water use could be re-used as graywater. Multiple manufacturers have developed untreated graywater systems and many households have installed such systems. However, these systems are not typically monitored, thus health and safety risks associated with the products have not been determined.

Under the recently approved revisions to the graywater system regulation, LADBS does not require a permit for untreated graywater systems supplied by only a clothes washer in a one or two-family dwelling as long as the system does not require modification of existing plumbing. Multiple requirements must be met for a system to be exempt from a permit including, but not limited to:

- Discharge shall be released not less than two inches below the surface of rock, mulch, or soil;
- Designs shall incorporate a means to allow the user to divert flow to the disposal area or the building sewer;
- Design of the system shall not allow contact with humans or pets;
- Water from diapers or other similarly soiled or infectious garments shall be diverted to the building sewer;
- Hazardous chemicals from washing activities, such as soiled rags, shall be diverted to the building sewer;
- An operation and maintenance manual shall be provided and remain with the building.

DRAFT

AR0071546

CASE STUDY:
Single-Family Home Graywater System

As a community environmental leader, Janie Thompson is taking extraordinary steps in efficient use of water and conservation. With the help of her husband, her household has become an excellent example of a rainwater capture residence, catching rain in 18 separate rain barrels with 60 gallons each. To save even more water, the couple is installing an impressive graywater network, distributing water to the furthest extent of their large 14,850 square foot property.

"In June 2009, when the Mayor announced the ordinance limiting watering to two days per week, we freaked out, and originally thought most of our landscaping would die. With all of our conservation, rainwater capture, and use of graywater, our usage has dropped from 117 hcf to around 54 hcf per month in the summer months. We couldn't be happier. It just goes to show you how much most people in the City over water." – Janie Thompson

Their existing graywater system currently uses the drainage pump from the clothes washer to pump water slightly up grade to tree and flower areas of the backyard. Upon exiting the washer, a 3-way valve reserves the option to divert washer effluent to the sewer system. The graywater piping travels beneath their raised foundation home, into the subsoil, and onto the areas it serves. Once construction is complete, all piping (left) will be buried with existing soil or mulch.

When the stream is pumped to the highest point of the yard, it is sent to numerous subsoil infiltration chambers, through a distribution system of 1" HDPE (High-density polyethylene) pipe. The infiltration chambers are made from 1 gallon paint buckets turned upside down with holes cut in the bottoms (below). The chambers allow for unobstructed exit flow and appropriate soil surface area for infiltration. In addition, they provide a significant volume for water storage during the surge of a pumped load of laundry. Plant roots are attracted toward these water outlets, essentially feeding on nutrients and organics in the graywater. The tops of the chambers are cutout for frequent access, and covered with mulch or stepping stone. The pipe exits can be checked as necessary to ensure free flow.

The next steps in the construction are connection of the bathtub and bathroom sinks. Effluent from these water sources will enter a surge tank and float switch assembly. A graywater dedicated pump will then automatically push water to existing and newly installed infiltration chambers throughout the yard.

AR0071547

Graywater used from these indoor sources will provide two main benefits. It will displace water used for irrigation and prevent additional water from entering the sewer. This decreases the load on the City sewer system lowering the overall cost of treatment for the Bureau of Sanitation.

The water savings are approximated in the following table. Please note that the clothes washer is a high efficiency front loading model. Showers are estimated at 10 minutes long with a head using 2.5 gallons per min.

Yearly Water Savings				
Washer	14 gal/use	10 uses/wk	140 gal/wk	7,280 gal/yr
Bathtub	40 gal/person/day	3 people	840 gal/wk	43,680 gal/yr
Bath Sink	2 gal/person/day	3 people	42 gal/wk	2,184 gal/yr
			Total	53,144 gal/yr

AR0071548

Treated Graywater Systems

Treated graywater systems treat water collected from non-kitchen and non-toilet sources for nonpotable reuse indoors and outdoors. Treated graywater systems for indoor use of graywater are not currently permitted by LADBS as there are no water quality standards nor mean to certify onsite treatment systems. Testing agencies are working to address safety concerns while manufacturers are working to improve the technology gap in the systems. Both manufacturers and testing agencies are working together to address gaps in standards to allow the future use of treated graywater for outdoor surface irrigation and for indoor uses in toilets and urinals.

The National Center for Disease Control and Prevention in conjunction with North Carolina State University is developing a program to examine the public health values and impacts associated with decentralized water reuse at eight project sites across the country. Under this program wastewater from homes would be treated to Title 22 standards as required by local health regulators. One of the proposed sites is located in Los Angeles County.

On the international level, treated graywater systems are used in both Europe and Australia. However, treated graywater systems in the United States are not common. A lack of accepted standards for graywater systems imposes a financial risk to companies manufacturing graywater systems. The International Association of Plumbing and Mechanical Officials (IAMPO) and NSF International are the two testing agencies working to develop standards for uniform treated graywater systems applicability in the US. LADWP is closely following the development of the NSF Standard 350 and IAPMO standards to ensure that once a set of standards have been approved by model codes and adopted by the Building Standards Commission, the citizens of Los Angeles can safely install treated graywater systems to maximize water reuse without any health and safety risks.

3.3.2 Demand Hardening

Although LADWP regularly assesses new water conservation opportunities, conservation programs may, at some point in time, diminish a customer's ability to further conserve water, in particular during short-term water supply shortages caused by droughts or other emergencies. This phenomenon is known as "demand hardening." The California Urban Water Agencies defines demand hardening as, "the diminished ability or willingness of a customer to reduce demand during a supply shortage as the result of having implemented long-term conservation measures." Long term conservation measures can include hardware conservation measures, such as the installation of high efficiency toilets and behavioral conservation, such as watering during specified periods of the day.

Demand hardening occurs when options available for reducing water use are limited as the customer base is saturated with hardware conversions causing efficient water usage patterns to prevail. During "dry" years, utility customers who have actively participated in water conservation programs can be disproportionately impacted by water reductions as there is a limited ability for further conservation. The impact of demand hardening would be most prevalent during water supply shortages where customers have already been implementing long-term water conservation measures. Proponents of demand hardening believe that implementation and saturation of new hardware-based conservation devices would generally not occur rapidly enough during a water supply shortage, such as a drought, to reduce short-term water use.

However, it can be argued that hardware-based conservation devices will continue to be developed, piloted and implemented, such as the previously discussed weather based irrigation controllers, thus improving the ability to further conserve in the future. During droughts, consumers will respond to the call for more conservation by behaviorally adjusting their water use

AR0071549

through methods such as not leaving water running and taking shorter showers. Additionally, full saturation of current conservation devices has not occurred. For these reasons, others believe demand hardening is irrelevant and there is a continued need for aggressive conservation programs.

Full implementation of current conservation measures, including reducing leaks, has the potential to reduce per capita water demands even further. Past water conservation efforts have reduced water use within LADWP's service area even though the population has continued to expand as illustrated in Exhibit 3A. It is expected that future water conservation efforts will continue this trend as increased saturation of water saving hardware devices occurs and new hardware devices are developed.

Though not easily quantifiable, saturation of current water saving hardware devices and installation of future water saving hardware devices combined with potential demand hardening have the ability to impact demand forecasts. As a worst case scenario, demand hardening and its effects are considered in LADWP's water demand forecasts to ensure that the appropriate supply of water is planned for. However, LADWP will continue to maintain its aggressive water conservation program discussed within this section. In the future, LADWP's water demand forecasts will continue to be examined and adjusted accordingly to compensate for additional implementation of long-term water conservation measures as saturation increases and new technology results in new hardware devices.

3.3.3 Projected Water Conservation Savings

To assist in planning future water demands, meeting the Water Supply Action Plan goal, and complying with 20x2020 requirements, LADWP has taken numerous steps to project future water conservation savings by major customer classification for indoor and outdoor use.

Indoor and outdoor active conservation through 2035 has been estimated by major billing sectors as provided in Exhibit 3I. Values presented are cumulative year to year. The bulk of conservation is expected to occur in the indoor portion of the commercial/government sector followed by the industrial sector. Past conservation programs have heavily focused on residential conservation reflecting the smaller residential conservation projections. Residential conservation initially provided the greatest volume saved for the cost. Water use in the CII sector is varied and relatively more expensive to achieve than in the residential sector.

Exhibit 3I
Active Conservation Projections by Sector

Sector	Acre-feet per Fiscal Year				
	2014/2015	2019/2020	2024/2025	2029/2030	2034/2035
Single-Family Residential	3,416	5,882	8,349	10,815	12,249
Multi-Family Residential	871	1,504	2,137	2,770	3,150
Commercial/Government	7,969	16,000	24,030	32,061	39,629
Industrial	1,924	3,847	5,824	7,774	9,339
Total Active Conservation Projections	14,180	27,260	40,340	53,420	64,368

AR0071550

To determine potential conservation savings for indoor water use in the CII sector, LADWP conducted a high-level study to first estimate CII water use for each subsector (e.g. hospitals, refineries, schools, business parks, restaurants, etc.) and indoor end-use (e.g., toilets, showers, kitchen, laundry, food processing, cooling/heating, etc.), and second determine the potential for indoor water savings for each subsector and end-use. This study involved a sample of water use for approximately 150 of LADWP's largest CII customers to estimate total sector water use, along with employment data from Dunn & Bradstreet. Additional data sources listed below were used to determine indoor end-use estimates for each subsector, as well as the potential for water savings. :

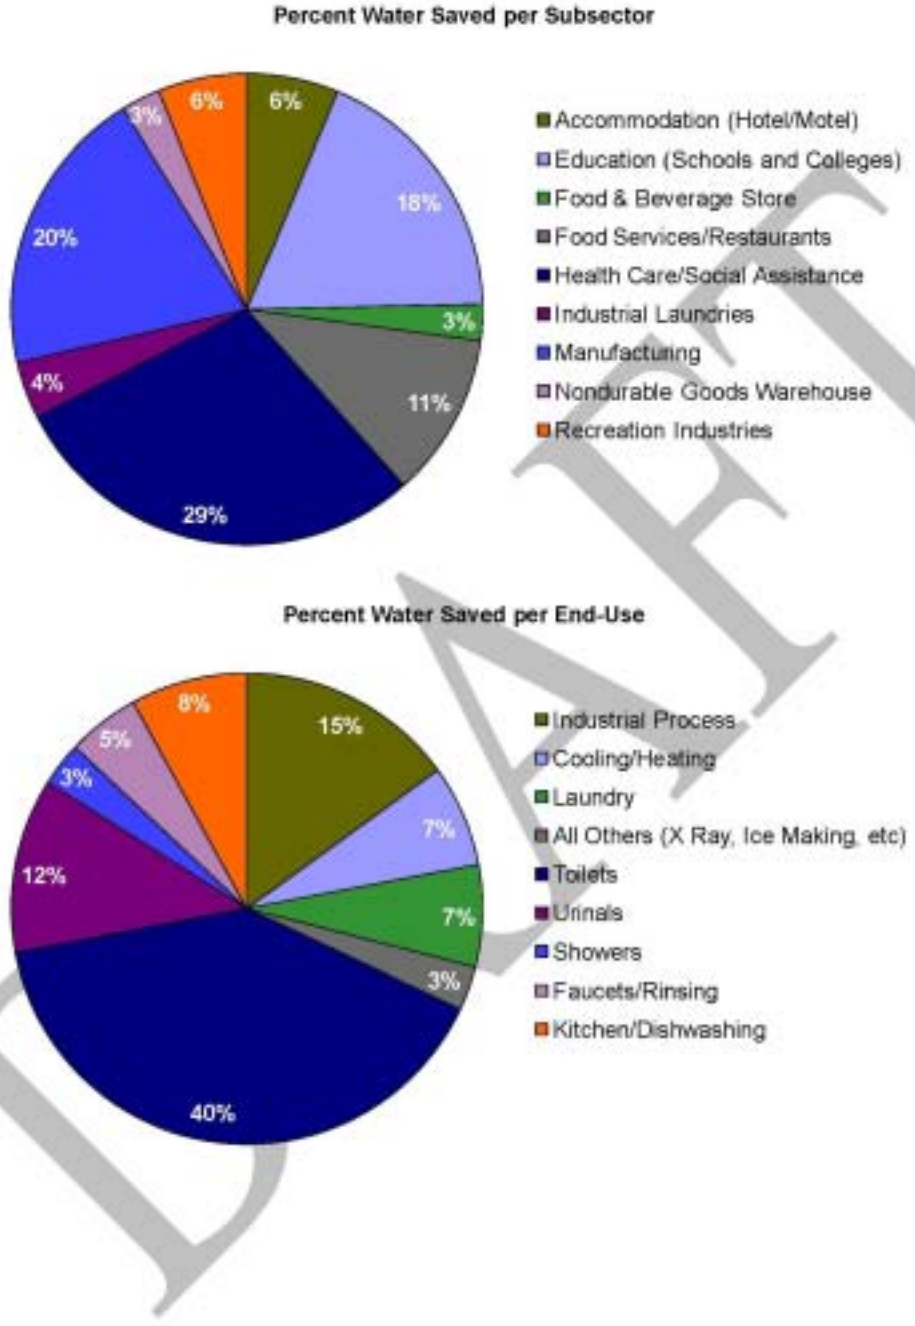
- *BMP 9: A Handbook for Implementing Commercial Industrial & Institutional Conservation Programs.* (2001). California Urban Water Conservation Council.
- *Commercial and Institutional End Uses of Water.* (2000). American Water Works Association Research Foundation.
- *Waste Not, Want Not: The Potential for Urban Water Conservation in California.* (2003). Pacific Institute.
- *Water Efficiency in the Commercial and Institutional Sector: Considerations for a WaterSense Program.* (2009). U.S. Environmental Protection Agency.
- *Watersmart Guidebook---A Water-Use Efficiency Plan-Review Guide for New Businesses.* (2008). East Bay Municipal Utility District.
- *Santa Clara Valley Water District Commercial Institutional Industrial Water Use & Conservation Baseline Study.* (2008). CDM.
- *Water and Energy Efficiency Program for Commercial, Industrial, and Institutional Customer Classes in Southern California.* (2009). U.S. Bureau of Reclamation.
- *Water Use Efficiency Comprehensive Evaluation.* (2006). CALFED Bay-Delta Program.

The study concluded that by targeting just the top 100 or so largest CII users, approximately 4,600 AFY of water could be saved (representing about 3 percent of total CII water use). The study also found that the subsectors that use the most water in the city are: health care (18%), education (14%), food services/drinking places (9%), accommodation (5%), fabricated metal product manufacturing (5%), textile mills (5%), amusement (4%), and food manufacturing (4%). The study also concluded that the potential for indoor water conservation was approximately 23,000 AFY or 15 percent of total CII water use. Exhibit 3J presents the breakdown of this potential indoor water conservation for subsectors and end-uses.

DRAFT

AR0071551

Exhibit 3J
Breakdown of Estimated CII Indoor Water Conservation Potential of 23,000 AF



Outdoor water use as a percentage of water use was approximated using three methodologies to determine the potential for outdoor water conservation savings. The methodologies and percent outdoor water use determined for each methodology are:

- Minimum-Maximum Methodology (outdoor water use is approximately 39.98%) – based on the premise that during wet months outdoor water use is minimal and during dry months outdoor water use is at its peak

DRAFT

- Wastewater Treatment Plant Influent Methodology (outdoor water use is approximately 38.32%) – based on determining the average monthly influent flows to the City's four wastewater treatment plants during the dry-weather months of June through September and adjusting for contract agency flows and dry-weather stormwater diversions

- Infrared Analysis Methodology (outdoor water use is 39.67%) – based on an infrared analysis of the City to determine tree canopy and landscape coverages for use in estimating applicable water use requirements for greenscapes based on rainfall data, plant factors, evapotranspiration rates, and irrigation efficiencies

The resultant range between the low and high outdoor water use percentage is approximately 1.35%. This narrow range resulting from the three methodologies confirms the methodologies are fairly accurate.

Greenscape areas related to commercial and residential land uses are the most likely areas to be targeted for outdoor water conservation. Rehabilitation of these areas to meet or exceed the evapotranspiration adjustment factor (ETAF) of 0.7 as required in the Model Water Efficient Landscape Ordinance would result in significant savings ranging from 21,774 to 165,870 AFY. Currently, these savings are not represented in the projected active conservation in Exhibit 3I. Exhibit 3K illustrates the potential savings under three scenarios by customer sectors. Scenario 1 represents an improvement in average irrigation efficiencies and/or installation of less water intensive vegetation to achieve and ETAF of 0.7. Scenario 2 represents an improvement in average irrigation efficiencies and/or replacement of high water use vegetation with less water intensive vegetation in the moderate to low water use range to achieve an ETAF of 0.49. Scenario 3 represents an improvement in average irrigation system efficiency and replacement of all vegetation with very low water use vegetation almost entirely dependent upon effective precipitation to achieve an ETAF of 0.07. This would require incentive programs, such as cash for grass programs. Other large greenscape area, including parks, cemeteries and golf courses, were not considered in the analysis as they would more than likely be preserved as turf or tree canopy areas to retain quality of life benefits. These areas are likely to be targets for recycled water use.

Exhibit 3K
Potential Outdoor Water Use Savings by Sector

Customer Sector	Scenario 1	Scenario 2	Scenario3
	(AFY)		
Single-Family Residential	13,246	42,464	100,901
Multi-family	5,956	19,095	45,371
Commercial	2,573	8,247	19,597
Total	**21,774**	**69,806**	**165,870**

3.4 Cost & Funding

The average cost of conservation rebates, incentives, and hardware installation programs ranges from approximately $325/AF to $400/AF based on current LADWP conservation programs. More than $200 million has been invested in water conservation since 1991. Conservation is the cornerstone of LADWP's water demand management activities and ongoing investments will be made in viable programs, subject to funding availability and LADWP's ability to implement such programs. Outside sources of funding are sought to complement the City's resources. A stronger commitment is also being made to acquire outside grant funding for City conservation projects.

Currently, the funding sources for conservation are:

AR0071553

- ***Water Rates*** – Water conservation programs are primarily funded through water rates.

- ***MWD Conservation Credits Program*** - MWD offers both commercial and residential rebates to member agency customers that install specified conservation devices. The rebates equate to $195 per AF of water saved, or half the project cost. In addition, MWD reimburses the LADWP for pre-approved projects when completed. In 2009 MWD reimbursed the Department $139,000 for a water broom distribution program. LADWP also expects to be reimbursed in 2011 through the MWD Member Agency Administered funding program for $968,000. The monies are reimbursement for 22.2 acres of turf reduction projects through the Department's Commercial/Industrial Drought Resistant Landscape Incentive Program.

- ***Outside Agency Co-Funding*** - Other agencies realizing benefits from conservation programs are solicited for co-funding of program costs.

- ***Grant Funding*** - LADWP has successfully received grant funding from the State under Proposition 13. A grant for $615,000 supplemented the rebate funding available for commercial ULF toilets and high efficiency clothes washers. LADWP expects to receive a final payment totaling $128,299 for the Commercial High Efficiency Clothes Washer and Ultra Low Flow Toilet Consolidated Water Use Efficiency grant. LADWP has already received $164,691 in support of 1,498 commercial high efficiency washer rebates. LADWP was awarded three grants in 2005 under Proposition 50, which are summarized below:
  - The Cooling Tower Conductivity Controller Replacement Program: Grant to improve the water efficiency of 100 cooling towers in the city of Los Angeles. Total grant amount up to $350,000. Expect completion in 2012.
  - The Los Angeles City Park Irrigation Efficiency Program: Grant to improve the irrigation efficiency at 15 City of Los Angeles municipal parks by installing Weather Based Irrigation Controllers and by upgrading irrigation piping and rotors. Total grant amount up to $362,000. Expect completion in 2011.
  - The Large Landscape "Smart Irrigation" Program: Grant to replace existing manually-adjusted irrigation controllers with "smart irrigation" Weather Based Irrigation Controllers at 75 large landscape customer sites. Total grant amount $131,000. Expect completion in 2011.

DRAFT

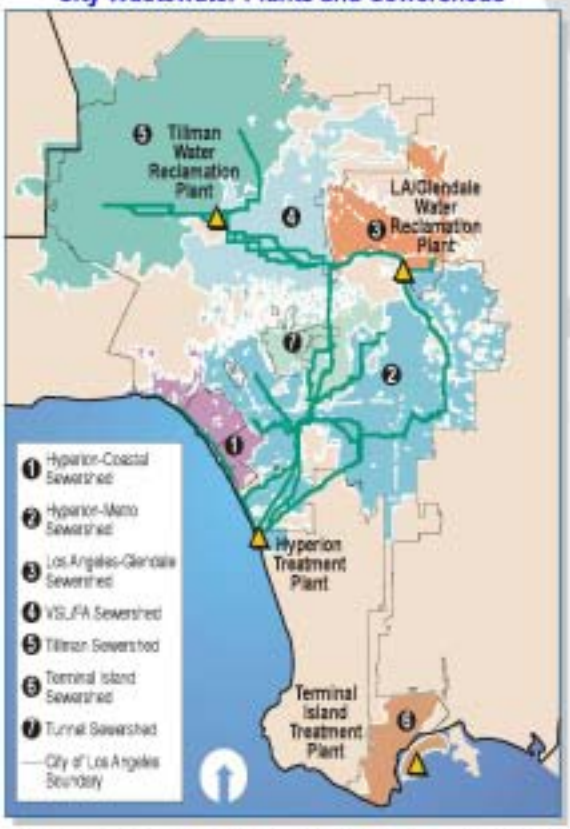
AR0071554

DRAFT Chapter Four
Recycled Water

LADWP is committed to significant expansion of recycled water in the City's water supply portfolio. Realizing multiple factors are decreasing the reliability of imported water supplies, LADWP released the City of Los Angeles Water Supply Action Plan (Plan), "Securing L.A.'s Water Supply" in May of 2008. The Plan established the goal of using 50,000 AFY of recycled water to offset demands on potable supplies. In order to meet this goal, LADWP, in conjunction with the Department of Public Works Bureau of Sanitation (BOS), are working together to develop a Recycled Water Master Plan (RWMP). Opportunities to expand the water recycling program are being studied through development of the RWMP. These include expanding the recycled water distribution system for Non-Potable Reuse (NPR) such as for irrigation and industrial use, along with replenishment of groundwater basins with highly purified recycled water. Beyond 50,000 AFY, LADWP expects to increase recycled water use by approximately 1,500 AFY annually, bringing the total to 59,000 AFY by 2035.

LADWP's water recycling program is dependent on the City's wastewater treatment infrastructure. Wastewater in the City of Los Angeles is collected and transported through some 6,500 miles of major interceptors and mainline sewers, more than 11,000 miles of house-sewer connections, 46 pumping plants, and four treatment plants. BOS is responsible for the planning and operation of the wastewater program. The City's wastewater system serves 515 square miles, of which 420 square miles are within the City. In addition to the City, service is provided to 29 non-City agencies through contract services. Exhibit 4A shows the City's four wastewater treatment plants and seven sewersheds that feed those plants.

Exhibit 4A
City Wastewater Plants and Sewersheds



A portion of the treated effluent from the wastewater plants is utilized by LADWP to meet recycled water demands.

As early as 1960, the City recognized the potential for water recycling and invested in infrastructure that processed water to tertiary quality, a high treatment standard for wastewater. This resulted in the building of tertiary wastewater treatment plants upstream instead of enlarging the two existing terminus treatment plants. These system enhancements brought about the City's expanded recycled water projects, which now supplement local and imported water supplies. The original policy allowing the use of recycled water was adopted by the State Legislature in 1969.

In 1979, LADWP began delivering recycled water to the Department of Recreation and Parks for irrigation of areas in Griffith Park. This service was later expanded to include Griffith Park's golf courses. In 1984, freeway landscaping adjacent to the park was also irrigated with recycled water. In addition, the Japanese Garden, Balboa Lake and Wildlife Lake in the Sepulveda Basin now utilize recycled water for environmentally beneficial reuse purposes. The Greenbelt Project, which carries recycled

AR0071556

water from the Los Angeles-Glendale Water Reclamation Plant to Forest Lawn Memorial Park, Mount Sinai Memorial Park, Lakeside Golf Club of Hollywood and Universal Studios, began operating in 1992, and represents LADWP's first attempt at water recycling. LADWP continues to successfully implement the use of recycled water for various purposes. In 2009 phase 1 of the Playa Vista development began receiving recycled water. Playa Vista is the first planned development in the City that uses recycled water for all landscape needs. Future recycled water projects will continue to build on the success of these prior projects so that recycled water becomes a more prominent component of the City's water supply portfolio.

The City's water recycling projects seek to displace the use of potable water with recycled water for non-potable uses where infrastructure is available. In compliance with Chapters 7.0 and 7.5 of the California Water Code, the quality of LADWP's Recycled water meets all of the following conditions:

- The source of recycled water is of adequate quality for those uses;
- The recycled water may be furnished for these uses at a reasonable cost to the user;
- The use of recycled water from the proposed source will not be detrimental to public health; and
- The use of recycled water will not adversely affect downstream water rights or degrade water quality.

In addition, the California Water Code requires public agencies, such as the LADWP, to serve recycled water for non-potable uses if suitable recycled water is available.

LADWP is expanding irrigation, industrial/commercial, and studying groundwater replenishment uses of recycled water. Demand for recycled water is driven by customer acceptance of recycled water as a viable alternative to traditional potable supplies. Outreach efforts designed to educate the public on the viability of recycled water and its potential uses are an essential part of the process as the City's recycled water program expands.

4.1 Regulatory Requirements

Recycled water use is governed by regulations at the State and local levels. These regulations are based on multiple factors including the type of use and water quality. LADWP currently uses recycled water for non-potable reuse and is pursuing in-direct potable reuse through groundwater replenishment (GWR) using advanced treated recycled water. Requirements for these two categories of recycled water use are different. This section provides a summary of the complex recycled water regulations, a more in-depth description of these regulations will be included as part of the RWMP.

4.1.1 Non-Potable Reuse Regulations

Non-potable water reuse (NPR) regulations in the City of Los Angeles are governed by the California Department of Public Health (CDPH), State Water Resources Control Board (SWRCB), Los Angeles Regional Water Quality Control Board (LARWQCB) and the Los Angeles County Department of Public Health (LACDPH).

California Department of Public Health

Criteria and guidelines for the production and use of recycled water were established by the CDPH in the California Code of Regulations, Title 22, Division 4, and Chapter 3 (Title 22). Title 22, also known as Water Recycling Criteria, establishes required wastewater treatment levels and recycled water quality levels dependent upon the end use of the recycled water. Title 22 additionally establishes recycled water reliability criteria to protect public health.

AR0071557

Title 22 specifies recycled water use restrictions based on the potential degree of public exposure to the water and the distance of drinking water wells and edible crops from the area of intended use. Recycled water use applicability also depends on the different levels of treatment. A higher quality water will have a wider variety of applicable uses than a lower quality water. At a minimum, secondary treatment of wastewater is required for recycled water use. In the City of LA, however, all recycled water used is treated, at a minimum, to tertiary levels with additional disinfection. Wastewater treatment levels are discussed in detail in subsection 4.2 of this chapter. Title 22 allows for other treatment methods, subject to CDPH approval. The reliability of the treatment process and the quality of the product water must meet the Title 22 requirements specified for each allowable treatment level. Exhibit 4B provides a summary of the currently approved recycled water uses.

Exhibit 4B
Allowable Title 22 Recycled Water Uses

Irrigation Uses
Food crops where recycled water contacts the edible portion of the crop, including all root crops
Parks and playgrounds
School yards
Residential landscaping
Unrestricted access golf courses
Any other irrigation uses not prohibited by other provisions of the California Code of Regulations
Food crops, surface irrigated, above ground edible portion, and not contacted by recycled water
Cemeteries
Freeway landscaping
Restricted access golf course
Ornamental nursery stock and sod farms with unrestricted public access
Pasture for milk animals for human consumption
Non edible vegetation with access control to prevent use as park, playground or school yard
Orchards with no contact between edible portion and recycled water
Vineyards with no contact between edible portion and recycled water
Non food bearing trees, including Christmas trees not irrigated less than 14 days before harvest
Fodder and fiber crops and pasture for animals not producing milk for human consumption
Seed crops not eaten by humans
Food crops undergoing commercial pathogen destroying processing before consumption by humans
Supply for impoundment
Non restricted recreational impoundments, with supplemental monitoring for pathogenic organisms
Restricted recreational impoundments and publicly accessible fish hatcheries
Supply for Impoundment Uses
Non restricted recreational impoundments, with supplemental monitoring for pathogenic organisms
Restricted recreational impoundments and publicly accessible fish hatcheries
Landscape impoundments without decorative fountains
Supply for cooling or air conditioning
Industrial or commercial cooling or air conditioning involving cooling tower, evaporative condenser, or spraying that creates a mist
Industrial or commercial cooling or air conditioning not involving cooling tower, evaporative

AR0071558

condenser, or spraying that creates a mist
Other Uses
Dual plumbing systems (flushing toilets and urinals)
Priming drain traps
Industrial process water that may contact workers
Structural fire fighting
Decorative fountains
Commercial laundries
Consolidation of backfill material around potable water pipelines
Artificial snow making for commercial outdoor uses
Commercial car washes, not heating the water, excluding the general public from washing process
Industrial process water that will not come into contact with workers
Industrial boiler feed
Nonstructural fire fighting
Backfill consolidation around non potable piping
Soil compaction
Mixing concrete
Dust control on road and streets
Cleaning roads, sidewalks and outdoor work areas
Flushing sanitary sewer
Groundwater recharge

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Non-Potable Reuse Regulatory and Policy Assessment TM, September 8, 2009

Areas where recycled water is used occurs within defined boundaries. Title 22 stipulates use area requirements to protect public health. Use area regulations include requirements addressing recycled water application methods and runoff near domestic water supply wells, drinking fountains, and residential areas. Other requirements include posting signs notifying the public where recycled water is being used, utilization of quick couplers instead of hose bibs, and the prohibition against connecting recycled water systems with potable water systems. Dual plumbed recycled water systems in buildings are also addressed; these systems must meet additional reporting and testing requirements.

To protect public health, Title 22 requires reliability mechanisms. During the design phase, a Title 22 Engineering Report is required to be submitted to CDPH and the local Regional Water Quality Control Board (RWQCB) for approval. Contents of the report include a description of the system and an explanation regarding how the system will comply with Title 22 requirements. Redundancy in treatment units or other means to treat, store, or dispose of recycled water are required in case the treatment unit is not operating within specified parameters. Alarms for operators are required to indicate treatment plant process failures or power failures. In case of power failures, either back-up power, automatically activated short-term or long-term recycled water storage, or a means of disposal is required. Furthermore, system performance must be monitored by water quality sampling and analyses.

As mentioned previously, cross-connections between the potable and recycled water systems are not permitted. The California Code of Regulations, Title 17, Division 1, Chapter 5, Group 4 prevents cross-connections between potable water supply systems and recycled water supply systems. Title 17 specifies that water suppliers must implement cross-connection control programs and backflow prevention systems.

AR0071559

In addition to Title 22 and Title 17 requirements, CDPH has additional regulations and guidance established in the following documents:

- Guidelines for the Preparation of an Engineering Report for the Production, Distribution, and Use of Recycled Water (2001)
- Treatment Technology Report for Recycled Water (2007)
- Guidance Memo No. 2003-02: Guidance for the Separation of Water Mains and Non-Potable Pipelines (2003)

State Water Resources Control Board and Los Angeles Regional Water Quality Control Board

In May 2009, the SWRCB adopted "Recycled Water Policy" developing uniform standards across all Regional Water Quality Control Boards for interpreting the "Anti-Degradation Policy". When planning and implementing recycled water projects the following must be taken into consideration:

- Mandate for recycled water use – encourages recycled water use and establishes targets to increase use
- Salt/nutrient management plans – requires submittal of salt/nutrient management plans by 2014
- Landscape irrigation projects' control of incidental runoff and streamlined permitting – addresses controlling incidental runoff and streamlining permit processes for recycled water use in landscape areas
- Groundwater recharge – establishes requirements for groundwater recharge projects
- Anti-degradation – establishes that salt and nutrient management plans can address groundwater quality impacts
- Chemicals of emerging concern – establishes a blue-ribbon advisory panel to develop a report on chemicals of emerging concern and update the report every five years.

Water Recycling Requirements (WRR) for each of the City's applicable wastewater treatment plants engaged in water recycling are issued by the LARWQCB. These requirements specify end-users of recycled water and enforce treatment and use area requirements.

In July 2009, the SWRCB adopted a general landscape irrigation permit, "General Waste Discharge Requirements for Landscape Irrigation Uses of Municipal Recycled Water" (General Permit). The General Permit streamlines the regulatory approval for landscape irrigation using recycled water. Agencies with existing WRRs, such as the City, are not required to apply for the General Landscape Irrigation Permit.

Earlier in April 2009, the LARWQCB adopted a general region-wide permit, "General Waste Discharge and Water Recycling Requirements for Non-Irrigation Uses over the Groundwater Basins Underlying the Coastal Watersheds of Los Angeles and Ventura Counties" for non-irrigation uses of recycled water. Similar to the General Permit, this permit streamlines the permitting process and specifies the application process for qualifying projects.

AR0071560

Los Angeles County Department of Public Health

Title 22 and Title 17 water use regulations are enforced by the LACDPH, Environmental Health Division. LACDPH has published "A Guide to Safe Recycled Water Use, Pipeline Construction and Installation" requiring compliance with Title 22, CDPH, and LARWQCB requirements. After CDPH has approved the plans and specifications and the City has an agreement to serve the customer, LACDPH reviews and approves all plans and specifications prior to construction. After construction LACDPH inspects the systems and conducts cross-connection, pressure, and back-flow prevention device tests. Recycled water use must occur in compliance with the Los Angeles County Recycled Water Advisory Committee's "Recycled Water Urban Irrigation User's Manual". Each site must also have a site supervisor responsible for recycled water use.

City of Los Angeles

Recycled water responsibilities of the City of Los Angeles include complying with all LARWQCB permits for the wastewater treatment plants and production of recycled water, approving recycled water use sites, conducting post-construction inspections, and periodically inspecting use areas and site supervisor records.

LADWP customers are permitted to use recycled water when service is available and per LADWP Ordinance No. 170435 (subsequently amended by Ordinance No. 178902 in 2008). Users are responsible for operations and maintenance of their recycled water systems up to the connection point with LADWP. Users are required to use recycled water in accordance with Titles 22 and 17 and the "Recycled Water Urban Irrigation User's Manual". If a customer is violating these requirements, LADWP may stop providing recycled water to the customer.

4.1.2 Groundwater Replenishment Regulatory Requirements

The regulations governing recharge of groundwater or groundwater replenishment (GWR) with recycled water are established by the CDPH and LARWQCB. Additional approval is required by the SWRCB and California Department of Fish and Game (DFG) if flows will be diverted from surface waters, such as in Los Angeles where recycled water is currently discharged by two treatment plants into the Los Angeles River. The City's GWR project as described in section 4.4.3 will be subject to these regulations.

For groundwater replenishment, LADWP will implement advanced treatment that includes reverse osmosis, microfiltration, and advanced oxidation. This level of treatment will address water quality concerns for the health of the basin along with emerging contaminants of concern.

California Department of Public Health

Regulatory oversight of groundwater recharge projects is provided by the CDPH. CDPH regulates groundwater recharge projects under Title 22 requiring the CDPH to make recommendations on a case by case basis after a public hearing. Requirements for recharge are not provided in Title 22. Draft Groundwater Recharge Reuse Criteria, released in August 2008, are used by the CDPH to evaluate projects for approval or denial. The draft regulations are designed to protect public health through the establishment of stringent requirements by:

- Requiring recycled water to meet maximum contaminant levels (MCLs) established for drinking water;
- Establishing the volume of recycled water used based on Total Organic Carbon (TOC), dilution, and treatment levels;
- Requiring retention of groundwater for six months before reaching a well used for drinking water with validation by a tracer study;

AR0071561

- Monitoring on a quarterly basis for specified pollutants and chemicals and yearly monitoring of constituents indicating the presence of wastewater in produced recycled water and in downgradient monitoring wells;
- Implementing a source control program; and
- Establishing additional requirements for projects with recycled water contributions greater than 50%, including a review by an Independent Advisory Panel.

Similar to non-potable reuse, project proponents must submit a Title 22 Engineering Report to the CDPH and LARWQCB for review. After completion of the report, the CDPH holds a public hearing followed by issuance of Findings of Fact and Conditions for submission to the LARWQCB.

Los Angeles Regional Water Quality Control Board

Prior to the issuance of a permit, the LARWQCB reviews CDPH's Findings of Fact and Conditions and considers provisions in the adopted Los Angeles Basin Plan (Basin Plan) for the LARWQCB region, applicable State policies (including the SWRCB Recycled Water Policy), and applicable federal regulations if recycled water is discharged to water of the US. The Basin Plan establishes water quality objectives for surface water and groundwater to protect beneficial uses. The LARWQCB then holds a public hearing to consider the permit. Ultimately, if approved, the LARWQCB issues permits in the form of water reclamation requirements and waste discharge requirements.

4.2 Wastewater Treatment Plants

There are four wastewater treatment plants owned and operated by the BOS. City wastewater treatment consists of a series of processes that, at a minimum, remove solids to a level sufficient to meet regulatory water quality standards. During the preliminary, primary, secondary, and tertiary treatment processes, progressively finer solid particles are removed. Preliminary treatment removes grit and large size particles through grit removal basins and screening. Primary treatment relies on sedimentation to remove smaller solids. With most of the grit, large sized particles, and solids already removed, secondary treatment converts organic matter into harmless by-products and removes more solids through biological treatment and further sedimentation. At the end of secondary treatment, most solids will have been removed from the water. Tertiary treatment follows secondary treatment to eliminate the remaining impurities through filtration and chemical disinfection. At this stage, sodium hypochlorite (the chemical contained in household bleach) provides disinfection. All recycled water used within the City is given, at a minimum, tertiary treatment and disinfection. In the Harbor, recycled water is also given advanced treatment with microfiltration/reverse osmosis (MF/RO). MF/RO is a two-stage process using high-pressure membrane filters to remove microscopic impurities from the source water. Exhibit 4C summarizes the treatment levels, capacity, and average flows at the four plants.

AR0071562

Exhibit 4C
Wastewater Treatment Plants Summary

WastewaterTreatment Plants	Treatment Level	Capacity (mgd)	Average Flows (mgd)[1]
Donald C. Tillman Water Reclamation Plant	Tertiary to Title 22 standards with Nitrification/Denitrification	80	53
Los Angeles - Glendale Water Reclamation Plant	Tertiary to Title 22 standards with Nitrification/Denitrification	20	17
Terminal Island Water Reclamation Plant	Tertiary; Advanced treatment (MF/RO) of 5 mgd	30	15
Hyperion Treatment Plant	Full secondary[2]	450	320

1. Average dry weather flows 2008, except for DCT January 2005 through December 2008.

2. 31 mgd of full secondary treated water delivered to West Basin Water Reclamation Plant operated by West Basin Municipal Water District. Water treated to Title 22 standards for recycled water use.

Sources: City of Los Angeles Recycled Water Master Plan Technical Memorandum, DCT Data Summary, January 29, 2010

City of Los Angeles Recycled Water Master Plan Technical Memorandum, Wastewater Treatment, November 2, 2009

4.2.1 Donald C. Tillman Water Reclamation Plant

In service since 1985, the Donald C. Tillman Water Reclamation Plant (DCT) has an average dry-weather flow capacity of 80 million gallons per day (mgd) and currently treats about 53 mgd. During wet weather, treatment capacity is limited to 40 mgd to prevent downstream infiltration surcharges on the sewer system while utilizing the remaining capacity for limited wet weather storage. Currently, the Bureau of Engineering (BOE) is designing wet-weather storage basins to allow year around operation at 80 mgd. The current level of treatment is Title 22 (tertiary) with nitrogen removal (nitrification/denitrification (NdN). Currently, this plant is providing recycled water to the Japanese Garden, Wildlife Lake, Lake Balboa, treatment plant reuse, irrigation, and industrial uses. Irrigation uses in the adjacent areas include golf courses, parks, and a sports complex. Industrial uses include the Valley Generating Station. The remaining tertiary-treated water is discharged into the Los Angeles River. The city intends on implementing a groundwater replenishment project supplied with tertiary treated Title 22 recycled water from DCT that is purified through advanced treatment to recharge the San Fernando Groundwater Basin. The project will initially recharge 15,000 AFY with the eventual goal of achieving 30,000 AFY.

4.2.2 Los Angeles-Glendale Water Reclamation Plant

The Los Angeles-Glendale Water Reclamation Plant (LAG) is a joint project of the City of Los Angeles and City of Glendale. LAG began treating wastewater in 1976. Originally the plant was designed without considering nutrient removal. Its average dry-weather flow design capacity is 20 mgd and it currently treats about 17.7 mgd. Each city is entitled to 50 percent of the plant's capacity. The City of Pasadena purchased rights to 60 percent of Glendale's capacity but has not yet exercised these rights. The current level of treatment is Title 22 (tertiary) with nitrogen removal (NdN). Recycled water from the LAG provides landscape irrigation to Griffith Park and the Los Angeles Greenbelt Project, including Forest Lawn Memorial Park, Mount Sinai Memorial Park, Universal Studios, and the Lakeside Golf Course. The City of Glendale retains the right to half of the recycled water produced at the plant and serves a number of customers in their service area. As with the DCT, the remaining tertiary-treated water from LAG is discharged into the Los Angeles River.

AR0071563

4.2.3 Terminal Island Water Reclamation Plant

Originally built in 1935, the Terminal Island Water Reclamation Plant (TIWRP) has been providing secondary treatment since the 1970s. Tertiary treatment systems were added in 1996. The current average dry-weather flow capacity is 30 mgd with average flows of about 15 mgd. Recent completion of the Advanced Wastewater Treatment Facility added MF/RO treatment to a portion of the wastewater effluent producing approximately 3.0 mgd of recycled water. Recycled water is supplied to the Dominguez Gap Seawater Intrusion Barrier to reduce seawater intrusion into drinking water aquifers and to LADWP's Harbor Generating Station for landscape irrigation. Effluent in excess of the MF/RO component is discharged to the Los Angeles Harbor. Future recycled water use is expected to increase to more fully supply the Dominguez Gap Seawater Intrusion Barrier along with other potential customers in the Harbor Area.

4.2.4 Hyperion Treatment Plant

Operating since 1894, the Hyperion Treatment Plant (HTP) is the oldest and largest of the City's wastewater treatment plants. Its $1.2 billion construction upgrade, completed in 1999, allows for full secondary treatment. The current average dry-weather flow capacity of HTP is 450 mgd during dry weather, with an average wastewater flow of 342 mgd. A majority of the treated water is discharged through a 5-mile outfall into the Santa Monica Bay, and the rest, approximately 31 mgd, is delivered to the West Basin Water Reclamation Plant to meet recycled demands in the West Basin Municipal Water District (WBMWD) service area and parts of the City of Los Angeles. As of 2008, approximately 37,000 AFY of water from HTP Plant is sold to West Basin for additional treatment. A portion of this water is sold back to LADWP for the Westside Water Recycling Project, and the rest is then used to meet recycled water demands in West Basin's service area. Users of the Westside Water Recycling Project include Loyola Marymount University and Playa Vista.

4.2.5 Projected Wastewater Volume

Average dry-weather wastewater influent projections for the City's wastewater treatment plants are expected to increase by approximately 20 percent over the next 25 years. Projections include 29 agencies outside of the City with contracts for wastewater treatment. Wastewater effluent that is not recycled is discharged to either the Los Angeles River to the Pacific Ocean or outfalls leading directly to the Pacific Ocean. Wastewater treatment projections for average dry-weather flows to 2035 and disposal methods are provided in Exhibit 4D.

Exhibit 4D
Wastewater Treatment Plant Average Dry-Weather Flows, Reuse and Dischargel Method

Wastewater Treatment Plants	Reuse and Discharge Method	Average Dry-Weather Flow Projections (AFY)					
		2010	2015	2020	2025	2030	2035
Donald C. Tillman Water Reclamation Plant	Recycling and Pacific Ocean via Los Angeles River	82,779	84,347	85,915	87,483	90,283	93,084
Los Angeles - Glendale Water Reclamation Plant	Recycling and Ocean via Los Angeles River	23,299	25,427	27,331	29,460	31,588	33,716

AR0071564

4.3 Existing Recycled Water Deliveries

The City has several recycled water projects currently providing recycled water for landscape irrigation, industrial, and commercial uses spread throughout four service areas:

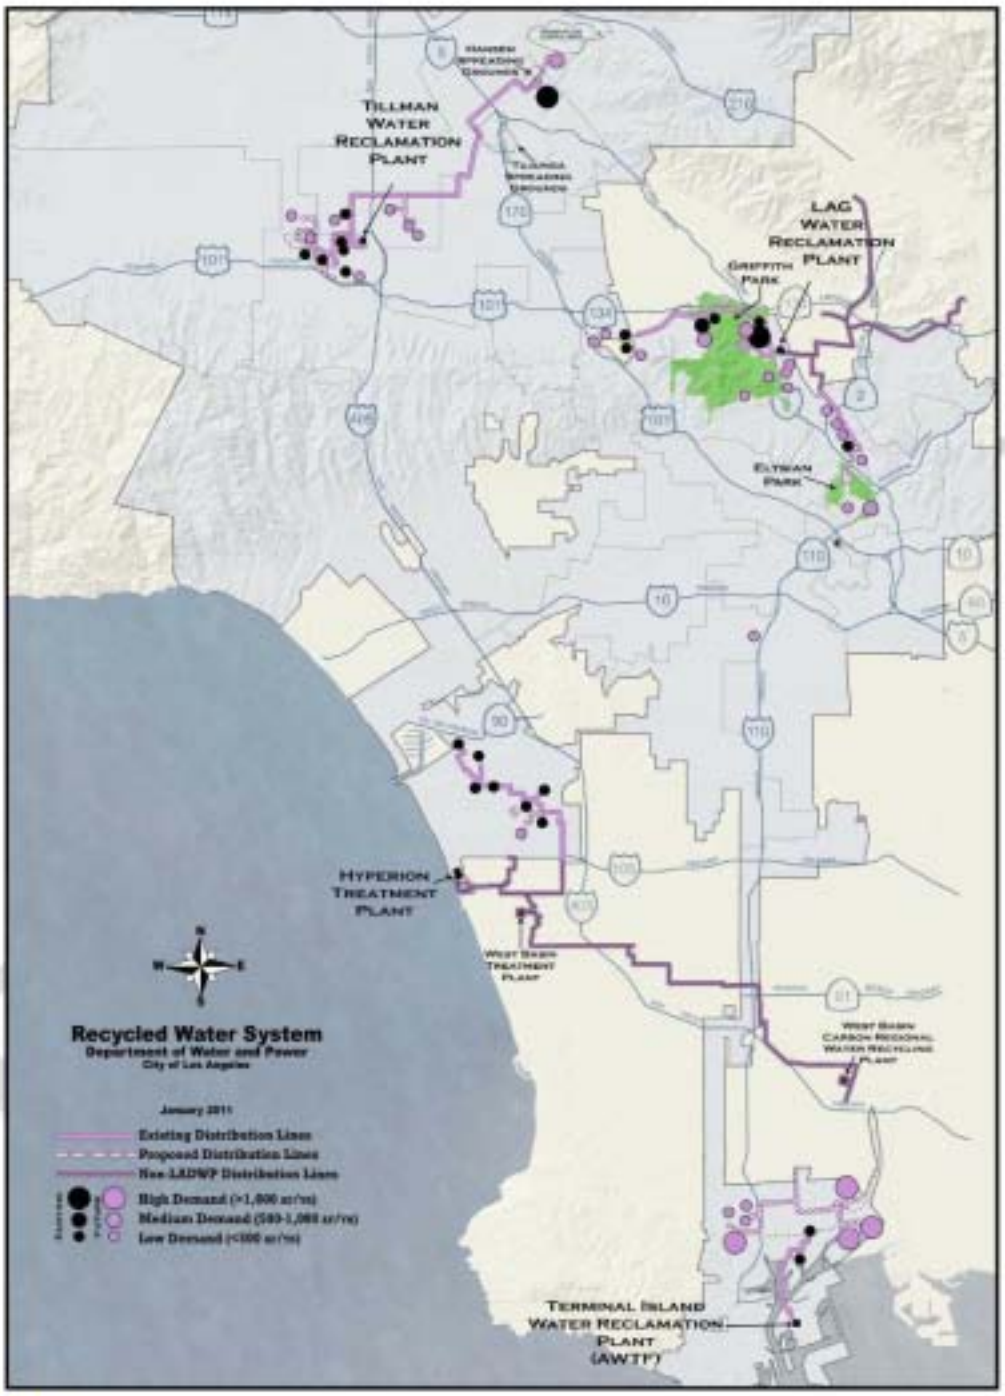
- Harbor – located in the southern portion of the City and currently served from the water reclamation plant at the TIWRP
- Central City (Metro) – located in the central/eastern portion of the City and is served by LAG
- San Fernando Valley – located in the northern portion of the City and is served by DCT
- Westside – location in the central/western portion of the City and is served by HTP through the WBMWD West Basin Water Reclamation Plant

Locations of the service areas are depicted in Exhibit 4E. Recycled water service areas coincide with potable water service areas. Recycled water deliveries for 2009 were 35,939 AFY, inclusive of municipal and industrial, environmental, and in-plant reuse. Estimated annual demands for online projects were 38,614 AFY.

DRAFT

AR0071565

Exhibit 4E
Recycled Water System



4.3.1 Harbor Area

Recycled water in the Los Angeles Harbor area is currently produced at the Advanced Water Treatment Plant (AWTP) located at the TIWRP. The AWTP was online in 2002 with first deliveries to customers commencing in 2006. This project was

AR0071566

developed jointly by LADWP, BOS, and BOE. Operations and maintenance is provided by BOS with funding from LADWP. Recycled water, treated using microfiltration and reverse osmosis, is currently used for landscape irrigation and groundwater injection with current demands of approximately 3,050 AFY. Treatment capacity of the AWTP is approximately 5,600 AFY. Excess recycled water is discharged into the Los Angeles Harbor. Exhibit 4F summarizes typical annual demands in the Harbor area. Currently two customers are served; LADWP's Harbor Generating Station and the Water Replenishment District (WRD).

Exhibit 4F

Harbor Generating Station

The Harbor Generating Station's demands that could potentially be met with recycled water are approximately 50 AFY including industrial cooling and landscape irrigation. Initially, recycled water was intended for use in the station's cooling tower and boiler make-up feed system components, however, recycled water is not used for these purposes currently as a result of concerns about potential incompatibility between recycled water and these systems. Connections have been installed for recycled water use in these systems and future use will be further investigated as part of the Recycled Water Master Plan.

Water Replenishment District

The WRD's recycled water demands are approximately 3,000 AFY for groundwater injection in the Dominguez Gap Seawater Intrusion Barrier. A blend of 50 percent recycled water and 50 percent imported water is injected into the barrier. The Dominguez Gap Barrier protects the West Coast Groundwater Basin from seawater intrusion.

LADWP is currently expanding recycled water infrastructure in the Harbor area that will increase recycled water usage at least 9,300 AFY by 2014/2015.

4.3.2 Metro Area

The Metro Recycled Water System has supplied the Metro Service Area with recycled water produced at LAG to irrigation customers since 1979. LAG provides recycled water treated to a tertiary level meeting Title 22 standards with Nitrogen removal to customers in the eastern San Fernando Valley. As previously stated, recycled water produced at LAG is equally split between the cities of Los Angeles and Glendale. Current recycled water demands for the Metro Service Area are 1,933

AR0071567

AFY. Unused recycled water is discharged to the Los Angeles River. Exhibit 4G summarizes current demands for Metro Recycled Water System. Currently 11 customers are served by the Metro Recycled Water System.

Griffith Park Project

Started in 1979, the Griffith Park project was the City's first recycled water project. Recycled water is used to irrigate two golf courses, parkland, The Los Angeles Zoo Parking Lot, and a seven-mile stretch along the Golden State Freeway (Interstate 5) adjoining the park. Current demands in the Griffith Park Project's service area are 1,120 AFY.

Greenbelt Project

Dedicated in 1992, the Los Angeles Greenbelt Project was the City's first commercial recycling project. Recycled water is used for landscape irrigation at Forest Lawn Memorial Park-Hollywood Hills, Mount Sinai Memorial Park, Lakeside Golf Course and Universal Studios. Current demands in the Greenbelt Project's service area are 720 AFY.

Taylor Yard Project

Rio de LA State Park was connected as the first Taylor Yard project in July 2009. Recycled water is used for landscape irrigation on the park. Current demands in the Taylor Yard Project's service area are 93 AFY.

4.3.3 San Fernando Valley Area

The Valley Recycled Water System receives water from DCT to satisfy irrigation, environmental, and industrial demands. Recycled water is treated to a tertiary level meeting Title 22 standards with Nitrogen removal. Water for in-plant uses at DCT and for environmental uses is dechlorinated. Current estimated recycled water demands for the San Fernando Valley Area are 33,594 AFY. Recycled water produced in excess of demand is discharged to the Los Angeles River providing added environmental benefits. Exhibit 4H summarizes current demands for the Valley Recycled Water System. The East Valley trunkline, a 54 inch diameter pipeline, was previously constructed as the initial backbone of the Valley Recycled Water System's distribution system to deliver water throughout the San Fernando Valley for irrigation, commercial, and industrial use. Eleven customers are currently served by the Valley Recycled Water System, excluding DCT reuse and environmental use.

2. Does not include environmental benefits provided to Los Angeles River.

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Tier 1 Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Sepulveda Basin Project

LADWP began serving recycled water to portions of the Sepulveda Basin area in 2007. The latest project was added in 2010. Current recycled water customers in the Sepulveda Basin recreation area include Woodley Golf Course, Balboa Golf Course, Encino Golf Course, Anthony C. Beilenson Park, Van Nuys Golf Course and the Balboa Sports Complex. Current demands in the recreation area are 1,570 AFY.

Van Nuys Area Project

The Van Nuys Area project currently provides recycled water for irrigation purposes to St. Elisabeth's Church, the First Foursquare Church of Van Nuys, Van Nuys High School, and LADWP's Power Distribution Station 81. Current Van Nuys Area Project demands are 14 AFY.

Hansen Area Project

The Hansen Area project currently provides recycled water for industrial purposes to the Valley Generating Station. Recycled water service began in 2008 and demands are approximately 2,100 AFY. Recycled water is used in a cooling tower for one of the generation units at the power generating facility.

AR0071569

Donald C. Tillman Water Reclamation Plant Reuse

Recycled water is used at DCT for in-plant purposes. Demands vary from year to year based on needs. Between 2006 and 2008 2,920 AFY were used on average.

Environmental Use

Recycled water from DCT has provided environmental benefits since 1984 commencing with deliveries to the Japanese Garden followed by Balboa Lake in 1990 and Wildlife Lake in 1991. Approximate demands are 26,990 AFY. Overflows from these facilities are discharged to the Los Angeles River providing additional environmental benefits in conjunction with unused recycled water discharges to the river.

Japanese Garden

The 6.5 acre Japanese Garden is located at the Sepulveda Dam Recreation Area. The Garden receives more than 10,000 visitors per year. DCT provides about 4,590 AFY of recycled water for the lake and landscaping at the Japanese Garden.

Wildlife Lake

Located in the Sepulveda Basin, the Wildlife Lake uses about 7,700 AFY of recycled water from DCT for wildlife habitat management.

Lake Balboa

Lake Balboa is the centerpiece of the Sepulveda Dam Recreation Area and is a popular recreational facility located in Anthony C. Beilenson Park. About 14,700 AF per year of recycled water is provided for this lake from DCT.

4.3.4 Westside Area

Recycled water supplied to the Westside Recycled Water System is provided by WBMWD via the Edward C. Little Water Recycling Plant (WBWRP), located in the City of El Segundo, for irrigation and commercial (toilet flushing) demands. The WBWRP further treats secondary-treated effluent received from HTP to a tertiary level meeting Title 22 standards. Under an agreement between WBMWD and the City, WBMWD purchases secondary-treated effluent from HTP and LADWP has a right to purchase up to 25,000 AFY of recycled water following tertiary treatment at the WBWRP. Approximately 37,300 AFY of secondary-treated effluent was purchased from HTP in 2008 and LADWP purchased 380 AF of recycled water to serve the Westside of Los Angeles. The WBWRP can treat up to 40 mgd. Recycled water not purchased by LADWP is sold to users within WBMWD's service area.

Deliveries of recycled water from the Westside Recycled Water System first began in 1996. To increase the use of recycled water on the Westside, LADWP has constructed more than five miles of distribution trunk lines to serve the Westchester, Los Angeles International Airport, and Playa Vista development areas. Current estimated recycled water demands for the Westside Area are 676 AFY as shown in Exhibit 4I. Currently 106 customers are served by the system.

Playa Vista, Phase 1

Playa Vista is the first planned development in the City to use recycled water for irrigation of all of its landscaping including residential outdoor use. This project began receiving recycled water in 2009 as part of Phase 1. Phase 2 is considered as a "Near-Term" project (or "Tier 1" use), which are projects to be implemented by the year 2015. Outdoor recycled water is required under the development's mitigation requirements established during the environmental review process. Recycled water is additionally used for toilet flushing in commercial buildings. Annual demands are approximately 200 AFY for Phase 1.

Los Angeles International Airport

Los Angeles International Airport began using recycled water in 1996 for landscape irrigation purposes along its boundaries. Current demands for the airport are 158 AFY.

Westchester Golf Course

Westchester Golf Course began using recycled water in 2009 for irrigation. Current demands for the airport are 62 AFY.

Loyola Marymount University

Loyola Marymount University has been connected to the Westside system since 1996. Recycled water is used to irrigate a portion of the campus landscaping area. Average annual demands are approximately 65 AFY. In 2006, Loyola Marymount

AR0071571

University installed an on-site disinfection system using hydrogen peroxide to address odor problems related to stagnant water in an oversized pipeline servicing the university.

Westchester Park and Carl Nelsen Youth Park

Westchester and Carl Nelsen Youth Parks both use recycled water for irrigation purposes. Both parks were connected to the system in 1996. Westchester Park demands are approximately 43 AFY and Carl Nelsen Youth Park demands are 16 AFY.

Scattergood Generating Station

Scattergood Generating Station operated by LADWP and located in El Segundo receives recycled water to meet irrigation demands. Average annual demand is approximately 31 AFY. The pipeline servicing the facility is oversized to potentially provide cooling water in the future.

Street Medians and The Parking Spot

Street medians on Manchester Avenue and The Parking Spot were connected to the recycled water system in 2008 and 2003, respectively. Recycled water is served to both facilities to meet irrigation demands. The Parking Spot is a commercially operated parking facility near Los Angeles International Airport. Demands for The Parking Spot are approximately 1 AFY and demands for the street medians are approximately 5 AFY.

Hyperion Treatment Plant

HTP uses recycled water for both landscaping and toilet flushing within the administration building. HTP was connected to the system in 1996. About 65 AFY of recycled water are provided to HTP per year. HTP also provides additional treatment for recycled water use onsite similar to Loyola Marymount University to address odor problems associated with stagnant water in an oversized supply pipe. The pipeline to HTP was oversized to accommodate expanded deliveries to the Scattergood Generating Station in the future. HTP uses filters and disinfection to treat the water prior to its use onsite.

4.3.5 Comparison of 2010 Projections Versus Actual Use

LADWP has made substantial progress in increasing recycled water use in the interim period between completion of the 2005 and 2010 UWMPs. Municipal and industrial recycled water use between 2005 and 2010 increased from 4,870 AFY to 10,651 AFY. The 2005 UWMP projected municipal and industrial recycled water use in 2010 would be approximately 19,870 AFY, however actual use was lower than estimated as shown in Exhibit 4J. Environmental water use of recycled water fluctuates slightly year to year based on lake levels, but is typically 26,990 AFY. For 2010 actual use was 25,129 AFY, or approximately 7 percent less than estimated. Overall total recycled water use in 2010 was approximately 23 percent less than projected.

AR0071572

Exhibit 4J
2005 UWMP Recycled Water Projections for 2010 versus Actual Use

Program	2005 Projection for 2010 (AFY)	09/10 Actual Use (AFY)
Municipal & Industrial Purposes[1]	19,870	6,864
Environmental Use[2]	26,990	25,008
Total	**46,860**	**31,872**

1. These recycled water supplies offset the demand for imported water within LADWP's service area and include DCT reuse of 2,920 AFY, but do not include deliveries to WBMWD of 34,000 AFY. DCT reuse was not included in 2005 UWMP projections for 2010.

2. Water is ultimately discharged into the Los Angeles River, providing additional environmental benefit. 2005 UWMP projections for 2010 is based on average demands.
Sources: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Tier 1 Recycled Water Systems TM, December 14, 2009; 2005 Urban Water Management Plan for the Los Angeles Department of Water Power, and LADWP Water Recycling Staff

Although LADWP did not meet the 2010 recycled water projection, significant progress has been made including the completion of multiple projects since 2005 as described in Section 4.3.1 through 4.3.4. Additional projects that are proposed for construction in the near future are described in Section 4.4, Recycled Water Master Planning Documents. Additionally, LADWP in conjunction with the BOS is currently developing the City's Recycled Water Master Plan (RWMP) to guide future optimization of this supply source with the goal of increasing municipal and industrial use of recycled water to 50,000 AFY, inclusive of indirect potable reuse.

4.4 Recycled Water Master Planning Documents

LADWP in partnership with BOS is developing the RWMP Documents to replace 50,000 AFY of potable water supplies with recycled water by 2029 and to plan for long-term recycled water use. As previously discussed, the City of Los Angeles' Water Supply Plan, "Securing LA's Water Supply", the City has established a goal of 50,000 AFY with recycled water to reduce the need for potable water and diversify LADWP's available water supply options. Exhibit 4K summarizes LADWP's timeline to achieve the goal of recycling 50,000 AFY by fiscal year (FY) 2029. This goal can be achieved sooner if additional funds are made available such as state and federal grants. The RWMP efforts were initiated in 2009 and are forecast for completion by the middle of 2011. To meet near-term challenges and plan for long-term recycled water the following major tasks were outlined for inclusion in the RWMP Documents:

- Groundwater Replenishment Report;
- Non-Potable Reuse Report;
- Groundwater Replenishment Treatment Pilot Study;
- Max Reuse Concept Report;
- Satellite Feasibility Concept Report;
- Existing System Reliability Concept Report; and

AR0071573

Within these tasks the RWMP Documents will determine where the existing recycled water system (purple-pipe network) should be expanded to satisfy needs of new customers. A cost benefit analysis will be conducted to identify potential customers considering location and projected use. A review of the wastewater treatment plants will be performed to determine which plants can supply the recycled water and the treatment technologies required. The RWMP Documents will also review available options for maximizing reuse through a combination of alternatives including expansion of non-potable uses, groundwater replenishment with advanced treated recycled water, and/or injection of recycled water as a seawater intrusion barrier. A set of alternatives will then be developed and analyzed for both the near-term and long-term goals. Alternatives will be evaluated as part of an integrated analysis.

The RWMP Documents will include Near-Term recycled water projects (projects to be implemented through 2015 to achieve 20,000 AFY of recycled water use), expansion of the non-potable distribution system beyond 20,000 AFY, and groundwater replenishment with advanced treated recycled water options. When combined with existing reuse, these options are expected to result in 50,000 AFY of reuse by FY 2029, exclusive of environmental reuse, DCT in plant reuse, and sales to WBMWD. Exhibit 4K provides a timeline for projects featured in the RWMP Documents.

Exhibit 4K
Recycled Water Master Planning Documents Implementation Timeline

Timeline	Reuse Volume[1] (AFY)	Description
Existing as of Fiscal Year 2009/2010	6,700	Existing demands already being served
Recycled Water Use by 2015	20,000	Near-Term projects already identified for implementation by 2015
Groundwater Recharge by 2021	15,000	New groundwater replenishment opportunities as identified as part of the Groundwater Master Plan task
Non-Potable Reuse Recycled Water by 2029	Up to 15,000	New projects identified between 2015 and FY 2029 to serve existing potable customers as part of the non-potable reuse master plan

1. Volume to offset municipal and industrial potable water demands. Does not include environmental use, DCT plant reuse, and sales to WBMWD.

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Tier 1 Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Recycled water projections in five year increments beginning in 2015 through 2035 are presented in Exhibit 4L. Total recycled water production is estimated to increase by 42,000 AFY over the projection period or 84 percent. Environmental reuse and seawater intrusion barrier water are expected to remain constant at 26,990 AFY and 3,000 AFY, respectively. Municipal and industrial use, inclusive of DCT reuse, is expected to increase by 27,000 AFY or approximately 136 percent. Indirect potable reuse (groundwater recharge) with advanced treated recycled water is forecast to provide 15,000 AFY of groundwater recharge beginning in 2021. Recycled water use up to 2025 is inclusive of the near-term options under development in the RWMP. Projections for 2030 and 2035 assume that long-term options being developed as part of the RWMP will increase recycled water use by approximately 1,500 AFY annually beyond FY 2029. Once the alternatives for the RWMP are finalized, the allocation of recycled water use by the municipal, industrial, and groundwater recharge categories may change to achieve the RWMP's recycled water goal of 50,000 AFY.

AR0071574

Exhibit 4L
Recycled Water Use Projections

Category	Projected Use (AFY)[1]				
	2015	2020	2025	2030	2035
Municipal and Industrial	20,000	20,400	27,000	29,000	29,000
Indirect Potable Reuse (Groundwater Recharge)	0	0	15,000	22,500	30,000
Subtotal[2]	**20,000**	**20,400**	**42,000**	**51,500**	**59,000**
Environmental[3]	26,990	26,990	26,990	26,990	26,990
Seawater Intrusion Barrier (Dominguez Gap Barrier)	3,000	3,000	3,000	3,000	3,000
Total	**49,990**	**50,390**	**71,990**	**81,490**	**88,990**

1. Projected use by category is subject to change per completion of Recycled Water Master Plan, but overall total will not change. Does not include deliveries of 34,000 AFY of secondary treated water to WBMWD for further treatment to recycled water standards.

2. To offset potable use and included in supply reliability tables in Chapter 11.

3. Environmental use includes Wildlife Lake, Balboa Lake, and the Japanese Gardens. Additional environmental benefits associated with recycled water discharges to the Los Angeles River are not included.

Estimates of projected use and implementation timelines in the tables above as well as the annual demands and service dates for individual customers in the following sections may be affected by varying usage patterns of potential customers, timelines to reach agreements, as well as potential financial constraints and changing regulatory requirements.

4.4.1 Near-Term Projects through 2015

"Near-Term" projects are classified in the RWMP Documents as projects that will result in recycled water service between July 1, 2009 and 2015 to achieve 20,000 AFY of recycled water use to displace potable water. All Near-Term projects are either in the planning, design, or construction stage. Near-Term target customers have already been identified as potential recycled water users with a total demand of 15,021 AFY. Implementation of Near-Term projects will result in the connection of approximately 40 additional recycled water customers adding to the existing 130 customers. Full implementation of Near-Term projects with existing projects will result in annual recycled water demand of 20,000 AFY, exclusive of both environmental use and DCT in-plant use (26,990 and 2,920 AFY, respectively). Near-Term reuse is the largest in the commercial/industrial sector followed by the irrigation sector.

Harbor Area

Two projects are planned to meet Near-Term demands in the Harbor area, the Harbor Refineries Water Recycling Project (HRWRP) and the Port of LA Harry Bridges Development, for an estimated total demand of 9,461 AFY. Uses include industrial, irrigation, and toilet flushing in commercial facilities. Most of the recycled water, approximately 9,520 AFY, will be used for industrial purposes, including cooling towers and boiler make-up water at oil refineries. Exhibit 4M summarizes Near-Term demands for the Harbor area.

AR0071575

Exhibit 4M
Harbor Area Near-Term Estimated Demands

Type	Estimated Annual Demand (AFY)	Estimated Service Date
Harbor Irrigation	300	2014
Port of LA Irrigation/Commercial/Industrial	220	2015
Harbor Commercial/Industrial	9,000	2014-2015
Total Harbor Area Near-Term Demands	**9,520**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Meeting demands in the Harbor Area will require construction of additional infrastructure. Approximately 12 miles of 8 to 30-inch diameter pipeline and a 1 million gallon storage tank are proposed. All infrastructure to serve the Port of LA Harry Bridges Development will be constructed by the Los Angeles Harbor Department.

Through an agreement with WBMWD, LADWP intends on acquiring nitrified Title 22 water from the WBMWD Juanita Millender-McDonald Water Treatment Plant (JMMWTP) to supply recycled water to these customers.

Metro Area

Nine water recycling projects and connection of three miscellaneous customers are planned in the Metro Area with annual demands of approximately 1,813 AFY. Almost all recycled water customers propose to use recycled water for irrigation. Commercial uses of recycled water include street sweeping, vehicle washing, train washing, and laundry. LAG will continue to meet all recycled water demands in the Metro area. Exhibit 4N summarizes Near-Term demands for the Metro area.

Exhibit 4N
Metro Area Near-Term Estimated Demands

Type	Estimated Annual Demand (AFY)	Estimated Service Date
Irrigation	1,713	2010-2015
Commercial/Industrial	100	2011-2013
Total Metro Area Near-Term Demands	**1,813**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

Multiple facilities are required in the Metro area to meet near-term demands. Approximately five pump stations ranging in size from 600 to 1,800 gallons per minute are planned for construction. Three water tanks with a combined capacity 4.75 million gallons, including the conversion of an abandoned potable water tank in Griffith Park into non-potable water storage tank, are necessary to meet demands. Pipeline construction will consist of 10 additional miles of pipeline ranging from 8 to 30-inch diameters, including conversion of an existing 16-inch pipeline to a 30-inch pipeline beneath Forest Lawn Road.

AR0071576

Valley Area

In the Valley area DCT will provide the potential Near-Term annual demands approximating 769 AFY. Almost all Near-Term use, except for 75 AFY, will be for irrigation purposes. These users are all located within close proximity to the existing recycled water system. Exhibit 4O summarizes the potential Near-Term demands for the Valley area.

Exhibit 4O
Valley Area Near-Term Estimated Demands

Type	Estimated Annual Demand (AFY)	Estimated Service Date
Irrigation	769	2010-2013
Commercial/Industrial	75	2010-2013
Total Metro Area Near-Term Demands	**844**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling staff

Only minor facilities will be required to connect near-term users to the existing system. Over 2 miles of pipeline ranging from 16 to 20-inch in diameter are proposed. Additionally, 1 storage tank between 1 to 1.5 million gallons and a pump station of an undetermined volume will be required to meet demands.

Westside Area

LADWP will continue to acquire recycled water from WBMWD to serve Near-Term demands of approximately 350 AFY in the Westside area. Near-Term demands include increasing use at Playa Vista and LAX and adding five new customers. Approximately two-thirds of the water will be for irrigation purposes and one-third for commercial/industrial uses in cooling towers located at LAX. Exhibit 4P summarizes Near-Term demands for the Westside Area.

Exhibit 4P
Westside Area Near-Term Estimated Demands

Project	Estimated Annual Demand (AFY)	Estimated Service Date
Irrigation		
Playa Vista Phase 2	100	2015
Westchester High School	10	2012
Subtotal Irrigation	100	
Commercial/Industrial		
LAX Cooling Towers	240	2015
Subtotal Commercial/Industrial	240	
Total Metro Area Near-Term Demands	**350**	

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Existing and Near-Term Recycled Water Systems TM, December 14, 2009 and LADWP Water Recycling Staff

AR0071577

Serving Near-Term demands will require limited expansion of the existing recycled water system in the area as additional users will connect to the existing system. Connection of the cooling towers at LAX will require construction of an additional 0.7 miles of 12-inch diameter pipeline.

4.4.2 Non-Potable Reuse (NPR) Projects to be completed between 2015 - 2029

NPR projects to be completed between 2015 – 2029 are being identified through the development of the RWMP. These projects will make up the balance of recycled water demand up to 15,650 AFY to achieve the overall city goal of 50,000 AFY of recycled water displacing potable water uses.

As presented in Exhibit 4Q, the project options will have a total demand of approximately 23,100 AFY, inclusive of demands greater than 5 AFY, which is larger than the goal of up to 15,650 AFY and larger than the initial targeted customer demand of 14,390 AFY. Ultimately, an implementation plan will be developed for the recommended project options with a goal of beginning operations for all projects included in the implementation plan by FY 2029.

Exhibit 4Q
Project Option Demands by Service Area

Service Area	Total Demand[1] (AFY)
Harbor	3,300
Metro	6,100
Valley	10,100
Westside	3,600
Total	**23,100**

1. Includes customers with non-potable demand estimates greater than 5 AFY.

Source: City of Los Angeles Recycled Water Master Plan Technical Memorandum, Draft Tier 2 Non-Potable Reuse Project Options, February 26, 2010

Project Selection

An initial step for evaluating these projects involves identification of potential potable customers that can utilize recycled water. These customers need to have sufficient demand and a viable use for recycled water. A preliminary list of potential of customers and associated demands was completed, identifying targeted customer demands of 14,390 AFY. Irrigation-only demands were focused on first as it is generally easier to convert irrigation-only customers to recycled water use than commercial or industrial users. As described below, during development of the project options potential additional recycled water customers were identified based on their non-potable water demands and distance from recycled water sources.

Next, recycled water project options were developed to meet the goal of maximizing recycled water use, while promoting cost efficiency as well as implement ability and adaptability. Two primary steps were utilized to develop recycled water project options:

- Identification of project segments to serve each customer with non-potable demands in excess of 50 AFY
- Identification of project options combining project segments that are linked and have similar unit costs

AR0071578

The first step in the development of project options was to define general project areas based on customers with non-potable demands in excess of 50 AFY. In the project areas, transmission pipeline alignments (backbone alignments) and laterals were defined to connect customers with demands greater than 50 AFY to existing recycled water infrastructure. Alignments were then redefined to connect demand clusters of less than 50 AFY, but large enough for consideration as a large demand. Finally, distribution pipeline (laterals) alignments were determined to connect customers with demands less than 50 AFY to backbone alignments.

Initial projects options and unit costs are being identified in the current phase of the RWMP. Refinement of these options will occur prior to development of the integrated alternatives for near-term recycled water use. Options for non-potable reuse transmission (purple) pipelines are considered in conjunction with options developed for groundwater replenishment (see section 4.4.3), maximizing reuse, and satellite plants to develop integrated alternatives. Additional information on recycled water unit cost is presented in section 4.4.5 – RWMP Cost and Funding.

Recycled Water Supply Sources

Recycled water availability varies by service area. Additional supplies may be required to meet longer term demands between 2015 – 2029 that may require a combination of expanding existing facilities, service connections to neighboring agencies outside the City, new facilities, and satellite treatment facilities. Satellite treatment facilities are being investigated in the Metro, Valley, and Westside service areas. The RWMP is investigating options to ensure adequate supplies are available for each service area. As part of the RWMP, LADWP met with neighboring agencies in 2009 to explore potential opportunities for regional development of recycled water reuse facilities. These agencies are listed in Exhibit 4T, in section 4.4.6, Stakeholder Process and Agency Coordination.

4.4.3 Groundwater Replenishment

As part of the RWMP, LADWP is pursuing a Groundwater Replenishment Project (GWR), also known as indirect potable reuse, using highly purified advanced treated recycled water from DCT for spreading in existing spreading basins in the San Fernando Valley area. A minimum goal of 15,000 AFY by 2021 has been set for recharging the San Fernando Basin, a major potable water supply for LADWP. The city anticipates having the ability to eventually deliver greater amounts of up to 30,000 AFY to the GWR. The RWMP includes a groundwater recharge plan providing a capital improvement program and outlines regulatory approval steps required to complete the "Phase 1". Additionally, the RWMP outlines various operational and infrastructure improvements required to meet the goal. When complete the RWMP will contain a recommended GWR alternative. Regulatory requirements for groundwater recharge are discussed in sub-section 4.1.2, Groundwater Recharge Regulatory Requirements.

Currently, LADWP uses multiple spreading grounds located in the eastern portion of the San Fernando Basin to recharge the underlying San Fernando Basin with stormwater and imported water. A detailed discussion of the San Fernando Basin and existing recharge operations is provided in Chapter 6, Local Groundwater. This project would recharge a minimum of 15,000 AFY of advanced treated water in the existing Hansen Spreading Grounds and possibly Pacoima Spreading Basins by allowing the water to percolate into the aquifer. It is expected that native stormwater recharge would continue to occur at the spreading grounds in conjunction with the project.

Infrastructure improvements are required to implement the groundwater replenishment program including an advanced water treatment facility and pipelines to convey the product water to the spreading basins.

AR0071579

An advanced water treatment facility is necessary to further treat tertiary effluent from DCT to produce highly purified recycled water for recharge. Goals for the advanced water treatment plant include as described in the RWMP are:

- Minimum capacity of 15,000 AFY; with the potential to expand to 30,000 AFY
- Initially in service by 2021;
- Utilization of proven technologies that have demonstrated effective removal of regulated chemicals, constituents of emerging concern, and microorganisms; additional removal of constituents of wastewater origin of interest to CDPH, including pharmaceuticals, personal care products, and endocrine disrupting compounds; and
- Product water shall comply with requirements from the CDPH, RWQCB, and SWRCB and be suitable for indirect potable reuse.

To develop and implement the project within the short-time frame, the advanced wastewater treatment plant will be based on the recently permitted Orange County Water District Groundwater Replenishment System Project. This system provides product water for indirect potable reuse by recharging a groundwater basin used for potable water and preventing seawater intrusion. Proposed technologies include microfiltration or ultrafiltration, reverse osmosis, advanced oxidation using ultraviolet light with hydrogen peroxide, and post-treatment for product water stabilization.

As a by-product of advanced water treatment brine is created. Multiple brine disposal alternatives are presented in the RWMP and a final alternative will be selected upon completion of the plan.

Pipelines to convey water to the Hansen spreading grounds are already in place and were constructed as a part of the previous recycled water initiatives for the East Valley Water Recycling Project. However, if the Tujunga spreading basin will also receive water for spreading then additional pipeline infrastructure will be required.

LADWP is working closely with BOS and regulatory agencies to expedite completion of the project by 2021. Current ongoing tasks include completion of the RWMP, public outreach, pilot testing of processes, and formation of an independent advisory panel. Environmental documentation is expected to be initiated in 2011 and completed in 2013.

Independent Advisory Panel

GWR projects typically have the involvement of an independent third party with scientific and technical expertise to provide expert peer review of key aspects of the project, which can ensure the technical viability of the GWR and facilitate the regulatory process. To accomplish this, LADWP awarded a contract with National Water Research Institute (NWRI) to form an Independent Advisory Panel (IAP) to provide expert peer review of the technical, scientific, regulatory, and policy aspects of the proposed groundwater replenishment project, pilot project testing, and other potential groundwater replenishment projects to maximize reuse as part of the LADWP Recycled Master Planning Documents. The IAP process will provide a consistent, thorough, and transparent review of any proposed GWR projects and pilot testing during their critical formation phase, as well as during the long- term implementation phase.

NWRI has vast experience in the organization and administration of the IAP processes for other agencies such as the Orange County Water District Groundwater Replenishment System Project. NWRI will assist the IAP process by assembling the IAP

AR0071580

members, developing a detailed scope and approach for the IAP's review, coordinating and facilitating meetings, and preparing IAP reports.

Some of the immediate activities that have been identified for the IAP to address during the initial participation include, but are not limited to review of the following:

- General approach for Recycled Water Master Planning
- Hydrogeology (in-basin groundwater blending)
- Treatment (barriers to replace the fifty-percent blend criteria)
- Reliability features of the Advanced Water Treatment Facility
- Source Control Evaluation for groundwater replenishment
- Draft Engineering Report for groundwater replenishment
- Response to technical concerns raised by regulators and the public

The "Independent Advisory Panel for the City of Los Angeles Groundwater Replenishment Project" consists of 13 members with scientific and/or professional expertise in issues related to the implementation of groundwater replenishment projects. Members with different areas of expertise are based on the requirements of the California Department of Public Health Draft Groundwater Recharge Reuse Regulations dated August 2008, as well as the composition of panels used by the Orange County District and the City of San Diego for the implementation of similar groundwater replenishment projects.

NWRI convened the Independent Advisory Panel for the first time in October 2010 to receive introductory information about the recycled water program and groundwater replenishment project. The Panel is expected to be involved throughout the planning, permitting, design, environmental documentation, and implementation of the groundwater replenishment project.

4.4.4 Efforts Beyond 50,000 AFY

As part of the RWMP, LADWP is developing long-term alternatives to maximize recycled water use beyond 50,000 AFY. After 2029 and through 2035 LADWP expects to increase recycled water use by approximately 1,500 AFY anually. To maximize recycled water use LADWP is investigating the following options in its RWMP:

- Recycled water satellite treatment facilities;
- Expansion of recycled water systems;
- Increasing treatment levels at HTP to tertiary and advanced treatment;;
- Reviewing opportunities for partnerships with agencies within the City and outside the City
- Treatment plant upgrades at DCT and LAG; and
- Methods to increase reliability of the system.

AR0071581

Additionally, the RWMP will identify how the city can maximize recycled water usage unto the future beyond the 50,000 AFY goal. The long-term recycled water alternatives analysis as part of the RWMP has not been completed. However, LADWP forecasts that in 2035 municipal and industrial recycled water demands along with groundwater replenishment will be approximately 59,000 AFY. In addition to this, 26,990 AFY will also be used for environmental beneficial reuse.

4.4.5 RWMP Cost and Funding

The capital cost of expanding the recycled water system to achieve the initial goal of 50,000 AFY to displace the need of potable water was initially estimated to cost approximately $1 billion. Exhibit 4R summarizes the initial estimated capital costs for the RWMP. However, these estimates are being refined as part of the RWMP that are expected to be updated by early 2011.

Exhibit 4R
RWMP Estimated Capital Costs

Phase	Capital Cost[1] ($ million 2008)
Near-Term projects through 2015	$ 265
Long-Term projects through 2029	$ 435
Groundwater Recharge Project	$ 300
Total RWMP Capital Cost	**$ 1,000**

1. Capital costs will be updated and refined as part of the RWMP.

Unit Cost

Non-Potable Reuse (NPR) and Groundwater Replenishment (GWR) projects are diverse, and result in a wide range of costs to implement and sustain. NPR projects present numerous challenges including distance from treatment plant and the associated transmission pipeline construction costs. This factor is weighed against customer size as well as the adaptability to a particular commercial site or process. For GWR projects, nearby spreading grounds must be acquired, along with the construction of a conveyance pipeline. Initial findings of the RWMP have determined the approximate range of unit cost for recycling to be from $600 - $1,500 / AF. This approximation includes capital, operation and maintenance costs.

Funding

Capital costs for RWMP projects will be covered by the sources identified below, as well as other sources as they become available.

- Water Rates – LADWP water rates are the primary funding source for the recycled water program.
- Federal Funding – LADWP will pursue federal funding as it becomes available. In the past LADWP has received funding for recycled water projects from the Federal Water Project Authorization and Adjustment Act of 1992, Public Law 102-575 (HR429), and the United States Bureau of Reclamation Title XVI Program.
- State Funding – LADWP will pursue state funding as it becomes available, through the SWRCB and DWR for recycled water projects. Propositions 13 and 50 had funds specifically marked for recycled water projects. Funding is available through Proposition 84, Integrated Regional Water Management, for implementation projects, including recycled water projects. Low-interest loans are available through the SWRCB for eligible projects.

AR0071582

- MWD Local Resources Program Incentive – The Local Resources Program provides funding for water recycling and groundwater recovery projects that prevent a new demand on MWD or displace an existing demand on MWD. Financial incentives up to $250 per acre-foot are available dependent upon MWD water rates and projects costs. Funding is not received until production occurs and terminates upon the expiration of the funding agreement for the project.

4.4.6 Stakeholder Process and Agency Coordination

Stakeholder outreach and coordination with agencies plays a key role in LADWP's recycled water program and the RWMP.

Stakeholder Process

To encourage input as recycled water strategies are developed over the next few years in conjunction with the RWMP, LADWP has initiated an extensive stakeholder process. LADWP has developed two formats for participation of stakeholders, a more intensive Recycled Water Advisory Group (RWAG) and a less intensive Recycled Water Forum.

Over 200 stakeholders were invited to participate in the RWAG representing broad interests across the City, including community groups, environmental groups, neighborhood councils, homeowners' associations, and others. Approximately 60 stakeholders are participating in the process. The RWAG first met in 2009 and will continue to have approximately 5 workshops per year over the next 3 to 4 years. Through the RWAG, stakeholders are provided the opportunity to represent their respective organizations and share input with LADWP and BOS and convey they knowledge gained to their organizations. Two main roles of the RWAG are:

1) Allow stakeholders to provide input on recycled water options from technical, environmental, financial, and social viewpoints

2) Consider key project issues and discuss implementation challenges and acceptability.

Less intensive stakeholder participation opportunities are available through the Recycled Water Forums. The Recycled Water Forums will provide stakeholders the opportunity to hear briefings on recycled water efforts through several weekend or evening meeting throughout the year held within local communities. Stakeholders will have the opportunity ask questions and provide comments and suggestions.

Agency Coordination

To maximize recycled water use and move forward with RWMP efforts, LADWP closely coordinated with agencies at the local and state levels. Coordination is necessary to ensure adequate funding, identification of end-users, adequate availability of supplies, permitting and regulatory approvals, and regional cooperation. If federal funding opportunities become available, LADWP will also coordinate with the applicable federal agencies. Exhibit 4S provides a summary list of agencies LADWP is currently coordinating with to maximize recycled water use. LADWP also coordinates recycled water end use with potential customers by assisting with facility retrofits, providing financial incentives, and public education.

AR0071583

Los Angeles County Sanitation Districts[1]	Water Replenishment District of Southern California[1]
Long Beach Water Department[1]	West Basin Municipal Water District[1]
Las Virgenes Municipal Water District[1]	Los Angeles Regional Water Quality Control Board
State Water Resources Control Board	Los Angeles County Department of Public Health
City of Los Angeles Department of Public Works, Bureau of Sanitation, Watershed Protection Division	City of Los Angeles Department of Public Works, Bureau of Sanitation
California Department of Public Health	

1. Met with agencies individually to discuss potential regional recycled water use.

4.4.7 Recycled Water Quality

All recycled water provided by LADWP meets at minimum Title 22 standards. Title 22, Chapter 4, of the California Code of Regulations establishes water quality standards and treatment reliability criteria for water recycling to ensure public safety as discussed in Section 4.1. Title 22 standards are achieved with tertiary treatment and disinfection.

Advanced wastewater treatment is currently provided at the TIWRP by the AWTP. Advanced treatment, which includes microfiltration and reverse osmosis, removes many of the impurities remaining after tertiary treatment and disinfection. Water treated with advanced treatment techniques has the potential to be used for seawater barriers and groundwater recharge. As part of the RWMP, advanced treatment is proposed for DCT to provide indirect potable reuse through groundwater recharge. Exhibit 4C, located in Section 4.2, summarizes the level of treatment provided by each of the City's wastewater treatment plants.

DRAFT

AR0071584

Chapter Five
Los Angeles Aqueduct System

5.0 Overview

Water has been an integral part of the City's history. The City's population and economy was initially supported through a combination of local surface flows primarily from the Los Angeles River, and groundwater pumping primarily from the San Fernando Basin. When it became apparent that much of the local groundwater supply and local surface flows were fully utilized, the citizens of Los Angeles under the leadership of William Mulholland, then Chief Engineer of the Los Angeles Water Bureau, approved by a 10 to 1 margin a $23 million bond measure to construct the First Los Angeles Aqueduct in 1913. This investment was equal to 12 percent of the entire City's assessed valuation at that time. Then in 1940, an additional $40 million was spent to extend the first aqueduct 40 miles north from the Owens River to streams that were tributaries to Mono Lake, see Exhibit 5A.

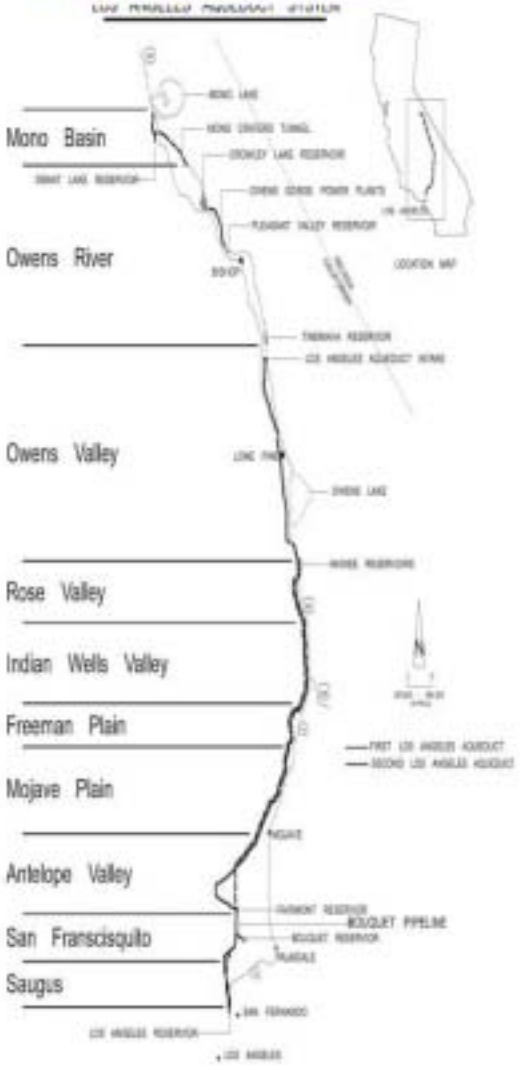
Finally, to meet the additional water needs of its population, the City decided to construct the second barrel of the Los Angeles Aqueduct in 1963, later to become known as the Second Los Angeles Aqueduct. Construction of the Second Los Angeles Aqueduct was completed in 1970. The second aqueduct increased the City's capacity to deliver water from the Mono Basin and the Owens Valley to Los Angeles from 485 cubic feet per second (cfs) to 775 cfs.

The value of the City's historical investment in the Los Angeles Aqueduct System is substantial. For nearly a century, the City has benefited from the delivery of high-quality, cost-effective water supplies from the eastern Sierra Nevada.

Over time, environmental considerations have required that the City reallocate approximately one-half of the Los Angeles Aqueduct (LAA) water supply to environmental enhancement projects. As a result, the City has used approximately 205,800 AF of water supplies for environmental enhancement in the Owens Valley and Mono Basin regions in 2010, which is in addition to the almost 107,300 acre-ft per year (AFY) supplied for agricultural, stockwater, and Native American Reservations. Limiting water deliveries to the City from the LAA has directly led to increased dependence on imported water supply from the Metropolitan Water District of Southern California (MWD). LADWP purchase of supplemental water from MWD in 2008-09 is at an all time high.

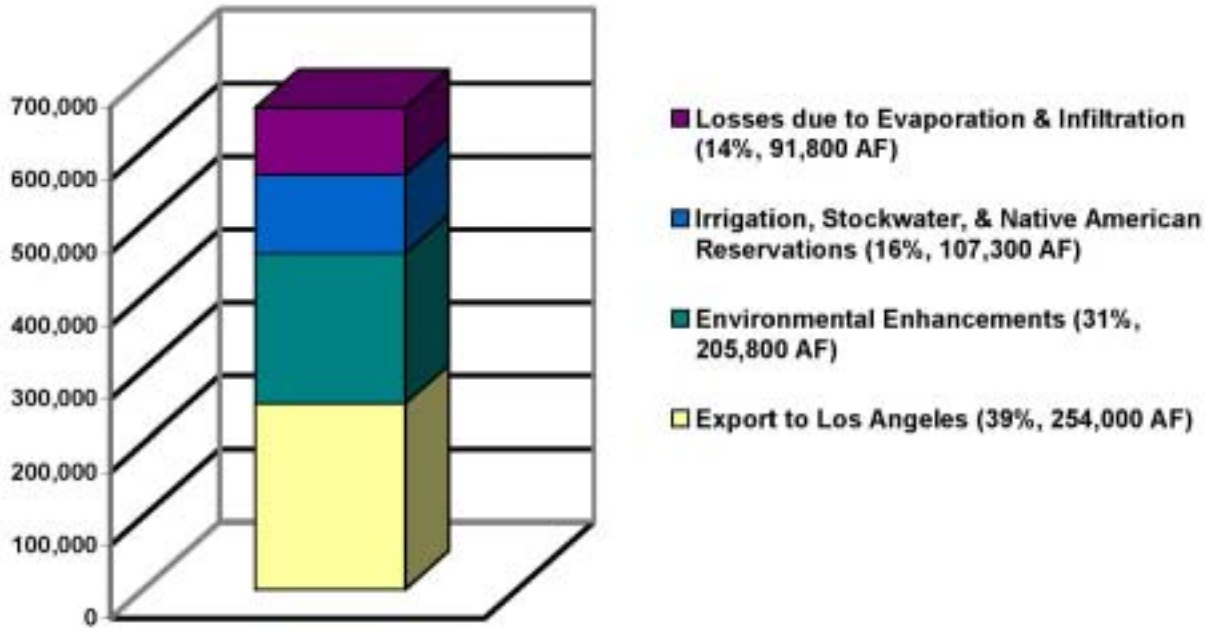
As indicated in Exhibit 5B, LAA deliveries comprise 39 percent of the total runoff in the Eastern Sierra in an average year. The vast majority of water collected in the Eastern Sierra stays in the Mono Basin, Owens River, and Owens Valley for ecosystem and other uses.

Exhibit 5A
Los Angeles Aqueduct System



AR0071586

Exhibit 5B
Mono Basin and Owens Valley Water Use Allocations



5.1 Historical Deliveries

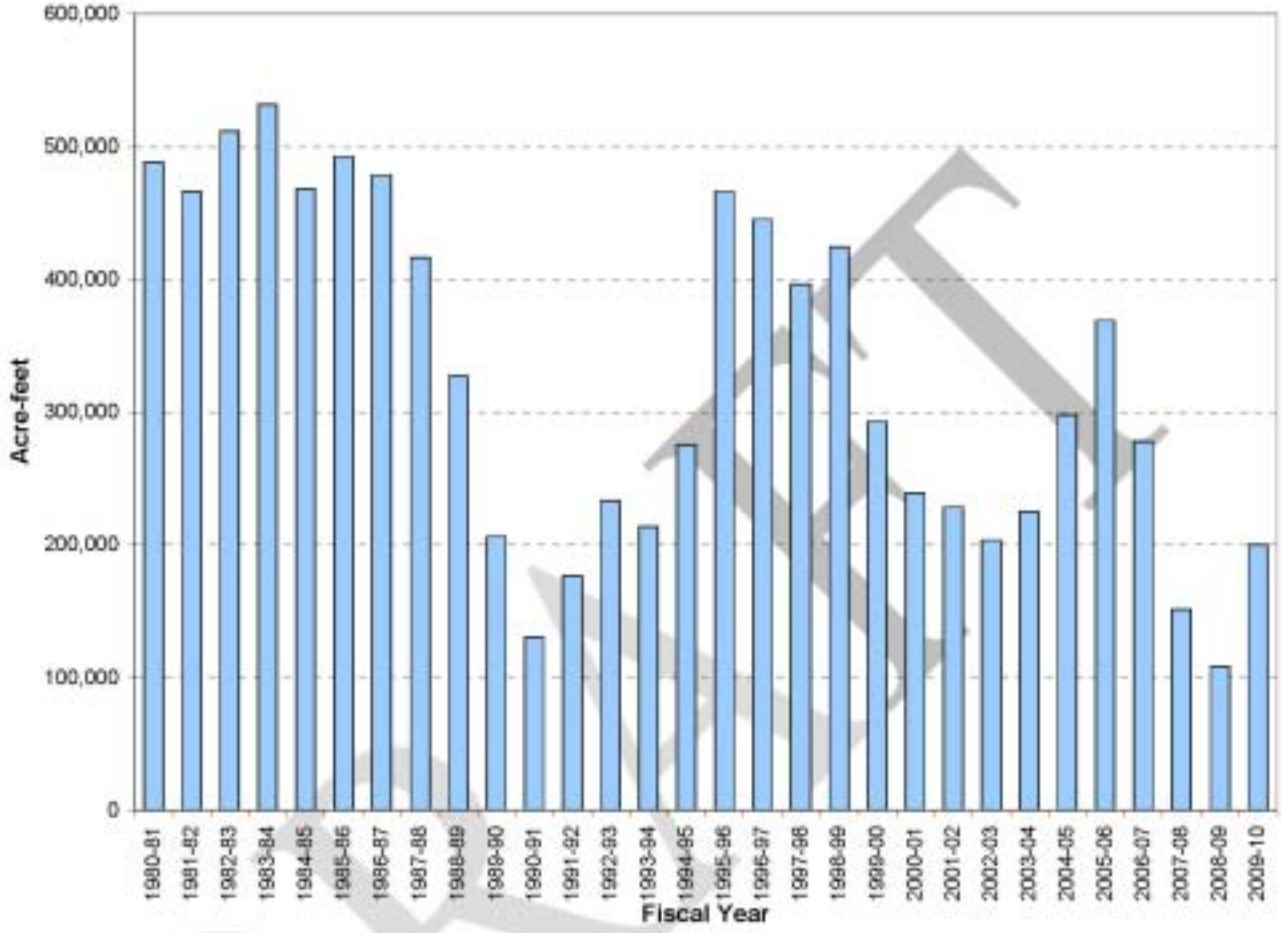
Annual LAA deliveries are dependent on snowfall in the eastern Sierra Nevada. Years with abundant snowpack result in larger quantities of water deliveries from the LAA, and typically lower supplemental water purchases from MWD. Unfortunately, a given year's snowpack cannot be predicted with certainty, and thus, deliveries from the LAA system are subject to significant hydrologic variability.

The impact to LAA water supplies due to varying hydrology in the Mono Basin and Owens Valley is amplified by the requirements to release water for environmental restoration efforts in the eastern Sierra Nevada. Since 1989, when City water exports were significantly reduced to restore the Mono Basin's ecosystem, LAA deliveries from the Mono Basin and Owens Valley have ranged from 108,503 AF in 2008-09 to 466,584 AF in 1995-96. Average LAA deliveries since 1989-90 have been approximately 264,799 AF, about 42 percent of the City's total water needs.

The cyclical nature of hydrology is exhibited best by Los Angeles Aqueduct (LAA) deliveries over the last ten years. This general period was characterized by a series of wet years, followed by a series of dry years. From 2000-01 through 2009-10, LAA deliveries supplied an average of 36 percent of the City's water needs. The reliability impact of hydrologic cycles on LAA supplies is evident through historical deliveries. A broader look at how deliveries from the LAA have fluctuated from year to year is shown in Exhibit 5C.

AR0071587

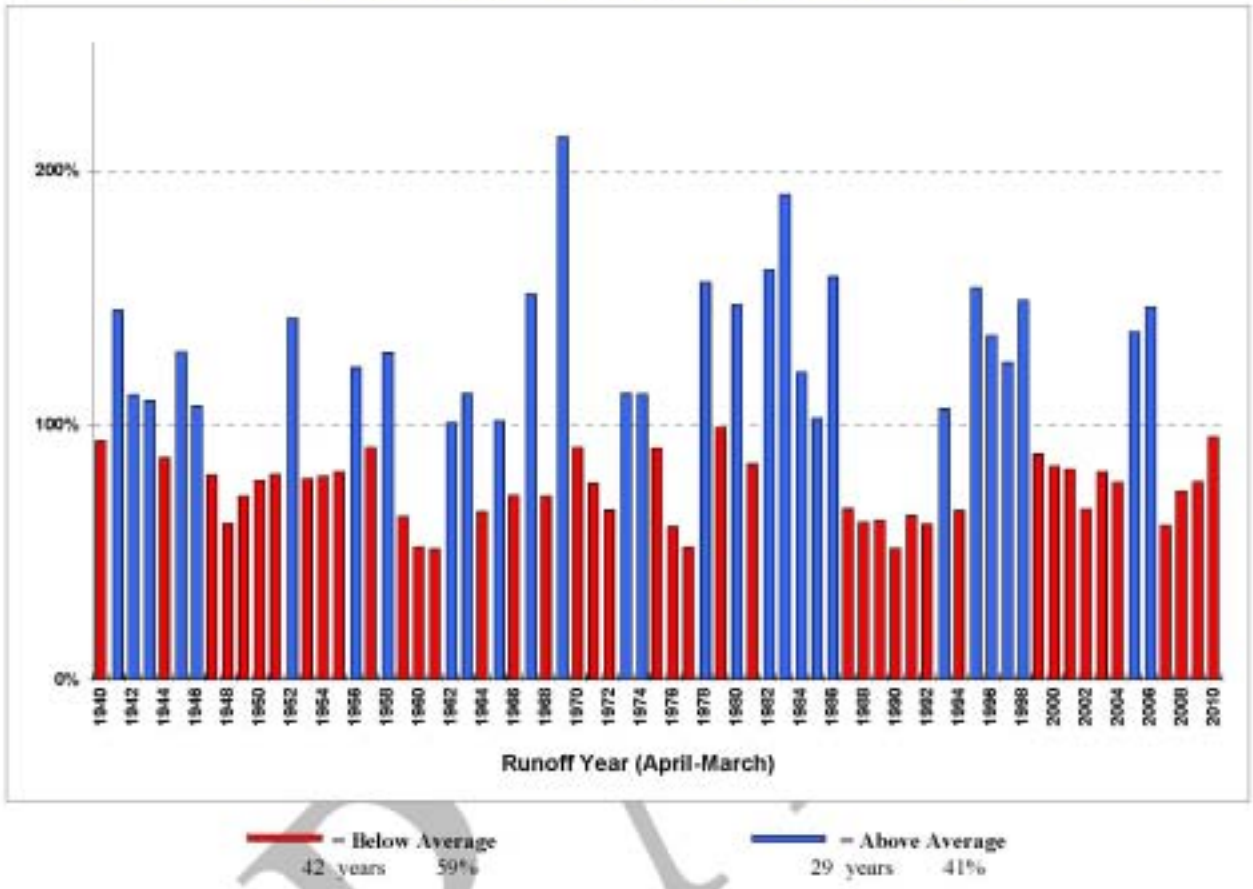
Exhibit 5C
Historical Los Angeles Aqueduct Deliveries



A long term perspective of the general cycle of wet and dry years for the Owens Valley is evident in Exhibit 5D, particularly since the late 1960s. As illustrated, reliance solely on one water supply source is not practical. Therefore, the City relies on the LAA in combination with the Colorado River Aqueduct and the State Water Project as the City's primary imported water sources. These imported sources combined with local groundwater, recycled water, and conservation make up the City's total water supply portfolio. This portfolio of water resources is fundamental to LADWP's ability to deliver a reliable water supply to meet the needs of over 4 million residents of Los Angeles.

AR0071588

Exhibit 5D
Eastern Sierra Nevada Runoff Owens Valley – Percent of Normal



5.2 Mono Basin and Owens Valley Supplies

Surface runoff from snowmelt in the eastern Sierra Nevada Mountains is the primary source of supply for the LAA. The LAA extends approximately 340 miles from the Mono Basin to Los Angeles. Water is conveyed the entire distance by gravity alone. LADWP regulates system output through storage control at seven reservoirs, beginning with Grant Lake Reservoir to the north and ending with Bouquet Reservoir to the south. The total combined reservoir storage capacity of the system is 300,560 AF. Hydroelectric power is also generated from 12 power plants along the LAA. Combined maximum capability of the power generation facilities is 205 mega-watts. Water-gathering activities for the LAA have a junior priority to meeting the Owens Valley and Mono Basin water obligations for environmental, domestic, agricultural, and recreational water needs.

The LAA is fed by runoff from the eastern slope of the Sierra Nevada. Runoff from the eastern slope reaches its maximum in the late spring and summer, after most of the year's precipitation has already occurred. The snowpack in the eastern Sierra Nevada provides natural storage for the LAA system. This snowpack storage is necessary in light of the minimal primarily regulatory storage capacity along the LAA system.

AR0071589

Water Rights

The City's export of water from the eastern Sierra Nevada is based on 166 Pre-1914 and 16 Post-1914 water right diversion licenses on various streams in the Mono Basin and Owens Valley. The majority of the City's water rights were filed prior to 1914 with the Counties of Mono and Inyo Recorder's Office. All Post-1914 licenses were granted by the State Water Resources Control Board. The most significant basis for export of surface water from the Eastern Sierra Nevada is an appropriation claim in 1905 to divert up to 50,000 miner's inches (1,250 cubic feet per second) from the Owens River at a location approximately 15 miles north of the town of Independence into the LAA for transport to Los Angeles. The City has since filed Supplemental Statements of Water Diversion and Use forms with the State Water Resources Control Board (SWRCB) for all LADWP diversions and licenses.

The City's water right licenses in the Mono Basin were amended by the SWRCB in 1994 through the Mono Lake Basin Water Right Decision 1631. Currently, water export from the Mono Basin is limited to 16,000 AF per year based on a court order to raise the target elevation of Mono Lake and restore four streams that flow to Mono Lake.

The primary groundwater right through which Los Angeles has developed groundwater resources in the Owens Valley is based on ownership of a majority of the land (approximately 314,000 acres) and associated water rights in the Owens Valley. Management of the groundwater supply in the Owens Valley is according to a 1991 agreement between Inyo County and LADWP. The goal of this agreement is to avoid defined decreases and changes in vegetation, and to cause no significant effect on the environment which cannot be acceptably mitigated, while providing a reliable supply of water for export to Los Angeles and for use in Inyo County.

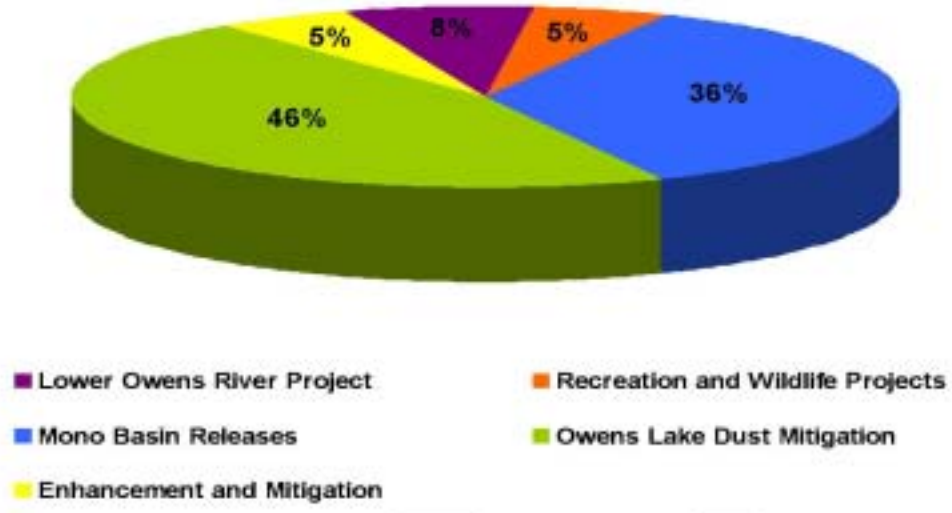
5.3 Environmental Issues and Mitigation

Over time an increasingly larger portion of the LAA water supply has been reallocated to the environment. As a result, the City's current supply for environmental enhancement in the Owens Valley and Mono Basin is approximately 205,800 AF per year. To accommodate LAA delivery reductions due to these environmental enhancements, LADWP has funded conservation and water recycling programs to improve water use efficiency within the City. Exhibit 5E illustrates the breakdown of LAA water supply commitments by category for Environmental Enhancement and Mitigation Projects have been implemented as part of the City's commitment to meet the environmental water needs of the Owens Valley. Among these environmental projects, LADWP is diverting 10,700 AF of water from the LAA for Owens Valley Enhancement and Mitigation Projects, 10,400 AF for Recreation and Wildlife Projects, and 15,700 AF for the Lower Owens River Project. These annual environmental project diversions are in addition to water that provides environmental benefits in the Mono Basin and Owens Lake.

DRAFT

AR0071590

Exhibit 5E
Mono Basin and Owens River Environmental Enhancement Commitments



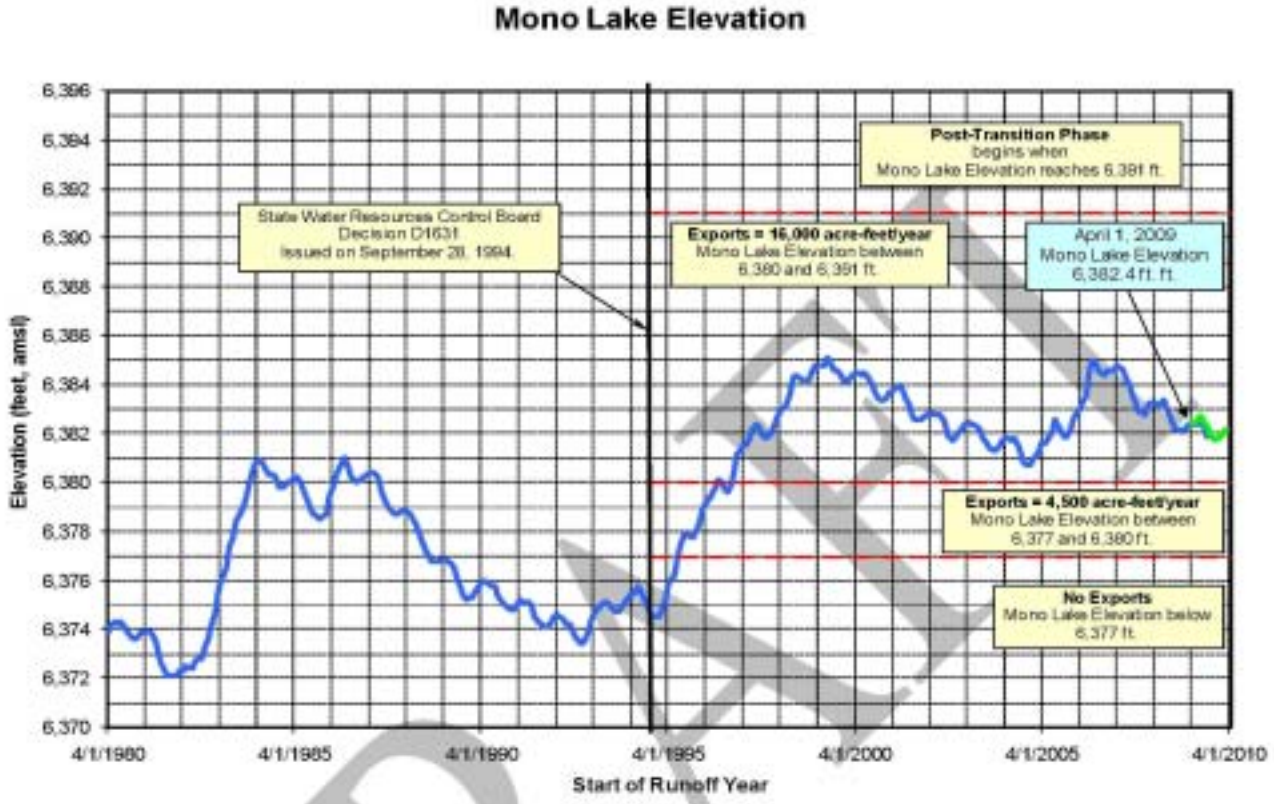
Environmental Enhancement Commitments	AFY
Lower Owens River Project	15,700
Recreation and Wildlife Projects	10,400
Mono Basin Releases	74,000
Owens Lake Dust Mitigation	95,000
Enhancement and Mitigation	10,700
Total	205,800

Mono Basin

Currently, Mono Basin exports will remain at no more than 16,000 AF per year until Mono Lake reaches its target elevation of 6,391 feet above mean sea level. Exhibit 5F provides the maximum export levels from the Mono Basin under specified conditions as defined in the State Water Resources Control Board Decision D1631 that was issued on September 28, 1994. Since the long-term average of Mono Basin exports before 1994 was approximately 90,000 AFY, the net reduction in water exports in the Mono Basin is estimated at 74,000 AFY of water mainly from Grant Lake Reservoir, Lee Vining Creek, Walker Creek, Parker Creek, and Rush Creek. As of January 2010, Mono Lake is at elevation 6,381 feet. Extensive restoration and monitoring programs in the Mono Basin have improved the streams, riparian, fishery, and waterfowl habitats. With reduced diversions from the basin, Mono Lake's elevation has risen, but has also been fluctuating due to lack of runoff as illustrated during the period of 2000 to 2005 on Exhibit 5F.

AR0071591

Exhibit 5F
Historical Mono Lake Elevations



To effectively maintain continuous base and peak water flows to the ecosystem restoration area of Lower Rush Creek in the Mono Basin, LADWP completed construction of the Mono Gate One diversion facility upgrade in November 2009. Exhibit 5G summarizes the base and peak flow requirements for Lower Rush Creek. Base and peak flow requirements vary in relation to seven hydrologic conditions ranging from dry to extreme wet as identified by forecasted runoff for Mono Basin. Mono Gate One was originally constructed to release excess water from the aqueduct system during high flows by diverting water into Lower Rush Creek with a system of diversion boards. However, it had no monitoring or flow control capabilities and was not designed for precise flow metering or full-time diversion. Construction completed in the fall of 2009, the new Mono Gate has enabled LADWP to greatly improve measuring and flow capabilities, satisfying one of the operational requirements of the SWRCB.

AR0071592

Exhibit 5G
Lower Rush Creek Base and Peak Flow Requirements

Hydrologic Condition	Base Flow (cfs)							Peak Flows (cfs)
	Apr	May - Jul	Aug - Sep	Apr - Sep	Oct- Mar	May - Aug	Sep - Mar

Lower Owens River Project

Beginning December 2006, the Lower Owens River Project, depicted in Exhibit 5H, releases water from the LAA to create a warm water fishery along a 62-mile section of the Owens River. Water is released near the LAA intake facility and a pump back station is located downstream to return flows to the LAA or to Owens Dry Lake for dust control measures. In accordance with the Memorandum of Understanding between LADWP and Inyo County and the approved Environmental Impact Report, annual monitoring reports are to be prepared to measure project success. The first Lower Owens River Project Annual Monitoring Report was prepared in 2008.

The MOU prescribes requirements for project flows. Both base flows and seasonal habitat peak flows are required by the project. A flow schedule is provided in Exhibit 5I. Seasonal habitat peak flows vary between 40 cfs (zero additional flows beyond the base flow requirements) to 200 cfs. For below average runoff years, seasonal habitat flows may be incrementally lowered from the average runoff year requirements of 200 cfs to 40 cfs (base flow) in proportion to the forecasted runoff flows in the watershed. Base flows are constant at 40 cfs regardless of forecasted runoff flows. It is estimated that the long-term use and transit losses from the project will be approximately 15,700 AFY.

Exhibit 5H
Lower Owens River Project Area

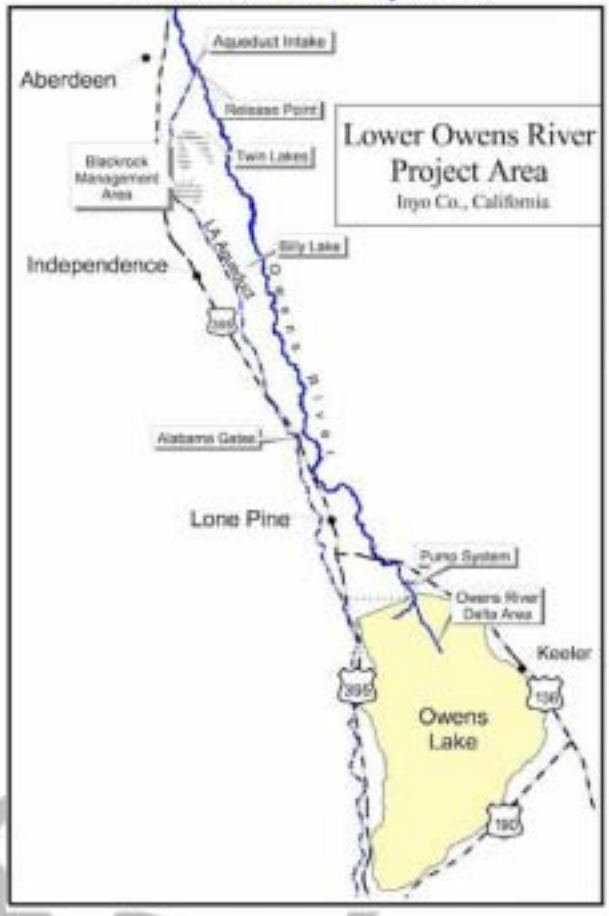

Exhibit 5I
Lower Owens River Base and Peak Seasonal Habitat Flow Requirements

Hydrologic Condition Forecasted[1] (Percent of Average Runoff)	Base Flow (cfs)	Peak Seasonal Habitat Flow (cfs)
50 percent or less	40	Base flow only
70 percent	40	100
100 percent or greater	40	200

1. Runoff forecast determined by LADWP's Runoff Forecast Model for Owens River Basin based on April 1st snow survey.

2. Peak season habitat flows are proportionately ramped up from 40 cfs to 200 cfs based on the percent of average runoff forecasted greater than 50 percent and less than 100 percent.

AR0071594

5.4 Owens Lake Dust Mitigation

Historically, the Owens River was the main source of water for Owens Lake. Diversion of water from the river, first by farmers in the Owens Valley and then by the City, resulted in the lake being reduced to a small brine pool. The exposed lakebed became a major source of windblown dust resulting in the United States Environmental Protection Agency (EPA) classifying the southern Owens Valley as a serious non-attainment area for particulates (dust) also known as PM_{10} emissions in 1991.

As a result of PM_{10} emissions exceeding regulations, the EPA required California to prepare a State Implementation Plan (SIP) to bring the region into compliance with Federal air quality standards by 2006. In July 1998, LADWP entered into a Memorandum of Agreement with the EPA that: 1) delineated the dust producing areas on the lakebed that needed to be controlled; 2) specified what measures must be used to control the dust; and 3) outlined a timetable for implementation of the control measures. The Memorandum of Agreement was incorporated into a formal air quality control SIP by the Great Basin Unified Air Pollution Control District (District). The plan was approved by the EPA in October 1999.

LADWP's water use for Owens Lake Dust Mitigation has been gradually increased over the years. Exhibit 5J summarizes yearly water use for the Owens Lake Dust Control Project. The 2005 UWMP estimated that up 55,000 AFY of water would be all that was required for the Project. Currently, up to 95,000 AF per year of water is expected to be diverted from the Aqueduct for dust mitigation at the Owens Lake.

Exhibit 5J
Yearly Water Use on Owens Lake (Fiscal Year)

Fiscal Year	Total AF
2002/2003	23,937
2003/2004	31,362
2004/2005	29,494
2005/2006	29,413
2006/2007	54,849
2007/2008	67,262
2008/2009	59,187
2009/2010	75,428
2010/2011	95,000

* Fiscal year 2010/2011 is projected

Since 2001, LADWP has diverted water from the LAA for the Owens Lake Dust Control Project. A combination of shallow flooding, managed vegetation, and a small amount of gravel are used at various lakebed locations as Best Available Control Measures (BACM) for dust control mitigation on almost 40 square miles. Exhibit 5K provides a description of the best accepted control methods. LADWP has completed 9.2 square miles of shallow flooding, 0.5 square miles of modified shallow flooding, and 0.4 square miles of sand fence as part of the Phase 7 project in accordance with the 2008 SIP. However, LADWP had proposed 3.1 square miles of a new waterless dust control measure called Moat and Row which was disallowed by the California State Lands Commission in April 2010. LADWP is working with the District to develop an alternative solution for the areas originally proposed for Moat and Row. LADWP has been ordered to complete an additional 2 square miles of dust control known as the Phase 8 project. LADWP is seeking a lease from the California State Lands Commission to construct Gravel BACM for Phase 8 as it does not require water for operation.

DRAFT

Exhibit 5K
Dust Control Mitigation Measures

Dust Control Measures		Description
Shallow Flooding	Sheet Flooding	Releases water from arrays of low-flow water outlets spaced at intervals of between 60 and 100 feet along pipelines laid along lake bed contours. Pipelines are spaced between 500 and 800 feet apart. This arrayed configuration of water delivery creates large, very shallow sheets of braided water channels. Water depths in sheet flooded areas are typically at most a few inches deep. The lower edge of sheet flooded areas has containment berms to capture and pond excess flows. The water slowly flows across the typically very flat lake bed surfaces downhill to tail-water ponds where pumps recirculate the water back to the outlets. To maximize project water use efficiency, flows to sheet flow areas are regulated at the outlets so that only sufficient water is released to keep the soil wet. Any water that does reach the lower end of the control area is collected and recirculated back through the water delivery system.
	Shallow Flooding (Pond Flooding)	Water containment berms that allow ponds to be formed that submerge the emissive lake bed areas. These ponds are up to four feet deep. The containment berms are typically rock-faced to protect them from delivery to the pond area until the pond reaches a size and depth sufficient to submerge the required amount of emissive water. Water delivery then ceases until evaporation reduces the pond size to a set minimum.
Managed Vegetation		Control measure consists of creating a farm-like environment from barren playa. The saline soil must first be reclaimed with the application of relatively fresh water and then planted with salt-tolerant plants that are native to the Owens Lake basin. Thereafter, soil fertility and moisture inputs must be managed to encourage rapid plant development and maintenance. Existing Managed Vegetation areas are irrigated with buried drip irrigation tubing and a complex network of buried drains to capture excess water for reuse on the Managed Vegetation area or in Shallow Flooding areas. Managed Vegetation is sustainable at Owens Lake only if salt from the naturally occurring shallow groundwater is prevented from rising back into the rooting zone.
Gravel Blanket		A four-inch layer of coarse gravel laid on the surface of the Owens Lake playa will prevent emissions by preventing the formation of efflorescent evaporate salt crusts, because the large pore spaces between the gravel particles disrupt the capillary movement of saline water to the surface where it can evaporate and deposit salts. The gravel also creates a surface that has a high threshold wind velocity so that direct movement of the large gravel particles is prevented and the finer particles of the underlying lake bed soils are protected. Gravel Blankets are effective on essentially any type of soil surface.

As part of an Interim Management Plan, LADWP and Inyo County have agreed to conduct a joint study to explore the feasibility of extracting and utilizing groundwater beneath Owens Lake to supplement the water supply necessary for dust mitigation activities. This feasibility study is scheduled for completion by November 2011. If groundwater pumping is considered feasible and acceptable, LADWP will first need to obtain required approval from Great Basin Unified Air Pollution Control District, California State Lands Commission, California Department of Fish and Game, and Inyo County.

AR0071596

5.5 Water Quality

As land owners of much of the Mono Basin and Owens River watersheds, LADWP has placed strict limits on the extent of development impacting the City-owned watersheds. Snowmelt from the eastern Sierra Nevada contains low total organic carbon (TOC), bromide concentrations, and other constituents that can form disinfectant byproducts during the water treatment process. LADWP conducts routine monitoring of all of its water supplies for over 170 constituents and contaminants. Ninety-eight of the constituents and contaminants have enforceable standards.

The LAA supply is the main source of arsenic in LADWP's water supply. Arsenic is collected as the Owens River makes its way down through volcanic formations in the vicinity of Hot Creek in Long Valley. Geothermal springs in these areas have arsenic concentrations of around 200 parts per billion (ppb). Concentrations are dramatically reduced as water in the area mixes with snow melt and other pristine water sources. Historic untreated LAA water arsenic concentrations have ranged from 10 to 74 ppb. During the latest 3-year routine compliance monitoring cycle from 2007 to 2009, the highest arsenic concentration after treatment was 8.1 ppb, while the average arsenic concentration within LADWP's water distribution system was 3.3 ppb, well below the current Federal and State drinking water standard of 50 ppb. In light of potential, more stringent arsenic regulations, LADWP is taking a proactive approach in addressing this issue by investing enhanced coagulation treatment.

LADWP completed an evaluation and preliminary design report for enhanced coagulation at the Los Angeles Aqueduct Filtration Plant in December 2006 as a means of addressing future water quality regulations faced by LADWP, including arsenic. An enhanced coagulation facility using the process as outlined in the report is planned as part of the treatment process at the Los Angeles Aqueduct Filtration Plant by 2021.

To comply with the Stage 2 Disinfectants and Disinfection Byproducts Rule, another water quality improvement effort being implemented is the conversion from chlorine to chloramine residual disinfectant. This transition, which is expected to be completed by April 2014, will allow LADWP to maintain the same high level of disinfection in its water supply while freeing itself from other potential disinfection issues associated with the use of chlorine. The use of chloramines will provide additional operational flexibility by allowing the blending of purchased MWD water (which is chloraminated) into the LADWP distribution system without the problems associated with creating a chlorine/chloramines interface when blending the two supplies.

5.6 Projected Deliveries

Near-term water deliveries are forecasted for the LAA using two models, the Runoff Forecast Model and the Los Angeles Aqueduct Simulation Model (LAASM). These two models used jointly and accurately predict the amount of water available from this the LAA.

The Runoff Forecast Model is used to predict total Owens Valley and Mono Basin stream runoff. The model's estimating equations were developed using historic rainfall and snowfall, as well as streamflow data of each year. Model input consists of 6 months of antecedent rainfall and streamflow data, as well as the final snowpack levels on April 1st. The model's output is the forecasted runoff for the Owens Valley and Mono Basin during the twelve month period following April 1st, assuming that median rainfall occurs during those twelve months.

Runoff flows from the Owens Valley to the City of Los Angeles are modeled by the LAASM. LAASM uses the output of the Forecast Model as input, along with estimates of various uses within the Owens Valley. LAASM uses historically derived

AR0071597

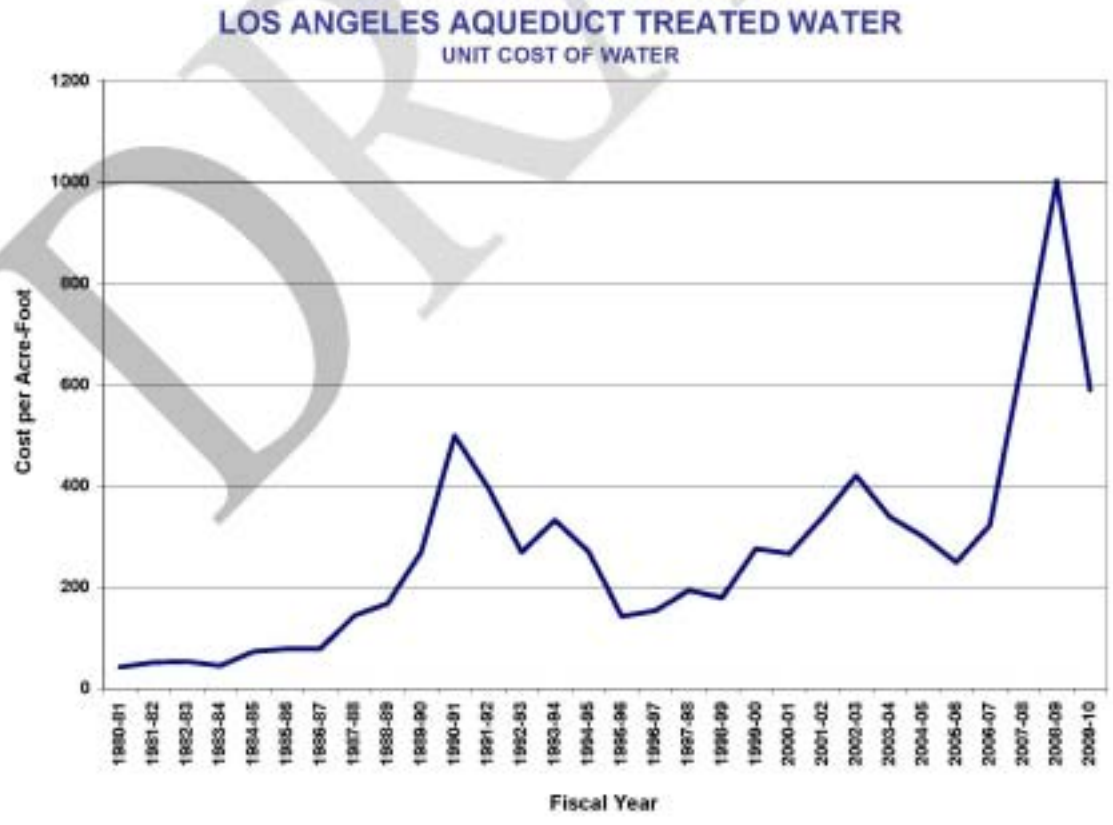
estimating equations to forecast various losses, including evaporation and infiltration, as well as other inflows such as unmetered springs. The final output from LAASM is the volume of LAA water projected to be delivered to the City of Los Angeles.

Taking the foreseeable factors discussed earlier in this chapter into consideration, the average annual long-term LAA delivery over the next 25 years is expected to be approximately 254,000 AFY and gradually decline to 244,000 AFY due to climate change impact. Deliveries for a series of dry years, using 1988/89 through 1992/93 hydrology, are expected to range from approximately 48,520 AFY to 105,770 AFY. A single dry year minimum of 48,520 AFY is expected with a repeat of the 1990/91 hydrology. Detailed LAA projected deliveries by year are provided in Chapter 11, Water Service Reliability Assessment.

5.7 LAA Delivery Cost

The costs associated with LAA water supply are primarily operation and maintenance costs. Therefore, the unit cost of exporting water from LAA to the City varies mainly with the quantity of water delivered and is highly dependent on hydrological conditions. During dry years, the amount of water delivered to the City decreases, which results in an increase to the unit cost. Over the years, eastern Sierra Nevada environmental enhancement projects also contributed to the overall LAA delivery cost, with increasing expenditures when the Owens Lake Dust Mitigation and Lower Owens River Project were initiated. Exhibit 5L summarizes the historical unit cost of treated water from LAA. The peaks occurred when LAA deliveries significantly decreased during fiscal years 1990-91, 2002-03, and 2008-09 with the LAA deliveries of 130,300 AF at $499/AF; 203,400 AF at $419/AF; and 108,500 AF at $1,003/AF respectively.

Exhibit 5L
Historical Cost of LAA Treated Water



AR0071598

Exhibit 5M shows the unit cost of LAA treated water from 2005/06 to 2009/10. The 5-year average was $563/AF. The sharp increase in 2008/09 was due to LAA delivery being the lowest on records.

Exhibit 5M
Annual Unit Cost

Fiscal Year	2005-06	2006-07	2007-08	2008-09	2009-10
Unit Cost	$248	$321	$654	$1,003	$589

DRAFT

AR0071599

DRAFT Chapter Six
Local Groundwater

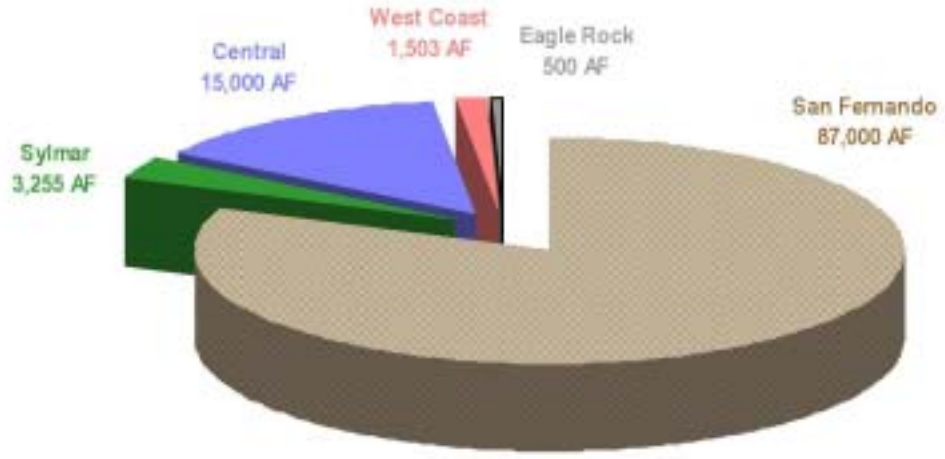
6.0 Overview

A key resource that the City has relied upon as the major component of its local supply portfolio is local groundwater. Over the last ten years local groundwater has provided approximately 12 percent of the total water supply for Los Angeles, and historically has provided nearly 30 percent of the City's total supply during droughts when imported supplies become unreliable. In recent years, contamination issues have impacted LADWP's ability to fully utilize its local groundwater entitlements. Additionally, reduction of natural infiltration due to expanding urban hardscape and channelization of stormwater runoff has resulted in declining groundwater elevations. In response to contamination issues and declining groundwater levels, LADWP is working clean-up of the San Fernando Groundwater Basin, and is making investments to recharge local groundwater basins through stormwater recharge projects, while at the same time replacing or rehabilitating old or deteriorating facilities.

6.1 Groundwater Rights

The City owns water rights in the San Fernando, Sylmar, Eagle Rock, Central, and West Coast Basins. Combined, these water rights total approximately 107,408 AFY. Water rights in the Upper Los Angeles River Area (ULARA), which comprises of the San Fernando, Sylmar, and Eagle Rock basins, total approximately 90,905 AFY which translates into approximately 87,000 AFY in the San Fernando Basin (SFB), 500 AFY in the Eagle Rock Basin, and 3,405 AFY in the Sylmar Basin. Water rights in the Central and West Coast Basin are 15,000 AFY and 1,503 AFY, respectively. However, LADWP does not exercise its pumping rights in Eagle Rock Basin and West Coast Basin at this time. Exhibit 6A summarizes the City's annual local groundwater entitlements by basin. Superior Court Judgments for the San Fernando, Sylmar, Eagle Rock, Central, and West Coast groundwater basins are attached in Appendices X, X, and X, respectively.

Exhibit 6A
Annual Local Groundwater Entitlement



Total: 107,258 AF per year

AR0071600

The ULARA Groundwater Basin Adjudication

The City's entitlements in the San Fernando, Sylmar, and Eagle Rock Basins were established in a Judgment by the Superior Court of the State of California for the County of Los Angeles in Case No. 650079, *The City of Los Angeles, Plaintiff, vs. Cities of San Fernando, et. al., Defendants*, dated January 26, 1979 (San Fernando Judgment) and the 1984 Sylmar Basin Stipulation (1984 Stipulation). Appendix X contains the Judgment and 1984 Stipulation. The Judgment was based on maintaining a safe yield operation for the basin, whereby groundwater extractions over the long-term will be maintained in a manner that does not create an overdraft condition in the basin. The City has no entitlement in the Verdugo Basin but may have the right to recapture a portion of its import return waters upon application to the Watermaster and issuance of an order after a hearing by the Court. The Judgment and 1984 Stipulation limit groundwater extraction from all four groundwater basins and establish a court-appointed Watermaster and an Administrative Committee made up of a representative from each of the five water supply agencies overlying the ULARA Basins. The five public agencies are the City of Los Angeles, the City of Glendale, the City of San Fernando, the City of Burbank, and the Crescenta Valley County Water District.

The Watermaster assists the Court in administering and enforcing the provisions of the 1979 Judgment and 1984 Stipulation. Among other duties, the Watermaster monitors groundwater levels, recharge operations, recycled water use, extractions, water imports and exports, and reports all significant water-related events in the Basin to the Court and to the parties to the Judgments. The activities of the Watermaster are key components for the effective management of the groundwater resources in the ULARA Basins. Key tasks of the Watermaster for the SFB include:

- Monitoring of radiological and synthetic organic compounds (SOCs) every three years;
- To continue to work with key regulators, such as the Los Angeles Regional Water Quality Control Board (LARWQCB), California Department of Public Health (CDPH), California Department of Toxic Substance Control (CDTSC), and the United States Environmental Protection Agency (USEPA), to expedite clean-up of groundwater at or near known contamination sites
- To continue to support the ongoing activities of the City of Los Angeles and others to recharge the groundwater basin at existing spreading basins on the east side of the San Fernando Valley;
- To help determine the technical feasibility of using advanced treated recycled water to recharge the groundwater basin;
- To continue to work with the Los Angeles Department of Public Works, Bureau of Sanitation, Watershed Protection Division, to enhance groundwater recharge of local basins via the Standard Urban Stormwater Mitigation Plans (SUSMP) procedures for stormwater infiltration at new development and redevelopment project sites; and
- To work with local purveyors in an effort to increase the quantity and quality of the groundwater database for the entire ULARA basin.

Historical Groundwater Production

On average over the past five years, about 83 percent (58,575 AFY) of the City's local groundwater supply was extracted from ULARA groundwater basins, while the Central Basin provided 17 percent (12,512 AFY). Exhibit 6B summarizes the City's local groundwater production by basin over the last five years.

DRAFT

Exhibit 6B
Local Groundwater Basin Supply
Fiscal Year (July through June in AF)

Groundwater Basin	2005-2006	2006-2007	2007-2008	2008-2009	2009-2010	Average	Percentage
San Fernando	35,486	75,640	57,060	49,106	62,218	55,902	79%
Sylmar	1,844	3,901	4,046	576	2,998	2,673	4%
Central	13,290	13,358	12,207	11,937	11,766	12,512	17%
Total	50,620	92,899	73,313	61,619	76,982	71,087	100%

Historically, LADWP operates groundwater production by utilizing conjunctive use of surface water and groundwater to optimize the supply and demand balance. Through conjunctive use, the timing of groundwater extractions can be used to meet varying demands. Furthermore, in the past, LADWP prevented against groundwater overdraft during multiple dry years through strategic pumping. When successive dry years occur, LADWP pumped at greater than average rates for the first few years of the drought, and then pumped at lower rates in subsequent years.

However, since 2007, groundwater contamination issues in the SFB have greatly limited LADWP's ability to pump its full groundwater entitlement. As a result, LADWP has been pumping the maximum amount capable that is not impacted by contamination sources, and therefore, has not been able to utilize its conjunctive use strategies for its groundwater operation. When the clean-up of the SFB is complete, LADWP will be able to return to these strategies to ensure reliability and protect from groundwater overdraft.

6.1 San Fernando Basin

The primary source of local groundwater for the City is the SFB providing over 79 percent of the City's groundwater supply ranging from 35,486 AF to 75,640 AF during the period Fiscal Year 2005-2006 to Fiscal Year 2009-2010. The SFB is the largest of the four ULARA basins. It consists of 112,000 acres and comprises 91.2 percent of the total valley in ULARA. It is bounded on the east by the Verdugo Mountains; on the north by the Little Tujunga Syncline and the San Gabriel and Santa Susana Mountains; on west by the Simi Hills; and on the south by the Santa Monica Mountains. A map of the basin is shown in Exhibit 6C. (ULARA Watermaster Service Report, Water Year 2008-2009)

LADWP has ten major wellfields within the SFB containing 115 wells: the Crystal Springs, Headworks, Tujunga, Rinaldi-Toluca, North Hollywood, Erwin, Verdugo, Whitnall, Pollock, and North Hollywood Operable Unit Wellfields. Of the ten major wellfields, LADWP is currently not pumping at Headworks. These wells were generally installed over a period spanning from 1924 to 1991, with the most recent installations being the Rinaldi-Toluca Wellfield in 1988 and the Tujunga Wellfield in 1991. Collectively these ten wellfields have the ability to pump and serve approximately 547 cubic feet per second (cfs) of water, of which the recent Rinaldi-Toluca and Tujunga wells comprise about 38 percent or 210 cfs.

Groundwater Rights

In accordance with the 1979 San Fernando Judgment, the City has the right to all native water within the SFB, based on its Pueblo Rights, and the right to imported water that is delivered and returned to the SFB by the City. With the native safe yield being fixed at 43,660 AFY and the return of imported water averaging approximately 43,000 AFY, the combined total equates to an average SFB entitlement for the City of approximately 87,000 AFY. The return of imported water right for LADWP is based on 20.8 percent of all water delivered within the San Fernando Basin including recycled water. The Judgment provides for storage of water within the basin when the amount pumped is less than the annual entitlement, and a portion of these stored water credits can be pumped in future years to supplement the City's water supply. The direct

DRAFT

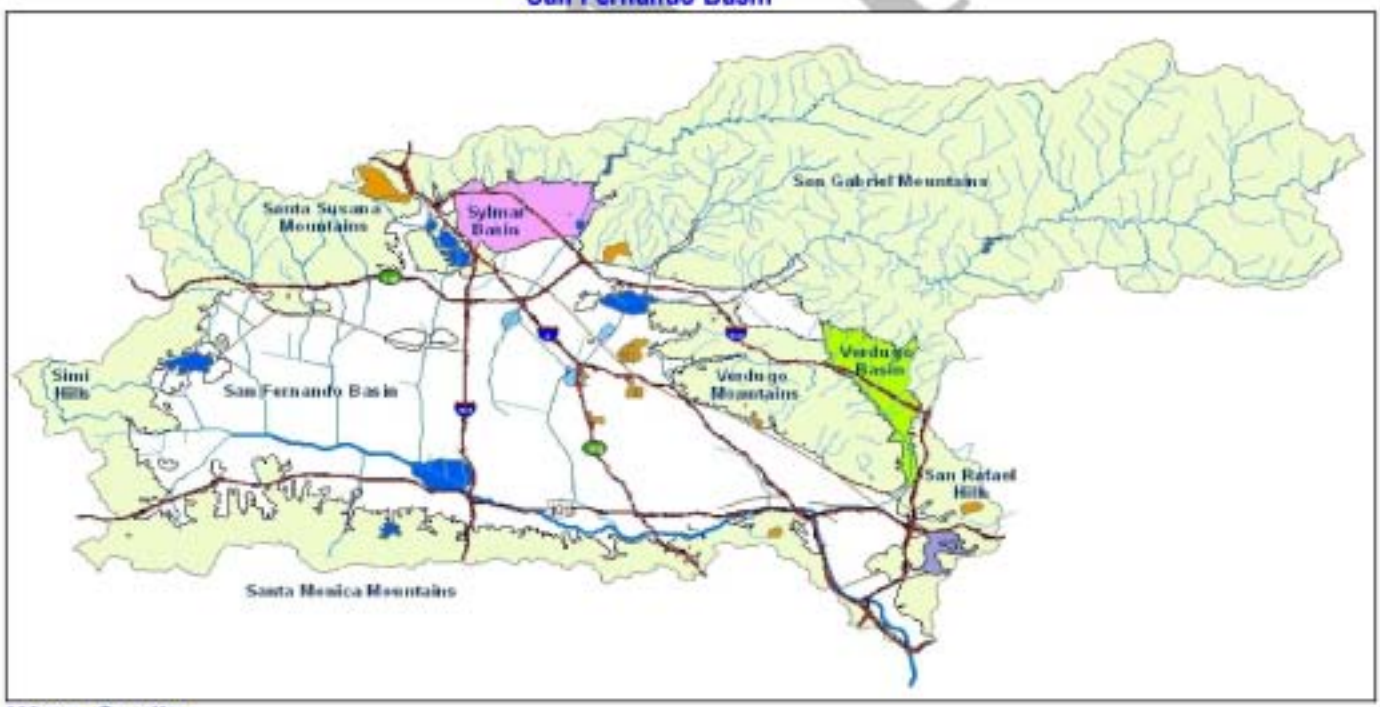
AR0071602

spreading of both imported or recycled water receives 100 percent stored water credit. Increased groundwater pumping due to stormwater capture activities will require an amendment to the Judgment to increase LADWP's groundwater pumping rights based on a demonstrated increase in groundwater levels.

In September 2007, the Cities of Los Angeles, Glendale and Burbank entered into a ten-year Interim Agreement for the Preservation of the San Fernando Basin Water Supply (Interim Agreement). The Interim Agreement is intended to address the overall long-term decrease in stored groundwater within the basin. The Interim Agreement restricts withdrawal of stored water credits and incorporates basin losses into groundwater basin accounting.

Under the Interim Agreement, stored water credits will be reduced for each party by 1 percent annually to account for outflow from the basin. Additionally as described in the Interim Agreement, a proportion of stored water credits available for use during a water year will be calculated for each year, and proportion not available for use during a given year will be reserved for later use. As of October 1, 2009, the City had a stored water credit of nearly 406,313 AF in the SFB, however LADWP's Available Credit or maximum allowable withdrawal of stored water credits for the year beginning October 1 was 108,574 AF. LADWP's Reserve Credits total was 321,316 AF. Reserve Credits (stored water credits minus available stored water credits) will not be available until groundwater levels in the basin recover to a level that will allow for their safe withdrawal. Total Reserve Credits held by all parties in the basin were 376,433 AF as of October 1, 2009.

Exhibit 6C
San Fernando Basin



Water Quality

During well testing in the SFB, trace levels of the contaminants trichloroethylene (TCE), perchloroethylene (PCE), and other volatile organic compounds (VOCs) were detected in the past. The presence of these contaminants is due to improper chemical disposal practices historically conducted by numerous companies in the San Fernando Valley utilizing such materials. Additionally, in the 1990s, detectable amounts of hexavalent chromium and perchlorate were found in various

AR0071603

wells within the SFB. Since the 1990s, SFB wells have also shown a trend of increasing nitrate levels. The source of nitrates is the result of decades of agricultural activity in the San Fernando Valley.

While LADWP is permitted to withdraw its allotted entitlement of 87,000 AFY from the SFB including a portion of its additional stored water, 2007 was the first year LADWP was unable to pump its allotted entitlement due to contamination impacts. LADWP has 115 wells in the SFB of which 54 wells have been inactivated due to contamination. These inactive wells represent a lost pumping capacity of approximately 221 cfs or 40 percent of LADWP's pumping capacity. Of the remaining 61 active wells, with a combined pumping capacity of approximately 326 cfs, 44 have recorded concentrations for various contaminants above the Maximum Contaminant Level (MCL). Most notable among these contaminants of concern are the VOCs (especially TCE, PCE, and carbon tetrachloride), nitrates, and perchlorate. The remaining 17 wells have recorded marginal levels of contamination, mostly due to VOCs. Hexavalent chromium threatens to be a significant future risk to LADWP's wells. Lastly, LADWP's two largest wellfields, Tujunga and Rinaldi-Toluca, which were the most recently-installed wells in an area believed to be outside the known contamination areas, are being significantly impacted by unknown contamination sources.

LADWP has developed programs to accelerate clean-up of the San Fernando Basin which includes a comprehensive Groundwater System Improvement Study, installing monitoring wells, interim wellhead treatment, and working with regulatory agencies and government officials to hold individuals responsible for the contamination responsible to help clean-up efforts.

Agency Cooperation of SFB Remediation

LADWP actively coordinates with the California Department of Public Health (CDPH), Los Angeles Regional Water Quality Control Board (LARWQCB), California Department of Toxic Substance Control (CDTSC), and the United States Environmental Protection Agency (USEPA) to pursue protective and remedial measures for the SFB. The CDPH, LARWQCB, and CDTSC are the three regulatory agencies with enforcement responsibilities within the SFB. The LARRWQCB and the CDTSC issue enforcement directives for pollutant sites and guide the development of cleanup workplans and the cleanup of polluted groundwater sites. The CDPH oversees the quality of potable water from groundwater sources.

In 1987, LADWP entered into a Cooperative Agreement with the USEPA to conduct the "Remedial Investigation of Groundwater Contamination in the San Fernando Valley." Under this agreement, LADWP has received more than $23 million in Federal grants from the USEPA's Superfund Program to carry out: (1) construction, operation, and maintenance of the North Hollywood Operable Unit, which consists of a groundwater treatment facility and a system of eight production wells (construction completed in 1989); and (2) completion of the Remedial Investigation (RI) to characterize the SFB and the nature and extent of its groundwater contamination. The RI included: (a) the installation in 1992 of 88 shallow and clustered monitoring wells that were developed to monitor contamination plumes of TCE, PCE, and nitrates in the SFB; (b) the development of a groundwater flow model (Flow Model) and the preparation of the RI report that was completed for the USEPA in 1992; and (c) on-going monitoring for TCE, PCE, nitrates, and emerging contaminants.

The Flow Model is a three-dimensional computer simulated model of the SFB based on the MODFLOW model program code that was developed by the United States Geological Survey. It consists of four layers that represent the various depth zones of the SFB. Geologic and hydrogeologic data for the basin, which was generated through field investigation, was analyzed to develop the physical site characterization of the basin for the MODFLOW Flow Model. The Flow Model produced simulated groundwater levels, gradients, and their fluctuations as a function of time. Based on field monitoring and

DRAFT

AR0071604

Flow Model simulations, groundwater production strategies are reviewed and adjusted monthly to balance the City's water supply need with SFB management.

San Fernando Basin Contamination Clean-Up Programs

In coordination with other agencies, LADWP has completed or is planning various projects to maintain its rights to use the SFB as a reliable local water supply for the City. The following are some of LADWP's completed, current, and planned projects for the SFB. Recharge projects are discussed separately in Chapter 7, Watershed Management.

Groundwater System Improvement Study

LADWP is working on a 6-year, $19.0-million Groundwater System Improvement Study (GSIS) in the SFB that will provide vital information to assist in developing both short- and long-term projects to maximize the use of the SFB. The $11.5-million GSIS professional service contract was awarded to Brown and Caldwell in February 2009.

The GSIS will aim to cover the following main objectives:

- Provide an independent study to identify, characterize, and evaluate emerging water quality constituents for the San Fernando Basin.
- Provide an independent expert evaluation of LADWP's existing groundwater facilities and its current operational strategies to address current issues on water quality regulations and groundwater treatments. Provide expert advice on the need of refurbishing existing groundwater wells.
- Research and evaluate the need for the installation of new monitoring wells in the SFB to characterize the basin for the constituents of concern.
- Develop a research monitoring program to characterize the nature and extent of the various constituents of concern that may pose a risk to LADWP maximizing the utility of the SFB.
- Provide independent expert recommendations on economically feasible short and long-term capital improvement projects to address all regulatory agency requirements.

Through the GSIS, the LADWP has begun developing a conceptual layout for Groundwater Treatment Facilities in the SFB that will include treatment facilities in the vicinity of LADWP's North Hollywood, Rinaldi-Toluca, and Tujunga Well Fields. It is anticipated that construction of the Groundwater Treatment Facilities could begin as early as July 2015. Construction of the Groundwater Treatment Facilities will greatly reduce LADWP's reliance on costly and scarce imported water supplies and will compliment LADWP's strategies for securing the City of Los Angeles' future water supply through sustainable means. The Groundwater Treatment Facilities will also enable LADWP to benefit from its activities to enhance local supplies through groundwater recharge and stormwater projects. An integral part of LADWP's Groundwater Treatment Facilities will be to work closely with the USEPA and the Cities of Burbank and Glendale to ensure that the facilities operations do not adversely affect the on-going cleanup activities being conducted by the aforementioned agencies. Towards this end, LADWP plans to enter into a Groundwater Management Plan with the USEPA.

As of November 2010, the work progress has included a technical review of USEPA's Focused Feasibility Study for the North Hollywood Operable Unit, preparation of conceptual layouts and renderings for the proposed Groundwater Treatment Facilities in the vicinity of the North Hollywood, Rinaldi-Toluca and Tujunga Well Fields, providing assistance in the planning

DRAFT

AR0071605

aspects for the installation of approximately 40 new monitoring wells in the San Fernando Basin, and providing an independent study to identify, characterize and evaluate emerging water constituents.

Tujunga Wellfield Joint Project. LADWP and MWD have developed a joint project utilizing simple liquid-phase granular activated carbon (GAC) to recover the use of two of the City's contaminated groundwater production wells in the Tujunga Wellfield. The total estimated cost of this project was approximately $7.0 million and was completed in November 2009. LADWP received the permit from the Department of Public Health in May 2010 and started to discharge into the distribution system on May 18, 2010.

Tujunga Wellfield Contamination. The Initial Discovery of the source of contamination at the Tujunga Wellfield by the USEPA and CDTSC is ongoing. Phase I is completed and has not conclusively identified the source of the contamination. The next phase will involve drilling 4-7 deep monitoring wells immediately up gradient of the wellfield to determine the direction of the contamination plumes. The well drilling is expected to be completed late 2011. LADWP is intending to construct up to 22 additional monitoring wells near other wellfields south of the Tujunga Wellfield. Water quality data from the new monitoring wells will assist with further characterizing the groundwater contamination in the SFB. Drilling of these additional wells is expected to begin in Fall 2011 and continue until Winter 2012.

North Hollywood Operable Unit. In 1989, the North Hollywood Operable Unit (NHOU) was placed into service with a capacity of 2,000 gallons per minute (GPM), or 3,230 AF per year. This facility has one aeration tower with vapor-phase granular activated carbon (GAC) air emissions control system. This technology uses air to remove the VOCs from the groundwater and uses the vapor-phase GAC to remove the VOCs from the air stream before it exits into the atmosphere. The fifteen year consent decree expired on December 31, 2004, however, the VOC plume has not been completely remediated. In Water Year 2008-2009, 1,038 AF of VOC contaminated groundwater was treated.

The USEPA is expected to start construction of the NHOU Second Remedy possibly as soon as 2014 to improve containment of contamination from two sites, the Honeywell and Lockheed sites. The primary plume contains high concentrations of VOCs, chromium, and other contaminants of concern. The USEPA issued the Record of Decision (ROD) in December of 2009. The first technical meeting with the potentially responsible party was held in July 2010. A consent decree is expected in early 2011. The ROD recommends more than doubling the capacity plus adding liquid phase GAC (a secondary treatment), construction of 37 monitoring wells, three new extraction wells, deepen existing abandoned well #1, rehabilitation of existing wells, and treatment of chromium and 1-4 Dioxane. As of 2010, Honeywell is continuing its removal of chromium plume at the source of contamination.

Chromium Treatment Research. A cost-effective treatment technology to remove low levels of hexavalent chromium from water does not exist for large scale applications. In 2001, LADWP, along with the Cities of Burbank, Glendale, and San Fernando, and the National Water Research Institute, entered into a research partnership with the American Water Works Association Research Foundation to identify and bench-test new technologies that can remove hexavalent chromium to extremely low levels. This research is being conducted in anticipation of a new standard for hexavalent chromium.

Pollock Wells Treatment Plant. In 1999, the Pollock Wells Treatment Plant was constructed and placed in service. This project was funded by LADWP, and it includes a groundwater treatment facility with four liquid-phase GAC units. Over 3,000 gallons per minute (4,840 AF per year) of groundwater is treated by direct adsorption with GAC to remove VOCs before delivery to customers.

AR0071606

Remedial Investigation. In 1992, the Remedial Investigation to characterize the nature and extent of groundwater contamination in the SFB was completed for the USEPA. The Remedial Investigation activity included the construction of 88 shallow and clustered monitoring wells, which were developed to monitor contamination plumes of TCE, PCE, and nitrates in the SFB. These monitoring wells are also being used to monitor for emerging chemicals. Updated information and reports can be found on USEPA Region 9 Superfund web page.

Biological Treatment Pilot Test . LADWP will be studying the effectiveness of biological treatment on removal of VOCs contaminants from the Tujunga Wellfield groundwater. Biological treatment is a proven technology for removal of perchlorate and nitrate contaminants from groundwater which are also present in the Tujunga Wellfield groundwater. If biological treatment can also effectively remove VOCs from the groundwater, LADWP can significantly reduce the capital as well as future operations and maintenance costs associated with cleanup and removal of contaminants from the Tujunga Wellfield groundwater.

Pilot Test of Advance and Emerging Groundwater Treatment Technologies. LADWP is investigating the utilization of other advance and/or emerging groundwater treatment technologies for removal of VOCs and perchlorate for possible pilot study(ies) at the Rinaldi-Toluca Wellfield within the next few years.

6.2 Sylmar and Eagle Rock Basins

The Sylmar Basin has provided slightly over 4 percent of the City's local groundwater ranging from 576 AF to 4,046 AF from Fiscal Year 2005-2006 through Fiscal Year 2009-2010. The Sylmar Basin, in the northern part of ULARA, consists of 5,600 acres and comprises 4.6 percent of the valley in ULARA. It is bounded on the north and east by the San Gabriel Mountains; on the west by a topographic divide in the valley fill between the Mission Hills and the San Gabriel Mountains; and on the south by the Little Tujunga syncline, which separates it from the SFB. (ULARA Watermaster Service Report, Water Year 2008-2009) LADWP originally had a total of 3 production wells installed in the Sylmar Basin between 1961-1977. One of these wells was removed from service and is no longer utilized. The remaining wells have the capacity to pump 5 cfs.

The Eagle Rock Basin is the smallest of the four basins. It is located in the extreme southeast corner of ULARA. It consists of 800 acres and comprises 0.6 percent of the total valley. LADWP is not pumping in the Eagle Rock Basin currently. The safe yield of Eagle Rock Basin is derived from imported water delivered by LADWP. There is no measurable native safe yield. LADWP has the right to extract the entire safe yield of the basin. Currently, the groundwater is being pumped by a private party and LADWP is reimbursed for such pumping in accordance with the San Fernando Basin Judgment.

Groundwater Rights

In 1996 upon the recommendation of the Watermaster, the ULARA Administrative Committee approved a temporary safe yield increase for the Sylmar Basin thus temporarily increasing LADWP's rights from 3,105 AFY to 3,255 AFY for a ten-year period. Per the 1984 Stipulation, the safe yield minus private party overlying rights are to be equally split between LADWP and the City of San Fernando. In 2006, a subsequent evaluation of the safe yield was conducted and completed in accordance with Section 8.2.10 of the 1984 Stipulation. Upon recommendation of the parties, the Court approved a new stipulation further increasing the temporary safe yield of the basin and resulting in a temporary increase in LADWP's rights to 3,405 AFY subject to multiple conditions. Conditions imposed on LADWP and the City of San Fernando include installing groundwater monitoring wells to assist in determining basin outflows. This new stipulation became effective on October 1, 2006 and is set to expire on October 1, 2016. As required by the 2006 Stipulation, the safe yield will be re-evaluated by October 1, 2011 and may result in a recommendation for additional changes to the safe yield of the Sylmar Basin.

DRAFT

AR0071607

Stored water credits accumulated in the basin are determined by adding the previous years stored water credit and the extraction right for the previous year together and then subtracting the actual extractions for the previous year. As of October 1, 2009, LADWP has accrued 9,423 AF of stored water credits in the Sylmar Basin. In 2006, the Watermaster recommended LADWP begin pumping these rights due to the large amount of stored water credits. LADWP has proposed the Mission Wells Improvement Project to initiate pumping the credits and to replace the existing wells that have significantly deteriorated. As proposed, the project consists of constructing a water tank, three wells, and other operational facilities at the Mission Wellfield. Phase 1 was completed in February 2009 and involved replacement of the water tank that was beyond its useful life. Phase 2 is in the planning stages and consists of three new wells with operational facilities and is forecast for completion in August 2014. These new facilities will allow LADWP to pump its current entitlement of 3,405 AFY on an annual basis and draw from its existing stored water credits.

Water Quality

Groundwater quality issues have occurred in the Sylmar Basin related to TCE contamination at one of the two production wells. The effluent from the wellfield is managed in such a way that the groundwater quality meets or surpasses water quality standards. Primary limitations on pumping are related to the deterioration of pumping facilities and not contamination. However, the Mission Wells Improvement Project as previously discussed, will replace the deteriorated wells and increase production capacity to allow LADWP to pump its annual water rights.

6.3 Central Basin

From Fiscal Year 2005-2006 through Fiscal Year 2009-2010 the Central Basin has provided on average approximately 17 percent of LADWP's local groundwater supply ranging from 11,766 AF to 13,358 AF through wells in two major production fields. The Central Basin Watermaster Service area overlies about 227 square miles of the Central Basin in the southeastern part of the Los Angeles Coastal Plain in Los Angeles County. The Watermaster Service Area is bounded by the Newport-Inglewood Uplift on the southwest, the Los Angeles-Orange County line on the southeast, and an irregular line that approximately follows Stocker Street, Martin Luther King Boulevard, Alameda Street, Olympic Boulevard, the boundary between the City of Los Angeles and unincorporated East Los Angeles, and the foot of the Merced and Puente Hills on the north. Twenty-three incorporated cities and several unincorporated areas are within the Central Basin Watermaster Service Area. Groundwater within the basin provides a large portion of the water supply needed by overlying residents and industries. In Fiscal Year 2008-2009 there were 140 parties with rights to water within the Central Basin (Central Basin Watermaster Service Report, Fiscal Year 2009-2010).

Two LADWP facilities provide groundwater supplies in the Central Basin, the Manhattan Wells and the 99th Street Wells. The active Manhattan Wells were installed between 1928-1974 and have a production capacity of 16.9 cfs. Wells at the 99 th Street location were installed between 1974-2002 and have a production capacity of 7.4 cfs. While the 99th Street Wells are newer and have relatively little mechanical or other problems, the Manhattan Wells are much older and have experienced maintenance problems and are approaching the end of their useful life. To restore the City's pumping capacity, LADWP is working on plans to install two new production wells, replace two deteriorated wells, and improve other related facilities at the Manhattan site.

Groundwater Rights

More than 50 years ago, groundwater overdraft and declining water levels in the Central Basin threatened the area's groundwater supply and caused seawater intrusion in the southern part of the Basin. However, timely legal action and adjudication of the water rights halted the overdraft and prevented further damage to the Basin. Today, groundwater use in the Basin is restricted to the allowed pumping allocations by a 1966 Superior Court Judgment and is monitored by a court-

DRAFT

AR0071608

appointed Watermaster, the Department of Water Resources (DWR). Annually, the Watermaster prepares a Watermaster Service Report indicating groundwater extractions, replenishment operations, imported water use, recycled water use, finances of Watermaster services, administration of the water exchange pool, and significant water-related events in the Basin.

The City's entitlement in the Central Basin of 15,000 AFY was established in a judgment by the Superior Court of the State of California for the County of Los Angeles through the Central Basin Judgment (Case No. 786,656 –second amended judgment). In addition to its annual entitlement, the Central Basin Judgment allows for carryover of unused water rights up to a maximum total cumulative amount of 20 percent of the purveyor's pumping allocation and also allows for over extraction of an additional 20 percent under emergency situations that would be debited against the purveyor's following year entitlement. The City uses its carryover storage right for operational flexibility and conjunctive use. LADWP has allowable carryover storage of 3,000 AF into Fiscal Year 2010-2011.

The Central Basin Judgment does not permit storing water in the basin for later extraction. Through the assistance of a facilitator, multiple parties with groundwater rights within the Central Basin have developed draft framework to allow conjunctive use groundwater storage in the basin and have filed to request amendment of the Judgment to allow groundwater storage.

Water Quality

Although the Manhattan and 99th Street Well fields in the Central Basin are located only approximately 4 miles apart, there is a large difference in water quality between the facilities. One of the Manhattan Wells currently exceeds the MCL of 5 ppb for TCE. The effluent from the wellfield is managed in such a way that the groundwater quality meets or surpasses water quality standards.

Water from 99th Street Wellfield complies with the National Primary Drinking Water Regulations, but requires treatment to comply with the National Secondary Drinking Water Regulations for manganese and iron. These contaminants are not considered to present a risk to human health, but at existing concentrations the contaminants may present taste, color, and odor problems. Corrosion control treatment using zinc orthophosphate as a sequestering agent and sodium hypochlorite to oxidize manganese has been in place at the wellfield for twenty years. Hydrogen sulfide is also present but not an imminent threat to the reliability of this well supply when chlorinated. In 2002, two new wells were drilled and placed into operation. During the first several months of operation of the new wells, numerous color complaints were received from customers. Adjustments in the treatment process were made which improved water quality.

6.4 West Coast Basin

LADWP has not been able to pump its water entitlement from the West Coast Basin since 1980 due to localized groundwater contamination issues and deterioration of the wells at the Lomita Wellfield. The West Coast Basin underlies 160 square miles in the southwestern part of the Los Angeles Coastal Plain in Los Angeles County. The Basin is bounded on the west by Santa Monica Bay, on the north by Ballona Escarpment, on the east by the Newport-Inglewood Uplift, and on the south by San Pedro Bay and the Palos Verdes Hills. Twenty incorporated cities and several unincorporated areas overlie the Basin (West Coast Basin Watermaster Service Report, Fiscal Year 2009-2010).

Groundwater Rights

In 1945, when intrusion of sea water caused by declining water levels threatened the quality of the groundwater supply, legal action was taken to halt the overdraft and prevent further damage to the West Coast Basin. In 1955, the Superior Court of

DRAFT

AR0071609

Los Angeles County appointed the DWR as the Watermaster to administer an Interim Agreement, and in 1961, the Court retained the DWR as the Watermaster of the Final West Coast Basin Judgment (Case No. 506,806 –amended judgment). Similar to the Central Coast Basin, an annual Watermaster Service Report is prepared. The West Coast Basin Judgment provided the City with a right to 1,503 AFY of groundwater.

Water Quality

Groundwater quality problems in the West Coast Basin were previously related to high levels of total dissolved solids and chlorides. LADWP abandoned operations in the basin in September of 1980 with closure of the Lomita Well Field, and intends to study the feasibility and cost of restoring groundwater pumping.

6.5 Water Quality Goals and Management

The groundwater management efforts that LADWP has undertaken have resulted in all groundwater delivered to customers meeting or exceeding all water quality regulations. As part of its regulatory compliance efforts, LADWP works with the California Department of Public Health (CDPH) to perform water quality testing on production and monitoring wells.

Groundwater Monitoring

LADWP conducts nearly 250,000 field and laboratory tests on more than 25,000 samples collected throughout the year for hundreds of different chemicals such as arsenic, chromium, lead, and disinfection by-products to ensure that they are will within the safe levels before we serve the water to our customers

Every well that is pumped to supply water to the City is actively monitored by LADWP as required by CDPH. LADWP's groundwater monitoring program is comprised of several distinct components, including monitoring of metals, coliform bacteria, inorganics, volatile organic compounds (VOCs) and unregulated compounds such as vanadium, boron, and perchlorate. The frequency and level of monitoring (i.e., annually, quarterly, or monthly), depending on the level of contamination found in each well.

Monitoring for all contaminants is performed at entry points into the distribution system in close proximity to where the water is being pumped from the wells. If water quality problems are detected, the well source is immediately isolated and retested.

Operating Goals

LADWP has established operating goals for TCE, PCE, nitrates, perchlorate, and total chromium that are more stringent than the maximum contaminant levels (MCLs) permitted by Federal or State regulations. These stricter operational goals provide an additional safety margin from these contaminants for City customers. Exhibit 6D summarizes these water quality goals and compares them with the State-regulated requirements, which are generally more stringent than Federal requirements.

DRAFT

AR0071610

Exhibit 6D
Operating Limits of Regulated Compounds

Compound	State of California Limit	LADWP Operational Goals	LADWP Added Safety Margin
Trichloroethylene (TCE)	5 ppb	3 ppb	40%
Perchloroethylene (PCE)	5 ppb	3 ppb	40%
Nitrate (N03)	45 ppm	30 ppm	33%
Perchlorate (ClO4)	6 ppb	4 ppb	33%
Total Chromium	50 ppb	30 ppb	40%

TCE and PCE compounds are commonly used in industries requiring metal degreasing. PCE is also used in dry cleaning and automotive repair industries.

Nitrate is a concern because of its acute effect of impeding the uptake of oxygen to the blood. Infants (who are in the earliest stages of development) are most sensitive to the effects of nitrates. The current standard for nitrate is 45 parts per million (ppm). A single exceedence of the nitrate standard is classified as an acute violation requiring immediate public notification. Treatment for nitrates may eventually become necessary for affected City groundwater supplies.

In October 2007, a MCL was adopted for perchlorate of 6 ppb. Perchlorate is an inorganic compound that is most commonly used in the manufacture of rocket fuels, munitions, and fireworks. In addition to its detection in groundwater, the compound has also been detected in Colorado River Aqueduct water.

Managing Emerging Contaminants of Concern

LADWP addresses emerging contaminants on many levels: 1) by encouraging the development of standardized testing to enable early detection, and supporting the regulatory framework by providing early occurrence data, 2) by advocating good science and a balanced approach to risk assessment, 3) by seeking to gain a risk perspective with other existing contaminants to manage the emerging contaminants in the absence of regulations, 4) by supporting early interpretation of emerging contaminants in collaboration with research and regulatory agencies, and 5) by supporting the research to develop cost-effective treatment for the removal and management of these emerging contaminants.

An example of how LADWP addresses an emerging contaminant is chromium VI (otherwise known as hexavalent chromium). Hexavalent chromium does not have an enforceable drinking water standard at this time. However, hexavalent chromium is included in the State total chromium standard of 50 ppb. CDPH is expected to establish drinking water standards for the compound in the near future. Chromium is a heavy metal that has been used in industry for various purposes including electroplating, leather tanning, and textile manufacturing, as well as controlling biofilm formation in cooling towers. LADWP began low level monitoring of hexavalent chromium long before monitoring was required by regulators. LADWP supported new health-effects research needed to support risk assessment, and advocated a balanced approach to risk management. LADWP funded research to develop new treatment technologies to reduce hexavalent chromium detection levels.

Most recent among emerging contaminants are pharmaceutically active compounds and personal care products that are finding their way into rivers, lakes, and waterways from urbanized areas. There are concerns about the occurrence and effects of endocrine disrupters, hormone-shifting compounds, and pharmaceuticals. Technology now allows the detection of compounds down to the parts per trillion levels, thus some of these compounds are now being detected. The risk

DRAFT

assessment field is finding it difficult to keep pace with advances in analytical technology. The question of these contaminants posing a health risk at low levels needs more investigation. LADWP will continue to proactively address emerging contaminants through early monitoring and utilization of a balanced approach to risk management.

LADWP will be incorporating appropriate treatment processes into future groundwater treatment facilities. LADWP has and will continue to solicit input from stakeholders to properly plan and develop processes for removal and treatment of emerging contaminants. LADWP's Recycled Water Advisory Group (RWAG) is an example of ongoing efforts to solicit input.

6.6 Groundwater Pumping Cost

The costs associated with groundwater pumping are primarily operation and maintenance costs. Therefore, the unit cost of groundwater pumping varies mainly with the quantity of water delivered. Exhibit 6F summarizes the historical unit cost of groundwater pumping.

Exhibit 6F
Historical Cost of Groundwater Pumping

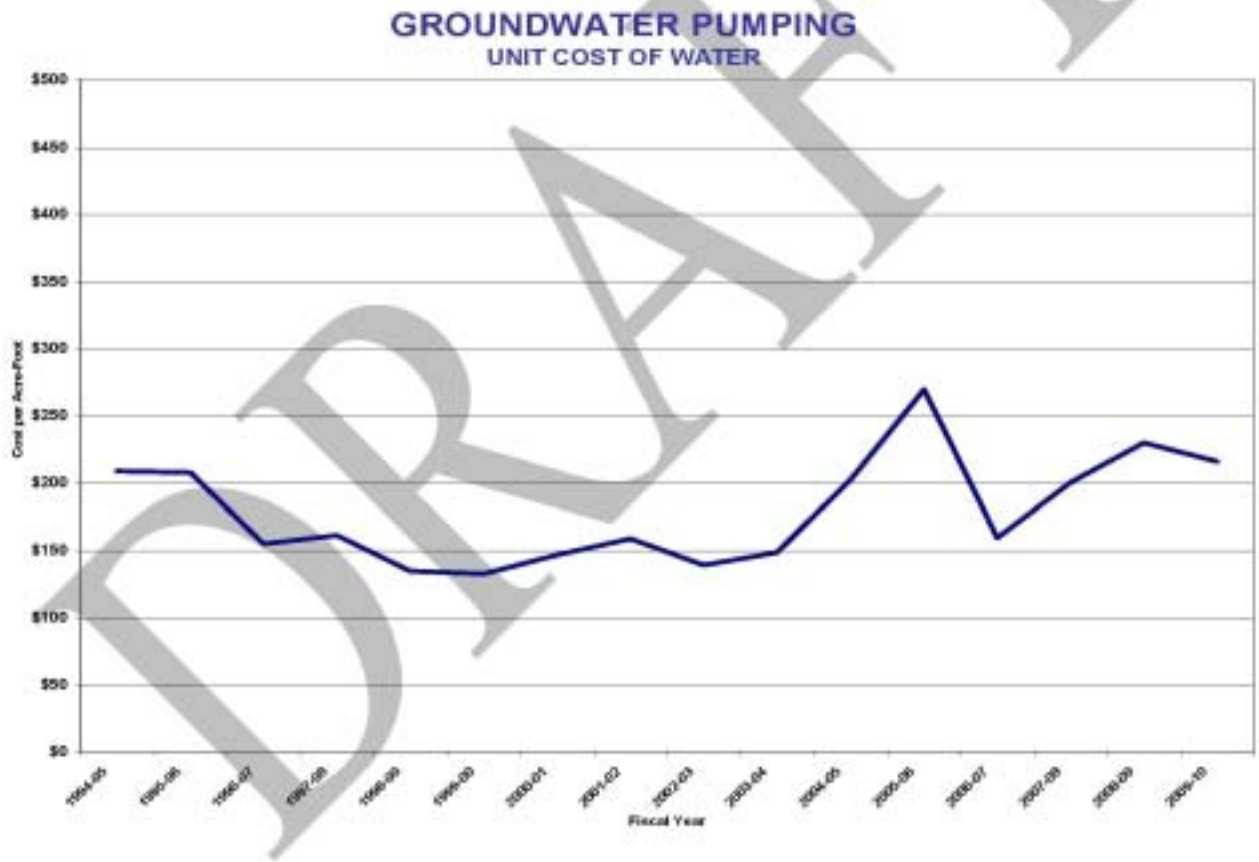


Exhibit 6G shows the unit cost of groundwater pumping from fiscal year 2005/06 to 2009/10. The 5-year average was $215/AF.

DRAFT

AR0071612

Exhibit 6G
Annual Unit Cost

Fiscal Year	2005-06	2006-07	2007-08	2008-09	2009-10
Unit Cost	$270	$160	$200	$230	$216

6.7 Groundwater Production Projections

Historically, with conjunctive use management of groundwater, storing imported water in the groundwater basins during wet and normal years, groundwater production can actually be increased during dry years. LADWP operated its groundwater resources in this manner. On average, LADWP pumped its adjudicated right of approximately 107,000 AFY, but in dry years LADWP could pump larger quantities of groundwater. For the purposes of an average, single-dry, and multi-dry year drought analysis, after the implementation of the purification complex for SFB and completing the construction of new wells in Sylmar and Central Basins, 110,405 AFY is assumed to be the City's local groundwater production in 2035. After completion of the purification complex for the SFB, if successive dry years occur, LADWP would likely pump at greater-than-average levels for the first few dry years, then start pumping at lower levels in order to prevent groundwater overdraft. LADWP would then replenish the groundwater in wet or normal years following the successive dry period. Exhibit 6E provides groundwater pumping projections by basin between 2010 and 2035 for average, single-dry, and multi-year dry weather conditions in five-year increments.

Exhibit 6E
Groundwater Production 2010 to 2035 for Average, Single-Dry, and Multi-Year Dry Weather Conditions
By Fiscal Year

Basin	FY 2009-10	FY 2014-15	FY 2019-20	FY 2024-25	FY 2029-30	FY 2034-35
	AFY					
San Fernando	62,218	21,000	76,800	92,000	92,000	92,000
Sylmar	2,998	4,500	4,500	4,500	4,500	3,405
Central	11,766	15,000	15,000	15,000	15,000	15,000
Total	76,982	40,500	96,300	111,500	111,500	110,405

- 2015 San Fernando pumping levels are decreased due to anticipated well contamination from plume migration.
- Assumes existing annual rights to 87,000 AFY in SFB will remain unchanged. The Purification Complex is expected to be in operation in 2018-19. Storage credit of 5,000 afy will be used to maximize the pumping thereafter.
- Sylmar Basin production temporarily increases to 4,500 AFY to avoid the expiration of stored water credits then return back to the entitlement of 3,405 AFY in 2030-31.

Not included in the figures above is increased groundwater pumping due to groundwater replenishment of advanced treated wastewater, as well as enhanced stormwater recharge. This Urban Water Management Plan projects increased groundwater pumping through groundwater replenishment of advanced treated wastewater of 15,000 AFY, and increased groundwater pumping through enhanced storm water recharge of and additional 15,000 AFY, both by 2035.

AR0071613

DRAFT Chapter Seven
Watershed Management

7.0 Overview

This Urban Water Management Plan projects stormwater capture providing increased groundwater pumping rights in the San Fernando Basin of 15,000 AFY, and 10,000 AFY of additional water conservation from capture and reuse solutions such as rain barrels and cisterns, for a total of 25,000 AFY by fiscal year ending 2035. The Stormwater Capture Master Plan (refer to Section 7.3 below) will comprehensively evaluate stormwater capture potential within the City.

Stormwater runoff from urban areas is an underutilized resource. Within the City of Los Angeles, the majority of stormwater runoff is directed to storm drains and ultimately channeled into the ocean. Unused stormwater reaching the ocean also carries with it many pollutants that are harmful to marine life. In addition, local groundwater aquifers that should be replenished by stormwater are receiving less recharge than in the past due to increased urbanization. Urbanization has increased the City's hardscape, which has resulted in less infiltration of stormwater and a decline in groundwater elevations.

In addition, development has encroached onto the floodplains requiring the channelization of large waterways that once recharged the groundwater aquifers with large volumes of stormwater runoff. When the floodplains were undergoing rapid development, LADWP and the Los Angeles County Flood Control District (LACFCD) reserved several parcels of land for use as spreading facilities, which are adjacent to some of the largest tributaries of the Los Angeles River, and the Pacoima and Tujunga Washes.

During average and below average years, these spreading facilities are very effective at capturing a large part of the stormwater flowing down the tributaries. However they are incapable of capturing a significant portion of the flows during wet and extremely wet years. Weather patterns in Los Angeles historically are highly varied between very wet years and very dry years. Some climate studies predict that these patterns may become more extreme.

Furthermore, a significant portion of the watershed is not located adjacent to large tributaries and therefore, cannot be served by existing spreading facilities. These areas are the urbanized low-lying flatlands that also produce stormwater, therefore a strategy to create and implement distributed stormwater infiltration solutions is needed. These distributed solutions include widespread, smaller projects at the neighborhood scale and landscape changes at the individual parcel scale.

With the increased attention being placed on stormwater capture, other challenging conditions beyond imperviousness and climate patterns have been identified. These include antiquated spreading facilities, landfills adjacent to spreading, floodplain encroachment, substructures, and other man-made conditions that limit the ability to capture stormwater for later use. Some conditions such as the antiquated delivery systems at the spreading facilities can easily be retrofitted with new gates and telemetry. Whereas other conditions such as the presence of large sanitary landfills adjacent to recharge facilities, are more difficult to rectify.

In January 2008, LADWP created the Watershed Management Group which is responsible for developing and managing the water system's involvement in emerging issues associated with local and regional stormwater capture. The Watershed Management Group coordinates activities with other agencies, departments, stakeholders and community groups for the purpose of planning and developing projects and initiatives to improve stormwater management within the City. The Group's primary goal is to increase stormwater capture by enhancing existing centralized stormwater capture facilities and promoting

AR0071614

distributed stormwater infiltration systems to achieve the City's long-term strategy of enhancing local stormwater capture. While working to increase stormwater capture for improving long-term groundwater reliability, other watershed benefits can be achieved including increased water conservation, improved water quality, open space enhancements, and flood control.

Additionally, the City is investigating recharge of the San Fernando Basin (SFB) with advanced treated recycled water. A more in-depth discussion of efforts to maximize groundwater recharge with advanced treated recycled water is provided in Chapter 4, Recycled Water.

7.1 Importance of Watershed Management to Groundwater Supplies

Managing native stormwater is a necessary step towards maintaining groundwater elevations in the underlying groundwater basin. Urbanization and its associated increase in impervious surfaces has altered the ability of groundwater basins to naturally replenish pumped groundwater. Stormwater systems in the City were designed primarily for flood control to convey stormwater runoff to the Pacific Ocean as quickly as possible, therefore minimizing the potential for flooding or damage to structures while maximizing land available for development. Within LADWP's service area, the SFB is the most amenable to regional stormwater capture and recharge through spreading basins because of its predominantly sandy soils. However, stormwater once percolated into the groundwater in the underlying SFB is being channeled across impervious surfaces then through concrete-lined canals or conduits to areas outside of the San Fernando Valley.

The essential task of watershed management is to retain as much stormwater runoff as possible for groundwater recharge. Groundwater recharge is the process of increasing an aquifer's water content through percolation of surface water. This occurs in the SFB primarily with captured stormwater, and imported water. Groundwater recharge is essential to maintain groundwater supplies, address the overall long-term decrease in stored groundwater within the SFB, and ensure the long-term water supply reliability of the basin. Furthermore, increasing groundwater recharge and improving the groundwater levels of the SFB could potentially lead to larger pumping rights for LADWP in the future.

During storm events, large portions of stormwater are captured with existing facilities for spreading purposes. LADWP coordinates these activities with the Los Angeles County Department of Public Works Flood Control District (LACFCD) to effectively recharge the SFB through the spreading of native stormwater. Flood control facilities are the primary means to divert native runoff into the spreading ground facilities listed and mapped on Exhibits 7A and 7B. LACFCD oversees operations at the Branford, Hansen, Lopez, and Pacoima Spreading Grounds. The Tujunga Spreading Grounds are operated by LACFCD in partnership with LADWP. LADWP has the ability to spread imported supplies at the Tujunga Spreading Grounds and the Pacoima Spreading Grounds for storage in the SFB, but LADWP has not utilized imported water for groundwater recharge since 1998.

7.2 Additional Benefits of Watershed Management

Watershed management provides additional important benefits to the City of Los Angeles, including surface water quality improvements, water conservation, open space enhancements, and flood control.

Water quality improvements are necessary because stormwater runoff is a conveyance mechanism that transports pollutants from the watershed into waterways and ultimately the Pacific Ocean. Pollutants include, but are not limited to, bacteria, oils, grease, trash, and heavy metals. The City must also comply with adopted Total Maximum Daily Loads (TMDLs) for pollutants. TMDLs set maximum limits for a specific pollutant that can be discharged to a water body without causing the water body to become impaired or limiting certain uses, such as water body contact during recreation. In 2008, the Los Angeles Board of Public Works adopted the Water Quality Compliance Master Plan for Urban Runoff (WQCMPUR). This 20-year plan provides a strategy for cleaning stormwater and runoff to protect the City's waterways and the Pacific Ocean. Capturing stormwater runoff for groundwater recharge removes a portion of the pollutant conveyance mechanism reducing downstream pollution thereby assisting the City with water quality compliance and improving the overall health of its waterways.

Water conservation is achieved by enhancing the capture and management of localized runoff for local uses. Centralized and distributed mechanisms that provide for water conservation include spreading grounds, rain barrels, and residential cisterns.

Open space enhancement is an added benefit of groundwater recharge projects, which typically provide additional open space areas that may include passive and/or active recreation, educational opportunities, and habitat restoration. Most projects involve increasing vegetation and recreational amenities to create opportunities for wildlife habitat and a recreational/educational resource for the local community. Additionally, open space enhancements assist the City in improving the overall quality of life for residents.

Flood control benefits are achieved when additional storage capacity is added to the storm drain system. Groundwater recharge projects reduce potential flooding by diverting a portion of storm flows into recharge areas, thereby increasing the overall capacity of the storm drain system.

7.3 Stormwater Capture Master Plan

The Stormwater Capture Master Plan (Master Plan) will investigate potential strategies for advancement of stormwater and watershed management in the City. The Master Plan will be used to guide decision makers in the City when making decisions affecting how the City will develop both centralized and distributed stormwater capture goals. The Master Plan will include evaluation of existing stormwater capture facilities and projects, quantify the maximum stormwater capture potential, develop feasible stormwater capture alternatives (i.e., projects, programs, potential policies, etc.), and provide potential strategies to increase stormwater capture. The Master Plan will also evaluate the multi-beneficial aspects of increasing stormwater capture, including potential open space alternatives, improved downstream water quality, and peak flow attenuation in downstream channels, creeks, and streams such as the Los Angeles River.

The Master Plan will recommend stormwater capture projects, programs, policies, and incentives for the City of Los Angeles.

Benefits of the Master Plan include:

AR0071618

- Investigate stormwater capture models such as the Groundwater Augmentation Model and the Watershed Management Modeling System to identify maximum potential groundwater recharge
- Increased water conservation
- Improved water quality
- Reduced peak flow in the Los Angeles River

Project partners and supporters include:

- City of Los Angeles Department of Water and Power
- City of Los Angeles Department of Public Works
- County of Los Angeles Department of Public Works
- TreePeople, Inc.

7.4 Tree People – Memorandum of Agreement

The Memorandum of Agreement (MOA) with TreePeople has been forged to facilitate a high-level of collaboration between LADWP and TreePeople with the aim of fostering a more sustainable Los Angeles. The partnership it outlines leverages TreePeople's experience in public education and agency integration to further the long-term sustainability objectives of LADWP. Specifically, LADWP and TreePeople are working together to research opportunities within LADWP's facilities and operations for widespread groundwater recharge. This research includes an educational component wherein LADWP and TreePeople learn about each other's initiatives and core business. Ultimately, this exchange of ideas will help the two partners develop concepts for projects that will increase stormwater capture for groundwater recharge.

LADWP was an early sponsor for the TreePeople Trans-agency Resources for Environmental and Economic Sustainability (T.R.E.E.S.) Project, during which time TreePeople developed best management practices for capturing, cleaning and using stormwater; published the handbook Second Nature; created a computerized cost-benefit model; and facilitated a number of design workshops for public agencies. TreePeople has also been integral to the construction and management of three demonstration sites -- a single-family home (Hall House) retrofitted to capture all the rainwater onsite, and two elementary schools (Broadous and Open Charter) that feature strategic landscaping and a cistern or underground infiltrators. LADWP has supported public tours and educational materials for Hall House, and is a key partner in the school projects which were partially funded through the Cool Schools and Sustainable Schools programs.

The overlap between the objectives of LADWP and those of TreePeople is notable in the Tujunga Wash and Sun Valley watersheds, where both have been especially active. Stakeholder processes where the two have worked successfully to further mutual goals including the City's Integrated Resources Plan, the Integrated Regional Water Management Plan, and objectives of the California Urban Water Conservation Council.

7.5 Centralized Stormwater Capture Projects

Existing stormwater capture facilities are inadequate for capturing runoff during very wet years. Weather patterns vary dramaticly in Los Angeles with very wet years and very dry years. Therefore, new projects are necessary to expand the

DRAFT

AR0071619

capability to capture a larger portion of stormwater flows during wet years. LADWP is working proactively in close partnership with LACFCD on multiple stormwater projects, as listed in Exhibit 7C. These projects will increase centralized stormwater recharge capacity by approximately 26,000 AFY in the SFB, raising groundwater levels and ensuring the future water supply reliability of the SFB. These projects are designed to maximize groundwater recharge into the basin by increasing the total average recharge to approximately 51,700 AFY.

Multiple opportunities exist to develop new recharge projects and improve existing recharge projects in the SFB. LADWP, in collaboration with LACFCD has supported and contributed resources toward the design, construction, and implementation of a variety of projects to increase groundwater recharge of the SFB. Additionally, multiple agreements between LADWP and LACFCD have been approved to facilitate preparing recharge studies, design work, and construction of projects in the SFB for groundwater recharge, flood protection, and other benefits.

Exhibit 7C
Planned LADWP Centralized Stormwater Capture Projects and Expected Annual Recharge

Project	Current Annual Recharge (AFY)	Increased Annual Capture/ Recharge (AFY)	Expected Annual Recharge (AFY)	Estimated Project Completion	Total Project Cost (millions)	LADWP Share (millions)
Sheldon-Arleta Gas Collection System	-	4,000 [1]	-	Complete Nov 2009	$8.2	$6.3
Big Tujunga Dam Rehabilitation [3]	-	4,500	-	Sep 2011	$105.7	$9.0
Hansen Spreading Grounds Upgrade	13,834	1,200	17,284 [2]	Dec 2011	$9.3	$4.8
Tujunga Spreading Grounds Upgrade	4,419	8,000	18,669 [4]	2015	$24.0	$24.0
Pacoima Spreading Grounds Upgrade	6,453	2,000	8,453	2015	$32.0	$16.0
Lopez Spreading Grounds Upgrade	527	750	1,277	2016	$8.0	$4.0
Strathern Wetlands Park	-	900	900 [5]	2016	$46.0	$4.0
Hansen Dam Water Conservation	-	3,400	3,400	2017	$5.0	$2.5
Valley Generating Station Stormwater Capture	-	700	700	2018	$9.7	$9.7
Branford Spreading Basin Upgrade	549	500	1,049	2018	$4.0	$2.0
Total Estimated Yield	**25,782**	**25,950**	**51,732**		**$251.9**	**$82.3**
Total Expenditure-to-date						$18.6
Total Expenditure Remaining						$63.7

1. This will allow increased collection of 4,000 AFY at Tujunga Spreading Grounds.
2. Includes 1/2 benefits from Big Tujunga Dam Rehabilitation Project.
3. No recharge occurs at the facility. All additional capture has been divided between Hansen & Tujunga Spreading Grounds.
4. Including benefits from Sheldon-Arleta Project and 1/2 benefits from Big Tujunga Dam Rehabilitation Project.
5. To be recharged at Sun Valley Park.

DRAFT

Sheldon-Arleta Methane Gas Collection Project. In 1998, a Task Force comprised of representatives from LADWP, other City Departments (Bureau of Sanitation (BOS), Bureau of Engineering, and Environmental Affairs) and the Upper Los Angeles River Area Watermaster was formed to review the issues surrounding the recharge of groundwater through spreading at the Tujunga Spreading Grounds. The objective of this Task Force was to maximize water spreading at the Tujunga Spreading Grounds without causing off-site landfill gas migration. An outcome of the Task Force was the Sheldon-Arleta Methane Gas Collection Project. The project is designed to restore the original Tujunga Spreading Grounds capacity of 250 cubic feet per second (cfs) with the potential for future enhancement by bringing the Tujunga Spreading Basins closest to the Sheldon-Arleta landfill back online. The Tujunga Spreading Grounds are located adjacent to the closed Sheldon-Arleta Landfill. During spreading operations, water displaces air from the ground potentially increasing migration of methane gas generated by the landfill. In the past, elevated levels of methane gas have been detected in the surrounding communities. Therefore, restrictions were enacted curtailing spreading operations to 20 percent of their original capacity. This project is a joint effort between LADWP and BOS to replace the methane gas collection system within the landfill and thereby contain methane gas onsite. The project is being implemented by LADWP through LABOS's Proposition "O" Clean Water Bond program. Proposition "O" funded approximately $3 million of the $9 million cost. Construction began in 2007 and was completed in November 2009.

Big Tujunga Dam – San Fernando Groundwater Enhancement Project. LADWP and LACFCD approved Cooperative Agreement No. 47717 on September 18, 2007 for the Big Tujunga Dam –San Fernando Groundwater Enhancement Project. This Project will increase stormwater capture and provide other benefits including improvements in flood prevention and environmental enhancement through seismically retrofitting the dam and spillway. Annual stormwater capture will increase by 4,500 AFY for a total capture amount of 6,000 AFY. The project is integrated with the following projects in this section: Hansen Spreading Grounds Enhancement Project, Tujunga Spreading Grounds Enhancement Project, and the Sheldon-Arleta Methane Gas Collection Project. Both the Integrated Regional Watershed Management Plan for the Upper Los Angeles River Watershed and the Tujunga/Pacoima Watershed Plan are being incorporated into the Project. LADWP is contributing $9 million of the $105 million project cost. Construction of the Project is in progress with an anticipated completion date by September 2011.

Hansen Spreading Grounds Enhancement Project. The Hansen Spreading Grounds is a 120 acre parcel located adjacent to the Tujunga Wash Channel downstream from the Hansen Dam. Under Cooperative Agreement No. 47739, the Los Angeles County Flood Control District (LACFCD) and LADWP propose to modernize the facility to increase intake and storage capacity thereby improving groundwater recharge, flood protection and water quality while providing recreational benefits and native habitat improvements. To accomplish the goals of the project, a phased approach is being proposed. Phase 1A will deepen and reconfigure the existing basins; Phase 1B will improve the intake capacity by replacing a radial gate with a new rubber dam and telemetry system; and Phase 2 will develop other compatible uses such as recreational trails and native habitat for the community. Estimated recharge is 17,284 AFY, and estimated cost of this project is $10 million of which LADWP will fund $5 million. The reconstruction of the spreading grounds was completed in December 2009 and the intake structure will be completed in December 2011.

Tujunga Spreading Grounds Enhancement Project. The Tujunga Spreading Grounds Enhancement Project is designed to increase average annual stormwater capture by 8,000 AFY through relocating and automating the current intake structure on the Tujunga Wash, installation of an automated intake structure on the Pacoima Wash, and reconfiguration of the Tujunga Spreading Basins. Other multiple benefits include habitat improvements, passive recreation, educational opportunities, flood protection, and water quality improvements. Owned by LADWP, the Tujunga Spreading Grounds are

DRAFT

AR0071621

operated by LACFCD in conjunction with other facilities along the Tujunga and Pacoima Wash Channels. Construction is expected to begin in 2012.

Valley Generating Station Stormwater Capture Project. LADWP is leading efforts to capture and infiltrate stormwater from the Valley Generating Station, from adjacent streets, and from the Tujunga Wash Channel. Phase 1 will capture and infiltrate all stormwater from the Valley Generating Station. Phase 2 will divert water from the Tujunga Wash Channel for infiltration at the abandoned gravel pit at the generating station. Total stormwater capture is estimated at 700 AFY. Project designs are expected to be completed at the end of 2011.

Pacoima Spreading Grounds Enhancement Project. LADWP in conjunction with LACFCD is proposing to upgrade the Pacoima Spreading Grounds by improving the intake and stormwater storage capacity. Annual average stormwater capture is expected to increase by approximately 2,000 AFY with completion of the project. Other project benefits include flood protection, water quality improvements, and passive recreation. The final concept report and design has an expected completion date by the end of 2012.

Lopez Spreading Grounds Enhancement Project. The Lopez Spreading Grounds Enhancement Project involves deepening the existing Lopez Spreading Grounds and improving the intake and delivery system. LACFCD is the lead agency for the project. Additional groundwater recharge to the SFB of approximately 750 AFY is expected from the project. Project designs are anticipated to begin in 2013.

Strathern Wetlands Park Project. The Strathern Wetlands Park Project involves the conversion of a 45-acre gravel pit into a multipurpose facility for flood protection, stormwater retention, treatment, groundwater recharge, habitat restoration, and recreation. Estimated stormwater capture is approximately 900 AFY. Proposition "O" funding of $17.8 million has been approved for acquisition of the site. LACFCD purchased the land and project planning is underway. Designs are expected in 2012, and construction is expected to occur in two phases from 2013 to 2016.

Hansen Dam Water Conservation Project. In 2000 the Army Corps of Engineers (ACOE) completed a feasibility study to examine operational changes and facility improvements at the Hansen Dam as part of a cost-shared study with LACFCD. Four scenarios are recommended with additional stormwater capture amounts of up to 3,400 AFY depending on the selected scenario. Designs for the project are anticipated in 2013.

Pacoima Dam Reservoir Sediment Removal Project. The Pacoima Dam Reservoir Sediment Removal Project involves removing sediment from behind Pacoima Dam to increase storage volume. The sediment build-up behind the Dam has decreased the capacity to about 3,300 acre-feet. In the fall of 2009 approximately 80 percent of the Pacoima Dam watershed was burned. This damage will likely increase sediment flow into the reservoir above the estimates provided based on 2005 topography. The Project will involve excavating 5 million cubic yards of sediment and increasing the storage volume by 3,000 acre-feet. Increased storage would decrease the number of reservoir spill events and increase the available recharge flow for the Pacoima and Lopez Spreading Grounds. The excavation will extend over 7,000 feet upstream of the existing dam. The project will produce an additional annual water recharge benefit of 670 AFY.

Branford Spreading Basin Upgrade. The Branford Spreading Basin Project will remove fine silts from the basin and install new pumps to drain the basin. These pumps could be used to drain the existing facility into the Tujunga Spreading Grounds. The expected additional recharge for this project is approximately 500 AFY.

DRAFT

AR0071622

7.6 Distributed Stormwater Capture

Throughout the City of Los Angeles there are opportunities to capture localized dry and wet weather runoff for local reuse. However, Los Angeles' storm drain systems have historically been designed to protect life and property from flood impacts by quickly redirecting rainfall and runoff from impervious surfaces into the City's storm drain system and ultimately the Pacific Ocean without regard to water quality impacts. The September 2, 2002 Municipal Stormwater National Pollutant Discharge Elimination System Permit (NPDES Permit No. CAS004001) for the Los Angeles region requires all new development or redevelopment projects to develop and comply with a Standard Urban Stormwater Mitigation Plan (SUSMP) to reduce runoff leaving the project site and to improve the project's water quality impacts.

Recently the City has taken initial steps towards promoting distributed capture and infiltration of runoff through development of a suite of distributed runoff demonstration projects. Distributed stormwater capture (also known as decentralized stormwater capture) is defined as any groundwater recharge system less then 500 af or any direct stormwater capture system capturing less then 10 af. In addition, the City is developing a Low Impact Development (LID) ordinance requiring retention of stormwater onsite for new and redevelopment projects which extends beyond SUSMP regulations. The Watershed Management Group is working with the Los Angeles and San Gabriel Rivers Watershed Council (LASGRWC), TreePeople, Los Angeles Department of Public Works Bureau of Sanitation (BOS), Department of Building and Safety (DBS), Los Angeles County Department of Public Works (LACDPW), The River Project and others to evaluate and study the impacts of localized stormwater capture and source control within the City.

LADWP is providing various resources for projects that would enhance the City's ability to capture additional dry and wet weather runoff for beneficial use. Both dry and wet weather runoff can be beneficially used. Dry weather runoff occurs in the absence of rainfall while wet weather runoff occurs as a direct result of rainfall. Dry weather runoff is typically related to inefficient irrigation systems, overwatering, and other wasteful outdoor water use practices. Wet weather runoff represents a significantly larger volume of water than dry weather runoff. Exhibit 7D summarizes the potential water yield and average unit cost of the different resources available to increase localized capture and infiltration of runoff.

7.6.1 Watershed Council – Water Augmentation Study

The Los Angeles Basin Water Augmentation Study (WAS) is a long-term research project, initiated in 2000, created to determine the benefits of implementing a broad-based approach to stormwater infiltration within the Los Angeles Region. The study was led by the Los Angeles & San Gabriel Rivers Watershed Council in partnership with local, state, and federal agencies and organizations, with major support from the federal Bureau of Reclamation. LADWP assisted in the funding and creation of the study report as part of the Technical Advisory Committee.

While centralized strategies such as spreading basins and dams are reliable and effective methods to capture stormwater, increased urbanization, high land costs, and scarcity of imported water for recharge signal the need to pursue additional stormwater capture methods. Furthermore, centralized stormwater infiltration is unable to capture the entire watershed which leaves a large quantity of additional stormwater to be tapped into. The WAS research has concluded that decentralized strategies (distributed stormwater capture such as rainbarrels & cisterns) would provide a local and reliable supply of water that would not negatively impact groundwater quality. Distributed stormwater capture and infiltration systems techniques provide a viable means of augmenting groundwater recharge and reducing the overall cost of treating urban runoff. Based on the findings of this study, the WAS partnership moved forward on a demonstration project in a 24-single family residential home neighborhood in northeast San Fernando Valley to validate study findings.

DRAFT

AR0071623

CASE STUDY:
Elmer Avenue Neighborhood Retrofit Project

The Background

Initiated in 2000, the Los Angeles Basin Water Augmentation Study (WAS) is a long-term research project led by the Los Angeles & San Gabriel Rivers Watershed Council in partnership with eight local, state, and federal agencies of which LADWP is an active partner. The study is evaluating the practical potential to improve surface water quality and increase local groundwater supplies through infiltration of urban stormwater runoff.

Based on positive findings of the study, the WAS partnership moved forward with a demonstration project to display an integrated and comprehensive approach to water management by retrofitting a neighborhood with strategies to address water conservation, pollution reduction and treatment, flooding, and habitat restoration. The Elmer Avenue Neighborhood Retrofit Project was chosen after an extensive selection process that evaluated neighborhoods based on more than 80 criteria.

The Project

The Elmer Avenue Neighborhood Retrofit Project commenced in July 2009 and was completed in June 2010 and cost approximately $2.5 million. Elmer Avenue receives stormwater runoff from approximately 40 acres of upstream residential area causing flooding in most storms. To address these 40 acres, the project encompasses improvements to both the public right-of-way as well as the private residences. As such, the project required active interaction and cooperation between the WAS partnership and the residents to work together and come up with a solution for the neighborhood.

Public Right-of-Way Improvements:

Infiltration Gallery-

A large infiltration gallery was installed underneath the street right-of-way which is estimated to infiltrate 16 acre-feet annually. The gallery is a sub-surface groundwater collection system, shallow in depth, constructed with perforated pipes where runoff water flows into and then is allowed to infiltrate into the ground to recharge the local groundwater basin.

Bioswale-

The newly installed sidewalks include bio-swales in the parkways to capture and treat stormwater runoff from the local sub-watershed mostly from residential landuse. The bioswales are open shallow channels with gently sloped sides and bottoms filled with vegetation and rip rap where stormwater runoff is collected. Bioswales help reduce the flow velocity and treat stormwater runoff through filtering by the vegetation in the channel, through the subsoil matrix, and/or into the underlying soils. In addition, bioswales trap particulate pollutants (suspended solids and trace metals), promote infiltration and serve as part of the whole stormwater drainage system installed for this project.

AR0071624

Private Residence Improvements:

Numerous improvements were offered to residents who chose to participate to help reduce runoff as well as exercise better outdoor water conservation such as porous pavers, rain gardens, rain barrels, and drought-tolerant and native landscaping.

The Benefits

The finished project incorporates a mixture of strategies to produce multiple levels of benefits (to the neighborhood but also to the local, regional, and national community whom can take this work as an encouraging model):

- Capture stormwater and dry-weather runoff to prevent flooding and decrease pollution of local rivers and oceans
- Reduce impermeable surfaces and increase groundwater recharge
- Improve neighborhood aesthetics through increased green space and public right-of-way improvements
- Increase community awareness of watershed issues
- Encourage community awareness to being more water and environmentally responsible.

As a result of the success and positive feedback from citizens for the Elmer Avenue Neighborhood Retrofit Project, a second phase is currently underway to Elmer Avenue to retrofit its alleyway. These small projects aim to spark large change by showing citizens and other communities that they too can make changes and improve their neighborhoods to be more water and environmentally friendly.

"By turning our yards into rain gardens and our streets into water recharge facilities, we can ensure clean water for the future. In contrast to a typical urban street, Elmer Avenue now reduces flooding and water pollution, improves water quality, replenishes groundwater supplies, and increases native habitat."

Nancy Steele, Executive Director
Los Angeles and San Gabriel Rivers Watershed Council

"This project is a prime example of how homeowners and the city can work together on a project that demonstrates smart watershed management through stormwater capture and water conservation measures that are beautiful and effective"

Edward Belden, Water Programs Manager
Los Angeles and San Gabriel Rivers Watershed Council

AR0071625

7.6.2 Integrated Water Resources Plan Analysis

As part of the City of Los Angeles Integrated Water Resources Plan (IRP), further described in Chapter 10, the City investigated the beneficial reuse of urban runoff for both dry and wet weather conditions.

7.6.2.1 Dry Weather Runoff Options

The beneficial use option for dry weather runoff consists of runoff capture, treatment, and reuse. For dry weather flow, most of the runoff could potentially be diverted directly for beneficial use, particularly during the summer months when demands for non-potable water are high (due to the higher irrigation demands in the summertime). The level of treatment of the runoff before being beneficially used would be determined by the ultimate use of the water.

A computer modeling analysis was performed during development of the IRP based on the recycled water demands in Los Angeles and the available dry weather runoff. Based on the data, the model determined which of the recycled water demands could be realistically met through treated runoff. The dry weather runoff available for reuse throughout the City is estimated at 97 mgd (approximately 26,000 million gallons per year). Exhibit 7E identifies the amount of this runoff that could, after treatment, be used to meet the recycled water demands.

Exhibit 7E

Potential Non-Potable Water Demands Met with Dry Weather Treated Runoff

Service Area	Total Demand Served	
	(AF per year)	(million gallon per year)
Aliso Wash	1,400	460
Canoga	3,250	1,050
Reseda	2,900	950
Tujunga / Burbank	9,050	2,950
LA River Reach 3	1,100	360
Dominguez Channel	8,500	2,770
Compton Creek	1,450	470
Ballona	10,850	3,530
Verdugo Wash	100	30
LA River/Arroyo	9,600	3,130
Total	48,200	15,700

Source: City of Los Angeles Integrated Resources Plan, Facilities Plan, Volume 3: Runoff Management

7.6.2.2 Wet Weather Runoff Options

Rain Barrels

Rain barrels are distributed stormwater capture devices used to store rainwater collected from roofs via roof rain gutter systems. Harvested water can be used for outdoor irrigation at a later time. Rain barrels vary in size with a typical rain barrel holding approximately 55 gallons that can be readily installed under any residential roof gutter downspout. Installation of rain barrels at residences throughout Los Angeles, assuming 400,000 residences, could potentially capture 6,400 AFY assuming an annual average rainfall of 17.8 inches, one 55-gallon rain barrel installed per residence, and an average roof area of 500

AR0071626

square feet. If overflow infiltration is provided, and/or greater roof area is utilized, annual rainfall volume captured can be significantly greater.

DRAFT

AR0071627

Case Study:
Ballona Creek Watershed Rainwater Harvesting Pilot Program

Funded by the Safe Neighborhood Parks, Clean Water, Clean air and Coastal Protection Bond Act of 2000 (Prop 12) through the Santa Monica Bay Restoration Commission and the California Coastal Conservancy, the City of Los Angeles, Department of Public Works, Bureau of Sanitation, Watershed Protection Division (Stormwater Program) began the City's first free Rainwater Harvesting pilot program in July 2009. The goal of this program is to engage as many property owners as possible, and limiting the installation to one downspout per property allows the City to reach the maximum number of residences.

Liz Herron, Land Use Chair of Mt. Washington Association, supports rainwater harvesting systems: "Rain barrel systems serve environmental purposes by allowing homeowners to collect the rainwater for personal irrigational purposes. It also reduces the amount of rainwater entering into the streets and ocean. These residential systems are successful programs that save water and prevent pollution."

Designed to conserve potable water and reduce the amount of polluted rainwater that runs untreated into the ocean, the $1-million pilot plan has enough funds to install 490 residential rain barrels, disconnect 100 barrels implemented with consultation on rain gardens, and provide one custom-made commercial planter box for each of ten businesses. It is estimated to save 584,100 gallons of water each year. The City estimates there are roughly 18 rain events in LA each year filling each barrel at least once each time.

In a typical year, about 9,600 gallons of water is generated on an average 1,000-square foot residential LA roof top. If each of the 400,000 residential parcels in LA were to install a single rain barrel, the City estimates that about 400 million gallons of water would be saved, which would reduce the demand for water. An evaluation of the program is scheduled for completion in Spring 2011.

The 55-gallon capacity rain barrel was chosen because the weight of 200 pounds is relatively manageable. The rain barrels are also made from food-grade plastic, repurposed from containers in case the harvested rainwater is used to grow food. They are equipped with mesh netting to keep out debris and mosquitoes and connected to the downspouts by a trained rain barrel installation specialist.

Planter boxes that businesses are eligible for will be custom-made to fit the layout and dimensions of the property. The City will be working with the business to make sure they are content with the presentation of the planter box.

The program addresses the City's broad problems of water scarcity and stormwater pollution. Currently outdoor water usage accounts for 1/3 of the average family's overall water consumption. The Rainwater Harvesting program helps to meet the City's water conservation goals by reducing the amount of potable water used for irrigation and other outdoor purposes.

AR0071628

Cisterns

Cisterns are larger than rain barrels and can range from 100 to 10,000 or more gallons. They store diverted runoff from roof areas and other impervious surfaces. This stored runoff can provide a source of untreated water for gardens and compost, free of most sediment and dissolved salts. Because residential irrigation can account for up to 40 percent of domestic water consumption, water conservation measures such as cisterns can be utilized to reduce demands, especially during hot summer months.

An analysis of the effect of installing cisterns in all single family and multi-family residences in the City was conducted as part of the IRP, which was based on projected household demands, irrigation needs, and historical rainfall data. The results showed that during a storm event of 0.45 inches, the result of installing 1,000-gallon cisterns at all single-family and multi-family residences in the City would be a maximum capture of approximately 440 million gallons. This provides a substantial amount of water conservation and reduction in potable water demands within the City.

The primary beneficial use of dry and wet weather runoff is to meet irrigation demands. These demands are typically non-existent during rain events and low throughout the rainy season. Therefore, the wet weather runoff would need to be stored until the demand exists. This can be done through a regional and/or a localized approach. A regional approach to seasonal storage could include the use of out-of-service reservoirs for seasonal storage. A localized approach would be to construct distributed underground storage facilities, located in open spaces, parks, schools, etc. throughout the City.

Exhibit 7F demonstrates a modular storage media that holds the runoff in a honeycomb-like box under the ground. The storage media has approximately 95 percent voids, so almost all of the storage volume would be filled with water. The maximum depth is 8 feet, which translates to approximately 2.44 million gallons per acre of water storage potential. The containers can also be constructed to be impermeable to prohibit infiltration.

Exhibit 7F
Construction of Underground Cistern for Stormwater Capture

(Photo courtesy of TreePeople)

DRAFT

AR0071629

According to studies conducted during the development of the IRP, the City currently has an estimated open space area of 6,000 acres, which includes parks, open space, and vacant lots. School sites are also a potential option for installing modular storage media under playgrounds and athletic fields. The total school area in the City is approximately 6,000 acres. Assuming that only 25 percent of this area has no buildings or other structures, this equals approximately 1,500 acres of potentially suitable land. Additionally, there are approximately 900 abandoned or no longer maintained alleys of various unknown dimensions that could potentially be converted to underground storage facilities. Exhibit 7G summarizes the approximate underground storage potential throughout the City.

Exhibit 7G

Underground Storage Potential throughout the City

Land Use	Acres (acres)	Potential Storage Volume[1] (million gallons)
Open space	6,000	15,000
Schools (assume only ~ 25 percent suitable land)	1,500	4,000
Alleys	900 count	Unknown
Total	7,500	19,000

Note: 1. Maximum storage potential shown assumes 4.22 million gallons of storage per acre of land. Actual usable volume may be less.
Source: City of Los Angeles Integrated Resources Plan, Facilities Plan, Volume 3: Runoff Management

The City has the potential to store a considerable volume of wet weather runoff in order to meet the potential future surface water quality regulations if the underground storage options were utilized. This stored water could then be drawn down and beneficially used during the dry weather months.

Rain Gardens

Rain Gardens are another simple form of relatively small scale rainwater harvesting. As gardens or depressions, usually constructed sub-grade, they act as small retention/percolations basins for rainwater collection. Not only do they provide for an attractive landscape, but they are effective in treating and infiltrating stormwater for local groundwater recharge.

While extremely functional, these are basically regular gardens and can be designed to fit well into the surrounding landscape. Many cities and states across the country have extensive rain garden programs, and years of research have gone into their design and performance. Acting as a bio-retention systems, rain gardens treat runoff naturally as it seeps underground. In the case of lowered percolation rates or in hillside developments, rain gardens are typically installed with impermeable liners and supplied with under drains.

Unit cost of rain gardens are similar to that of rain barrels, as the mechanism for collecting water is the same. Cost is dependent upon the form and extent of construction and on the type and quantity landscape used, as well as the associated maintenance. Installation of rain gardens at residences throughout Los Angeles, assuming 400,000 residences, could potentially capture 6,400 AFY assuming an annual average rainfall of 17.8 inches, and an average roof area of 500 square feet. Under these conditions, assuming a 10-15 year lifespan, the cost of rain gardens varies from $308-$5,000 / AF.

Neighborhood Recharge

Neighborhood recharge involves installing recharge facilities in portions of vacant urban lots, abandoned alleys, and City parklands, where the soil is highly permeable. This option involves installing underground storage (such as a honeycomb

DRAFT

AR0071630

shaped device shown in Exhibit 7F, but without the lining to allow infiltration). This would allow the runoff to be stored underground, while still maintaining a safe area above ground for human activity. The runoff would be pumped or would flow by gravity to the site where it would be collected temporarily until it is able to infiltrate.

The amount of runoff that could be managed by neighborhood recharge was determined as part of the IRP by assuming that only the east San Fernando Valley area has predominantly permeable soils appropriate for infiltration (though there may be other areas within the City that could be usable for recharge with smaller-scale projects). Based on an analysis of the City's Geographical Information System, the maximum total area available for neighborhood recharge facilities is approximately 831 acres, which includes vacant urban lots, abandoned alleys, and 25 percent of City parklands. Assuming an infiltration rate of 2 feet per day, the maximum runoff that could potentially be managed by recharge facilities would be 550 million gallons per day (mgd).

7.6.3 Distributed Stormwater Capture Projects

As an outgrowth of the IRP, neighborhood recharge concept efforts are moving from the conceptual stage visualized in the IRP to actual identified projects in the City which infiltrate wet weather runoff as close as possible to the point of origin. A few of the identified projects are highlighted here.

Whitnall Highway Power Line Easement Stormwater Capture Project. This project involves the capture, treatment, and infiltration of stormwater from streets in the eastern San Fernando Valley using LADWP's Whitnall Power Line Easement in the lower Sun Valley Watershed. Average annual recharge is estimated at 110 AFY. Additional uses of the project site may include open space and recreational enhancements. Designs are anticipated for completion by the end of 2011.

Elmer Avenue Neighborhood Retrofit Project. In December of 2008, the City of Los Angeles partnered with TreePeople and the LASGRWC to retrofit an existing neighborhood in the Sun Valley portion of Los Angeles that is prone to flooding during wet weather events. A combination of Best Management Practices (BMPs); including vegetated swales, infiltration trenches, rain gardens, rain barrels, native and drought tolerant landscaping, roof gutters, street tree plantings, and aligning driveways to drain to vegetated swales are incorporated into this project. This project was designed to capture and infiltrate the equivalent of a 2-year storm, increasing groundwater recharge. Project funding was provided by the US Bureau of Reclamation, DWR, LACDPW, MWD, Water Replenishment District of Southern California and LADWP. Construction was completed in June 2010.

Woodman Avenue Median Retrofit Demonstration Project. LADWP in partnership with the BOS Watershed Protection Division and The River Project, a non-profit organization, are developing the Woodman Avenue Median Retrofit Demonstration Project to capture, treat, and infiltrate stormwater runoff along a portion of Woodman Avenue. The Project will replace the existing median with pre-treatment devices, a vegetated swale, and an underground retention system. Project benefits include reductions in localized flooding, open space enhancements, groundwater recharge, and native habitat enhancement. The CalFed Watershed Program awarded the project a $1.6 million grant. Construction is expected to be completed by the end of 2012.

North Hollywood Alley Retrofit BMP Demonstration Project. The Project's goal is to demonstrate the ability to infiltrate stormwater near the point of origin while increasing groundwater recharge, reducing flooding, and improving water quality. Four segments of alleyways in the San Fernando Valley are proposed to be retrofitted with pervious surfaces and diversion of flows from intersecting streets into these alleyways. Construction is anticipated to begin in early 2011.

AR0071631

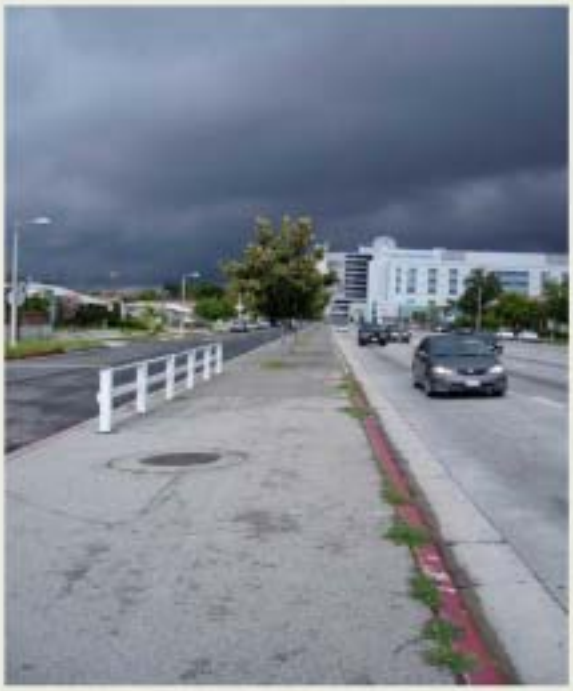
Laurel Canyon Parkway Infiltration Swale Project. Construction of the Laurel Canyon Parkway Infiltration Swale Project will involve construction of an infiltration trench and parkway swale between the street curb and sidewalk near LADWP's Tujunga Spreading Grounds in the San Fernando Valley. Stormwater will be collected and infiltrated into the groundwater from the local residential neighborhood. Construction of the project is anticipated to occur in late 2011.

DRAFT

AR0071632

CASE STUDY:
Woodman Avenue Multi-Beneficial Storm Water Capture Project

Originally proposed by the local Panorama City Neighborhood Council for the Tujunga-Pacoima Watershed Plan, the Woodman Avenue project represents an innovative example of stormwater capture, which includes extensive benefits for the environment, the City's groundwater basin, and the surrounding community. The Woodman Avenue median is located along the west side of Woodman Avenue from Lanark Street to Saticoy Street.



The Project's construction will be relatively simple but effective. The Project will capture surface runoff from approximately 130 acres that currently flows along street gutters to storm drains, through the Tujunga Wash and ultimately down the Los Angeles River and into the Pacific Ocean. Instead flows will now be directed through pre-treatment devices into a vegetated swale and an underground retention system for groundwater basin infiltration. The vegetated swale and underground retention/infiltration system will replace an existing 16-foot wide, 3,500-foot long concrete median. After construction of the project, participants will conduct active monitoring of water flows, water quality, and vegetation for approximately three years. This data should provide valuable information to facilitate the development of future projects, and optimize system processes.

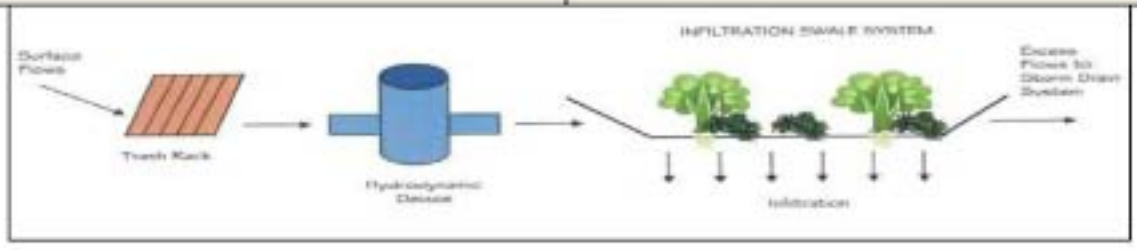
The direct water resource related benefits from this project are three fold. First, the additional water captured will recharge the San Fernando Groundwater Basin with approximately 80 AF per year. This replenishes the City's local groundwater supply, and helps protect pumping rights for City, which ultimately guarantees a more reliable water supply. Secondly, diverted flow alleviates local flooding, particularly during sizable rain events. Finally, the infiltration prevents contaminant carrying runoff and debris from entering local waterways and ultimately coastal areas.

Also recognized are the Community benefits associated with this project. These include creation of open space enhancements such as improved aesthetics and pedestrian access near schools, a walking path, benches, and native vegetation. The River Project will be running an active education program with the local community, including workshops with nearby business owners/residents and the introduction of a curriculum for students at the local elementary school. The organization's goal is to get the students involved in monitoring and maintenance of the project as part of their service learning requirements. Establishing knowledge of sustainable water supplies with the City's youth is an investment in constituent water use practices for generations to come.

Project participants include the Panorama City Neighborhood Council, Council District 6, the Los Angeles Bureau of Sanitation, the Los Angeles Bureau of Street Services, the State of California Water Resources Control Board (SCWRCB), The River Project, and LADWP. This cooperative partnership is anticipating the project's construction to be completion around the end of 2012.

State funding used for the project is provided through Proposition 50. SCWRCB has dedicated $1.6 million through the CALFED Watershed Grant Program, which covers roughly half of the overall project cost.

Melanie Winter from The River Project speaks positively of this stormwater capture project: "The community's involvement in the watershed planning process helped them identify a prime opportunity site that maximizes all the potential benefits. It helps reduce our dependence on imported supplies, addresses peak flows, improves water quality, and re-establishes habitat. It's gratifying to receive State funding to work in a well-rounded partnership to implement this integrated watershed project conceived at the grassroots level."



AR0071633

7.6.4 Low Impact Development and Best Management Practices

LADWP, in conjunction with other City Departments, is developing programs to highlight water conservation through Low Impact Development (LID) and installation of BMPs. Low Impact Development (LID) is a stormwater management strategy that has been adopted by many localities across the country for the past several years. It is a stormwater management approach that is designed to reduce runoff of water and pollutants from the site(s) at which they are generated.

The past few decades of stormwater management have resulted in the current convention of control-and-treatment strategies. They are largely engineered, end-of-pipe practices that have been focused on controlling peak flow rate and suspended solids concentrations. Conventional practices, however, fail to address the widespread and cumulative hydrologic modifications within the watershed that increase stormwater volumes and runoff rates and cause excessive erosion and stream channel degradation.

In general, implementing integrated LID practices into new development and retrofit of existing facilities can result in enhanced environmental performance while at the same time reducing development costs when compared to traditional stormwater management approaches.

According to the USEPA, infrastructure costs associated with LID practices as compared to traditional stormwater treatment practices result in significant cost savings ranging between 15 percent and 80 percent less than traditional practices. BMPs consist of practices designed to infiltrate runoff for groundwater recharge, reduce runoff volume, and capture rainwater for reuse. Programs under development include pilot projects, retrofitting of existing facilities, new development standards, and assistance in ordinance development.

Retrofit of LADWP Facilities to Meet LID Standards

LADWP is assessing its existing facilities for potential retrofits using LID BMPs. LID BMPs under consideration include pervious pavement, stormwater capture, curb cuts, bioretention cells, and amended soils. Expected benefits include:

- Increased groundwater recharge;
- Decreased outdoor water use;
- Increased compliance with stormwater regulations;
- Improved environmental conditions for employees and the public;
- Improved public image;
- Increased awareness of LID and provide examples for residents; and
- Compliance with Model Water Efficient Landscape Ordinance.

New LADWP Facility Development Using LID Standards

LADWP's Watershed Management Group is developing a framework for implementation of LIDs and BMPs during the new facility development process. Within the framework, LID and BMPs are taken into consideration during the planning, design, implementation, and maintenance processes associated with new LADWP facilities. Benefits include:

DRAFT

AR0071634

- Reductions in costs associated with stormwater infrastructure and landscape maintenance;
- Reduced costs for grading by using natural drainage;
- Reduced sidewalk costs by using narrower sidewalks;
- Increased groundwater recharge;
- Reduced runoff volume and pollutant loading;
- Reductions in long-term maintenance and operation costs by using drought tolerant landscaping;
- Reduction in life cycle costs of replacing or rehabilitating pipe and below ground infrastructure.

Assistance in Ordinance Development

LADWP is represented on the City of Los Angeles Landscape & Stream Protection Ordinances Joint Meeting Committee through the Watershed Management Group. Other committee members include the Department of Parks and Recreation, the Department of Public Works, the Department of Environmental Affairs, the Department of City Planning, and the Department of Building and Safety. The committee is tasked with developing ordinances for city-wide implementation that in combination reduce water use and improve groundwater recharge among other multiple benefits. Ordinances under review include the:

- Green Building Ordinance using the US Green Building Council's Leadership in Energy and Environmental Design (LEED) Green Building Rating System;
- LID Ordinance to incorporate improvements in stormwater management at the point of origin;
- Stream Protection Ordinance to incorporate methodologies for improving surface and groundwater quality;
- Hillside Ordinance revisions to include modifications in policies regarding front yards, side yards, height, fire protection, street access, lot coverage, off-street parking requirements, and exceptions in relation to the ordinances above.

7.6.5 Future Distributed Stormwater Programs

LADWP continues to investigate the potential for implementation of future distributed stormwater programs. Through its Watershed Management Group, LADWP will continue to develop partnerships and programs to improve utilization of stormwater runoff for outdoor water use and groundwater recharge. Potential programs that could be considered in the future include rain barrel/cistern rebates and retrofit incentives for installation of LID BMPs.

7.7 Integrated Regional Water Management Plan (IRWMP) Program

LADWP is a participating agency for the IRWMP which encompasses 92 cities in the Greater Los Angeles County Region. The IRWMP aims to address the water quality, resource, and supply issues of the region. A final plan was adopted on December 16, 2006.

Highlights of the plan that pertain to Watershed issues include:

AR0071635

- Short and long term objectives to comply with water quality regulations (including TMDLs) by improving the quality of urban runoff, stormwater, and wastewater
- Optimize local water resources to reduce the Region's reliance on imported water
- Long term priority to protect groundwater supplies through stormwater recharge
- Target goal to reduce and reuse 150,000 AFY (40%) of dry weather urban runoff and capture and treat an additional 170,000 AFY (50%) for a total target of 90%
- Target goal to reduce and reuse 220,000 AFY (40%) of stormwater runoff from developed areas and capture and treat an additional 270,000 AFY (50%) for a total of 90%

For more detailed information on the IRWMP, please refer to Chapter 10.

7.8 Cost Analysis

Exhibit 7H compares side by side the various watershed management opportunities LADWP is pursuing and/or investigating to add to its water portfolio.

Exhibit 7H

Water Source	Water Yield (AFY)	Average Unit Cost ($/AF)
Centralized Stormwater Capture[1]	25,950	$60 - $200
Distributed Stormwater Capture		
Urban Runoff Plants[2]	5,000	$4,044
Rain Barrels[3]	6,400	$701 - $1,875
Cisterns[4]	8,000	$2,426
Rain Gardens[5]	6,400	$308 - $5,000
Neighborhood Recharge[6]	12,000	$3,351

Notes:

1. Water Yield and cost is based on LADWP's current planned centralized stormwater capture projects. Additional centralized stormwater capture potential will be identified once the Stormwater Master Plan is complete. Cost assumes 50 year project life.

2. Source: City of Los Angeles Integrated Resources Plan (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSA.

3. Source: Tree People. Assumes 10 - 15 year life, 55 gallon barrels, 1 barrel per residence, 17.8 in annual rainfall, $200-$300 per barrel installed, average used roof area 500 square feet, and 400,000 residences for yield (AFY); 2010 dollars

4. Source: City of Los Angeles Integrated Resources Plan (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSA; capturing and reusing stormwater on-site for schools and government only.

5. Source: Tree People. Assumes 10 - 15 year life, 17.8 in annual rainfall, $3.30 - $25.66 / ft² for rain garden construction, average used roof area 500 square feet, and 400,000 residences for yield (AFY); 2010 dollars

6. Source: City of Los Angeles Integrated Resources Plan (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSMSA.

DRAFT

It is important to note that the centralized stormwater capture values are based on the planned projects listed in Section 7.5. LADWP is currently compiling a Stormwater Master Plan (see Section 7.3) which will investigate the maximum potential for stormwater capture within the City (for both centralized and distributed capture). Nevertheless, even with this fraction of the potential, it is clear that centralized stormwater capture is a very cost effective, plentiful water supply asset to be pursued. Recognizing its great potential, LADWP will proceed with its efforts on the centralized stormwater capture projects listed in Section 7.5, and closely monitor findings of the Stormwater Master Plan to determine future potential centralized stormwater capture projects.

Distributed stormwater capture values are based on the maximum potential achievable by the City. While the cost listed is high, distributed stormwater capture options are highly variable based on a variety of factors such as the magnitude of the overall program, project locations, etc. Furthermore, distributed stormwater capture projects yield additional benefits to the public outside of water supply generation such as community beautification, public right of way improvements, as well as private residence safety and aesthetic improvements. LADWP will continue to investigate these options to evaluate the best approach to establish a cost effective program that will help add to LADWP's water portfolio.

DRAFT

AR0071637

Chapter Eight
Metropolitan Water District Supplies

8.0 Overview

As a member agency, the City of Los Angeles purchases water from the Metropolitan Water District of Southern California (MWD) to supplement its supplies from local groundwater, LAA deliveries, and recycled water. LADWP has historically purchased MWD water to make up the deficit between demand and other City supplies. As a percentage of the City's total water supply, MWD water varies from 4 percent in 1983-84 to 71 percent in 2008-09 with the 5-year average of 52 percent between 2005-06 and 2009-10. Exhibit 1F in Chapter 1 illustrates the City's reliance on MWD water during dry years and increasingly in recent years when LAA supply is being cut back for environmental enhancement projects. Although the City plans to reduce its reliance on imported water including LAA and MWD supplies, it has made significant investments in MWD and will continue to rely on the wholesaler to meet its current and future supplemental water needs.

MWD is the largest water wholesaler for domestic and municipal uses in California providing nearly 19 million people with on average 1.7 billion gallons of water per day to a service area of approximately 5,200 square miles. MWD was formed by the MWD Act, and exist pursuant to this statute which was adopted by the California legislature in 1927. MWD's adopted purpose is to develop, store, and distribute water to southern California residents. Additionally, the MWD Act allows MWD to sell additional water when it is available for other beneficial uses. In 1928 MWD was incorporated as a public agency following a vote by residents in 13 cities in southern California. Operating solely as a wholesaler, MWD owns and operates the Colorado River Aqueduct (CRA), is a contractor for water from the California State Water Project (SWP), manages and owns in-basin surface storage facilities, stores groundwater within the basin via contracts, engages in groundwater storage outside the basin, and conducts water transfers to provide additional supplies for its member agencies. Today MWD has 26 member agencies consisting of 11 water districts, one county water authority, and 14 cities, including the City of Los Angeles.

This Urban Water Management Plan projects LADWP's reliance on MWD water supplies will be reduced by half; from the five-year average of 52 percent of total demand between 2005-06 and 2009-10, to 24 percent by 2034-35 under average weather conditions.

8.0.1 History

Initially formed to import water into the southern California region from, MWD's first project was to build the CRA to import water from the Colorado River. The City of Los Angeles originally provided the capital dollars to initiate and complete land surveys of all proposed alignments for the project. Construction was financed through $220 million in bond sales during the Great Depression. Ten years after initiating construction Colorado River water reached southern California in 1941. To meet further water demands in the southern California region, MWD contracted with the SWP in 1960 to deliver almost half of the SWP's water from the San Francisco Bay-Delta region via the California Aqueduct into southern California. After completion of the California Aqueduct, deliveries of SWP water were first received in 1972.

8.0.2 Governance

MWD is governed by a Board of Directors composed of 37 individuals with a minimum of one representative from each of MWD's 26 member agencies. The allocation of the directors and voting rights are determined by each agency's assessed valuation. The city of Los Angeles has four Directors on MWD's Board and controls 19.44 percent of the vote. MWD's Administrative Code defines various tasks which the Board has delegated to MWD staff. A General Manager oversees MWD

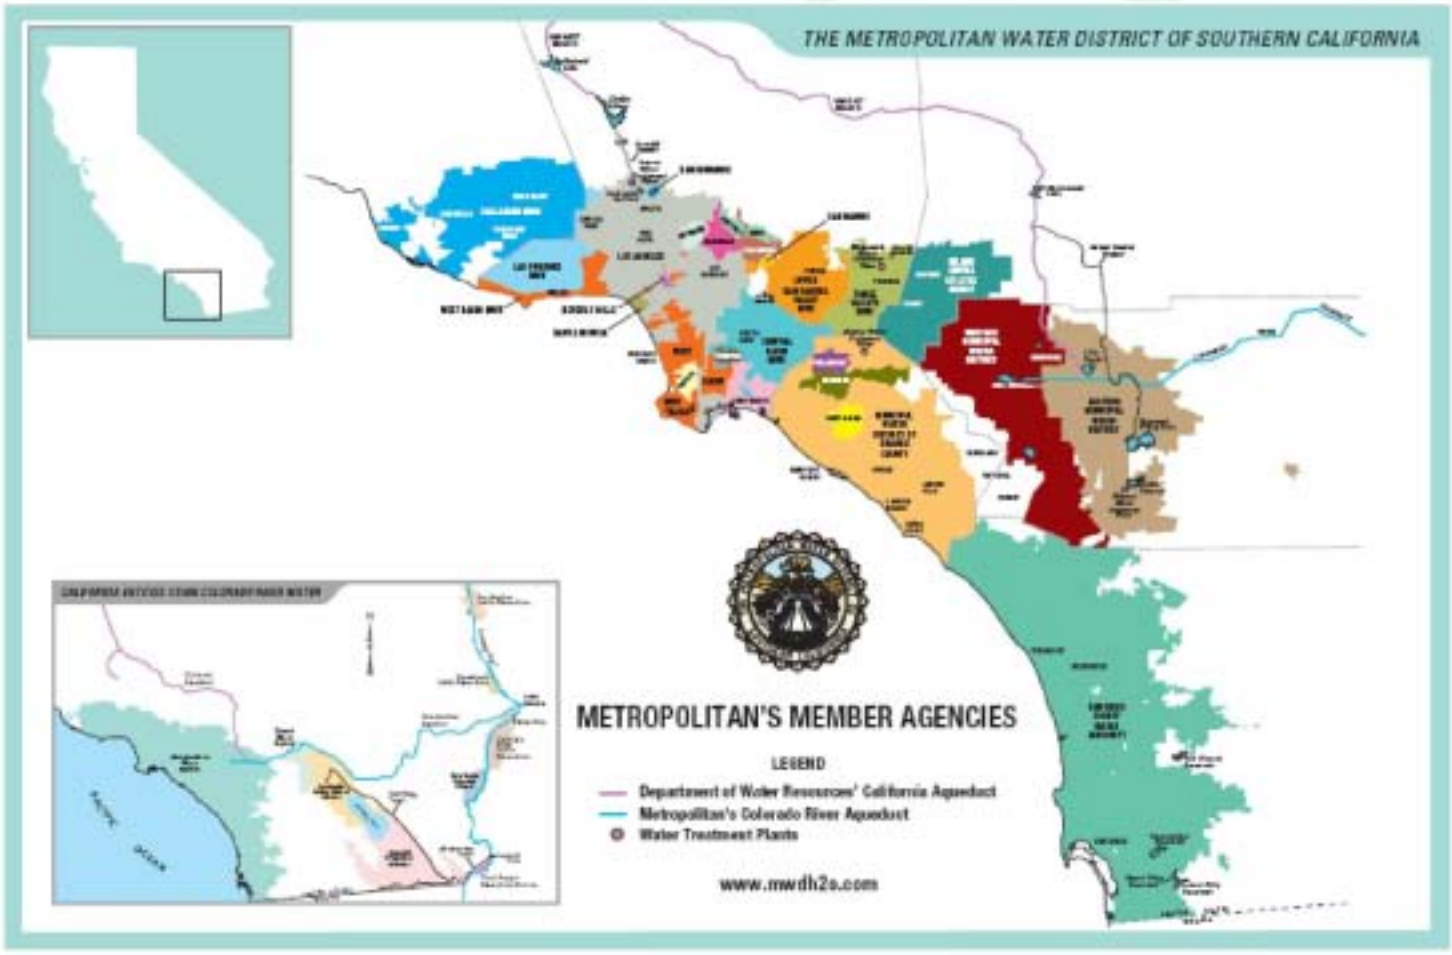
AR0071638

staff. The General Manager, General Auditor, General Counsel, and Ethics Officer serve under direction and authority given directly by the Board.

8.0.3 Service Area

Originally serving an area of 675 square miles in 1928, MWD's service area has grown to approximately 5,200 square miles serving 19 million people via its 26 member agencies. MWD's service area covers portions of Los Angeles, Ventura, Orange, Riverside, San Bernardino, and San Diego counties as depicted in Exhibit 8A. MWD member agencies serve 152 cities and 89 unincorporated areas. Member agencies provide wholesale, retail, or a combination of wholesale/retail water sales in their individual service territories.

Exhibit 8A
MWD Service Area



8.0.4 Major Infrastructure

MWD delivers approximately 6,000 AF per day of treated and untreated water to its member agencies through its vast infrastructure network. Major facilities include the CRA, pumping plants, pipelines, treatment plants, reservoirs, and

AR0071639

hydroelectric recovery power plants. A summary of the major facilities and capacities are provided in Exhibit 8B and Exhibit 8C illustrates the geographic locations of the facilities.

Exhibit 8B
Major MWD Facilities Summary

Facility	Units	Capacity
Colorado River Aqueduct		
Aqueduct	242 miles	1.3 million AFY
Pumping Plants	5 plants	1,617 feet of total lift
Pipelines	819 miles	
Water Treatment Plants		
Joseph Jensen		750 mgd
Robert A. Skinner		630 mgd
F.E. Weymouth		520 mgd
Robert B. Diemer		520 mgd
Henry J. Mills		220 mgd
Total Treatment Capacity		2,640 mgd
Reservoirs		
Diamond Valley Lake		810,000 AF
Lake Matthews		182,000 AF
Lake Skinner		44,000 AF
Copper Basin		24,200 AF
Gene Wash		6,300 AF
Live Oak		2,500 AF
Garvey		1,600 AF
Palos Verdes		1,100 AF
Orange County		212 AF
Total Reservoir Capacity		1,071,912 AF
Hydroelectric Recovery Plants	16 plants	122 megawatts

DRAFT

AR0071640

Exhibit 8C
Major MWD Facilities

8.1 Supply Sources

Colorado River supplies, State Water Project supplies, In-Basin Storage, Outside-Basin Storage, and Water Transfers together comprise MWD's total system water supply sources. These sources provide supplemental water to meet the demands in Venture, Los Angeles, Riverside, Orange, San Bernardino and San Diego Counties.

8.1.1 Colorado River

The Colorado River forms California's border with Arizona to the east. The drainage area in California that contributes water to the Colorado River is relatively small and has an arid climate. Accordingly, California has no major tributaries contributing water to the Colorado River.

AR0071641

The Colorado River Board of California (CRB) is the California state agency given authority to protect the interests and rights of the state and its citizens in matters pertaining to the Colorado River. The Board is comprised of 10 gubernatorial appointees representing the LADWP, MWD, San Diego County Water Authority, Palo Verde Irrigation District, Coachella Valley Water District, Imperial Irrigation District, Department of Water Resources, Department of Fish and Game, and two public members.

8.1.1.1 The Law of the River

The Secretary of the Interior (Secretary) is vested with the responsibility to manage the mainstream waters of the Colorado River pursuant to applicable federal law. This responsibility is carried out consistent with a body of documents referred to as the Law of the River. Water rights to Colorado River water are governed by a complex collection of federal laws, state laws, a treaty with Mexico, other agreements with Mexico, Supreme Court decrees, contracts with the Secretary, interstate compacts, state, and administrative actions at the federal and state levels. Collectively, these documents and associated interpretations are commonly referred to as the "Law of the River" and govern water rights and operations on the Colorado River.

Particularly notable among these documents are:

1) the Colorado River Compact of 1922, which apportioned beneficial consumptive use of water between the Colorado River Upper Basin and Lower Basin; and defined the term "States of the Lower Division" to mean the States of Arizona, California, and Nevada. Serving as the basis of the "Law of the River" the Compact apportioned water to each basin in anticipation of a dam on the Colorado River. The Upper Basin is the portion of the Basin upstream of Lee Ferry, Arizona, while the Lower Basin is downstream of this point. Each basin was apportioned 7.5 million MAF annually and the Lower Basin received the option to an additional 1 MAF annually based on excess flows. California is within the Lower Basin along with Arizona and Nevada;

2) the Boulder Canyon Project Act of 1928 was enacted by Congress to authorize construction of Hoover Dam and the All-American Canal, the Act required that water users in the Lower Basin have a contract with the Secretary, and established the responsibilities of the Secretary to direct, manage, and coordinate the operation of Colorado River dams and related works in the Lower Basin. The Act stipulated conditions, one of which required California to limit Colorado River water use to 4.4 MAF annually plus one-half of the excess water unapportioned by the Colorado River Compact. To satisfy the condition, the California Legislature enacted the Limitation Act in 1929 limiting its use of Colorado River water to the basic apportionment of 4.4 MAF;

3) the California Seven Party Agreement of 1931 was developed in response to the Limitation Act and through regulations adopted by the Secretary, established the relative priorities of rights among major users of Colorado River water in California. The Seven Party Agreement apportioned California's share of Colorado River water to California contractors. Within the agreement priorities were established for each of the four agencies holding contracts for Colorado River Water with the U.S. Bureau of Reclamation. These priorities are shown in Exhibit D. Seven priorities were established with the first four priorities satisfying California's allocation of 4.4 MAF annually and the fifth and sixth priorities relating to California's share of excess Colorado River flows. MWD holds the fourth and fifth priorities. The fourth priority allocates 550 thousand acre-feet (TAF) of California's apportionment to MWD and the fifth priority allocates 662 TAF of California's share of excess flows to MWD.

4) the 1944 Treaty (and subsequent minutes of the International Boundary and Water Commission) related to the quantity and quality of Colorado River water delivered to Mexico. The Treaty guaranteed an annual quantity of 1.5 MAF to be delivered in accordance with the provisions of the Treaty.

AR0071642

5) the 1963 United States Supreme Court Decision in *Arizona v. California* which confirmed the Lower Basin mainstream apportionments of:

2.8 million acre-feet per year (AFY) for use in Arizona,
4.4 million AFY for use in California, and
0.3 million AFY for use in Nevada;

provided water for Indian reservations and other federal reservations in Arizona, California, and Nevada; and confirmed the significant role of the Secretary in managing the mainstream Colorado River within the Lower Basin;

6) the 1964 United States Supreme Court Decree (Decree) in *Arizona v. California* which implemented the Supreme Court's 1963 decision; allocated 50 percent of the surplus water available for use in California; and allowed the Secretary to release water apportioned to but unused in one state for use in the other two states; the Decree was supplemented over time after its adoption and the Supreme Court entered a Consolidated Decree in 2006 which incorporates all applicable provisions of the earlier-issued Decrees; and

7) the Colorado River Basin Project Act of 1968, which authorized construction of a number of water development projects including the Central Arizona Project (CAP), provided existing California, Arizona, and Nevada water contractors a priority over the CAP and other users of the same character in Arizona and Nevada whenever less than 7.5 million afy is available, and required the Secretary to develop the Long Range Operating Criteria and issue an Annual Operating Plan for mainstream reservoirs.

Exhibit 8D

Listing of Priorities - Seven Party Agreement		
Priority Number	**Agency and Description of Service Area**	**Beneficial Consumptive Use (Acre-feet/year)**
1	Palo Verde Irrigation District - 104,500 acres	
2	Yuma Project, California Portion, not exceeding 25,000 acres	
3(a)	Imperial Irrigation District	
3(b)	Palo Verde Irrigation District - 16,000 acres	3,850,000
4	Metropolitan Water District, City of Los Angeles and/or others on the coastal plain	550,000
5	Metropolitan Water District, City of Los Angeles and/or others on the coastal plain	662,000
6(a)	Imperial Irrigation District	
6(b)	Palo Verde Irrigation District - 16,000 acres of adjoining mesa	300,000
	Total	**5,362,000**

8.1.1.2 Colorado Supply Reliability

Reliability of CRA water for MWD has decreased overtime as a consequence of multiple events. Historically California had used up to 5.4 million afy as Arizona and Nevada were not using their normal apportionments of Colorado River water and surplus water was made available by the Secretary. The 1964 Decree and the 2006 Consolidated Decree of the US Supreme

AR0071643

Court in *Arizona v. California* confirmed California's allocation was limited to 4.4 MAF annually. As a result MWD can now only rely on its fourth priority allocation of 550 TAF annually. Prior to this, MWD was able to satisfy its fifth priority allocation with Nevada and Arizona's unused water. However, in 1985 Arizona began increasing deliveries to its Central Arizona Project reducing the availability of unused apportionment to fill MWD's fifth priority.

Because of dry years on the Colorado River system and Arizona and Nevada using their full apportionment, the U.S. Secretary of Interior asserted that California must come up with a plan to live within its 4.4 MAF apportionment. Therefore, users from California have developed California's Colorado River Water Use Plan (California Plan). The users included: MWD, Palo Verde Irrigation District (PVID), Imperial Irrigation District (IID), and Coachella Valley Water District (CVWD). This plan identifies actions that California will take to operate within its 4.4 million acre-foot entitlement.

California currently consumes its normal apportionment of 4.4 million AFY, Exhibit 8E and Exhibit 8F illustrate the order of priority, is as follows:

1. PVID - gross area of 104,500 acres of land in the Palo Verde Valley.
2. Yuma Project-Reservation Division - not exceeding a gross area of 25,000 acres in California.

3(a). IID - lands in the Imperial Valley served by the All-American Canal. Export out of basin, primarily agricultural usage. Also, second 63,000 AF in priority 6(a) and balance of any remaining priority 6(a) and 7 water available.

3(b). CVWD - lands in the Coachella Valley served by the Coachella Branch of the All-American Canal. Export out of basin, agricultural usage. Also third 119,000 AF in priority 6(a) and balance of any remaining priority 6(a) and 7 water available.

3(c). PVID - 16,000 acres of land on the Lower Palo Verde Mesa, also priority 6(b).

4. MWD – 550,000 af, also 662,000 af in priority 5, and first 38,000 af in 6(a)

Exhibit 8E

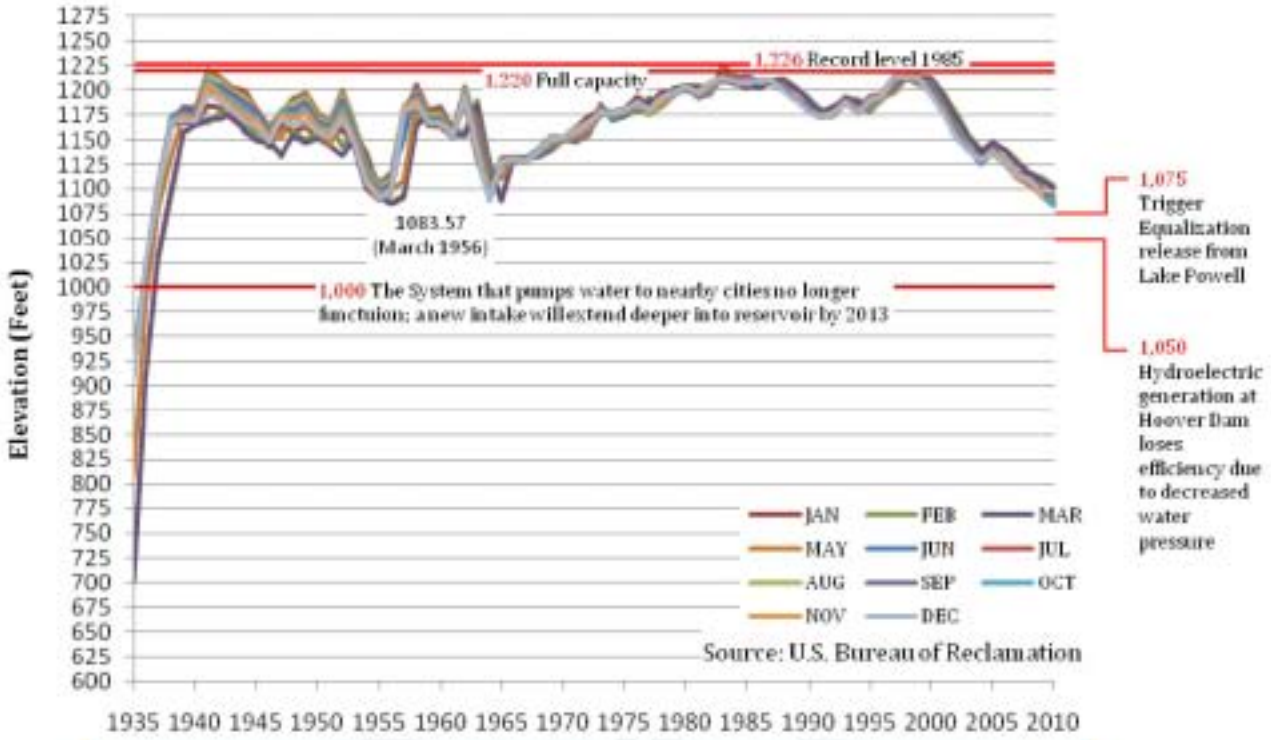
AR0071644

Exhibit 8F
Historical Lake Mead Elevation



The bathtub ring at Lake Mead, August 2010, lake elevation 1,087 feet.

AR0071645

A component of the California Plan was completion of the Quantification Settlement Agreement (QSA) in 2003, which established baseline water use for each California party with Colorado River water rights. Key to the agreement is the quantification of IID at 3.1 MAF, and CVWD at 330 TAF. Completion of the QSA facilitates the transfer of water from agricultural agencies to urban water suppliers by allowing water conserved on farm land to be made available for urban use. As a result of litigation, the QSA and eleven other agreements were ruled as invalid on February 11, 2010. MWD in conjunction with, CVWD and the SDCWA, have appealed the court's decision. Ultimately, the total impact of the court's decisions on MWD's Colorado River supplies cannot be determined at this time pending the outcome of the appeal. However, MWD's existing conservation, land fallowing, and transfer programs for Colorado River supplies are independent of the QSA and will not be impacted by the QSA lawsuit.

Along with MWD's apportionment, MWD has developed a number of water supply programs to improve reliability of Colorado River supplies, such as agricultural water transfers and storage programs, and has multiple programs under development as listed in Exhibit 8F. Developed programs in conjunction with MWD's apportionment will provide MWD with approximately 1.14 MAF in 2035 under an average year (1922 – 2004 hydrology). Proposed programs under development could add another 182 TAF per year. Non-MWD supplies conveyed through the CRA are forecast at 296 TAF for a total CRA supply capability of 1.61 MAF. However, the CRA has a supply capacity constraint of 1.25 MAF. After subtracting MWD's conveyance obligation of non-MWD supplies, MWD's supplies for 2035 under average year, single-dry year (1977 hydrology), and multi-dry year (1990 – 1992 hydrology) scenarios are all forecast at 954 TAF. Exhibit 8G summarizes the CRA supply forecast for 2035 under an average year.

Exhibit 8G
MWD's CRA Forecast Supplies in 2035, Average Year (1922 – 2004 Hydrology)

Program	Supply (Thousands of AF)/ Year
Current	
Basic Apportionment - Priority 4	550
Imperial Irrigation District/MWD Conservation Program	85
Priority 5 Apportionment (Surplus)	13
Palo Verde Irrigation District Land Management Crop Rotation and Water Supply Program	133

Minus Non-MWD Supplies[3]	**-296**
Maximum MWD Supply Capability[4]	**954**

1. Subject to satisfaction of conditions specified in agreement among MWD, the US, and the San Luis Rey Settlement Parties
2. Total amount of supplies available without taking into consideration of CRA capacity constraint of 1.25 MAF annually.
3. Exchange obligation for San Diego County Water Authority - Imperial Irrigation District transfer and the Coachella and All-American Canal Lining Projects
4. The amount of CRA water available to MWD after meeting exchange obligations.

Source: 2010 Regional Urban Water Management Plan, Metropolitan Water District of Southern California

8.1.1.3 Water Quality Issues

Water quality issues for Colorado River supplies encompass high salinity levels, perchlorate, nutrients, uranium, chromium VI, N-nitrosodimethlamine (NDMA), and pharmaceuticals and personal care products (PPCPs). High salinity levels present the most significant issue and the only foreseeable water quality constraint for the Colorado River supply. MWD expects its source control programs for the CRA to adequately address the other water quality issues. MWD has also bolstered its water security measures across all of its operations since 2001, including an increase in water quality tests. Details of MWD's water quality initiatives are available in MWD's 2010 Regional Urban Water Management Plan (RUWMP).

Salinity

Water obtained from the Colorado River has the highest salinity levels of all MWD supply sources averaging 630 mg/L since 1976. Salts are eroded from saline sediments deposited in prehistoric marine environments in the Basin, dissolved by precipitation, and conveyed into the Basin's water courses.

Salinity issues have been recognized in the Basin for over 30 years. The seven basin states formed the Colorado River Basin Salinity Control Forum (Forum) to mutually cooperate on salinity issues in the Basin. The Forum recommended the U.S. Environmental Protection Agency (USEPA) to act upon the Forum's proposal and in response the USEPA approved water quality standards and established numeric criteria for controlling salinity increases. Each Basin State adopted the water quality

AR0071647

standards, which are designed to limit the flow-weighted average annual salinity level to 1972 levels or below. An outgrowth of the Forum was the Colorado River Basin Control Program. At the core of the program is the reduction in salts entering the river system by intercepting and controlling non-point sources, wastewater, and saline hot springs. Salinity reduction projects have reduced salinity concentration of Colorado River water by over 100mg/L approximating $264 million per year, in 2005 dollars, in avoided damages.

MWD adopted a Salinity Management Policy in 1999 with the goal of achieving salinity concentrations of less than 500 mg/L at delivery. To reduce salinity levels, Colorado River supplies are blended with SWP water supplies to achieve the salinity target in seven out of ten years. In the other three years the target is not possible to achieve as a result of hydrologic conditions that increase salinity on the Colorado River and less SWP water is available for blending. Additionally, to maximize the use of recycled water in agriculture, MWD is trying to obtain lower salinity imported water during the spring/summer months to reduce salinity levels in recycled water.

Perchlorate

In 1997 perchlorate was first detected in the Colorado River attributed to an industrial site upstream of the Las Vegas Wash in Nevada, ultimately draining to the river. Subsequently, an additional groundwater plume was found to be migrating from an additional industrial site, but had not reached the Las Vegas Wash. Since the initial discovery of contamination, remediation efforts have significantly reduced perchlorate loading from the Las Vegas Wash. At Lake Havasu, downstream of the convergence of the Las Vegas Wash and Colorado River, perchlorate levels have decreased from 9 µg/L at their peak in 1998 to less than 6 µg/L in October 2002. Since June 2006 typical levels have been less than 2 µg/L.

Nutrients

Excessive nutrient levels in water can stimulate algal and aquatic weed growth leading to taste and odor concerns. Nutrients include both phosphorous and nitrogen compounds. Other impacts of algal and aquatic weed growth include reductions in operating efficiencies and potentially provide an additional food source for invasive aquatic species, such as quagga and zebra mussels.

Naturally, the Colorado River system has relatively low concentrations of phosphorous. Additional loading to the system as upstream urbanization increases has the ability to increase phosphorous concentrations and impact MWD's ability to blend low nutrient concentration CRA water with high nutrient concentration SWP water. MWD continues to work with agencies located along the lower Colorado River to improve their wastewater management to reduce phosphorous loading.

Uranium

Near Moab, Utah a 16-million ton pile of uranium tailings located approximately 750 feet from the Colorado River is a potential source of uranium loading to the river. In 1999, the US Department of Energy began remediating the site by removing tailings and treating contaminated groundwater. Complete removal of the pile is expected by 2025 or 2019 if additional funding is secured. MWD is tracking clean-up progress and continues to support rapid clean-up of the site.

To address recent uranium mining claims in the vicinity of the Colorado River and the Grand Canyon Area, MWD has sent letters to the Secretary of Interior to highlight MWD's concern of source water protection and recommended close federal oversight. In 1999, the Department of Interior placed a two-year hold on mining claims for 1 million acres adjacent to the Grand Canyon area to conduct additional analyses and H.R. 644, Grand Canyon Watersheds Protection Act, was introduced in 2009. H.R. 644, if approved, would prohibit new mining activities around the Grand Canyon area.

AR0071648

Chromium VI

Chromium VI has been detected in a groundwater aquifer in the vicinity of the Colorado River near Topock, Arizona. The source of the contamination is a natural gas compression site operated by Pacific Gas and Electric (PG&E) that previously used chromium VI in its operations. Currently, PG&E is engaged in interim clean-up operations to protect the Colorado River. A final treatment alternative is anticipated to be released in 2010. Monitoring upstream and downstream of the site range from non-detect (0.03 µg/L) to 0.06 µg/L which are considered within the background range for the river. MWD is actively involved in the corrective action process through its participation in stakeholder workgroups and partnerships with State and federal regulators, Indian tribes, and other stakeholders.

NDMA and Pharmaceuticals and Personal Care Products

N-nitrosodimenthylamine is a by-product formed by secondary disinfection of some natural waters with chloramines. MWD is involved with projects to understand the potential sources of NDMA precursors in its source watersheds and to develop treatment strategies to minimize NDMA formation at its water treatment facilities. In 2007, MWD initiated monitoring efforts to measure Pharmaceuticals and Personal Care Projects (PPCPs) in its source supplies. PPCPs have been detected at very low levels (low ng/L level; parts per trillion) consistent with monitoring results from other utilities. MWD is involved with programs to improve analytical testing methods, characterize PPCP in drinking water sources in California, and effects of PPCPs on groundwater recharge and recycled water use.

8.1.2 State Water Project

MWD began receiving water from the State Water Project (SWP) in 1972. MWD is the largest of 29 contractors for water from the SWP, holding a contract for 1.912 MAF per year, or 46 percent of the total contracted amount, of the 4.173 MAF ultimate delivery capacity of the project. Variable hydrology, environmental issues, and regulatory restrictions in the San Francisco Bay/Sacramento-San Joaquin River Delta (Bay-Delta) have historically reduced the quantity of water that the SWP delivers to MWD.

8.1.2.1 Major State Water Project Facilities

The SWP is owned by the State of California and operated by the Department of Water Resources (DWR) delivering water to two-thirds of the population of California and 750,000 acres of farmland. Major facilities in the SWP system consist of 701 miles of aqueduct, 34 storage facilities totaling 5.8 MAF of storage, five hydro-electric power plants, four pumping-generating plants, 17 pumping plants, and three pump stations. Exhibit 8H illustrates the location of major SWP facilities. SWP facilities originate in Northern California at Lake Oroville on the Feather River. Water released from Lake Oroville flows into the Feather River, goes downstream to its confluence with the Sacramento River, and then travels into the Bay-Delta. Water is pumped from the Bay-Delta region to contractors in areas north and south of the San Francisco Bay and south of the Bay-Delta. SWP deliveries consist solely of untreated water. In addition to delivering water to its contractors, the SWP is operated to improve water quality in the Delta region, control flood waters, and provide recreation, power generation, and environmental enhancement.

MWD receives SWP water at three locations, Castaic Lake in Los Angeles County, Devil Canyon Afterbay in San Bernardino County, and Box Spring Turnout at Lake Perris in Riverside County. In addition, MWD has flexible storage rights of 65 TAF at Lake Perris at the terminus of the East Branch of the SWP and 153.95 TAF at Castaic Lake at the terminus of the West Branch.

AR0071649

8.1.2.2 Contract Allocations

Contract allocations, also known as entitlements, for SWP contractors are provided by DWR in a table commonly referred to as Table A. Allocations are based on the original projected SWP maximum yield of 4.173 MAF. Table A is a tool used by DWR to allocate fixed and variable SWP costs and yearly water entitlements to the contractors. Table A contract amounts do not reflect actual deliveries a contractor should expect to receive. MWD has a Table A contract amount of 1.912 MAF. MWD's full Table A contract amount was made available to MWD for the first time in 2006.

Table A Maximum Annual SWP Amounts (acre-feet)

Contractor	Maximum SWP Table A
North Bay	
Napa County Flood Control and Water Conservation District	29,025
Solano County Water Agency	47,756
Subtotal	**76,781**
South Bay	
Alameda County Flood Control and Water Conservation District, Zone 7	80,619
Alameda County Water District	42,000

Subtotal	**2,593,100**
Delta Delivery Total	**4,132,986**

Feather River

Butte County	27,500
Plumas County Flood Control and Water Conservation District	2,700
Yuba City	9,600
Subtotal	**39,800**
Total	**4,172,786**

DWR annually approves the amount of contract allocations SWP contractors will receive. The contract allocation amount received by contractors varies based on contractor demands and projected available water supplies. Variables impacting projected water supplies include snowpack in the Sierra Nevada, capacity available in reservoirs, operational constraints, and demands of other water users. Operational constraints include pumping restrictions related to fish species listed as either threatened or endangered under the federal or state Endangered Species Acts. Contractors' requests for portions of their entitlements cannot always be met. In some year there are shortages and in other years surpluses. In 2008 and 2009 SWP contractors received only 35 percent and 40 percent, respectively, of their SWP contract allocations. In 1991 and 1992 MWD received 391 TAF and 710 TAF, respectively, less than their requests.

DWR bi-annually prepares the State Water Project Delivery Reliability Report to provide contractors with current and projected water supply availability for SWP. The 2009 draft released in January 2010 indicates expected deliveries for multiple-dry year periods will vary from 32 to 38 percent of maximum Table A amounts and for multiple-year wet periods 72 to 94 percent of maximum Table A amounts. Overall the report shows increased reductions in water deliveries on average when compared to the previous 2007 report. Factors impacting deliveries include environmental constraints and hydrologic changes as a result of climate change.

AR0071651

Exhibit 8H
State Water Project Major Facilities

AR0071652

In addition to MWD's Table A amount, MWD has long term agreements in place to obtain additional SWP supplies through four other programs:

- Article 21
- Turnback Pool
- Yuba River Accord
- San Luis Carryover Storage
- Desert Water Agency and Coachella Valley Water District Table A Transfer.

Article 21 is in reference to a provision in the SWP contract with DWR that allows SWP contractors, such as MWD, to take additional water deliveries in addition to Table A amounts. Article 21 water is only available under certain conditions as outlined in Article 21. SWP Article 21 of the contracts permits delivery of water excess to delivery of SWP Table A and some other water types to those contractors requesting it. SWP Article 21 water is apportioned to those contractors requesting it in the same proportion as their SWP Table A.

Turnback Pool (Pool) water allows a contractor that has been allocated Table A annual entitlement that the contractor will not use to sell that water to other SWP Contractors through the Pool. If there are more request from contractors to purchase water from the Pool than the amount in the Pool, the water in the Pool is allocated among those contractors requesting water in proportion to their Table A entitlements. If requests to purchase water from the Pool total less than the amount of water in the Pool, the sale of water is allocated to the selling contractors in proportion to their respective amounts of water in the Pool.

In 2007, MWD and DWR signed an agreement allowing MWD to participate in the Yuba Dry Year Water Purchase Program. Under this program, transfers are available from the Yuba County Water Agency during dry years up to 2025. MWD completed purchases of 26.4 TAF and 42.9 TAF in 2008 and 2009, respectively.

As part of the Monterey Amendment, which modified the contractors' long term contracts with DWR, the use of carryover storage by contractors was permitted in the San Luis Reservoir for use during dry years. Carryover storage is curtailed if it impedes with the storage of SWP water for project needs.

MWD entered into a transfer agreement with the Desert Water Agency (DWA) and Coachella Valley Water District (CVWD) for their Table A contract amounts in exchange for an equal amount of water from the CRA. Both DWA and CVWD are SWP contractors, but have no physical connections to obtain SWP water. MWD is able to transfer CRA water to both agencies as a result of their locations adjacent to CRA facilities. DWA and CVWD have a combined Table A amount of 1.912 MAF per year. MWD additionally can provide DWA and CVWD with deliveries of MWD's other SWP water supplies and non-SWP supplies utilizing SWP facilities, thus allowing MWD additional flexibility in managing its water supply portfolio.

MWD also engages in short-term transfer agreements using SWP facilities to bolster supplies as opportunities become available as discussed in the Groundwater Storage and Transfers sub-section. Historically, MWD has obtained transfers through the Governor's Water Bank, Dry-Year Purchase Programs, and the State Water Contractors Water Transfer Program.

AR0071653

MWD expects to receive 2.046 MAF through its SWP supplies in 2035 under average conditions (1922 – 2004 hydrology). Exhibit 8I summarizes MWD's SWP supplies by program. Current programs are expected to result in 1.441 MAF and programs under development are expected to add an additional 605 TAF. Under multi-year dry conditions (1990 -1992 hydrology), MWD expects to receive only 956 TAF and 1,003 TAF under a single-dry year (1977 hydrology).

Exhibit 8I
MWD Forecast Supplies of SWP Water in 2035, Average Year (1922 – 2004 Hydrology)

Program	Supply (Thousands of AF)
Current	
MWD Table A	1,026
Desert Water Agency and Coachella Valley Water District SWP Table A Transfer	155
San Luis Carryover Storage[1]	208

8.1.2.3 Water Quality Issues

Water quality issues for SWP supplies include total organic carbon (TOC), bromide, arsenic, nutrients, NDMA, and pharmaceuticals and personal care products (PPCPs). TOC and bromide in SWP water present the greatest water quality issues and have restricted MWD's ability to use SWP water at various times as the contaminants form disinfection byproducts during water treatment processes. MWD has initiated a process to upgrade its treatment processes to ozone disinfection to reduce formation of disinfection byproducts and lift potential restrictions on SWP water usage. MWD requires low salinity levels of SWP water to meet blending requirements for CRA water, therefore any increase in salinity levels in SWP supplies is a concern to MWD.

MWD supported DWR in the establishment of a policy regarding water quality of non-SWP water transported through the SWP system and in the expansion of Municipal Water Quality Investigations Programs to include additional monitoring and advanced warnings to Contractors that may impact water treatment processes.

MWD is utilizing its water supply portfolio options to conduct water quality exchanges to reduce total organic compounds and bromide MWD has stored SWP water during periods of high water quality in groundwater storage basins for later use when

AR0071654

SWP is at a lower water quality. These storage programs were initially designed to provide water during dry SWP conditions, but a few of these programs are now operated for dual-purposes.

TOC and bromide in high concentrations lead to the formation of disinfection byproducts when source water is treated with disinfectants, such as chlorine. Agricultural drainage to the Delta and seawater comingling with Delta supplies increases these contaminants. The Bay Delta Conservation Plan (BDCP) has outlined multiple options to improve the water supply reliability and habitat protection, which is being prepared through a collaboration of state, federal, and local water agencies, state and federal fish agencies, environmental organizations, and other interested parties. The overall goal of BDCP is identifying water flow and habitat restoration actions to both improve water supply reliability and recover endangered and sensitive species and their habitats in California's Sacramento-San Joaquin River Delta. MWD is in the process of computing upgrades to its water treatment plants to use ozone as the primary disinfectant. Ozone disinfection is very effective treatment for control of bromate formation and will allow MWD to treat higher quantities of SWP supplies without blending those supplies with CRA water.

Arsenic

SWP supplies not banked in MWD's SWP groundwater storage programs naturally contain low levels of arsenic ranging from non-detect to 4.0 µg/L and do not require additional treatment for arsenic removal. SWP supplies banked in at least one of these groundwater storage programs contain arsenic levels close to or at the regulatory threshold of 10 µg/L requiring additional treatment for arsenic removal. Historically, MWD has at times restricted flows from one groundwater storage program as a result of arsenic levels. One groundwater storage partner has initiated a pilot arsenic removal program, albeit raising the cost of the groundwater storage program. Arsenic can also be removed at water treatment plants by increasing coagulant doses. To handle arsenic removed during water treatment processes, MWD has had to invest in solids handling facilities.

Nutrients

Nutrient levels in SWP water are significantly higher than in Colorado River water. Both phosphorous and nitrogen compounds are a concern in SWP water, but similar to CRA supplies phosphorous is the limiting nutrient. Nutrient sources in SWP water include wastewater discharges, agricultural drainage, and sediments from nutrient rich soils in the Delta. MWD reservoirs have been temporarily by-passed at times as a result of taste and odor events related to nutrients leading to short-term supply impacts.

MWD is working with other water agencies also receiving SWP water from the Delta region to reduce the impact of nutrient loading from wastewater plants discharging to the Delta. To assist in managing its operations, MWD has implemented an algae monitoring and management program designed to provide warnings in advance of algae and taste and odor issues at its reservoirs allowing adjustments in other system operations.

NDMA and Pharmaceuticals and Personal Care Products

Similar to all of its water supply sources, NDMA and PPCPs are constituents of emerging concern. As described above for Colorado River supplies, MWD is involved with efforts to address both NDMA and PPCPs.

Salinity

Over the long term salinity concentrations in SWP water are significantly lower than in CRA water, but the timing of supply availability and TDS concentrations can vary in response to hydrologic conditions. Additionally, salinity concentrations vary in

AR0071655

the short term in response to seasonal and tidal flow patterns. MWD requires lower salinity SWP water to blend with CRA water to meet salinity requirements for its member agencies. MWD's blended salinity objective is 500 mg/L.

Environmental constraints also impact MWD's ability to meet its salinity objective. Since 2007 pumping operations in the Bay-Delta have been limited to prevent environmental harm (as discussed in the Delta Issues subsection below). MWD must rely on higher salinity CRA water resulting in an exceedance in MWD's salinity objective at times.

SWP salinity concentrations as specified in the SWP Water Service Contract have not been met. Article 19 of SWP Water Service Contract specifies ten-year average salinity concentrations of 220 mg/L and a monthly maximum of 440 mg/L. MWD is working with DWR and other agencies to reduce salinity in SWP Delta supplies through multiple programs. These programs include modifying agricultural drainages and completing basin plans on the San Joaquin River, modifying levees around flooded islands in the Delta, and installing gates to reduce transportation of salts from seawater.

8.1.2.4 Bay-Delta Issues

The San Francisco Bay-Delta is a major waterway at the confluence of the Sacramento and San Joaquin rivers serving multiple and at times conflicting purposes exacerbated during dry years when water to meet the needs of both people and the environment is in short supply. Approximately two-thirds of Californians receive at least a portion of their water from the Bay-Delta. Almost all water delivered via the SWP to southern California must pass through the Bay-Delta. Runoff from more than 40 percent of the State is also conveyed through the Bay-Delta forming the eastern edge of the San Francisco bay's estuary. A large portion of the Bay-Delta region lies below sea level and is protected by more than 1,100 miles of levees to prevent flooding. Deterioration of the Bay-Delta ecosystem coupled with infrastructure concerns, hydrologic variability, climate change, litigation, regulatory restrictions, and previously discussed water quality issues have resulted in supply reliability challenges for SWP contractors who depend upon the Bay-Delta for water supplies.

Environmental

As an estuarine environment, the Bay-Delta provides habitat for migratory and resident fish and birds, including those placed on the threatened or endangered species list under the federal or California Endangered Species Act (ESA). Five fish species residing in the Bay-Delta were listed as endangered under the ESA, and one additional species was listed as threatened in 2009 under the California ESA. As a result of a combination of lawsuits regarding the ESA listed species and biological opinions and incidental take permits (permits for inadvertently harming ESA listed species) from the U.S. Fish and Wildlife Service and National Marine Fisheries Service, SWP exports and pumping operations in the Bay-Delta have been significantly curtailed. However, DWR prepared a Water Allocation Analysis in 2010 indicating that MWD could receive 150 to 200 TAF less water than forecast for 2010 under average hydrologic conditions. Ongoing litigation, additional species listing, and regulations could further curtail pumping operations and have an additional adverse impact on MWD's supplies and reserves. MWD has filed a lawsuit in conjunction with other SWP contractors challenging one of the biological opinions. As discussed below under the Delta Plan, the Delta Vision process is designed to develop long term solutions to these issues.

Infrastructure

Bay-Delta channels are constrained by a levee system to protect below sea level islands in the Bay-Delta from flooding. Land in the Bay-Delta subsides mainly from ongoing oxidation of aerated peat soils. Some islands are presently twenty feet or more below sea level. Land subsidence is expected to continue increasing the risk of levee failure and island flooding. Many of the levees are old and do not meet modern engineering standards. A catastrophic earthquake could cause widespread levee failure shutting down SWP operations for an extended period of time. Following a levee failure he flow of water onto an island

AR0071656

can pull saline water fro the San Francisco Bay into the central Delta area and if coupled with pumping in the south Delta draw saline water into the south Delta area. Therefore, pumping in the south Delta may need to be stopped or slowed down for an extended period, and additional flows may need to be released from Lake Oroville to flush saline water out of the Delta. Any salinity introduced into Delta may also impact Delta water quality for an extended period of time.

Recognizing the need for protecting these vulnerable Delta levees, the Bay-Delta Levees Program was formed to coordinate improvements to and maintenance of the Delta levees. Over the next few years the DWR and other agencies will conduct a Comprehensive Program Evaluation. This Program will supplement existing risk studies, develop a strategic plan, recommend priorities, and provide estimates for the Bay-Delta Levees Program.

8.1.2.5 Delta Plan

Former California Governor Arnold Schwarzenegger established the Delta Vision Process in 2006 to address ongoing Bay-Delta conflicts through long-term solutions. The independent Blue Ribbon Task Force completed their vision for sustainable management of the Bay-Delta in 2008. After delivery of the Delta Vision recommendations and goals, the State Legislature initiated the process to conduct information hearings and draft legislation. Ultimately, the Governor called the Seventh Extraordinary Session to address the Delta and water issues in the State. Resulting legislation included the approval of SB 1 X7 addressing Delta policy reforms and governance of the Delta.

A key concept of SB 1 X7 is the formation of a Delta Stewardship Council (Council). The Council is an independent State agency tasked to equally further the goals of Delta restoration and water supply reliability. One of the Council's first major tasks is to develop, adopt, and begin implementation of a Delta Plan by January 1, 2012. Key requirements of the plan as summarized in the MWD RUWMP are:

- Further the coequal goals of ecosystem restoration and water supply reliability;
- Attempt to reduce risks to people, property, and State interests;
- Promote Statewide water conservation, water use efficiency, and sustainable use of water to achieve the coequal goals;
- Improvements to water conveyance/storage and operations of such facilities to achieve the coequal goals;
- Consider including the Bay Delta Conservation Plan (BDCP) into the Delta Plan and allow the BDCP to be eligible for State funding if specific conditions are met.

The BDCP is a joint effort of State and federal fish agencies; State, federal, and local water agencies; environmental organizations; and other parties with the goal of providing for both improvements in water reliability through securing long-term permits to operate the SWP and species/habitat protection in the Delta. MWD is a member of the Steering Committee. An outcome of the plan will be the identification of water flow and habitat restoration actions that assist in recovery of ESA listed and sensitive species and their associated habitats in the Bay-Delta. A range of options to accomplish the outcome will be carried forward to the environmental review phase.

AR0071657

8.1.3 In-Basin Storage

In basin-storage facilities play a key role in maintaining MWD's reliability during droughts or other imported water curtailments and emergency outages. In-basin storage facilities consist of surface reservoirs and contracted groundwater basin storage. Conjunctive use of surface reservoirs and groundwater basins was first initiated by MWD in the 1950's. Long term storage goals for in-basin storage facilities were established in MWD's Water Surplus and Drought Management Plan (WSDM). The WSDM plan allows storage for hydrology variances, water quality, and SWP and CRA issues.

MWD has established emergency in-basin storage requirements based on a major earthquake that could potentially cutoff all supplies for six months from the all aqueducts serving the region, the CRA, both SWP branches, and LADWP's LAA. Under this scenario, MWD would maintain deliveries by suspending interruptible deliveries, implementing mandatory water use reductions of 25 percent of normal-year demands, water would be made available from surface reservoir and groundwater supplies stored as part of MWD's interruptible supply program, and full local groundwater production would occur. MWD's emergency storage requirement is a function of projected demands and varies with time.

8.1.3.1 Surface Reservoirs

MWD owns and operates seven in-basin surface storage reservoirs. Four of the reservoirs, Live Oak, Garvey, Palos Verdes, and Orange County, are used for regulatory purposes and do not provide drought or emergency storage. Additionally, MWD owns and operates two reservoirs, Copper Basin and Gene Wash, along the CRA outside of the basin for system regulation purposes. Outside its basin, MWD has 1.45 MAF storage rights in Lake Mead on the Colorado River pursuant to its intentionally created surplus agreement with the U.S. Bureau of Reclamation. MWD also has storage rights in DWR's SWP terminal reservoirs, Lake Perris and Castaic Lake, as previously discussed. The total capacity of all in-basin surface reservoirs, inclusive of the rights in the terminal reservoirs, is 1.26 MAF, as listed in Exhibit 8J.

Exhibit 8J
Major MWD Facilities Summary

Reservoir	Capacity (AF)
Dry Year/Emergency/Seasonal Storage Purposes	
Diamond Valley Lake	810,000
Lake Matthews	182,000
Lake Skinner	44,000
Lake Perris (Storage Rights)[1]	65,000
Castaic Lake (Storage Rights)[1]	153,940
Subtotal	1,254,940
Regulatory Purposes	
Live Oak	2,500
Garvey	1,600
Palos Verdes	1,100
Orange County	212
Subtotal	5,412
Total Reservoir Capacity	**1,260,352**

1. MWD holds storage rights for flexible use in DWR terminal storage facilities, Lake Perris and Castaic Lake. In addition, MWD has emergency storage of 334 TAF in DWR's reservoirs.

AR0071658

MWD operates its three main storage reservoirs, Diamond Valley Lake, Lake Skinner and Lake Matthews, for dry-year, emergency, and seasonal storage. MWD has identified a dry-year storage capacity goal of 620 TAF by 2020. To date this goal has been met and will be sustained with storage at Diamond Valley Lake and the two terminal reservoirs. Under an average year scenario for 2035 (1922-1994 hydrology), 576 TAF per year of in-basin surface storage is projected to be available, exclusive of emergency supplies, as summarized in Exhibit 8K.

Exhibit 8K
MWD Forecast Supplies of In-Basin Surface Storage Supplies in 2035, Average Year (1922 – 2004 Hydrology)

Program	Supply (Thousands of AF)/Year
In-Basin Surface Storage (Diamond Valley Lake, Lake Skinner, Lake Matthews)	444
Lake Perris and Castaic Lake MWD Storage Rights	132
Maximum MWD Supply Capability	**576**

Source: 2010 Regional Urban Water Management Plan, Metropolitan Water District of Southern California

MWD reserves a portion of its in-basin surface reservoir storage capacity for emergencies. MWD's emergency surface reservoir storage portfolio is split between storage in its three main reservoirs and DWR reservoirs. MWD's emergency storage capacity, based on demands for 2030, is forecast to be approximately 610 TAF. Approximately 276 TAF is projected to be stored in MWD's facilities and the balance of 334 TAF in DWR's facilities. The balance of available storage capacity, 975 TAF, is for dry-year and seasonal storage.

Any additional reservoir capacity is used for seasonal storage and system operations. Seasonal storage is required to meet peak demands. MWD incorporates reserves of 5 percent into reservoir operations to account for imported water transmission infrastructure maintenance that would restrict or temporarily halt imported water flows.

8.1.3.2 Contracted Groundwater Basin Storage

To improve reliability MWD engages in contracted groundwater basin storage within the basin area. By 2020 MWD aims to develop an annual dry supply of 300 TAF. To meet this goal MWD has worked with local water agencies to increase groundwater storage. Groundwater storage occurs using the following methods:

- Direct delivery – Water is delivered directly by MWD to local groundwater storage facilities including through the use of injection wells and spreading basins.
- In-lieu delivery – Water is delivered directly to a member agency's distribution system and the member agency uses the delivered water and forgoes pumping allowing water to remain in storage.

MWD engages in three main types of contracted storage programs, replenishment, cyclical, and conjunctive use. These programs are designed to deliver water to agencies prior to the actual need for the demands allowing MWD to store supplies for use in dry years. Since 2007 MWD has used these programs to address SWP shortages. MWD provides financial incentives and funding to assist agencies to assist with developing contracted storage programs.

AR0071659

Replenishment programs provide water to agencies at a discounted cost and can be withdrawn by the recipient after one year. Cyclic storage contracts allow surplus imported water to be delivered for recharge in advance of the actual water purchase. The delivered water is in excess of an agency's planned and budgeted deliveries. The agency purchases the water at a later time when they have a need for groundwater replenishment deliveries.

Conjunctive use contracts allow MWD to request an agency to withdraw previously stored MWD water from storage during dry periods or emergencies. Agencies must pay MWD the current water rate when they are requested to withdraw water from storage. Water withdrawn from storage allows MWD to temporarily curtail delivers by an equal amount. MWD currently has ten conjunctive use programs with a combined storage capacity of 421.9 TAF and a dry-year yield of 117.3 TAF per year as summarized in Exhibit 8L.

MWD prepared a Groundwater Assessment Study in 2007 in conjunction with local agencies and groundwater basin managers. As indicated in the report there is substantial groundwater storage available in the basin, but there are multiple challenges that must be met to utilize the identified storage. Challenges include infrastructure limitations, contamination, legal issues, and funding.

To further increase the availability of in-basin groundwater storage, MWD has identified nine potential storage programs in the basin and an additional two programs are under development. The Raymond Basin Conjunctive Use Program and the LADWP Groundwater Recovery Project are expected to add an additional 34 TAF per year in 2035 under an average year (1922 – 2004 hydrology).

AR0071660

In 2009 a reconnaissance-level analysis was prepared for analyzing the potential for using recycled water as a supply source for a conjunctive use program. The study concluded up to 100 TAF of groundwater storage and production could be potentially developed in four major groundwater basins using Los Angeles County Department of Sanitation supplies. MWD initiated a formal study in 2010 to further study. This concept along with the potential to use City of Los Angeles recycled water supplies from the Hyperion Waste Water Treatment Plant as an additional source.

Exhibit 8M provides a summary of forecast groundwater storage supplies available in 2035 under an average year (1922 - 2004 hydrology). Approximately 289 TAF per year are forecast to be available.

8.1.4 Groundwater Storage and Water Transfers

MWD engages in groundwater storage outside of the basin and water transfers to increase the reliability of SWP dry-year supplies. Groundwater storage and water transfers were initiated by MWD in response to concerns that MWD's supply reliability objectives could not be met by the SWP. Groundwater storage and transfer programs were developed to allow MWD to reach its SWP reliability goal. All groundwater storage and water transfer programs designed to bolster SWP reliability are located within the vicinity of the SWP or Central Valley Project (CVP) facilities to facilitate the ultimate deliver of water to MWD. Groundwater storage programs involve agreements allowing MWD to store its SWP contract Table A water in excess of MWD demands and to purchase water for storage. MWD calls for delivery of the stored water during dry years. Transfers involve purchases by MWD from willing sellers during dry years when necessary.

Exhibit 8N summarizes MWD's out of basin groundwater storage and transfer programs supplies in 2035, under an average year (1922 – 2004 hydrology). Current programs are expected to deliver 293 TAF in 2035. Five programs under development are forecasted to deliver an additional 110 TAF for a total of 403 TAF in 2035.

8.1.4.1 Groundwater Storage

MWD has four Central Valley groundwater storage programs with a fifth program under development as described below.

The Semitropic Water Banking and Exchange Program is a partnership formed in 1994 between Semitropic Water Storage District (SWSD) MWD, and five other banking partners. The bank has a total storage capacity of 650 TAF, of which MWD has 350 TAF of storage volume. During years of excess SWP deliveries, beyond MWD's demands, a portion of MWD's SWP entitlement water is stored for withdrawal during dry years. Deliveries for storage are transferred via SWP facilities for direct use by agricultural users that in turn forgo pumping an equal volume of water. In dry years water is pumped from storage to SWP facilities for delivery to MWD or entitlements are exchanged. MWD's average annual supply capability for a dry year (1977 hydrology) is 125 TAF and for multiple dry years (1990 – 1992 hydrology) 107 TAF. By the end of 2009, MWD had 45 TAF in storage.

Since 1997 MWD has had an agreement with Arvin-Edison Water Storage District to use 350 TAF of storage in their groundwater basins. The agreement was amended in 2008 to include the South Canal Improvement project to deliver higher quality water to MWD. During wet years MWD delivers SWP water in excess of its demands for storage and receives return water in dry years in a similar manner as the Semitropic program, except a combination of SWP and CVP facilities are used to

AR0071662

transfer the water and water can be stored by a combination of direct spreading or in lieu use by agricultural users. MWD's average supply capability is 75 TAF for either a single dry year (1977 hydrology) or multiple dry years (1990 – 1992 hydrology). In 2009 MWF had 95 TAF in storage.

The San Bernardino Municipal Water District Program allows for the purchase and storage of SWP water on behalf of MWD. MWD has a minimum purchase agreement with San Bernardino Municipal Water District (SBMWD) of 20 TAF per year of SBMWD's SWP Table A amount. Additionally, MWD has the option to purchase SBMWD's additional SWP allocation when available and the first right-of-refusal to purchase additional SWP supplies available to SBMWD beyond the minimum and option agreements. If MWD does not require the minimum purchase amount for operations, MWD can store up to 50 AF for future use in dry years within SBMWD's groundwater basins. Water is delivered to MWD via SWP facilities and groundwater pumping conveyed through local connections to MWD's service area. MWD's average annual supply capability for a dry year (1977 hydrology) is 70 TAF and for multiple dry years (1990 – 1992 hydrology) 37 TAF. By the end of 2009, MWD had no water in storage and deliveries have been suspended upon a mutual agreement between MWD and SBMWD.

MWD entered into an agreement with the Kern Delta Water District (Kern-Delta) for the Kern-Delta Water Management Plan in 2001 to allow up to 250 TAF of groundwater storage. During wet years MWD delivers SWP water in excess of its demands for storage and receives return water in a similar manner as the Semitropic program, except the water can be stored by direct recharge or in lieu use by agricultural users. Per terms of the agreement MWD can potentially store beyond 250 TAF. In dry years water is pumped from storage to SWP facilities for delivery to MWD or entitlements are exchanged. When the project is completed 50 TAF per year of dry year supply can be withdrawn. At the close of 2009 MWD had 10 TAF in storage and expects to fully withdraw the amount in 2010.

The Mojave Groundwater Storage Program is currently a demonstration project between MWD and Mojave Water Agency. Similar to the other groundwater storage programs, MWD's excess SWP water will be stored during wet years for withdrawal during dry years. When fully operational, the program is expected to have a dry year yield of 35 TAF.

8.1.4.2 Transfers

MWD utilizes Central Valley water transfers to obtain additional supplies originally destined for agricultural users on an as needed basis. Past transfer agreements have used both spot markets and option contracts. Spot markets occur when there are willing sellers and buyers. Option contracts lock-in MWD's ability to have the option to purchase supplies if needed. Additionally, MWD has multiple long-term transfer programs under development. MWD's ability to conduct transfers and the amount of water to be transferred using SWP facilities are a function of hydrologic conditions, market conditions, and pumping restrictions in the Bay-Delta region. Transfers may require the use of the Bay-Delta for conveyance dependent upon the origin of the water. Historic transfers, as listed in Exhibit 8O, indicate MWD is capable of negotiating contracts with agricultural districts and the State's Drought Water Bank to obtain transfers. MWD also has demonstrated it can work with DWR and the U.S. Bureau of Reclamation (USBR). Cooperation of both agencies is required as transfers use a combination of DWR's SWP and USBR's CVP facilities. Transfers from north of the Delta result in the loss of 20 percent of the water during conveyance while transfers via the California Aqueduct to MWD's service area result in the loss of 3 percent water during conveyance. During dry years and when pumping capacity in the Bay-Delta is available, MWD expects to be able to transfer 125 TAF through SWP facilities.

AR0071663

Exhibit 8O
MWD Historic Central Valley Water Transfers

Program	Purchases by MWD[1] (AF/Year)
1991 Governor's Water Bank	215,000
1992 Governor's Water Bank	10,000
1994 Governor's Water Bank	100
2001 Dry Year Purchase Program	80,000
2003 MWD Transfer Program	126,230
2005 State Water Contractors Water Transfer Program[2]	0
2008 State Water Contractors Water Transfer Program	26,621
2009 Governor's Water Bank	36,900

1. Transfers requiring use of Bay-Delta result in a water loss of 20 percent. Transfers requiring the California Aqueduct for delivery to MWD's service area result in a 3 percent water loss.

2. 127,275 in options were secured, but not needed.

8.2 MWD Supply Reliability and Projected LADWP Purchases

MWD's 2010 Integrated Water Resources Plan (IRP) Update serves as the foundation for supply forecasts discussed in the RUMWP and continues to ensure system reliability for its member agencies. The 2010 IRP update concluded that the resource targets identified in previous updates, taking into consideration changed conditions identified since that time, will continue to provide for 100 percent reliability through 2030. MWD's subsequent evaluation to extend the resource targets by an additional five years through their 2010 draft RUWMP also concluded the same full reliability during average (1922 – 2004 hydrology), single dry (1977 hydrology), and multiple dry years (1990 - 1992 hydrology). For each of the scenarios there is a surplus in every forecast year. Exhibit 8P summarizes MWD's reliability in five year increments extending to 2035.

The City purchases MWD water to make up the deficit between demand and other City supplies. Whether LADWP can provide reliable water services to the residents of Los Angeles is highly dependent on MWD's assurance on supply reliability. However, the recent water supply shortage caused by dry weather and pumping restrictions in the Delta prompted the City to develop a more sustainable water supply portfolio with emphasis on local water supplies such as recycled water, groundwater cleanup, stormwater capture, and conservation. LADWP's reliance on MWD water supply is projected to be cut in half from the five-year average of 52 percent of the total demand between 2005-06 and 2009-10, to 24 percent by 2034-35 under average weather conditions.

The reliability of MWD's water supply is more fully discussed in Chapter 10, Integrated Resources Planning. The projected LADWP water purchase is further discussed in Chapter 11, Water Service Reliability Assessment under various weather scenarios.

AR0071665

8.3 MWD Rate Structure and LADWP's Purchased Water Costs

8.3.1 MWD Rate Structure

MWD's rates are structured on a tier–based system with two tiers and a surplus category. Nine major elements determine the actual price a member agency will pay for deliveries. All of the elements are volumetric based except for two fixed rates, the Readiness-to Serve Charge and the Capacity Charge.

Tier 1 rates are reflective of actual costs of existing supplies and are designed to recover most of the supply costs. Member agencies are allocated a specified volume of Tier 1 water that can be purchased within a given year. In 2011 LADWP's Tier 1 limit is 304,970 AF. Any purchases above this are charged at the Tier 2 rate. MWD has instituted a temporary Delta surcharge to recover costs associated with lower SWP deliveries related to pumping restrictions. The surcharge will remain in effect until SWP yields improve.

Tier 2 rates send a price signal associated with MWD's costs of developing additional long-term firm supply options. Member agencies with growing demands on MWD will have a higher proportion of deliveries within the Tier 2 range.

Surplus water is water in excess of consumptive municipal and industrial demands. Surplus water is available at two discounted levels dependent upon the end use. Replenishment Program water is discounted for replenishing local agency supplies. The program has been suspended as a result of dry conditions and uncertain future supplies. The Interim Agricultural Water Program (IAWP) provides discounted water for agricultural use. This program is being phased out and will terminate beginning in 2013.

Exhibit 8Q summarizes the rates and charges for member agencies effective on January 1 of 2010, 2011, and 2012.

8.3.2 LADWP's Purchased Water Costs

MWD's water rates vary from $484 per AF of tier 1 untreated water to $811 per AF of tier 2 treated water in 2010. The average unit cost of MWD water supply depends on the proportions of treated water and untreated water, tier 1 water and tier 2 water purchased in a given period. From 2003 to 2009, LADWP purchased 88 percent tier 1 water and 12 percent tier 2 water, and 70 percent untreated water and 30 percent treated water on average. The tier 2 water purchase varied from no purchase in 2005 and 2006 to 29 percent in 2007 and 2008. The treated water purchase varied from 20 percent in 2007 to 46 percent in 2005. Exhibit 8R illustrates the various combinations.

The Readiness-to-Serve Charge and Capacity Charge are predetermined fixed charges for each member agency and not affected by the quantity of MWD water purchased. However, they add on to the unit cost of the City's MWD water purchase. The City's current share of the Readiness-to-Serve Charge is 15.12 percent or $17.24 millions in 2010. The Capacity Charge is calculated based on the summer daily peak flow from the previous three years. LA's 2010 Capacity Charge is $5.9 millions based on the daily peak flow of 822 cfs in 2008 summer. Both charges added an additional $110 per AF to the unit cost of LADWP's MWD water purchase in 2010.

DRAFT

DRAFT Chapter Nine
Other Potential Water Supplies

9.0 Overview

LADWP continually investigates other potentially feasible water supplies to ensure the sustainability of water supply for the City of Los Angeles. In recent years, LADWP has actively pursued and investigated various supply options including water transfers and banking and seawater desalination. Evaluating the viability of these and other water resource options is a key element to ensuring the City's future water supply reliability. Such options, with proper planning, can contribute toward fulfilling future demand under various conditions. Future water resource challenges, which include increased demand that must be met without increasing imported supply, warrant thoughtful consideration of these and other potentially feasible water supply resources.

Following is a discussion of each of the potential supply options described above, highlighting LADWP's progress in developing each alternative source of water. Factors that affect feasibility and influence potential implementation are also discussed, as well as advances that facilitate development of the resource option.

9.1 Water Transfers and Banking

Water transfers involve the lease or sale of water or water rights between consenting parties. Water Code Section 470 (The Costa-Isenberg Water Transfer Act of 1986) states that voluntary water transfers between water users can result in a more efficient use of water, benefiting both the buyer and the seller. The State Legislature further declared that transfers of surplus water on an intermittent basis can help alleviate water shortages, save capital outlay development costs, and conserve water and energy. This section of the Water Code also obligates the California Department of Water Resources (DWR) to facilitate voluntary exchanges and transfers of water.

The DWR is required to establish an ongoing program to facilitate the voluntary exchange or transfer of water and implement the various State laws that pertain to water transfers. In response to this mandate, DWR established an internal office dedicated specifically to water transfers in June 2001 and has developed various definitions and policies for transfers. Of particular importance are the rules protecting existing water rights. Water rights cannot be lost when they are transferred to another user if the transferor has an underlying right to the transferred water. DWR also developed three fundamental rules specifically regarding water transfers:

- There can be no injury to any legal user of water;
- There can be no unreasonable effect to fish and wildlife; and
- There can be no unreasonable economic effects to the economy of the county of origin.

Water banking, a form of conjunctive use, is the storage of water in groundwater basins for future use. Typically, during wet periods water is stored or banked within groundwater basins for potential extraction during dry periods. Water banking sets up accounts to track the volumes of water recharged and extracted per terms of contract agreements between water agencies. Water banking may occur outside of a water agency's service area. If the water agency's own conveyance facilities are not directly adjacent to the water bank, stored water can be extracted and transferred through wheeling and exchange via other

AR0071670

conveyance and storage facilities. Such movements of water involve institutional transfer agreements among water users and agencies.

9.1.1 LADWP Opportunities

LADWP is considering opportunities to acquire water through transfers to replace a portion of LAA water used for environmental enhancements in the eastern Sierra Nevada. The City would purchase water when available and economically beneficial for storage or delivery to LADWP's transmission and distribution system. The City is seeking non-State Water Project water to replace the reallocation of LAA water supply for environmental enhancements. MWD holds an exclusive contractual right to deliver State Water Project entitlement water into its service territory, which includes the City of Los Angeles. Purchasing only non-State Water Project supplies will ensure the City's compliance with MWD's State Water Project contract.

To facilitate water transfers, LADWP is constructing an interconnection between the LAA and the State Water Project's California Aqueduct, located where the two aqueducts intersect in the Antelope Valley (Neenach, California). This interconnection, the Neenach Temporary Pumping Station (NTPS) will allow for water transfers from the East Branch of the State Water Project to the LAA System, as well as provide operational flexibility in the event of a disruption of flows along the LAA System. Construction of the NTPS required a four-way agreement between DWR, MWD, LADWP, and the Antelope Valley-East Kern Water Agency (AVEK). When completed, the NTPS facility will be owned by DWR but will be designated as an AVEK interconnection. The NTPS will be operated on behalf of the LADWP. MWD is involved in the agreement to provide consent for the transferred water to enter its service territory.

LADWP's current goal is to transfer up to 40,000 AF per year once the NTPS facilities are in place. This will provide LADWP with the ability to replace some Los Angeles Aqueduct supplies reallocated to environmental enhancement projects. This will also provide increased operational flexibility and the ability to yield cost savings.

A demonstration study will be performed during the NTPS's first two years of operations; this study will include an evaluation of the operational and water quality aspects of the NTPS.

Neenach Temporary Pumping Station, construction site, looking northerly, taken September 16, 2010, by Aqueduct Aerial Patrol.

AR0071671

To supplement water transfers, LADWP is also investigating the possibility of water banking. A request for proposal (RFP) was issued in 2008 and five proposals were received for evaluation to determine the most mutually beneficial agreement for a water banking program. However, LADWP has decided to not pursue full scale water banking projects at this time and has instead chosen to proceed with the Indian Wells Valley Water District's proposal to explore a potential water banking opportunity directly adjacent to the LAA.

The City supports Statewide water transfer legislation that will ensure the efficient use of the State's limited water resources and provide safeguards to the environment, public facilities, water conservation efforts and local economies. LADWP will continue to develop a responsible water transfer program that can assist in replacing City supplies that have been reallocated to the environment in the Eastern Sierra Nevada.

9.1.2 MWD Opportunities

Regionally, MWD has been active with water transfers and banking, seeking and implementing agreements and cooperative arrangement opportunities to supplement southern California's water supply. MWD's water transfer activities are classified as *spot transfers*, *option transfers*, *core transfers*, *storage transfers*, or *exchanges*. Each activity is described briefly below.

- *Spot transfers* make water available through a contract entered into the same year that the water is delivered.
- *Option transfers*, through multi-year or single-year contracts, allow MWD to obtain water on an "as-needed" basis.
- *Core transfers* make water available through multi-year contracts that convey specific water entitlement to MWD each year.
- *Storage transfers* allow MWD to store and later recover available water that can then be transported immediately to southern California.
- *Exchange agreements* involve the transfer to MWD of another agency's entitlements in exchange for water entitled to MWD from another source.

MWD is in the process of developing and implementing transfer/storage projects in the Central Valley, and off-stream banking and dry year supplies of Colorado River water. Water transfers, including the programs highlighted below, are an important element of California's plan to live within its 4.4 million acre-feet per year entitlement to Colorado River water. These programs have also helped MWD adjust to regulatory restrictions on State Water Project pumping from the San Francisco Bay-Delta. Current and potential MWD transfer, storage, and exchange agreements/activities include:

- Semitropic Water Storage Program
- Kern Delta Water District Water Management Program
- Arvin-Edison Water Transfer and Storage Program, Kern County
- San Bernardino Valley Transfer and Storage Program
- Desert Water Agency/Coachella Valley Water District Exchange Program

- Chuckwalla Groundwater Storage Program (under development)
- Coachella Valley Water District Agreement (under development)

MWD's water rate structure is designed to allow water transfers using MWD infrastructure by establishing a water wheeling rate, which is a combination of the System Access Rate, Water Stewardship Rate, System Power Rate, and Treatment Surcharge. The wheeling rate applies to all water conveyed through MWD's infrastructure, regardless of the agency using the

DRAFT

AR0071673

system. MWD's unbundled rate structure and its associated wheeling rate encourage development of water markets by providing for competition at the supply level; MWD's member agencies can purchase supplies from any source and pay MWD's wheeling rate to transmit the water. MWD's current water rate structure establishes charges for each component on a per acre foot basis for all water moving through MWD's system. As of January 1, 2010, current wheeling rate charges are:

- System Access Rate: $154/AF
- Water Stewardship Rate: $41/AF
- System Power Rate: $119/AF
- Treatment Surcharge: $217/AF

The System Access Rate recovers costs associated with conveyance and distribution capacity to meet average annual demands. The Water Stewardship Rate recovers the cost associated with providing financial incentives for investments in local water resources, such as water conservation and recycled water programs. The System Power Rate recovers the cost for power to move water through MWD's system. The treatment surcharge applies to all water that is treated at one of MWD's five treatment plants.

MWD's water rate structure also incorporates a tiered supply rate format. The first tier price applies to a fixed base quantity of water as defined by each MWD member agency's purchase order contract. The second tier price reflects the incremental cost for MWD to acquire additional supplies that are above the first tier contract base amount

9.2 Seawater Desalination

Seawater desalination, the process of removing salts and other impurities from seawater, has reached an all-time high in terms of worldwide production capacity. According to the International Desalination Association, between 2007 and 2009, worldwide seawater desalination capacity increased by approximately thirty percent to a total capacity of 9.5 bgd. This is partly driven by the fact that the cost to desalinate water has reached an all-time low due to technological and process advancements. Of the more than 14,000 seawater and groundwater desalination plants in operation worldwide, the majority are located in the Middle East, where energy costs are relatively low. The world's largest seawater desalination plant in Saudi Arabia produces 232 mgd of desalted water. In contrast, the largest facility in the US, located in Tampa Bay, FL, produces 25 mgd.

LADWP's current water resource strategy does not include seawater desalination as a water supply. There are concerns with cost and the environmental impacts associated with the implementation of desalination. LADWP is primarily focused on enhancing recycling and conservation. While someday desalination may be explored further, it currently remains as a supply alternative.

9.2.1 Desalination Technology

Technology to desalt seawater to produce potable water which meets or exceeds drinking water standards has been available for some time, but has not been widely implemented primarily due to its high cost. Although the cost to desalinate seawater is still more expensive than obtaining water from conventional sources, continued research and development, as well as large scale projects, are being implemented in the United States and other parts of the world to improve technology and further drive costs down. Additionally, increasing costs associated with new water supplies and existing supplies is reducing the cost

AR0071674

differential between desalinated water and other water sources improving the viability of desalinated water as a part of an overall water supply portfolio.

The two basic seawater desalination processes are: 1) use of the distillation process to evaporate water from salts; and 2) use of semi-permeable membranes to filter the water while straining out the salts. While distillation has been the dominant seawater desalination technology (primarily in the Middle East), current worldwide desalination development is rapidly migrating toward membrane technology. Facilities using distillation are still prevalent in the Middle East. However, new plant installations are increasingly taking advantage of technological advancements (higher yield and lower energy requirements) in membrane-based process technology. Today, membrane filtration accounts for over half of the world's desalting capacity.

9.2.2 DWR Desalination Efforts

Recognizing the potential of seawater as a water resource, the DWR through a legislative mandate, convened a California Water Desalination Task Force in 2002. The task force was responsible for making recommendations to the Legislature on potential opportunities, impediments, and the State's role in furthering desalination technology.

The task force was effective in providing a forum where stakeholders could convene and discuss critical issues related to desalination. Key seawater desalination issues that have been raised through the task force fall into six general categories: environmental, economic, permitting, engineering, planning, and coordination.

To assist in addressing these issues, the California Water Desalination Task Force has developed draft guidelines for developing environmentally and economically acceptable desalination projects. These include the following:

- Each project should be considered on its own merits;
- Sponsoring agencies should be determined early in the planning process;
- Public and permitting agencies should be engaged early in the planning process;
- Collaborative processes should be used to enhance support for project implementation;
- A feedback loop should be incorporated to allow for continuously revisiting and revising the project at each step of the planning process; and
- Key decision points (e.g., costs, environmental acceptability) should be identified to test the general feasibility of the project as early in the planning process as possible.

After establishment of the task force, desalination was added to the California State Water Plan as an alternative for consideration in regional water supplies. Furthermore, in 2008, DWR published the *California Desalination Planning Handbook*, building upon the Task Force efforts. The handbook provides guidance on determining appropriate conditions for desalination plants, addressing concerns, and building public trust.

Proposition 50, Chapter 6, has provided funding for desalination research, feasibility studies, pilot projects, and construction of new facilities. Over $45 million was distributed under this proposition in two rounds of funding for both seawater and groundwater desalination. Fund recipients included LADWP.

AR0071675

With increasing demand for water and limited new supply options, the future value of seawater desalination as a part of California's water supply portfolio has become apparent. Within southern California, a range of 270,000 AFY to 422,000 AFY of desalinated seawater could be potentially produced based on current efforts (see Exhibit 9A). While this production represents less than five percent of the region's total water supplies, it is nonetheless considered by water planners as an important part of the region's water supply portfolio.

9.2.3 MWD Desalination Efforts

MWD first incorporated desalinated seawater as a potential new water supply source in its 2003 Integrated Resources Plan Update. Subsequently in 2009, MWD's Board of Directors created a special committee on Desalination and Recycling to study MWD's role in regional efforts to develop desalination facilities.

In response to a proposal solicitation in 2001, MWD received proposals by five member agencies to provide up to 142,000 AFY of potable water. To provide an incentive for the development of desalinated seawater, MWD is offering subsidies of up to $250 for each acre-foot (326,000 gallons) of desalinated seawater produced. LADWP, Long Beach Water Department, West Basin Municipal Water District, Municipal Water District of Orange County, and San Diego County Water Authority submitted detailed proposals that qualified for the MWD's Seawater Desalination Program. Exhibit 9A summarizes the status of the desalination efforts in MWD's service area, including projects not in the Seawater Desalination Program. Each of these agencies serves coastal areas, and is looking to desalination as a means to further diversify their water supply sources.

Exhibit 9A
Desalination Efforts in MWD Service Area

Project Name	Member Agency	Capacity (AFY)	Status
MWD Seawater Desalination Program			
Long Beach Seawater Desalination	Long Beach	10,000	Pilot Study[1]
Los Angeles Seawater Desalination	LADWP	28,000	On-hold
South Coast Coastal Ocean Desalination	Municipal Water District of Orange County	16,000 - 28,000	Pilot Study
Carlsbad Seawater Desalination	San Diego County Water Authority	56,000	Permitting Complete
West Basin Seawater Desalination	West Basin Municipal Water District	20,000	Pilot Study[1]
Subtotal		130,000 - 142,000	
Other Potential Projects in MWD Service Area			
Huntington Beach Seawater Desalination	Municipal Water District of Orange County	56,000	Initiating Permitting
Camp Pendleton Seawater Desalination	San Diego County Water Authority	56,000 - 168,000	Planning
Rosarito Beach Seawater Desalination	San Diego County Water Authority	28,000 - 56,000	Feasibility Study
Subtotal		140,000 - 280,000	
Total		270,000 - 422,000

AR0071676

9.2.4 LADWP Seawater Desalination Efforts

Scattergood Generating Station Seawater Desalination Plant

LADWP initiated efforts in 2002 to evaluate seawater desalination as a potential water supply source with the goals of improving reliability and increasing diversity in its water supply portfolio. These efforts led to the selection of Scattergood Generating Station as a potential site for a seawater desalination plant. For the City, seawater desalination is a potential resource that could also offset supplies that had been committed from the LAA for environmental restoration in the eastern Sierra Nevada. LADWP has reallocated approximately fifty percent of its historical average LAA supplies to benefit the eastern Sierra Nevada environment. As an identified program in MWD's Seawater Desalination Program, the proposed full-scale project would have qualified for MWD's grant of $250 per acre-foot of water produced. However, in May 2008, LADWP decided to focus on water conservation and water recycling as the primary strategies in creating a sustainable water supply for the City.

While seawater desalination is not a potential water supply strategy at this time, studies performed to date have provided beneficial data that in the future can assist LADWP with any future evaluations of seawater desalination. Completed studies include the LADWP Proposed Seawater Desalination Plant Site Selection Fatal Flaw Analysis (2002), LADWP Seawater Desalination Facility Feasibility Study for the Scattergood Generating Station in Playa Del Rey (2004), Brine Dilution Study for the LADWP Desalination Project at Scattergood Generating Station (2005), and Scattergood Seawater Desalination Pilot Project Preliminary Evaluation Report (2008).

To determine the proper site location for a City desalination plant, LADWP conducted the LADWP Proposed Seawater Desalination Plant Site Selection Fatal Flaw Analysis evaluating three City-owned coastal power generating plants. Based on the findings from this analysis, LADWP initially decided to investigate development of a 12 to 25 mgd desalination facility at the Scattergood Generating Station.

Optimum capacity of a future desalting facility at the Scattergood Generating Station was evaluated in the LADWP Seawater Desalination Facility Feasibility Study. Results of the study indicated a 25 mgd facility would be the most economical. Estimated capital costs for a 25mgd facility were approximately $148.5 million in 2004 dollars with an annual operations and maintenance cost of $28.9 million (2004 dollars) resulting in a total water cost of approximately $1,257 per acre-foot. The study also identified the five-mile Hyperion Treatment Plant Outfall, which is adjacent to the Scattergood Generating Station, as the most environmentally advantageous method to dispose of the brine concentrate produced from the desalting process.

In an effort to develop an environmentally compatible project, LADWP evaluated the feasibility of discharging the desalted concentrate into Hyperion Wastewater Treatment Plant's 5-mile outfall. The Brine Dilution Study for the LADWP Desalination Project at Scattergood Generating Station performed by the Scripps Institute of Oceanography found that there are potential environmental benefits to the Santa Monica Bay's marine biology due to improved salt balance if the effluent discharged by the Hyperion Wastewater Treatment Plant were to include brine from a desalination facility.

In March 2008 the Preliminary Evaluation Report of the Scattergood Generation Station Seawater Desalination Pilot Project was completed. This was the first task of multiple tasks that was to ultimately result in the operation of a pilot plant. Co-funded by the US Bureau of Reclamation and DWR through Proposition 50 funding the overall goal was to further investigate the viability of seawater desalination for LADWP. Recommendations on site specific technologies and processes were provided for carry over to the pilot plant design stage. Items for further study included subsurface intake evaluation, cooling alternatives for warm water, second pass RO, post treatment stabilization, and finished water blending strategy.

AR0071677

After completion of the first task, the other tasks were not initiated reflecting the City's new primary strategies of conservation and recycled water to create a sustainable water supply for the City. Studies completed to date and LADWPs other seawater desalination efforts discussed below have provided important data that can assist LADWP to move forward with seawater desalination in the future, if conditions are amenable.

Other LADWP Seawater Desalination Efforts

LADWP historically engaged in multiple partnerships to advance seawater desalination in southern California. Seawater desalination is hindered by multiple challenges including, but not limited to, capital costs, operating costs, environmental considerations, water quality, and public acceptance. To overcome these challenges, LADWP has supported efforts to lower the capital and operating costs of producing desalinated ocean water. LADWP also participated with California stakeholders through multiple venues, such as the MWD and the California Water Desalination Task Force to develop desalination study projects within southern California.

LADWP, the Long Beach Water Department (LBWD), and the United States Bureau of Reclamation partnered in the construction of a 300,000 gpd prototype seawater desalination facility to complete testing of LBWD's proprietary two-stage nanofiltration process (using membranes that require lower operating pressures and thus, the potential for lower operating costs). LBWD successfully performed a 9,000-gpd bench-scale testing of this technology and began testing on a larger scale in October 2006 at LADWP's Haynes Generating Station in Long Beach. By March 2010, LBWD has completed its testing and is currently preparing the final report.

LADWP also partnered with the West Basin Municipal Water District and other agencies in the American Water Works Association Research Foundation Tailored Collaboration project, "Water Quality Implications for Large-Scale Applications of MF/RO Treatment for Seawater Desalination." A 30,000-gpd pilot facility operating off the coast of El Segundo, California, from 2002 to 2008, was tested for membrane performance, water quality, and operational cost.

In a joint study by LADWP, LBWD, and West Basin Municipal Water District, preliminary sampling of raw seawater quality was initiated at three potential seawater desalination sites - Scattergood Generating Station in Playa Del Rey, Haynes Generating Station in Long Beach, and El Segundo Power Generating Station. Water quality analysis on the seawater was performed at various times of the year to analyze seawater quality variations during storm events when city surface runoffs drain into the ocean. The next step would be to collaborate with the California Department of Health Services on developing guidelines to ensure that product water from future desalting facilities will meet all State and Federal water quality regulations.

9.3 Potential Water Supply Yield and Cost

The range of potential water supply, the unit cost, risks, and other benefits besides reductions in water demands for these potential water supplies are presented in Exhibit 9B.

LADWP recognizes the value of potential water supplies to offset unanticipated changes to supply or demand. Strategic water planning necessarily includes continuous monitoring of existing and future alternative water resources in preparation of these needs.

AR0071678

Exhibit 9B

Other Potential Water Supplies

Potential Water Supplies	Potential Water Yield (AFY)	Average Unit Cost ($/AF)	Implementation Risks	Additional Benefits
Seawater Desalination [1]	25,000	$1,500-$2,000	Environmental permitting may be difficult.	Replaces water committed to the environment. Hedges against climate change.
Water Transfer	40,000	$440-$540[2]	Wheeling and other institutional issues must be addressed.	Replaces water committed to the environment.

For Comparison Purposes:
Local Groundwater Pumping Unit Cost = $230/AF
MWD Treated Tier 2 Water Supply Unit Cost = $811/AF

Notes:

1. Source: LADWP Seawater Desalination Facility Feasibility Study for the Scattergood Generating Station in Playa Del Rey (2004); updated from 2004 to 2009 dollars using annual CPI index for LA-Riverside-Orange County MSA. While the ocean is a virtually unlimited supply, yield shown here is the maximum given available land, outfall capacity, and other constraints.
2. Cost includes cost of water and wheeling fees. Treatment costs not included.

DRAFT

AR0071679

Chapter Ten
Integrated Resources Planning

10.0 Overview

Integrated resources planning is a process used by many water and wastewater providers to meet their future needs in the most effective way possible, and with the greatest public support. The integrated planning process incorporates:

- public stakeholders in an open, participatory process;
- multiple objectives such as reliability, cost, water quality, environmental stewardship, and quality of life;
- risk and uncertainty; and
- partnerships with other agencies, institutions, and non-governmental organizations.

LADWP has been actively involved in integrated resources planning since 1993, when the Metropolitan Water District of Southern California (MWD) initiated the region's first Integrated Resources Plan (IRP). LADWP was an active member of the technical workgroup that oversaw the development of alternatives and recommendations from MWD's IRP. In 1999, the City of Los Angeles embarked on its first IRP for wastewater, stormwater and water supply. The LADWP was a partner in this effort, working with the City's Bureau of Sanitation (BOS). In 2006, the Greater Los Angeles County IRWMP was approved. LADWP is a member of the IRWMP Leadership Committee and serves as the chair of the of the Upper Los Angeles River Watersheds sub-region for the IRWMP region.

10.1 City of Los Angeles Integrated Water Resources Plan

Description and Purpose

The City's Water Integrated Resources Plan (IRP) is a unique approach of technical integration and community involvement to guide policy decisions and water resources facilities planning. As part of the IRP development, an Environmental Impact Report (EIR) was prepared identifying the recommended alternatives for implementing the City's wastewater, runoff, and recycled water programs for 2020. On November 14, 2006, the City Council unanimously adopted the IRP recommendations and implementation strategy and certified the final EIR. The IRP development was a seven year stakeholder-driven process that at the time was an innovative approach to guide the City's policy decisions and facilities planning. The IRP recognizes the interrelationship of water, wastewater, and runoff management in forming a future vision for the City's water resources activities and functions. In the past, the City traditionally utilized single-purpose planning efforts for each agency, such as one plan for wastewater and a separate plan for water supply. With the IRP, the City can meet its 2020 needs in a more cost-effective and sustainable way by addressing and integrating all its water resources. Additionally, the IRP was designed to meet multiple objectives, including evaluation of innovative supply opportunities that were once thought of as being too expensive. The City's LADWP and BOS are partners in this effort, joined by public stakeholders and other agencies.

The objectives for the IRP were developed by the City and public stakeholders, and represent the major reasons why the plan was developed. These objectives are:

- Protect Public Health and Safety
- Effectively Manage System Capacity

AR0071680

- Protect the Environment
- Enhance Cost Efficiency
- Protect Quality of Life
- Promote Education

The IRP was developed in three phases. The first phase set policy guidelines for managing the City's water resources for the next 20 years. The second phase had three main deliverables: (1) detailed facility plans for wastewater, stormwater, and recycled water; (2) comprehensive financial plans for wastewater and stormwater; and (3) a certified Environmental Impact Report (EIR). The third phase of the IRP, which is now underway, represents implementation of the facility plans and more detailed studies to support implementation.

Integrated Watershed Approach

By taking an integrated watershed approach, the IRP identified opportunities that would normally not have been identified if water, wastewater, and stormwater were planned separately. The IRP recognized that all of the City's water resources are linked from a technical, social, and institutional aspect.

The City's IRP has also assisted in identifying partnerships between City agencies for project implementation potentially leading to increases in outside funding from grants and low-interest loans.

An example is the potential three-way partnership between the City's Recreation and Parks Department, BOS, and LADWP. Land reclamation of blighted industrial and warehouse uses allows the City to create more parks and recreational areas while simultaneously allowing for underground storage of wet weather runoff for subsequent beneficial reuse. With this integrated approach, the City can potentially obtain more parkland, assist BOS in reducing wet weather runoff to improve water quality, and assist LADWP in increasing water supplies. The integrated approach also allows the City to better position itself for grants and loans that typically prioritize projects that demonstrate multiple benefits (e.g., water quality, water supply and recreation).

Stakeholder Involvement

A key element of the IRP was involvement of stakeholders at the beginning and throughout the entire IRP process. Stakeholders represent a wide range of the City's interests including, but not limited to, community, business, and environmental organizations. Stakeholders were instrumental in development of the guiding principles and identification of innovative water resource opportunities.

During Phase 2, stakeholders participated in a Steering Group. Steering Group members regularly attended scheduled workshops and provided on-going input on the technical, environmental, and financial development of the IRP. Members provided necessary feedback to keep the facilities planning efforts aligned with the decision-making process. The Steering Group also considered key project issues in regards to the development of alternatives, such as facilities siting, implementation risks, and acceptability of costs that will invariably arise during the project.

IRP Alternatives

The IRP evaluated a broad range of integrated alternatives. Each alternative represented different combinations of wastewater treatment options, wastewater collection system options, recycled water options, conservation options, and dry and wet weather urban runoff management options.

AR0071681

Twenty-one (21) preliminary alternatives were created with different focuses, allowing stakeholders and decision-makers to see trade-offs in key planning objectives. Based on the evaluation of the preliminary alternatives, nine (9) hybrid alternatives were created that incorporated the best elements from the preliminary alternatives in order to improve overall performance. City staff recommended the top-scoring four (4) hybrid alternatives to be carried through to the EIR process. Public stakeholders concurred with staff recommendations.

In November 2006, City Council approved the staff-recommended alternative, which consists of "Go-Projects" , "Go-If-Triggered Projects" and "Go-Policy Directions". "Go-Projects" are projects recommended for immediate implementation because the flow and regulatory triggers have already been met. "Go-If-Triggered Projects" will only be implemented if or when additional information or circumstances, such as regulatory requirements, population growth, or increases in sewage flow are reached.. "Go-Policy Directions" are specific directions to City staff on the next studies and evaluations necessary to progress on programmatic elements.

IRP Implementation Status

The City's Department of Public Works (DPW) in partnership with the Department of Water and Power (DWP) has been working collaboratively along with other City departments on coordinating and implementing the various IRP recommendations. As part of the IRP implementation phase, the City has worked on keeping IRP stakeholders engaged through annual stakeholder meetings. Through these meetings, the City has provided updates on the IRP implementation and has obtained valuable input from stakeholders on IRP related issues. In addition, the Board of Water and Power and the Board of Public Works have held three public joint meetings to review the IRP progress and provide directions on policy issues. Since the adoption of the IRP by Council in November 2006, a number of initiatives have been undertaken by the City which fulfill the IRP goals, including the Green Streets and Green Alleys Committee, the development of a Low Impact Development Ordinance, Conservation Initiatives (Chapter 3), the Recycled Water Master Plan (Chapter 4), and Watershed Management (Chapter 7). Projects and policies in the IRP implementation strategy are detailed below. Some projects are currently being implemented, while others continue to be monitored for triggers or policy direction:

Go Projects

- Construct wastewater storage facilities at Tillman
- Construct wastewater storage facilities at Los Angeles-Glendale Water Reclamation Plant (LAG)
- Construct recycled water storage facilities at LAG
- Construct solids handling and truck loading facility at Hyperion
- Construct two new sewer lines, Glendale Burbank Interceptor Sewer (GBIS) and Northeast Interceptor Sewer (NEIS) Phase II

Go-If-Triggered Projects

- Potential upgrades at Tillman to advanced treatment at current capacity (if triggered by regulations and/or decision to reuse Tillman effluent for groundwater replenishment)

AR0071682

- Potential expansion and upgrade of Tillman to 100 mgd (if triggered by an increase in population, regulations, and/or groundwater replenishment decision), In the unlikely event that the overall framework for recycled water changes to disallow its use, then Hyperion would be potentially expanded to 500 mgd instead.

- Potential upgrades at LAG to advanced treatment at current capacity (if triggered by regulations and/or availability of downstream sewer capacity)

- Design and construct additional secondary clarifiers at Hyperion to provide 450 mgd operational performance

- Design and construct up to 12 solids digesters at Hyperion (if triggered by increased biosolids production in the service area)

- Design/construction of Valley Spring Interceptor Sewer

Of the "Go-Policy Directions" which provide specific directions to City staff on the next studies and evaluations necessary to progress on programmatic elements., those applicable to or with the potential to impact LADWP operations include:

Recycled Water – Non-Potable Uses

- Direct LADWP and Public Works to work together to maximize use and identify recycled water for non-potable uses in the Terminal Island Treatment Plant service area, west side, and LAG service areas. LADWP is to conduct additional Tier 1 and 2 customer analyses to verify potential demands and feasibility. Develop a long-range marketing strategy for recycled water that includes a plan for recruiting and retaining new customers.

- Direct Building and Safety to evaluate and develop ordinances to require installation, where feasible, of dual plumbing for new multi-family, commercial and industrial development, schools, and government properties in the vicinity of existing or planned recycled water distribution systems in coordination with the LA River Revitalization Master Plan. Proximity and demand will be considered when determining feasibility. The dual plumbing will consist of separate plumbing and piping systems, one for potable water and the second for recycled water for non-potable uses, such as irrigation and industrial use

- Direct Public Works and LADWP to continue to coordinate, where feasible, the design/construction of recycled water distribution piping (purple pipe) with other major public works projects, including street widening, and LA River Revitalization Master Plan project areas. Also coordinate with other agencies, including the Metropolitan Transit Authority and Caltrans, on major transportation projects.

Recycled Water –Indirect Potable Uses (Groundwater Replenishment)

- Direct LADWP to develop a public outreach program to explore the feasibility of implementing groundwater replenishment with advanced treated recycled water.

Recycled Water – Environmental Uses

- Direct LADWP and Public Works to continue to provide water from Tillman to Lake Balboa, Wildlife Lake, and the Japanese Garden at Sepulveda Basin, and the LA River to meet baseline needs for habitat.

AR0071683

Water Conservation

- Direct DWP to continue conservation efforts, including programs to reduce outdoor water usage, including using smart irrigation devices on City properties, schools, and large developments (those with 50 dwelling units or 50,000 gross square feet or larger), and to increase incentives to residential properties

- Direct LADWP to work with Building and Safety in continued conservation efforts, including evaluating and considering new water conservation technologies, including no-flush urinal technology

- Direct LADWP to continue conservation efforts, including working with Building and Safety to evaluate and develop a policy that requires developers to implement individual water meters for all new apartment buildings

- Direct LADWP to continue conservation awareness efforts, including increasing education programs on the benefits of using climate-appropriate plants with an emphasis on California friendly plants for landscaping or landscaped areas developed in coordination with the LA River Revitalization Master Plan, and to develop a program of incentives for implementation.

- Direct the Planning Department to consider development of a City Directive to require use of California friendly plants in all City projects where feasible and not in conflict with other facilities usage

Runoff Management – Wet Weather Runoff

- Direct Public Works to review SUSMP (Standard Urban Stormwater Management Plan) requirements to determine ways to require, where feasible, on-site filtration and/or treat/reuse, rather than treat and discharge, including in-lieu fees for projects where infiltration in infeasible

- Direct Building and Safety to evaluate and modify applicable codes to encourage all feasible Best Management Practices (BMPs) for maximizing on-site capture and retention and/or infiltration of stormwater instead of discharge to the street and storm drain, including using porous pavement.

- Direct Public Works and Planning to evaluate the possibility of requiring porous pavement in all new public facilities in coordination with the LA River Revitalization Master Plan, and large developments greater than one acre. Program feasibility should consider slope and soil conditions

- Direct Planning to evaluate ordinances that would need to be changed to reduce the area of on private properties that can be paved with non-permeable pavement

- Direct Public Works to evaluate and implement integration of porous pavements into sidewalks and street programs where feasible.

- Direct Public Works, LADWP, and Recreation and Parks to prepare a concept report and determine the feasibility of developing a powerline easement demonstration project for greening, public access, stormwater management, and groundwater replenishment.

- Direct Public Works and LADWP to work with the Los Angeles Unified School District to determine the feasibility of developing projects for both new and retrofitted schools, as well as for government/city-owned facilities, with

AR0071684

stormwater management BMPs (cisterns to store runoff for irrigation, reduce paving and hardscapes, add infiltration basins).

- Direct Public Works, General Services, and Recreation and Parks, to identify sites that can provide on-site percolation of wet-weather runoff in surplus properties, vacant lots, parks/open spaces, abandoned alleys in the East Valley area, and along the LA River in the East Valley where feasible. Program feasibility should consider slope and soil conditions.

- Direct Public Works, General Services, and the Department of Transportation to maximize unpaved open space in City-owned properties and parking medians using all feasible BMPs and by removing all unnecessary pavement.

- In the context of developing Total Maximum Daily Load implementation plans, direct Public Works to consider diversion of dry weather runoff from Ballona Creek to constructed wetlands, wastewater system, or urban runoff plants for treatment and/or beneficial use. For inland creeks and storm drains tributary to the LA River, direct Public Works to consider diversion of dry weather runoff to the wastewater system or constructed wetlands or treatment/retention/infiltration basins.

- Direct General Services, in coordination with Planning and Public Works, to evaluate feasibility of all City properties identified as surplus for potential development of multiple-benefit projects to improve stormwater management, water quality, and groundwater recharge.

Los Angeles River

The IRP planning effort included the Los Angeles River (River). The Los Angeles River is a valuable resource to the City providing habitat as well as recreational and economic opportunities. Since the City's water reclamation plants were built, recycled water has been released to the River resulting in the development of significant environmental benefits from riparian habitat in the unlined portions of the River near Glendale, to regionally significant migratory shore bird habitat in Long Beach. As a result many efforts have been developed to protect existing habitat and interest in habitat restoration and river revitalization.

The IRP established that treated wastewater is needed for the operation of Lake Balboa, the Japanese Gardens, and the Wildlife Lake in the Sepulveda Basin. Treated wastewater flows through these features and ultimately is released to the River from the Donald C. Tillman Water Reclamation Plant. The remainder of the treated wastewater produced by the City's water reclamation plants is available for recycled water use and distribution to LADWP customers.

Shortly after work on the IRP began, the Los Angeles City Council Ad Hoc Committee on the Los Angeles River (Ad Hoc Committee) was formed to address River revitalization. LADWP staff routinely attends Ad Hoc Committee meetings and functions, and monitors River-related activities.

LADWP also funded the preparation of a Los Angeles River Revitalization Master Plan which was approved in 2007. This plan addresses economic development opportunities, water quality, water resources, flood control, and recreation along the Los Angeles River. The plan also discusses opportunities to improve access to the Los Angeles River and increase community awareness and pride.

In addition, LADWP staff also actively participates on the City Department Los Angeles River Task Force, which was formed in response to instructions by the Ad Hoc Committee to:

AR0071685

- inventory all current and future City Department projects, studies, and programs along the River;
- assess opportunities for future funding, projects, and studies; and
- coordinate River related activities of City Departments and other agencies.
- partner with the United States Army Corps of Engineers for a Habitat Restoration Project Study

LADWP recognizes the importance of the Los Angeles River as a resource that provides multiple benefits to the City.

Agency Coordination

LADWP was a partner with the Bureau of Sanitation (BOS) in developing the IRP along with public stakeholders and other agencies. As with any integrated plan that extends beyond traditional departmental boundaries and government jurisdictions, close coordination is required with multiple City, state, and federal agencies including but not limited to, the Cities of Burbank and Glendale, County of Los Angeles, Caltrans, United States Army Corps of Engineers, United States Bureau of Reclamation, and City Parks and Recreation Department. Since approval of the IRP, ongoing project implementation and "Go-Policy Directions" continue to require close coordination with City departments and with the agencies listed above.

IRP Implications for City's Urban Water Management Plan

One of the primary purposes for developing the IRP was to explicitly consider the relationship between wastewater facility planning and other water resources issues, such as water supply and urban runoff. Implementation of the IRP has and will continue to result in increased beneficial reuse of water, water conservation, and groundwater supplies. IRP alternatives examined ways in which to decrease potable water needs by expanding the City's recycled water program; increase water efficiency by installing smart irrigation and other water efficient devices that reduce irrigation and indoor water demands; and increase groundwater resources by using wet weather runoff to recharge the aquifer. All of these options will have to be tested from a technical, institutional, and public acceptance perspective. Ongoing work on programmatic elements identified in the "Go-Policy Directions" applicable to LADWP will continue to investigate means of increasing local water supplies, water conservation, and groundwater recharge opportunities in an integrated manner. The IRP has demonstrated that by integrating water resources planning for the City, more opportunities for water supply development can be identified.

10.2 Greater Los Angeles County Integrated Regional Water Management Plan (IRWMP)

Description and Purpose

The Los Angeles County Department of Public Works led efforts to develop an Integrated Regional Water Management Plan (IRWMP) for the Greater Los Angeles County Region. Water quality, resource, and supply issues within the region are complex and managed by a myriad of government agencies subjected to a plethora of regulations. Exponential growth over the last century has required water managers to develop creative solutions to meet growing demands. Previously projects addressing water issues were designed to appease single-focused visions and solutions of organizations operating independently in silos. At the core of the plan a clear vision and direction for the sustainable management of water resources within the region for the next twenty years was formulated. Over 1,600 projects were collected and synthesized for inclusion in the plan bringing together hundreds of local government agencies all working cooperatively to develop cost-effective, sensible, and economically feasible solutions to address regional water issues. New partnerships were forged joining together potential funding partners from within and outside the region. An innovative partnership between agencies was formed

AR0071686

creating a new model of integrated regional planning to address competing water demands, water supply reliability, and project financing.

An Interim Draft of the IRWMP was adopted by the Leadership Committee on June 28, 2006 with a final plan adopted on December 16, 2006. To date the plan has received $25 million from the Department of Water Resources (DWR) under Proposition 50, Chapter 8, for implementation of fourteen priority projects identified in the plan and $1.5 million from DWR for development of the IRWMP. Since completion of the document a revised Memorandum of Understanding (MOU) was executed by each of the sixteen agencies serving on the Leadership Committee for the purpose of developing, administering, updating, and implementing the IRWMP.

Region

The IRWMP region encompasses 92 cities, portions of four counties, and hundreds of government agencies and districts spread over 2,058 square miles. Approximately 10.2 million residents, or equivalent to roughly 28% of the population of California, reside within the region. To facilitate input, variations in geographic and water management strategies, and effective planning the region was further subdivided into five sub-regions:

- Lower San Gabriel and Los Angeles River Watersheds
- North Santa Monica Bay Watersheds
- South Bay Watersheds
- Upper Los Angeles River Watersheds
- Upper San Gabriel River and Rio Hondo Watersheds.

Mission and Purpose

A collaborative process resulted in the following mission statement of the IRWMP, "[T]o address the water resources needs of the Region in an integrated and collaborative manner." The IRWMP recognizes that in order to meet future needs water supply planning must be integrated with other resource strategies. Additionally, in a region with significant urban challenges, including population growth, densification, traffic congestion, poor air quality, and quality of life issues, it is imperative to consider water resources management in conjunction with other urban planning issues. The IRWMP's purpose is to proactively:

- Improve water supplies
- Enhance water supply reliability
- Improve surface water quality
- Preserve flood protection
- Conserve habitat
- Expand recreational access.

DRAFT

AR0071687

Stakeholder Involvement

Over 1,400 invitations to participate in the IRWMP process were sent out to cities, counties, agencies, districts, disadvantaged communities, and community organizations. Stakeholders participated in workshops, project identification, and development of the IRWMP. Stakeholders were involved in plan development and through development of technical memorandums and participation in regional workshops, subregional workshops, and the Leadership Committee. Stakeholders assisted in the development of the following:

- Development of the IRWMP mission and objectives
- Refinement of procedures for incorporation of projects into the IRWM
- Identification of implementation strategies
- Recommendation of stakeholder workshop improvements.

Recommended Projects

Over 1,600 projects were submitted and analyzed for inclusion in the IRWMP. This list was narrowed down to fourteen priority projects that met the objectives and priorities established by the IRWMP process and assist in meeting the targets established for the planning region. Objectives and priorities were established to guide the project selection process. The IRWMP is a living document and will be updated as needed. Projects can continuously be submitted as they are identified by stakeholders.

Objectives and Priorities

Six objectives and six long-term priorities were developed through the stakeholder process to guide project selection based on stakeholder input and previously completed documents, including UWMPs, MWD's IRP, Common Ground, Santa Monica Bay Restoration Plan, and watershed plans for the major tributaries in the region. The objectives are:

- Optimize local water resources to reduce the Region's reliance on imported water
- Comply with water quality regulations (including TMDLs) by improving the quality of urban runoff, runoff, stormwater, and wastewater
- Protect and improve groundwater and drinking water quality
- Protect, restore, and enhance natural processes and habitats
- Increase watershed friendly recreational space for all communities
- Maintain and enhance public infrastructure related to flood protection, water resources, and water quality.

Long term regional priorities are:

- Maintain a regional and subregional structure to oversee plan implementation and assure continued stakeholder input
- Optimize use of recycled water, groundwater, desalination, and stormwater to enhance water supply reliability
- Reduce demand on imported water sources

AR0071688

- Protect groundwater supplies
- Improve surface water quality to meet applicable water quality regulations, including TMDLs
- Preserve open space, conserve and restore functional habitats, and protect special-status species.

Targets

Targets for the region were developed to assist in prioritizing projects. Targets include:

- Increase water supply reliability by providing 800,000 AFY of additional water supply and demand reduction through conservation, including infiltration or reuse of 130,000 AFY of reclaimed water
- Reduce and reuse 150,000 AFY (40%) of dry weather urban runoff and capture and treat an additional 170,000 AFY (50%) for a total target of 90%
- Reduce and reuse 220,000 AFY (40%) of stormwater runoff from developed areas and capture and treat an additional 270,000 AFY (50%) for a total of 90%
- Treat 91,000 AFY of contaminated groundwater
- Restore 100+ linear miles of functional riparian habitat and associated buffer habitat
- Restore 1,400 acres of functional wetland habitat
- Develop 30,000 acres of recreational open space focused in under-served communities
- Repair/Replace 40% of aging water resources infrastructure.

Projects

Fourteen priority projects were developed for the greater Los Angeles County region. As a regional plan encompassing an area larger that LADWP's service area, many of the IRWMP projects do not directly benefit LADWP's service area, but rather provide benefits towards improving water resources in the region as a whole. However, for projects not within LADWP's service area LADWP can utilize the results of other projects and apply the knowledge to potentially develop similar programs within the service area. Brief descriptions of the priority projects are provided below.

Southeast Water Reliability Project

The Southeast Water Reliability Project consists of an 11.4 mile recycled water transmission pipeline from the City of Pico Rivera to the City of Vernon to complete Central Basin Municipal Water District's recycled water transmission system. Recycled water will be mainly provided by the County Sanitation Districts of Los Angeles County via the San Jose Creek Water Reclamation Plant.

Joint Water Pollution Control Plant Marshland Enhancement

The Joint Water Pollution Control Plant Marshland Enhancement Project is designed to improve and maintain plant and wildlife habitat at the seventeen acre freshwater marshland located at the Joint Water Pollution Control Plant (JWPCP) in

DRAFT

AR0071689

Carson. As proposed the project will serve as a mitigation measure for upgrading the JWPCP to full secondary wastewater treatment. The JWPCP is operated by the County Sanitation Districts of Los Angeles County.

Large Landscape Water Conservation, Runoff Reduction, and Educational Program (Central Basin)

The Large Landscape Water Conservation, Runoff Reduction, and Education Program is an end use water management program to reduce runoff and address water/energy management associated with large landscapes, residential land uses, and street medians within the Central Basin Municipal Water District's Service Area. Weather-based irrigation controllers coupled with GIS to monitor runoff and two-way communication technologies will provide necessary information to address emergency, drought, and end use management challenges.

Large Landscape Water Conservation, Runoff Reduction, and Educational Program (West Basin)

West Basin Municipal Water District's Large Landscape Water Conservation, Runoff Reduction, and Educational Program is a four component project. The first component targets large landscape sites of 1 acre or more by providing centralized weather-based irrigation controllers with the goal of conserving 1 AFY per acre of land. The second component will provide 1,350 rebates for the purchase of smart irrigation controllers for the top residential water users. A third component will consist developing and offering classes on residential landscaping for residences and businesses. The last component involves installing ten "Ocean Friendly" demonstration gardens throughout watersheds in the service area.

Las Virgenes Creek Restoration Project

The City of Calabasas is initiating the Las Virgenes Creek Restoration Project to restore 450 linear feet of a concrete-lined section of the creek to a natural function. Native vegetation will be planted in place of the concrete liner to establish connectivity between riparian habitat north and south of the existing liner.

Malibu Creek Watershed Urban Water Conservation and Runoff Reduction Project

As proposed the Malibu Creek Watershed Urban Water Conservation and Runoff Reduction Project seeks to conserve water and reduce runoff in the City of Westlake Village and within the Las Virgenes Municipal Water District (LVMWD) service areas. Irrigation controllers on city-owned land in Westlake Village will be replaced with weather-based irrigation controllers. Within the LVWMD service area indoor conservation will be addressed by continuing rebates for residential and multi-family customers to install water saving devices. This project will also continue existing efforts to reduce urban runoff and outdoor conservation in the LVMWD service area by targeting customers with persistent and substantial irrigation runoff in the vicinity of stormdrains. These customers are offered water efficient equipment rebates and free on-site assistance to upgrade irrigation systems to eliminate runoff.

Morris Dam Water Supply Enhancement Project

The Morris Dam Water Supply Enhancement Project would allow the capture of additional local runoff (5,720 AF) for groundwater recharge and extraction in the San Gabriel River watershed. This project would reduce the minimum pool required by the Los Angeles County Flood Control District to prevent sediment damage to the outlet works of the dam by modifying the dam valves and control systems.

Pacoima Wash Greenway Project

The Pacoima Wash Greenway will treat storm runoff from neighborhoods adjacent to the wash in a series of parks incorporating stormwater treatment best management practices along the wash. Project development will be a joint effort between the City of San Fernando and the Mountains Recreation and Conservation Authority.

AR0071690

San Gabriel Valley Riparian Habitat Arundo Removal Project

Arundo donax a non-native plant classified federally and by California as noxious weed will be removed from approximately 30 acres of riparian habitat in the San Gabriel Watershed. Removal will increase surface water flows to the Rio Hondo percolation basins and improve native habitat.

Solstice Creek Restoration Project

The Solstice Creek Restoration Project will restore side drainages of Solstice Creek and areas negatively impacting riparian habitat through sediment and invasive species introduction. This project is part of an overall larger project to restore Solstice Creek.

South Los Angeles Wetlands Park

The South Los Angeles Wetlands Park project will involve purchasing a 9 acre parcel in Los Angeles on Avalon Boulevard for conversion to a wetlands park. As proposed, the wetlands park will treat urban runoff from a 520 acre area through a series of best management practices. Park vegetation will consist of plants not requiring supplemental irrigation.

Whittier Narrows Water Reclamation Plant UV Disinfection

The Whittier Narrows Water Reclamation Plant UV Disinfection project will convert current disinfection processes at the 15 mgd plant to a UV disinfection process. Currently, tertiary-treated water is disinfected to Title 22 recycled water standards using chloramination resulting in the production of NDMA byproducts.

Wilmington Drain Restoration Multiuse

As proposed, the Wilmington Drain Restoration Multiuse Project involves restoration of the Wilmington Drain. Restoration will involve creation of a public park, improved public access, native revegetation, stormwater treatment, and educational signage. The drain is within the City of Los Angeles on an easement held by the Los Angeles County Flood Control District.

North Atwater Creek Restoration

As a component of the overall Los Angeles River Revitalization efforts, the North Atwater Creek Restoration Project will restore North Atwater Creek at North Atwater Park by providing stormwater runoff capture and treatment and the provision of habitat linkage to the Los Angeles River. Additionally, the project will provide an educational component and provide BMP implementation at adjacent horse stables and riding trails.

Implications of IRWMP for LADWP's Urban Water Management Plan

LADWP is a member of the IRWMP Leadership Committee and additionally serves as the chair of the of the Upper Los Angeles River Watersheds sub-region for the IRWMP region. As member of the Leadership Committee, LADWP is a signatory to the MOU for the IRWMP approved by the Board of Water and Power Commissioners on July 15, 2008.

Participating agencies in the IRWMP coordinate and share information concerning water resources management planning programs and projects, share grant funding information, and improve and maintain overall communication among the participants. Coordination and information sharing assists LADWP and other agencies in achieving their respective missions and contribute to overall IRWMP goals.

AR0071691

10.3 MWD's Integrated Resources Plan

In 1993, MWD and its member agencies embarked on a three year process to develop Southern California's first IRP. Six main objectives for this plan were defined as:

- Supply and System Reliability
- Affordability
- Water Quality
- Diversity
- Environmental Issues
- Institutional Constraints

In order to meet these objectives, supply and conservation options that included everything from groundwater desalination, water transfers, Colorado River and SWP improvements, and new surface storage were evaluated. Complete portfolios, representing different combinations of supply and conservation options, were assembled. Based on extensive participation from water providers and other stakeholders as well as detailed evaluations, a "preferred resource mix" was recommended. The preferred resource mix balanced local and imported water supply projects with significant water conservation in order to best meet the needs of the region. This preferred resource mix also established regional targets for the development of water supply to be made by MWD, its member agencies, and retail water providers.

The 20-year plan was designed so that MWD and its member agencies would be able to meet their full service demands through 2020. MWD's Board of Directors formally adopted the IRP in January 1996.

MWD IRP 2004 Update

In 2001, the MWD Board of Directors developed a work plan to update the 1996 IRP in order to accommodate changed conditions and extend the targets through 2025. Specifically, the IRP Update has three main objectives: (1) review the resource development targets and implementation achievements of the 1996 IRP; (2) identify significant changed conditions for water resource development since the adoption of the 1996 IRP; and (3) evaluate the reliability of the IRP Preferred Resource Mix through 2020, adjust targets as needed to reflect changed conditions, and extend resource targets through 2025.

The results of the IRP Update analysis demonstrate that the resource targets of the 1996 IRP, factored in with the changed conditions discussed in this report, provide for 100 percent reliability in 2020 and up to 2025 (MWD, 2004). Although the current targets provide 100 percent reliability in 2020 and up to 2025, the IRP Update recommends a 10 percent supply buffer. The "planning buffer" identified additional supplies, both imported and locally developed, that could be implemented to address uncertainty in future supplies and demands. The most significant changed conditions include:

- Lower projected retail demands due primarily to conservation savings.
- Higher projected local water resource development.
- Lower projected dry-year MWD demands.
- Board revised targets for the SWP and Colorado River Aqueduct (CRA).

AR0071692

- More stringent water quality regulations.
- Recognition of implementation risks.

MWD IRP 2010 Update

In 2008, the MWD and its member agencies updated the 2004 IRP in order to accommodate changed conditions and extend the targets through 2035. The 2010 IRP Update has three main objectives: (1) develop an Emergency Response Plan for hydrologic, regulatory, and other types of uncertainties in the Sacramento-San Joaquin Delta; (2) identify energy-efficient and cost-effective energy management initiatives; and (3) evaluate the reliability of the IRP Preferred Resource Mix through 2035, adjust targets as needed to reflect changed conditions, and extend resource targets through 2035.

The IRP Update modified the resource targets to take into account the changed conditions and recommended buffer. A summary of the 2004 IRP Update and 2010 Update targets are shown in Exhibit 10A.

Exhibit 10A

MWD's IRP Resource Targets

IRP Resource Targets	2004 IRP Update 2025	2010 IRP Update 2025	Change	2010 IRP Update 2035
Conservation	1,107,000	1,412,000	305,000	1,538,000
Local Projects*	750,000	905,000	155,000	926,000
Colorado River Aqueduct **	1,250,000	1,250,000	0	1,250,000
State Water Project	650,000	713,000	63,000	713,000
Groundwater Conjunctive Use	300,000	300,000	0	300,000
Central Valley/State Water Project Storage and Transfers	550,000	1,070,000	520,000	1,092,000
MWD Surface Water Storage***	620,000	620,000	0	620,000

* Includes recycled water, brackish groundwater desalination, and seawater desalination

** Target for specific year types; the CRA is not intended to be full at all times

*** Represents the total amount that can be withdrawn from surface reservoirs

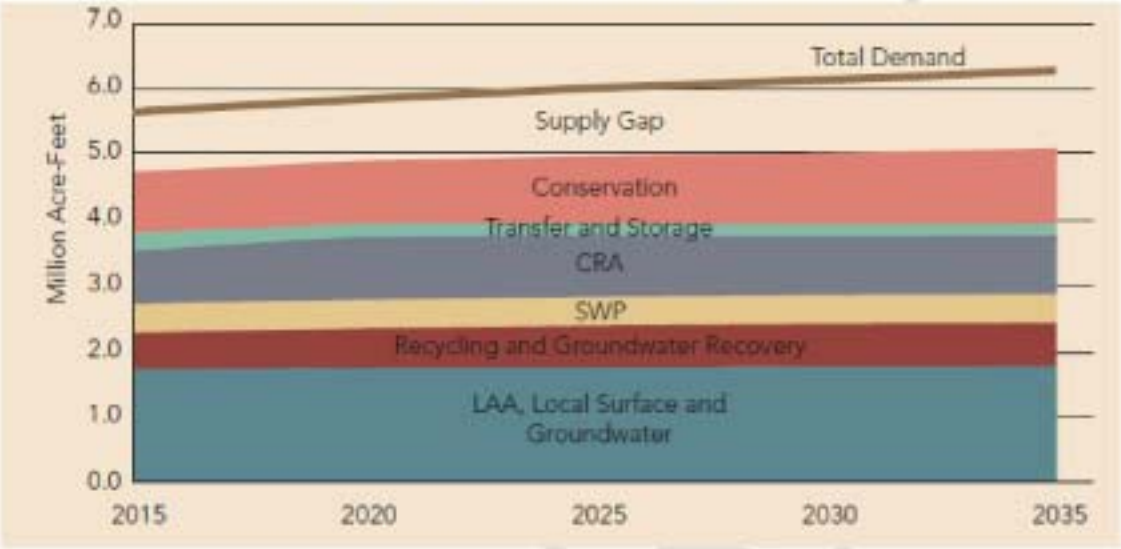
DRAFT

AR0071693

Exhibit 10B shows regional water demands without conservation from 2015 to 2035 under dry weather. The graph also depicts the supply sources and water conservation identified in MWD's 2010 IRP Update.

Exhibit 10B
Meeting Regional Water Needs Through MWD's IRP



Stakeholder Participation

MWD's 1996 IRP was developed in concert with its member agencies. A technical workgroup was established that consisted of MWD staff, member agency and local retail agency managers, and groundwater basin managers. This workgroup met frequently and spent hundreds of hours reviewing analyses and providing guidance. LADWP was an active participant in this workgroup.

To provide more direct involvement of MWD in the IRP Process, the IRP Steering Committee was created. The IRP Steering Committee, consisting of five MWD directors who are also members of the Water Planning and Stewardship Committee, recommended policy options, reviewed proposed resource strategies, and managed public forums.

In addition, regional assemblies were held at critical milestones of the IRP development that provided a platform to collectively discuss strategic direction and regional water solutions. Participants of these assemblies included Board members, water agency managers, local retail water providers, groundwater basin managers, and invited public stakeholders. Public forums and several member agency sponsored workshops attended by stakeholders from business, environmental, agricultural, and water interests were held throughout the IRP process. Finally, findings of the IRP 2010 Update were adopted in October 2010 to a diverse group of stakeholders including elected officials, environmental groups, and the general public.

Agency Coordination

In preparation of MWD's IRP, all member agencies were closely involved, including LADWP. LADWP was involved with providing data and reviewing documents. Additionally, LADWP was an active member of the technical workgroup.

AR0071694

Funding MWD's IRP

In accordance with MWD's Board adoption of the IRP Update, a revised Long-Range Finance Plan (LRP) was developed and approved by MWD's Board. The LRP (2010) identifies MWD's planned capital improvement program (CIP) and operating expenses from 2015 to 2035.

The following summarizes the MWD's CIP and operating expenses needed to implement the IRP:

- **Core Resources (Fixed costs to maintain Delta habitat conservation and conveyance program, LRP contracts, CRA programs, and conservations funding)** – costs for water supply will increase from the current $853/AF in 2015 to $1,484/AF in 2035.
- **Water Use Efficiency** – costs for water supply will increase from the current $892/AF in 2015 to $1,608/AF in 2035.
- **Capital Expenditures** – costs for water supply will increase from $919/AF in 2015 to $1,844/AF in 2035.
- **Demand Management & Local Projects** – costs from water supply will increase from $953/AF to $2,021/AF in 2035.

IRP Implications for City's Urban Water Management Plan

As LADWP evaluates its water supply options, it is important to understand the significance of a reliable and cost-effective water supply from MWD. The City's water supply reliability is directly linked to MWD's reliability, and LADWP's local supply development uses the cost of MWD water as one of the benchmarks for feasibility evaluation. Through the IRP Update, MWD has shown that it will be able to meet the supplemental needs of all its member agencies reliably through 2035, even during prolonged drought events. MWD has also developed a plan to implement and finance the approved IRP targets.

DRAFT

AR0071695

DRAFT Chapter Eleven
Water Supply Reliability and Financial Integrity

11.0 Overview

Providing for a reliable water supply in a semiarid climate with wet and dry years is challenging. This is mainly due to the fact that surface water supplies are imported from the LAA and MWD and vary substantially due to hydrology. LADWP has made significant investments in groundwater, recycled water, stormwater capture and water conservation. These supplies provide local water supplies that are more reliable due to variability of imported supply sources.

11.1 Unit Cost and Funding of Supplies

11.1.1 Unit Cost Summary of Supplies

Unit costs play an important role in planning future water supply sources and determining where supply investments provide the greatest benefits to LADWP. Unit costs vary dramatically by water supply sources. Exhibit 11A summarizes the unit cost for each water supply source.

Costs per acre-foot ranged from a high of $1,500 for certain recycled water projects to a low of $215 for locally produced groundwater among LA's existing and planned water supplies. Los Angeles Aqueduct supply has required operation and maintenance costs regardless of water availability. Therefore, hydrology and increased water for environmental commitments in the Eastern Sierras result in unit cost fluctuations year to year. Local groundwater supply is the least expensive source. However, its production is limited by contamination. Unit costs for MWD purchased water vary based on tier allocations. MWD's water rates vary from $484 per AF of tier 1 untreated water to $811 per AF of tier 2 treated water in 2010. LADWP has a Tier 1 allocation of 304,970 AF. Any purchases above this amount will be at the Tier 2 rates. Conservation is relatively inexpensive to offset water supplies that may otherwise be required to meet water demand. Conservation unit costs are based on costs of conservation rebate and incentive programs and their potential water use reduction. Recycled water cost is project specific and varies widely depending on the infrastructure requirements of each project. Water transfers using a future connection between the LAA and the California Aqueduct is planned. Its costs include the purchase price of water and conveyance fees.

Unit costs for potential water supplies including stormwater reuse (harvesting) and increased groundwater production (stormwater recharge) are highly variable based on factors such as the magnitude of the overall program, project locations, etc. Centralized stormwater capture unit cost is based on LADWP's current planned centralized stormwater capture projects and distributed stormwater capture unit costs are from various sources as referenced in Chapter 7, Watershed Management. These projects are joint efforts among agencies, city departments, stakeholders and community groups and yield additional benefits beyond water supply.

Seawater desalination unit costs are based on the estimate from MWD's 2010 IRP. Seawater desalination was a planned supply identified in the 2005 UWMP but is excluded from this 2010 UWMP. Its impacts to marine habitats and high energy consumption make seawater desalination less desirable comparing to options such as recycled water, conservation, and stormwater capture.

AR0071696

Exhibit 11A
Unit Costs of Supplies

Exhibit 11A		
Water Source	**Chapter Reference**	**Average Unit Cost ($/AF)**
Los Angeles Aqueduct[1]	**Chapter 5 - Los Angeles Aqueduct System**	$563
Groundwater[1]	**Chapter 6 - Local Groundwater**	$215
Metropolitan Water District[2]	**Chapter 8 - Metropolitan Water District Supplies**	$484 - $811
Conservation	**Chapter 3 - Conservation**	$325 - $400
Recycled Water	**Chapter 4 - Recycled Water**	$600 - $1,500
Water Transfer	**Chapter 9 - Other Potential Supplies**	$440 - $540
Stormwater Capture	**Chapter 7 - Watershed Management**	
- Centralized Stormwater Capture		$60 - $200
- Distributed Stormwater Capture		
Urban Runoff Plants		$4,044
Rain Barrels		$701 - $1,875
Cisterns		$2,426
Rain Gardens		$308 - $5,000
Neighborhood Recharge		$3,351
Seawater Desalination	**Chapter 9 - Other Potential Supplies**	$1,300 - $2,000

[1] Los Angeles Aqueduct supply and groundwater supply are based on FY2005-06 to FY2009-10 five-year average.
[2] MWD Water Rates effective on January 1, 2010.

11.1.2 Funding of Supplies

Funding for water resource programs and projects are primarily provided through LADWP water rates, with supplemental funding provided by the Metropolitan Water District (MWD), and state and federal grants. Funding for water conservation, water recycling, and stormwater capture projects has increased significantly in recent years. Currently, approximately $100 million is collected annually through water rates for these initiatives. The current level of annual expenditures is believed to be sufficient to achieve projected goals.

Funding for groundwater cleanup will require water rate increases. LADWP will also seek reimbursement from potential responsible parties to assist with cleanup program costs.

AR0071697

Water Resource Project Funding

- Water Rates – currently provides approximately $100 million annually for water conservation, water recycling, and stormwater capture programs.
- MWD – Currently provides funding up to $250 per AF for water recycling through their Local Resources Program. MWD also provides some water conservation incentive funding.
- State Funds – Funds for recycling, conservation, and stormwater capture have been available on a competitive basis though voter approved initiatives, such as Propositions 50 and 84. The proposed 2010 Water Bond, approved by the Legislature but not yet placed on the ballot, also includes potential funding for groundwater cleanup. Occasionally low or zero-interest loans are available though State Revolving Fund programs.
- Federal Funds – Funding for recycling may be obtained through periodic Water Resource Development Act legislation. Also, LADWP has received recycled water funds through the Bureau of Reclamation Title XVI program.
- Potentially Responsible Parties – LADWP may be able to recover some costs for groundwater cleanup through potentially responsible parties.

Receipt of state or federal funding will allow water resource goals to be achieved sooner than projected, or allow for increased local supply development.

11.2 Reliability Assessment Under Different Hydrologic Conditions

11.2.1 Los Angeles Aqueducts

Water supply from the LAA can vary substantially from year to year due to hydrology. In very wet years, LAA supply can exceed 500,000 AFY. During average year weather conditions the LAA supply is projected to gradually decrease from 254,000 AFY to 244,000 AFY by 2035 due to climate change impact. Critical dry year (defined as a repeat of a 1990/91 drought) supplies can be as low as 48,520 AFY.

11.2.2 Groundwater

Groundwater is also affected by local hydrology. However, with conjunctive use management of groundwater—storing imported water in the groundwater basins during wet and average years - groundwater production can actually be increased during dry years. During average weather conditions, LADWP projects it will pump approximately between 40,500 AFY and 111,500 AFY of groundwater during the projection period to fiscal year 2035. These projections are based on the Purification Complex in operation in 2018-19 and storage credit of 5,000 AFY is used to maximize the groundwater production thereafter. Although in dry years LADWP can pump larger quantities of groundwater, a more conservative approach was adopted by assuming the same level of projected groundwater production for both single dry year and multi dry year analysis.

11.2.3 Conservation

LADWP has developed conservation goals in the Water Supply Action Plan to decrease water use in the City and to comply with the new State 20 percent by 2020 requirements. Multiple actions will be taken to increase water conservation including education, targeting the CII sector, reducing outdoor water use, and continuing participation in MWD's rebate programs.

AR0071698

LADWP is planning to increase water conservation levels during the projection period with an increase of over 60,000 AFY between 2010 and 2035, assuming average weather conditions.

11.2.4 Recycled Water

Recycled water is based on wastewater effluent flows, which do not vary significantly due to hydrology. Therefore, recycled water use is mainly limited by system capacities and demands. This makes recycled water a more reliable supply than imported water. As outlined in Chapter 4 on Recycled Water, LADWP is planning an extensive expansion of its recycled water system to not only include expansion of irrigation and industrial uses, but also groundwater replenishment. Under average weather conditions recycled water supply for irrigation and industrial purposes is projected to increase from 20,000 AFY in 2015 to 29,000 AFY in 2035. Groundwater replenishment with recycled water is projected at 30,000 AFY in 2035. For a critical dry year available supplies would not change.

11.2.5 Water Transfers

Water transfers are being developed to replace a portion of the City's Los Angeles Aqueduct water that has been dedicated for environmental enhancement uses in the eastern Sierra Nevada. Water acquired through transfers helps increase water supply reliability for the City. The Los Angeles Aqueduct and California Aqueduct interconnection is under construction and estimated to be completed in January 2013. LADWP is expected to enter into agreements to obtain 40,000 AF per year under average weather conditions beginning in FY2013-14 and continuing throughout the projection period.

11.2.6 MWD Imported Supplies

Historically, water from MWD (like supplies from the LAA) has been subject to severe variability (i.e., 1976/77, 1987-1992, and the current water shortage). This is due to the fact that MWD's core sources of water supply are the Colorado River and SWP, both of which are highly affected by hydrology. More recently restrictions to protect threatened fish species have further decreased pumping from the Bay-Delta, and limiting SWP supplies available to MWD. After the 1987-1992 drought, MWD started to diversify its water supplies. Partnering with its member agencies, MWD launched the IRP in 1993 and most recently updated it in 2010. As a result of the resource targets in the IRP, MWD implemented a variety of projects and programs designed to reduce its dependency on imported water during water shortages and environmental related SWP pumping restrictions. Efforts have included: (1) providing financial incentives for local projects and conservation; (2) increased surface storage via Diamond Valley Lake and use of the SWP terminus reservoirs; (3) groundwater storage programs in the Central Valley, Imperial Valley, and Coachella Valley; (4) short- and long-term water transfers; and (5) contracted groundwater storage programs with participating member agencies.

In the 2010 IRP Update MWD developed a three-part adaptive resource strategy: (1) meet demands by building on existing core resources to provide reliability under foreseen conditions; (2) implement a supply buffer of 10 percent of retail demand through multiple actions to adapt to short-term uncertainty; and (3) implement adaptive management through low-regret foundation actions, monitoring key vulnerabilities and bringing adaptive resources online, if required, and using a comprehensive approach to meet specific needs and degrees of shortages. The 2010 IRP adaptive management concept seeks to mitigate against supply uncertainty to further increase reliability.

The 2010 IRP Update concluded that the resource targets identified in previous updates, taking into consideration changed conditions identified since that time, will continue to provide for 100 percent reliability through 2035. The 2010 RUWMP also concluded the same full reliability through 2035 during average (1922 – 2004 hydrology), single dry (1977 hydrology), and

AR0071699

multiple dry years (1990 - 1992 hydrology). For each of the scenarios there is a surplus in every forecast year (see Exhibit 11B).

Source: MWD 2010 Regional Urban Water Management Plan Tables 2-9 to 2-11

As part of the implementation of MWD's IRP, MWD and its member agencies worked together to develop MWD's Water Surplus and Drought Management Plan (WSDM Plan) in 1999. The WSDM Plan established broad water resource management strategies to ensure MWD's ability to meet full service demands at all times and provides principles for supply allocation if the need should ever arise. The WSDM Plan splits MWD's resource actions into two major categories: Surplus Actions and Shortage Actions. The Shortage Actions of the WSDM Plan are split into three sub-categories: Shortage, Severe Shortage, and Extreme Shortage. Under Shortage conditions, MWD will make withdrawals from storage and interrupt long-term groundwater basin replenishment deliveries. Under Severe Shortage conditions, MWD will call for extraordinary drought conservation in the form of voluntary savings from retail customers, interrupt 30 percent of deliveries to Agricultural Water Program users, call on its option transfer water, and purchase water on the spot market. Under Extreme Shortage conditions, MWD will equitably allocate supplies to its member agencies on the basis of agencies' needs. The overall objective of MWD's IRP and WSDM Plan is to ensure that shortage allocations of MWD water supplies are not required.

If shortage allocations are required, MWD will rely on the calculations established in its Water Supply Allocation Plan (WSAP) adopted in 2008. The plan equitably allocates shortages among its member agencies based on growth, local investments, changes in supply conditions, demand hardening, and water conservation programs for each of its member agencies.

AR0071700

11.2.7 Potential Supplies

Other planned and potential water supplies that LADWP is exploring include capturing stormwater for reuse and infiltration leading to increased groundwater production (see Chapter 7). Development of these supplies will offset water purchased from MWD. The beneficial reuse of stormwater presents significant opportunity. The City must reduce pollutants in impaired receiving waters (rivers, creeks, and beaches in the Santa Monica and Los Angeles watersheds) as required by the Clean Water Act. By managing urban runoff during dry and wet periods, pollution will be reduced. Traditional ways of managing urban runoff would be to divert the runoff into existing wastewater treatment plants and/or build satellite treatment plants specifically designed to treat urban runoff.

During the City's IRP process, stakeholders expressed the desire to examine other ways to manage runoff that would reduce pollution and provide for other benefits such as water supply and open space. These methods involve local and regional storage of wet weather runoff for groundwater infiltration, on-site storage and recovery of wet weather runoff for irrigation using cisterns and other devices, and reuse of treated dry weather effluent for irrigation (much like recycled water). As an outgrowth of the IRP, neighborhood recharge concept efforts are moving from the conceptual stage visualized in the IRP to actual projects in the City to infiltrate wet weather runoff as close as possible to the point of origin with multiple projects either complete, under construction, or in final design.

Under average weather conditions LADWP is projecting stormwater capture and reuse in 2015 will potentially be 2,000 AFY increasing to 10,000 AFY by 2035. Increased groundwater production as a result of stormwater infiltration will potentially be 15,000 AFY in 2035. This potential is contingent on modifying the court judgment. If these resources reach fruition, LADWP will be able to reduce imported demands on MWD by 25,000 AFY in 2035 under average weather conditions.

11.2.8 Service Area Reliability Assessment

To determine the overall service area reliability, LADWP defined three hydrologic conditions: average (or normal weather); single dry year (such as a repeat of the 1990/91 drought); and multi-dry year period (such as a repeat of FY1988-89 to FY1992-93).

The water supply reliability summaries are shown in Exhibit 11C for the 5-year average from FY 2005-06 to FY 2009-10 and in Exhibit 11 D for FY 2034-35 under average weather conditions with new water conservation shown as a supply source. The exhibits show that the City's reliance on MWD supply will decrease from 52 percent to 24 percent by FY 2034-35 while the combined imported supplies of LAA and MWD water will decrease from 88 percent to 57 percent by FY 2034-35. The locally-developed supplies will increase from 12 percent to 43 percent by FY 2034-35.

AR0071701

Exhibit 11C
LADWP Supply Reliability FYE 2006-2010 Average

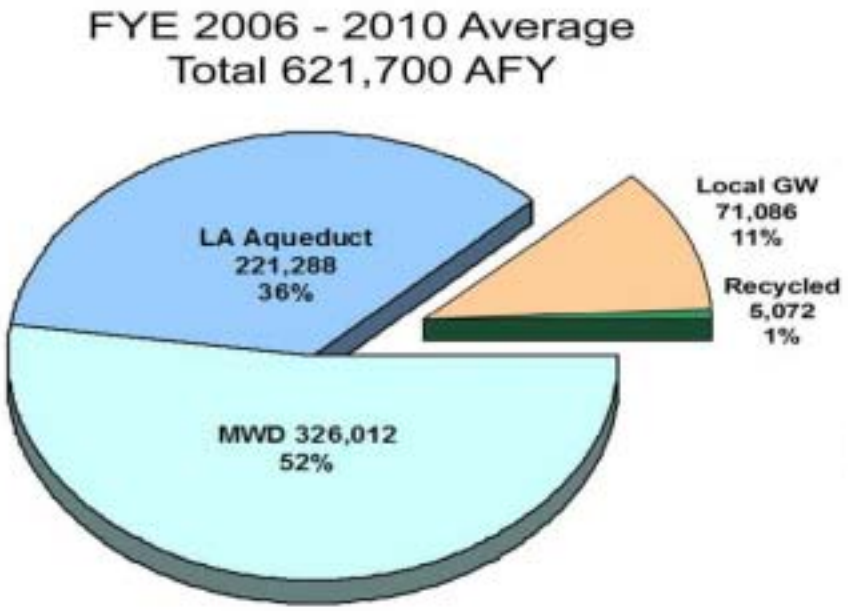

Exhibit 11D
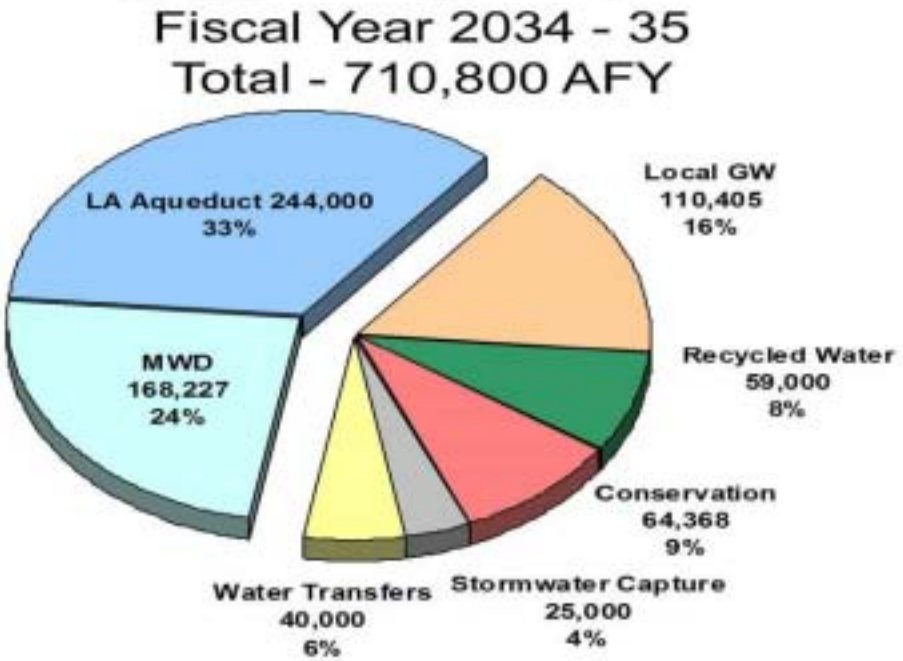
LADWP Supply Reliability Under Average Weather Conditions in Fiscal Year 2034-35



AR0071702

Exhibits 11E and 11F tabulate the service reliability assessment for normal and single dry year conditions, respectively. Exhibits 11G through 11K show reliability assessments in five year increments from 2010 to 2035 with each five year period assuming that a multiple dry year condition occurs. For these reliability tables, existing water conservation has been already subtracted from projected demands, but new water conservation is included as a supply source. Under all scenarios all demands are met by the available supplies.

AR0071709

11.3 Water Shortage Contingency Plan

The Los Angeles City Municipal Code Chapter XII, Article I, Emergency Water Conservation Plan is the City's water shortage contingency plan. It was developed to provide for a sufficient and continuous supply of water in case of a water supply shortage in the service area. There are two scenarios that can cause a water shortage: 1) a severe hydrologic drought affecting surface and groundwater supplies and 2) a catastrophic event that severs major conveyance and/or distribution pipelines serving water to the City. The following discusses LADWP's compliance with the Act as outlined in Section 10632 (a) through (i) of the California Water Code.

11.3.1 Stages of Action – 10632 (a)

As set forth in the Emergency Water Conservation Plan, the City has phases or stages of action that can be undertaken in response to water supply shortages. Phase I prohibited uses of water are in effect at all times within the City. These prohibited uses, defined in article 10632 (d) (see section 11.3.4), are intended to eliminate waste and increase public awareness of the need to conserve water. There are further stages of compounding actions in addition to the Phase I prohibited uses that might be imposed. Phase II to Phase V progressively responds to different severity of shortage with the authority to implement additional prohibited uses of water in Phase V in order to cope with up to a 50 percent reduction in water supply. They are described as follows:

Moderate Shortage, Phase II

1. Should Phase II be implemented, uses applicable to Phase I shall continue to be applicable, except as specifically provided herein.

2. No landscape irrigation shall be permitted on any day other than Monday, Wednesday, or Friday for odd-numbered street addresses and Tuesday, Thursday, or Sunday for even-numbered street addresses. Street addresses ending in ½ or any fraction shall conform to the permitted uses for the last whole number in the address. Watering times shall be limited to: (a) Non-conserving nozzles (spray head sprinklers and bubblers) – no more than eight minutes per watering day per station for a total of 24 minutes per week; (b) Conserving nozzles (standard rotors and multi-stream rotary heads) – no more than 15 minutes per cycle and up to two cycles per watering day per station for a total of 90 minutes per week.

3. Upon written notice to LADWP, irrigation of sports fields may deviate from non-watering days to maintain play areas and accommodate event schedules; however, to be eligible for this means of compliance, a customer must reduce his overall monthly water use by LADWP's Board of Water and Power Commissioner's (Board) adopted degree of shortage plus an additional 5 percent from the customer baseline water usage within 30 days.

4. Upon written notice to LADWP, large landscape areas may deviate from the non-watering days by meeting the following requirements (1) must have approved weather-based irrigation controllers registered with LADWP (eligible weather-based irrigation controllers are those approved by MWD or the Irrigation Association Smart Water Application Technologies (SWAT) initiative (2) must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus an additional 5 percent from the customer baseline water usage within 30 days; and (3) must use recycled water if it is available from LADWP.

5. These provisions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase II except between the hours of 9:00 am and 4:00 pm.

Severe Shortage, Phase III

1. Should Phase III be implemented, uses applicable to Phases I and II shall continue to be applicable, except as specifically provided herein.

AR0071710

2. No landscape irrigation shall be permitted on any day other than Monday for odd-numbered street addresses and Tuesday for even-numbered street addresses. Street addresses ending in ½ or any fraction shall conform to the permitted uses for the last whole number in the address.

3. No washing of vehicles allowed except at commercial car wash facilities.

4. No filling of residential swimming pools and spas with potable water.

5. Upon written notice to LADWP, irrigation of sports fields may deviate from the specific non-watering days and be granted one additional water day (for a total of two watering days allowed). To be eligible for this means of compliance, a customer must reduce his overall monthly water use by LADWP's Board's adopted degree of shortage plus an additional 10 percent from the customer baseline water usage within 30 days.

6. Upon written notice to LADWP, large landscape areas may deviate from the specific non-watering days and be granted one additional watering day (for a total of two watering days allowed) by meeting the following requirements (1) must have approved weather-based irrigation controllers registered with LADWP (eligible weather-based irrigation controllers are those approved by MWD or the Irrigation Association Smart Water Application Technologies (SWAT) initiative (2) must reduce overall monthly water use by LADWP's Board adopted degree of shortage plus an additional 10 percent from the customer baseline water usage within 30 days; and (3) must use recycled water if it is available from LADWP.

7. These provisions do not apply to drip irrigation supplying water to a food source or to hand-held hose watering of vegetation, if the hose is equipped with a self-closing water shut-off device, which is allowed everyday during Phase III except between the hours of 9:00 am and 4:00 pm.

Critical Shortage, Phase IV

1. Should Phase IV be implemented, uses applicable to Phases I, II, and III shall continue to be applicable, except as specifically provided herein.

2. No landscape irrigation allowed.

Super Critical Shortage, Phase V

1. Phase I, II, III, and IV shall continue to remain in effect.

2. The Board is hereby authorized to implement additional prohibited uses of water based on the water supply situation. Any additional prohibitions shall be published at least once in a daily newspaper of general circulation and shall become effective immediately upon such publication and shall remain in effect until cancelled.

11.3.2 Driest Three-Year Supply – 10632 (b)

In the event that three consecutive dry-years curtailing the City's LAA System deliveries should follow the 2010 water supply conditions, LADWP will rely on increased groundwater pumping and purchases from MWD to meet City water demands. This particular sequence is quantified in Exhibit 11L, including relevant assumptions.

AR0071711

Exhibit 11L
Driest Three-Year Water Supply Sequence

Demand and Supply Projections (in acre-feet)	FY2009-10 Actual	Followed by Repeat of Driest Three Consecutive Years FY1958-59 to 1960-61 Hydrology Fiscal Year Ending on June 30		
		2011	2012	2013
Total Demand	**554,140**	**588,900**	**607,300**	**626,000**
Existing / Planned Supplies				
Los Angeles Aqueduct[1]	199,739	104,530	50,849	59,382
Groundwater[2]	76,982	61,090	53,660	46,260
Conservation	8,178	5,670	7,310	8,950
Recycled Water				
- Irrigation and Industrial Use	6,703	7,500	8,300	9,000
- Groundwater Replenishment	0	0	0	0
Water Transfers	0	0	0	40,000
Subtotal	291,602	178,790	120,119	163,592
MWD Water Purchases				
With Existing/Planned Supplies	262,538	410,110	487,181	462,408
Total Supplies	**554,140**	**588,900**	**607,300**	**626,000**

1. Driest three consecutive years on record in LAA watershed (FY1958-59 to FY1960-61) averaged 28 percent of normal runoff.
2. LAA deliveries reflect increased releases for environmental restoration in the Owens Valley and Mono Basin.
3. Dry year demands are 5 percent greater than normal year demands
4. MWD's Water Surplus and Drought Management Plan actions sufficient to meet LADWP demands.

During such severe drought periods, the City's supplemental water supplier, MWD, may use an allocation strategy that is consistent with the framework developed in its Water Surplus and Drought Management (WSDM) Plan. Developed by MWD with substantial input from its member agencies, the WSDM Plan provides for a needs-based allocation strategy, and establishes priorities for the use of MWD's water supplies to achieve 100 percent retail reliability.

Following are actions that could be taken by MWD in accordance with their WSDM Plan to augment its water supplies prior to implementation of any drought allocation action:

1. Draw on Diamond Valley Lake storage
2. Draw on out-of-region storage in Semitropic and Arvin-Edison Groundwater Banks
3. Reduce/suspend local groundwater replenishment deliveries
4. Draw on contractual groundwater storage programs in MWD's service area

AR0071712

5. Draw on State Water Project terminal reservoir storage (per Monterey Agreement)
6. Call for voluntary conservation and public education
7. Reduce deliveries from MWD's Interim Agricultural Water Program
8. Call on water transfer options contracts
9. Purchase transfers on the spot market
10. Allocate imported water if necessary

In 2008 MWD adopted the Water Supply Allocation Plan (WSAP) designed to allocate supplies among its member agencies in a fair and efficient manner. The WSAP establishes the formula for calculating member agency allocations if MWD cannot meet firm demands in a given year.

11.3.3 Catastrophic Supply Interruption Plan – 10632 (c)

LADWP has Emergency Response Plans (ERPs revised January 2010) in place to restore water service for essential use in the City if a disaster should result in the temporary interruption of water supply. Department personnel responsible for water transportation, distribution, and treatment have established ERPs to guide the assessment, prioritization, and repair process of City facilities that have incurred damage during a disaster. Citywide, an Emergency Operations Center (EOC) serves as a centralized point for citywide management of information about disasters and for coordination of all available resources. The EOC supports the City's Emergency Operations Organization to achieve its mission of saving lives, protecting property, and returning the City to normal operations in the event of a disaster. LADWP coordinates its efforts with the EOC and will utilize the EOC to resume water supply service after a catastrophic event.

11.3.4 Mandatory Water Use Prohibitions – 10632 (d)

Phase I prohibited uses of the Emergency Water Conservation Plan contain 13 wasteful water use practices that are permanently prohibited for all City of Los Angeles customers. These prohibited uses are intended to eliminate waste and increase public awareness of the need to conserve water. During times of shortage, education and enforcement of the following provisions will be increased:

1. No customer shall use a water hose to wash any paved surfaces including, but not limited to, sidewalks, walkways, driveways, and parking areas, except to alleviate immediate safety or sanitation hazards. This section shall not apply to LADWP approved water conserving spray cleaning devices. Use of water pressure devices for graffiti removal is exempt. A simple spray nozzle does not qualify as a water conserving spray cleaning device.
2. No customer shall use water to clean, fill, or maintain levels in decorative fountains, ponds, lakes, or similar structures used for aesthetic purposes unless such water is part of a recirculating system.
3. No restaurant, hotel, cafe, cafeteria, or other public place where food is sold, served, or offered for sale shall serve drinking water to any person unless expressly requested.
4. No customer shall permit water to leak from any pipe or fixture on the customer's premises; failure or refusal to affect a timely repair of any leak of which the customer knows or has reason to know shall subject said customer to all penalties

AR0071713

for a prohibited use of water.

5. No customer shall wash a vehicle with a hose if the hose does not have a self-closing water shut-off device or device attached to it, or otherwise to allow a hose to run continuously while washing a vehicle.

6. No customer shall irrigate during periods of rain.

7. No customer shall water or irrigate lawn, landscape, or other vegetated areas between the hours of 9:00 a.m. and 4:00 p.m. During these hours, public and private golf courses greens and tees and professional sports fields may be irrigated in order to maintain play areas and accommodate event schedules. Supervised testing or repairing of irrigation systems is allowed anytime with proper signage.

8. All irrigating of landscape with potable water using spray head sprinklers and bubblers shall be limited to no more than ten minutes per watering station per day. All irrigating of landscape with potable water using standard rotors and multi-stream rotary heads shall be limited to no more than fifteen minutes per cycle and up to two cycles per watering day per station. Exempt from these irrigation restrictions are irrigation systems using very low drip type irrigation when no emitter produces more than four gallons of water per hour and micro-sprinklers using less than fourteen gallons per hour. This provision does not apply to Schedule F water customers or water service water service that has been granted the General Provision M rate adjustment under the City's Water Rates Ordinance, subject to the Customer having complied with best management practices for irrigation approved by the Department. The 9:00 a.m. to 4:00 p.m. irrigation restriction shall apply unless specifically exempt as stated in subsection 7 of the Emergency Water Conservation Ordinance.

9. No customer shall water or irrigate any lawn, landscape, or other vegetated area in a manner that causes or allows excess or continuous flow or runoff onto an adjoining sidewalk, driveway, street, gutter, or ditch.

10. No installation of single pass cooling systems shall be permitted in buildings requesting new water service.

11. No installation of non-recirculating systems shall be permitted in new conveyor car wash and new commercial laundry systems.

12. Operators of hotels and motels shall provide guests with the option of choosing not to have towels and linens laundered daily. The hotel or motel shall prominently display notice of this option in each bathroom using clear and easily understood language. LADWP shall make suitable displays available.

13. No large landscape areas shall have irrigation systems without rain sensors that shut-off the irrigation systems. Large landscape areas with approved weather-based irrigation controllers registered with LADWP are in compliance with this requirement.

11.3.5 Consumption Reduction Methods during Water Shortages – 10632 (e)

Short-Term Actions

During a water shortage or emergency condition, LADWP's existing rate structure (enacted in 1993) serves as a basis for further reducing consumption. First tier water allotments are reduced during shortages by the degree of the shortage. For single-family residential users, the adjusted first tier allotments apply for the entire year. For other users, the adjusted first tier allotments apply only during the high season (June 1 through October 31). Details of LADWP's water rate structure are provided in Appendix X – Water Rate Ordinance.

AR0071714

Additional measures can be phased in as the dry cycle continues to provide some immediate demand reductions and increase public awareness of the need to conserve water. Included among these measures are water conservation public service announcements (through television and/or radio), billboard ads, flyer distributions, and conservation workshops. LADWP also actively participates in public exhibits to disseminate water conservation information within its service area. Conservation is a permanent and long-term application used within the City to counter the potentially adverse impacts of water supply shortages.

State law further regulates distribution of water in extreme water shortage conditions. Section 350-354 of the California Water Code states that when a governing body of a distributor of a public water supply declares a water shortage emergency within its service area, water will be allocated to meet needs for domestic use, sanitation, fire protection, and other priorities. This will be done equitably and without discrimination between customers using water for the same purpose(s).

Long-Term Actions

LADWP's long-range water conservation program is driven by the need to continuously increase water use efficiency. This will reduce demand, extend supply, and therefore, provide greater reliability. Dry cycle experiences, public trust responsibilities, and regulatory mandates have raised the level of awareness within the City of Los Angeles of the need to approach demand reduction from a permanent and long-term perspective.

LADWP will continue to maintain and increase its existing conservation programs and pursue the development of new and innovative programs as outlined in Chapter 3, Water Conservation with the goal of reducing potable water demands by 60,000 AFY by 2035. Emphasis continues to be placed on structural conservation for the residential and CII sectors (HETs, high-efficiency washing machine rebates, etc.) which result in permanent per capita water use reduction. Substantial efforts are also being placed on landscape water use efficiency and CII conservation opportunities. It should, however, be recognized that the ability to achieve water reduction during shortages by requesting additional voluntary measures is likely to be more difficult in the future. As customers adjust to a conservation ethic and adopt permanent measures to reduce water use, their water demands harden and become less susceptible to voluntary conservation.

11.3.6 Penalties for Excessive Use (Non-Compliance to Prohibited Use) – 10632 (f)

The Emergency Water Conservation Plan sets penalties for violations of prohibited uses outlined in Sections 10632 (a) and (d). The penalties vary by water meter size. For water meters smaller than two inches the following penalties shall apply:

1. The first violation consists of a written warning

2. The second violation within the preceding 12 month period will result in a surcharge in the amount of $100 added to the customer's water bill.

3. The third violation within the preceding 12 month period will result in a surcharge in the amount of $200 added to the customer's water bill.

4. The fourth violation within the preceding 12 month period will result in a surcharge in the amount of $300 added to the customer's water bill.

5. After a fifth violation or subsequent violation within the preceding 12 month period, LADWP may install a flow-restricting device of 1 gpm capacity for services up to 1 ½ inches in size and comparatively sized restrictors for larger services or

AR0071715

terminate a customer's service, in addition to the aforementioned financial surcharges. Such action shall only be taken after a hearing held by LADWP.

For water meters two inches and larger the following penalties shall apply:

1. The first violation consists of a written warning
2. The second violation within the preceding 12 month period will result in a surcharge in the amount of $200 added to the customer's water bill.
3. The third violation within the preceding 12 month period will result in a surcharge in the amount of $400 added to the customer's water bill.
4. The fourth violation within the preceding 12 month period will result in a surcharge in the amount of $600 added to the customer's water bill.
5. After a fifth violation or subsequent violation within the preceding 12 month period, LADWP may install a flow-restricting device or terminate a customer's service, in addition to the aforementioned financial surcharges. Such action shall only be taken after a hearing held by LADWP.

11.3.7 Analysis and Effects on Revenues and Expenditures of Reduced Sales during Shortages – 10632 (g)

The City's Water Rate Ordinance, adopted in June 1995 and last amended in June 2008, provides a remedy to the impact of reduced water sales on revenues in the form of a Water Revenue Adjustment Factor (Adjustment). The Adjustment recovers any shortage in revenue due to variation in water sales. It is intended to support a fiscal year revenue target that is deemed sufficient to cover LADWP's essential expenses. The formula takes into account target and actual revenues as well as projected water sales to determine the appropriate Adjustment.

The Adjustment is currently limited to $.18 per hundred-cubic-feet. It cannot exceed this limit unless the Board determines that a surcharge in excess of $0.18 per hundred-cubic-feet is financially required and approval from the Los Angeles City Council is obtained. The Board also has the authority to reduce the factor to less than the formula-calculated amount.

A billing factor is calculated annually on January 1 and is added to the standard commodity charge. The factor is set to zero if a negative value is calculated. A Water Revenue Adjustment Account is maintained and updated each month by LADWP. This account is adjusted annually on July 1.

The City's Water Revenue Adjustment Factor ensures that the required funds are available to fund Department activities aimed at providing continuous water service to Los Angeles water users, even during periods of low water sales.

11.3.8 Water Shortage Contingency Resolution or Ordinance – 10632 (h)

A draft water shortage contingency resolution is shown in Exhibit 11M. Moreover, the City's Emergency Water Conservation Plan Section 121.07.B has the following conservation phase implementation procedures:

AR0071716

"The Department (LADWP) shall monitor and evaluate the projected supply and demand for water by its Customers monthly, and shall recommend to the Mayor and Council by concurrent written notice the extent of the conservation required by the Customers of the Department in order for the Department to prudently plan for and supply water to its Customers. The Mayor shall, in turn, independently evaluate such recommendation and notify the Council of the Mayor's determination as to the particular phase of water conservation, Phase I through Phase V, that should be implemented. Thereafter, the Mayor may, with the concurrence of the Council, order that the appropriate phase of water conservation be implemented in accordance with the applicable provisions of this Article. Said order shall be made by public proclamation and shall be published one time only in a daily newspaper of general circulation and shall become effective immediately upon such publication. The prohibited water uses for each phase shall take effect with the first full billing period commencing on or after the effective date of the public proclamation by the Mayor. In the event the Mayor independently recommends to the Council a phase of conservation different from that recommended by the Department, the Mayor shall include detailed supporting data and the reasons for the independent recommendation in the notification to the Council of the Mayor's determination as to the appropriate phase of conservation to be implemented."

The City's Water Rate Ordinance No. 170435 also has specific provisions for LADWP's Board, through a resolution, to determine the degree of shortage and apply corresponding commodity charges in case of a water shortage (see Section 11.3.5 and Appendix X – Water Rate Ordinance). If a water shortage is declared, certified copies of the resolution will be transmitted to the offices of the Mayor and of the Los Angeles City Clerk, and the Los Angeles City Council for final approval. This particular water shortage act is included under Section 3 – General Provisions, Article R – Shortage Year Rates of the City's Water Rate Ordinance.

DRAFT

AR0071717

Exhibit 11M
Draft Water Shortage Contingency Resolution

BE IT RESOLVED that the Board of Water and Power Commissioners (Board) recognizes that a Water Shortage Contingency Plan has been prepared and incorporated into the City of Los Angeles 2010 Urban Water Management Plan pursuant to the Urban Water Management Planning Act; the Urban Water Management Plan is on file with the Secretary of the Board; this Board has reviewed and considered the information and recommendations contained in this document, and makes the following findings and determinations:

1. The water supply available to the City of Los Angeles is insufficient to meet the City's normal water supply needs; and
2. The Department of Water and Power has developed a Water Shortage Contingency Plan for the City of Los Angeles that compiles with all the requirements of the Urban Water Management Planning Act; and
3. The Urban Water Management Plan has been developed, adopted, and implemented pursuant to Article 3, Sections 10640 through 10645 of the Urban Water Management Planning Act; and
4. The Water Shortage Contingency Plan includes stages of action that can be taken in response to water supply shortages, including up to a 50 percent reduction in water supply, a driest three-year water supply scenario, mandatory water use prohibitions, and penalties for non-compliance; and
5. The Water Shortage Contingency Plan identifies both short-term and long-term actions to maximize water use efficiency and minimize the effects of the current water shortage as well as future water supply shortages.

BE IT FURTHER RESOLVED that this Board has adopted the Water Shortage Contingency Plan as incorporated in the Urban Water Management Plan, and declares the provisions of the Water Shortage Contingency Plan in full force and effect during the duration of this period of water shortage.

I HEREBY CERTIFY that the foregoing is a full, true, and correct copy of the resolution adopted by the Board of Water and Power Commissioners of the City of Los Angeles at its meeting held

11.3.9 Methodology to Determine Actual Water Use Reductions during Shortages – 10632 (i)

Water use is monitored closely by LADWP throughout its service area regardless of the supply conditions. With 100 percent of its over 700,000 service connections metered, there is a high degree of accountability on the quantity of water used within the Los Angeles service area. Information from meter reads is collected for billing and accounting purposes, with reports prepared on a monthly basis from the data compiled.

LADWP also used a conservation model to estimate conservation efforts within the City since the early 1990s. The model estimated City water demand without conservation efforts using population and weather variables. A new conservation model was developed in 2010 to account for additional factors such as economic recession and drought conservation is discussed in Chapter 2, Water Demand. The conservation effort is derived by comparing estimated pre-conservation demand with actual demand. Conservation efforts derived from this model are shown in Chapter 3, Water Conservation.

AR0071718

11.4 Water Supply Assessments

Background

In 1994, the California Legislature enacted Water Code section 10910 (Senate Bill 901), which requires cities and counties, as part of the California Environmental Quality Act (CEQA) review, to request the applicable public water system to assess whether the system's projected water supplies were sufficient to meet a proposed development's anticipated water demand. The intent was to link the land use and water supply planning processes to ensure that developers and water supply agencies communicate early in the planning process. However, a study of projects approved by local planning agencies revealed that numerous projects were exempted due to loopholes in the statute, and that the intent of the legislation has largely gone unfulfilled.

Subsequently, California Senate Bill (SB) 610 and SB 221, modeled after SB 901, amended State law effective January 1, 2002, to ensure that the original intent of the legislation is fulfilled. SB 610 and 221 are companion measures which seek to promote more collaborative planning between local water suppliers and cities and counties. These bills improve the link between information on water supply availability and certain land use decisions made by cities and counties. Both statutes require detailed information regarding water availability to be provided to the city and county decision-makers prior to approval of specified large development projects. Both statutes also require this detailed information be included in the administrative record that serves as the evidentiary basis for an approval action by the city or county on such projects. Both measures recognize local control and decision making regarding the availability of water for projects and the approval of projects.

Under SB 610 a water supply assessment (WSA) must be furnished to local governments for inclusion in any environmental documentation for certain development projects subject to the CEQA. Specifically, SB 610 requires that for certain projects, the CEQA lead agency must identify any public water system that may supply water to the proposed project and request the public water system to determine the water demand associated with the project and whether such demand was included as part of the most recently adopted UWMP. If the projected water demand associated with the proposed project was accounted for in the most recently adopted UWMP, the public water system may incorporate the supporting information from the UWMP in preparing the elements of the assessment. If the proposed project's water demand was not accounted for in the most recently adopted UWMP, the WSA for the project shall include a discussion with regard to whether the public water system's total projected water supplies available in normal, single dry, and multiple dry water years during a 20-year projection will meet the proposed project's water demand.

Per Section 10912 of the California Water Code, a project which is subject to the requirements of SB 610 includes: (1) a proposed residential development of more than 500 dwelling units; (2) a proposed shopping center or business establishment employing more than 1,000 persons or having more than 500,000 square feet of floor space; (3) a proposed commercial office building employing more than 1,000 persons or having more than 250,000 square feet of floor space; (4) a proposed hotel or motel, or both, having more than 500 rooms; (5) a proposed industrial, manufacturing, or processing plant, or industrial park planned to house more than 1,000 persons, occupying more than 40 acres of land, or having more than 650,000 square feet of floor area; (6) a mixed-use project that includes one or more of the projects specified in this subdivision; or (7) a project that would demand an amount of water equivalent to, or greater than, the amount of water required by a 500 dwelling unit project.

The assessment would include an identification of existing water supply entitlements, water rights, or water service contracts relevant to the identified water supply for the proposed project and water received in prior years pursuant to those

AR0071719

entitlements, rights, and contracts. If the assessment concludes that water supplies will be insufficient, plans for acquiring additional water supplies would need to be presented.

Under SB 221, approval by a city or county of certain developments requires an affirmative written verification of sufficient water supply; which is a "fail safe" mechanism to ensure collaboration on finding the needed water supplies to serve a new large development occurs before construction begins.

Methodology

During the years from 2005 to 2010, LADWP has been requested to develop over 40 WSAs. Each WSA performed by LADWP is carefully evaluated within the context of the current adopted UWMP and current conditions, such as restrictions on State Water Project (SWP) pumping from the Sacramento-San Joaquin Delta imposed by a Federal Court. The Metropolitan Water District of Southern California (MWD), from whom the City purchases its State Water Project and Colorado River water supplies, has also been actively developing plans and making efforts to provide additional water supply reliability for the entire Southern California region. LADWP coordinates closely with MWD to ensure implementation of MWD's water resource development plans and supplemental water reliability report prepared by MWD.

LADWP's UWMP uses a service area-wide method in developing City water demand projections. This methodology does not rely on individual development demands to determine area-wide growth. Rather, the growth in water use for the entire service area was considered in developing long-term water projections for the City to the Year 2035. The driving factors for this growth are demographics, weather, and conservation. LADWP used anticipated growth in the various customer class sectors as provided by MWD who reallocated projected demographic data from the Southern California Association of Governments (SCAG) into member agencies' service areas. The data used was based on SCAG's 2008 Regional Transportation Plan Forecast.

As governed by City Charter Sections 673 and 677, LADWP can serve surplus water supplies to areas outside of the City boundaries. There are approximately 4,500 services for customers outside of the City, with a combined annual water use less than 1 percent of all water delivered. Water served outside of the City includes a surcharge to account for the increased MWD purchased water.

The water demand forecast model in the UWMP was developed using LADWP total water use, including the water served by LADWP for use outside of the City. The service area reliability assessment was performed for three hydrologic conditions: average year, single dry year, and multiple-dry years; and a Shortage Contingency Plan was developed to provide for a sufficient and continuous supply in LADWP's service area. This Shortage Contingency Plan included water provided for use outside of the City.

An important part of the water planning process is for LADWP to work collaboratively with MWD to ensure that anticipated water demands are incorporated into MWD's long-term water resources development plan and water supply allocation plan. The City's allotment of MWD water supplies under MWD's water supply allocation plan is based on the City's total water demand which includes services to areas outside the City. The ongoing collaboration between LADWP and MWD is critical in ensuring that the City's anticipated water demands are incorporated into the development of MWD's long-term Integrated Resources Plan (IRP). MWD's IRP directs a continuous regional effort to develop regional water resources involving all of MWD's member agencies. Successful implementation of MWD's IRP has resulted in reliable supplemental water supplies for the City from MWD.

AR0071720

In summary, the WSAs are performed to ensure that adequate water supplies would be available to meet the estimated water demands of the proposed developments during normal, single-dry, and multiple-dry water years, as well as existing and planned future uses of the City's water system. LADWP will continue to perform WSAs as part of its long-term water supply planning efforts for its service area.

WSA Procedure

The CEQA lead agency, such as the Department of City Planning or the Community Redevelopment Agency of the City of Los Angeles, evaluates the proposed project against the requirements for a WSA in accordance with the Water Code. If the proposed project falls within the requirements for a WSA, a formal request is submitted to LADWP to perform a WSA.

In evaluating the proposed project's water demand, LADWP applies the Sewer Generation Factors (published by City of Los Angeles Bureau of Sanitation) to the development's project description for calculating indoor water use. Outdoor landscape water demand is calculated by using computer software which takes into account various factors such as landscape area square footage, location, and plant types. Historical billing records are used to establish existing baseline water demand on the property.

LADWP also encourages all projects to implement additional water conservation measures above and beyond the current water conservation ordinance requirements. As an example, if the proposed development is near an existing or future recycled water pipeline system, commitment to use recycled water for irrigation, toilet flushing and cooling towers is highly recommended as part of the additional conservation measures for the proposed development.

The net increase/decrease in water demand, which is the projected additional water demand of the development, is calculated by subtracting the existing baseline water demand and water saving amount from the total proposed water demand.

The net increase/decrease in water demand, which is the projected additional water demand of the development, is calculated by subtracting the existing baseline water demand and water saving amount from the total proposed water demand. If the land use of the proposed development is consistent with the City's General Plan, the projected water demand of the development is considered to be accounted for in the most recently adopted UWMP. The City incorporates the projected demographic data from the SCAG in its General Plan. MWD utilizes a land use based planning tool that allocates SCAG's projected demographic data into water service areas for their member agencies, which was adopted for water demand projection in the UWMP.

If the proposed land use is not consistent with the City's General Plan, the WSA will further evaluate if the projected supplies from the UWMP are able to accommodate the proposed project's water demand, which may include other resource options to offset the projected water demand.

All WSAs are subject to approval by the Board of Water and Power Commissioners. Upon approval, the lead agency is responsible for enforcing the requirements of the WSA as part of the approval for the project.

AR0071721

DRAFT Chapter Twelve
Climate Change

12.0 Overview

LADWP is considering impacts of climate change during development of its long-term water supply plan. Climate change is a global-scale concern, but is particularly important in the western United States where potential impacts on water resources can be significant to supplies for water agencies. Climate change can impact surface supplies from the LAA, imported supplies from MWD, and local demands. As a result, LADWP is completing a study to analyze the operational and water supply impacts of potential shifts in the timing and quantity of runoff along the LAA system due to climate change. Such potential shifts may require LADWP to develop, enhance, and modify management of local water resources. Projected changes in climate are expected to alter hydrologic patterns in the Eastern Sierra through changes in precipitation, snowmelt, relative ratios of rain and snow, winter storm patterns, and evapotranspiration.

To understand some of the key issues surrounding climate change impacts, it is important to put it into the context of LADWP's water supplies. California lies within multiple climate zones. Therefore, each region will experience unique impacts to climate change. Because LADWP relies on both local and imported water sources, it is necessary to consider the potential impacts climate change could have on the local watershed as well as the western and eastern Sierra Nevada watersheds where a portion of MWD's imported water originates and LADWP's imported LAA supplies originate, respectively, and the Colorado River Basin where the remainder of MWD's imported supplies originate.

Generally speaking, any water supplies that are dependent on natural hydrology are vulnerable to climate change, especially if the water source originates from mountain snow pack. For LADWP, the most vulnerable water sources subject to climate change impacts are imported water supplies from MWD and the LAA. However, local sources can expect to see some changes in the future as well. In addition to water supply impacts, changes in local temperature and precipitation are expected to alter water demand patterns. However, there is still general uncertainty within the scientific community regarding the potential impacts of climate change for the City of Los Angeles. LADWP will continue to stay abreast of developments in climate change to better understand its potential implications to the City's water supplies.

12.1 Potential Impacts of Climate Change on Water Service Reliability

Scientists predict future climate change scenarios using highly complex computer global climate models (GCMs) to simulate climate systems. Although most of the scientific community agrees that climate change is occurring and, as a result, mean temperatures for the planet will increase, the specific degree of this temperature increase cannot be accurately predicted. Predictions of changes in precipitation are even more speculative, with some scenarios showing precipitation increasing in the future and others showing the opposite.

It is important to acknowledge that the predictions of the GCMs lack the desired precision due to the presence of uncertainties inherent in the analyses. The uncertainty to future emissions of greenhouse gases and the chaotic nature of the climate system leads to uncertain response of the global climate system to the increases in greenhouse gases. In addition, the science of climate change still lacks the complete understanding of regional manifestations that will result from global changes, thus restraining the projecting capacity of these models. However, these projections are consistent with the state of science today, and they help predict the manner of which hydrologic variables are likely to respond to a range of possible future climate conditions, and thus provide invaluable insight to water managers in their decisions pertaining to water supply reliability.

AR0071722

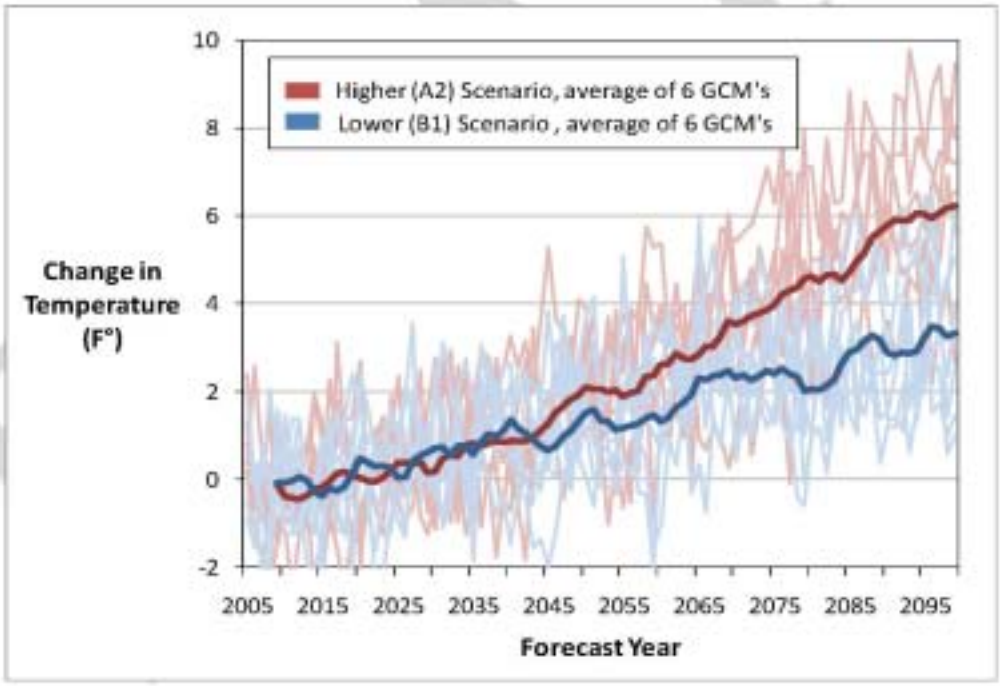
The regional areas of interest in assessing climate change impacts to LADWP include the local service area and sources of origination for imported water supplies in northern California, eastern Sierra Nevada Mountains, and the Colorado River Basin. Data regarding climate change impacts for the various regions of interest is provided in this section.

12.1.1 Local Impacts

Most scientific experts believe that because of the uncertainty involved with each model, several models should be used to test the potential impact of climate change. To downsize the global coarse-scale climate projections to a regional level incorporating local weather and topography, the GCMs are "downscaled". Future projections of precipitation and temperature were obtained for six GCMs under two greenhouse gas emission scenarios (A2 - higher and B1 - lower) for Los Angeles County. [1,2] Exhibits 12A and 12B plot the changes in projected average annual mean temperature and precipitation, respectively for the model scenarios. The bold line represents the running average of all six models for each emission scenario. The six models were also used in the preparation of the 2008 California Climate Change Scenarios assessment.

Note Exhibits 12X and 12X are placeholders and are for illustrative purposes only of the type of data that will be presented for Los Angeles. The data in the figures represent data obtained from the Scripps Institute of Oceanography for the Pasadena area. Similar data has been requested for Los Angeles.

Exhibit 12A
Climate Change Impacts to Local Temperatures for Los Angeles (Placeholder)



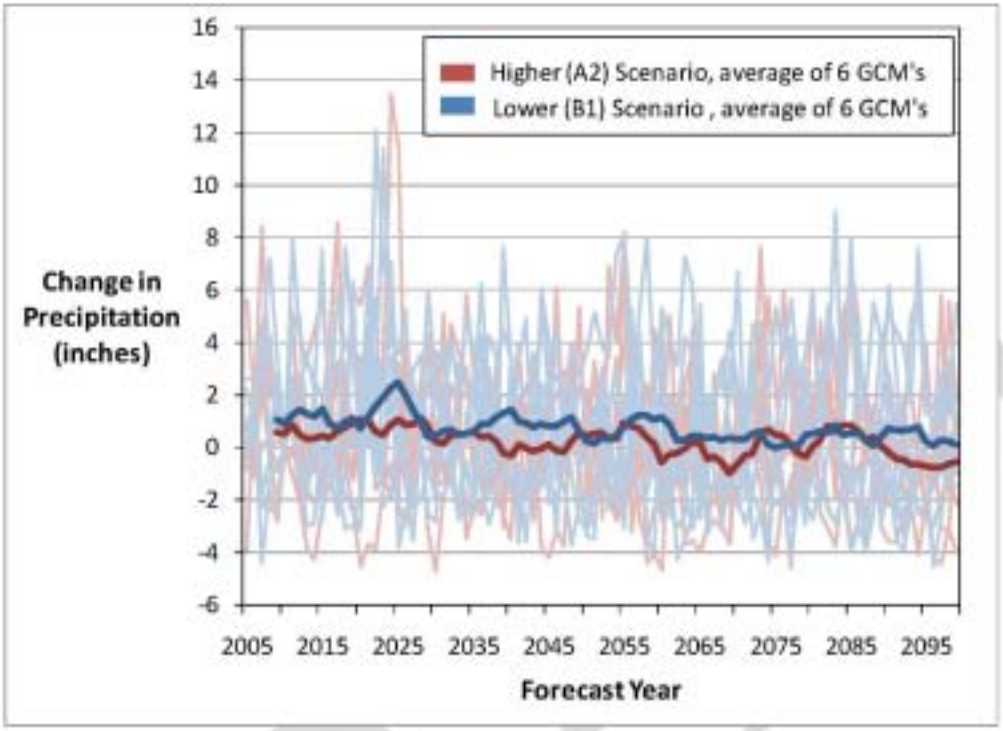
[1] Dan Cayan and Mary Tyree (University of California, San Diego, Scripps Institute of Oceanography) provided downscaled data for Pasadena under two emissions scenarios from six climate models: CNRM CM3, GFDL CM2.1, Miroc3.2 (medium resolution), MPI ECHAM5, NCAR CCSM3, NCAR PCM1.

[2] Note: These scenarios do not bracket the highest and lowest emission futures possible, but represent a status quo approach (A2) and a pro-active mitigation (B1) approach to reduce carbon emissions.

AR0071723

Exhibit 12B

Climate Change Impacts to Local Precipitation for Los Angeles (Placeholder)



Local climate changes within the vicinity of the LADWP service area are expected to include:

- An increase in average temperatures that will be more pronounced in the summer than in the winter with annual mean temperatures in 2100 increasing greater than 3°Fwhen lower greenhouse gas emission scenarios are used and may exceed 7°F when high higher emissions scenarios are used dependent upon the GCM utilized
- An increase in extreme temperatures
- An increase in heat waves and droughts that will extend for a longer duration
- A decrease in precipitation with the potential for 30 year deficits of more than 10% below historical levels that, coupled with higher temperatures, will increase evaporation/transpiration
- An increase in short-duration/high volume intense storm events during the winter

The impact of these climate effects will likely be increased water demands for irrigation and cooling purposes earlier in the year and for extended periods coupled with decreased local surface runoff available to recharge groundwater basins. Other impacts might include increased fire events that could impact water quality and sedimentation, decreased groundwater recharge due to lower soil moisture, and sea level rise increasing seawater intrusion into coastal groundwater basins.

AR0071724

12.1.2 Los Angeles Aqueduct Impacts

The LAA is one of the major imported water sources delivering a reliable water supply to the City of Los Angeles. The LAA originates approximately 340 miles away from snowmelt runoff in the eastern Sierra Nevada; hence LAA is subject to hydrologic variability associated with climate change. Since the majority of precipitation occurs during winter in the eastern Sierra Nevada watershed, water is stored in natural reservoirs in the form of snowpacks, and is gradually released into streams that feed into the LAA during spring and summer. More detailed information regarding the LAA is presented in Chapter 5, Los Angeles Aqueduct Systems.

Higher concentrations of greenhouse gases in the atmosphere are often indications of pending climate change. These changes threaten the hydrologic stability of the eastern Sierra Nevada watershed through alterations in precipitation, snowmelt, relative ratios of rain and snow, winter storm patterns, and evapotranspiration, all of which have major potential impacts on the LAA water supply and deliveries.

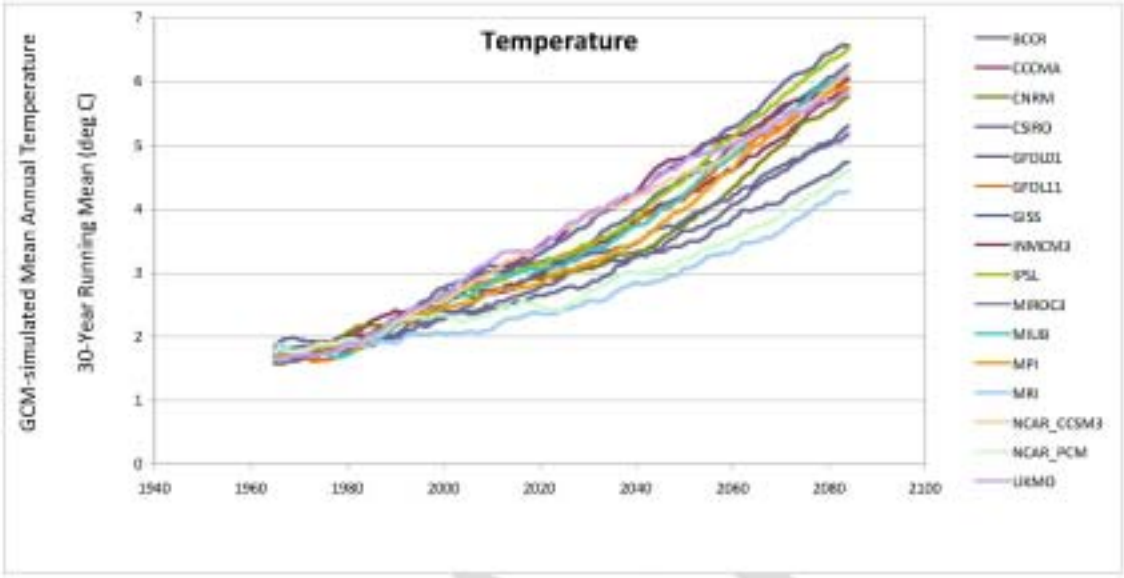
To address the possible challenges posed by climate change on the LAA, LADWP commenced a climate change study in 2009 to evaluate the potential impacts of climate change on the eastern Sierra Nevada watershed and the LAA water supply and deliveries, and investigate opportunities to improve the LAA system as a result of these impacts over the next hundred years. In this study, future climate conditions are predicted using a set of sixteen GCMs and two greenhouse gas emission scenarios.

The impacts of these climate change scenarios and the associated hydrology on the LAA's eastern Sierra Watershed includes an analysis of historical temperature, precipitation, water quality, and runoff records. Hydrologic modeling will be performed to estimate runoff changes from current conditions and an evaluation will be provided to determine their effects on the performance of the existing infrastructure with regards to storage and conveyance capacity to Los Angeles. As part of the evaluation of potential adaptation measures if existing infrastructures are inadequate, recommendations will be provided to modify the existing infrastructure and operations to accommodate these impacts.

Preliminary results of the study are showing steady temperature increases throughout the 21st century and are consistent with other prior studies performed in the scientific community. Exhibit 12C displays the time series of 30-year running means of the projected temperature of one of the greenhouse gas emission scenarios considered in the study, A2 (higher greenhouse gas emissions), averaged over the simulation area for each of the sixteen GCMs. All GCMs project temperature increases throughout the 21st century.

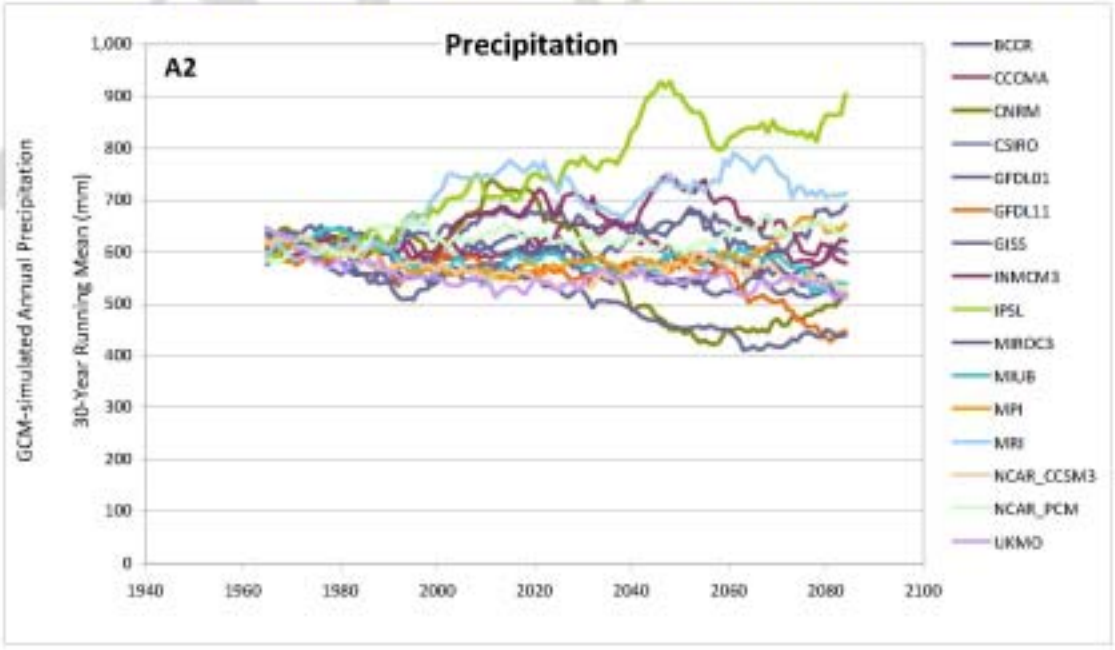
AR0071725

Exhibit 12C
30-Year Time Series Projected Temperature Means for Eastern Sierra Nevada Watershed



On the other hand, forecasts for precipitation differ greatly between the GCMs. Some GCMs are projecting increases, but the majority of the model outputs are projecting decreases in precipitation over the study period. Exhibit 12D displays the time series of 30-year running means of the projected precipitation using the A2 greenhouse gas emission scenario (higher greenhouse gas emissions) averaged over the simulation area for each of the sixteen GCM models.

Exhibit 12D
30-Year Time Series Projected Precipitation Means for Eastern Sierra Nevada Watershed



AR0071726

Temperature is the main climate variable that is projected to rise significantly in the coming years and decades. The rise in temperature directly affects several variables including:

- Whether precipitation falls as snow or rain;
- The ground-level temperature determines the timing and rate of snowmelt; and
- The temperature profile in the canopy that determines the rate of evapotranspiration.

Preliminary results have shown that future predictions for the early-21st century suggested a warming trend of 0.9 to 2.7 °F and almost no change in average precipitation. Mid-21st century projections suggested a warming trend of 3.6 to 5.4 °F and a small average decrease in precipitation, approximately 5 percent. This warming trend is expected to increase by the end of 21st century, as the results suggest further warming of 4.5 to 8.1 °F and a decrease in precipitation of approximately 10 percent. In addition, preliminary results indicate an increase in the frequency and length of droughts in the end-of-century period.

Projected changes in temperature (warmer winters) will change precipitation patterns to rain with larger fractions than historically encountered. Consequently, peak Snow Water Equivalent (SWE) and runoff are projected to undergo a shift in timing to earlier dates.

At elevations of up to about 9,800 feet, the snowpack of the eastern Sierras is susceptible to earlier melt and less accumulation with a long term-shift in mean temperature of 3.6°F, especially in the southern Sierras. On average, mean temperature rises are in the range of 3.6 to 10.8 °F resulting in about a 17 to 50 percent loss in snowpack storage, respectively. This vulnerability shows up in average to warm winters and will directly affect the stream levels and stream discharge. This raises potential concerns for LADWP in the areas of adequate storage and operations, especially the capacity of the LAA system to store the early runoff in surface reservoirs.

The projected temperature and precipitation dataset form the basis of the hydrologic model projections for runoff, snow-water equivalent (SWE), and rain-to-snow ratio. To compare the future projections of these variables, the trends that dominated the second half of the 20th century are considered baselines for future trends. The baseline values for runoff, SWE, and rain-to-snow ratio are 0.6 million acre-feet (MAF), 15 inches, and 0.2, respectively. By Early 21st century (2010 – 2039), preliminary results illustrate runoff is projected to undergo increases and decreases averaging between 0.5 to 0.85 MAF; SWE is projected to undergo decreases and increases ranging between 10.6 to 19.0 inches, and the rain-to-snow ratio is projected to increase between 0.24 to 0.33. By mid-century (2040 – 2069), the same trends are expected to dominate, with runoff ranging between 0.34 to 0.9 MAF, SWE ranging between 7.0 to 19.7 inches, and the rain-to-snow ratio increasing between 0.25 to 0.43. These trends are expected to govern until the end-of-century (2070 -2099) with runoff ranging between 0.35 to 1.1 MAF, SWE ranging between 5.0 to 16.0 inches, and rain-to-snow ratio increasing between 0.28 to 0.54. Exhibit 12E summarizes the projections for runoff, SWE, and rain-to-snow ratio for the 21st century.

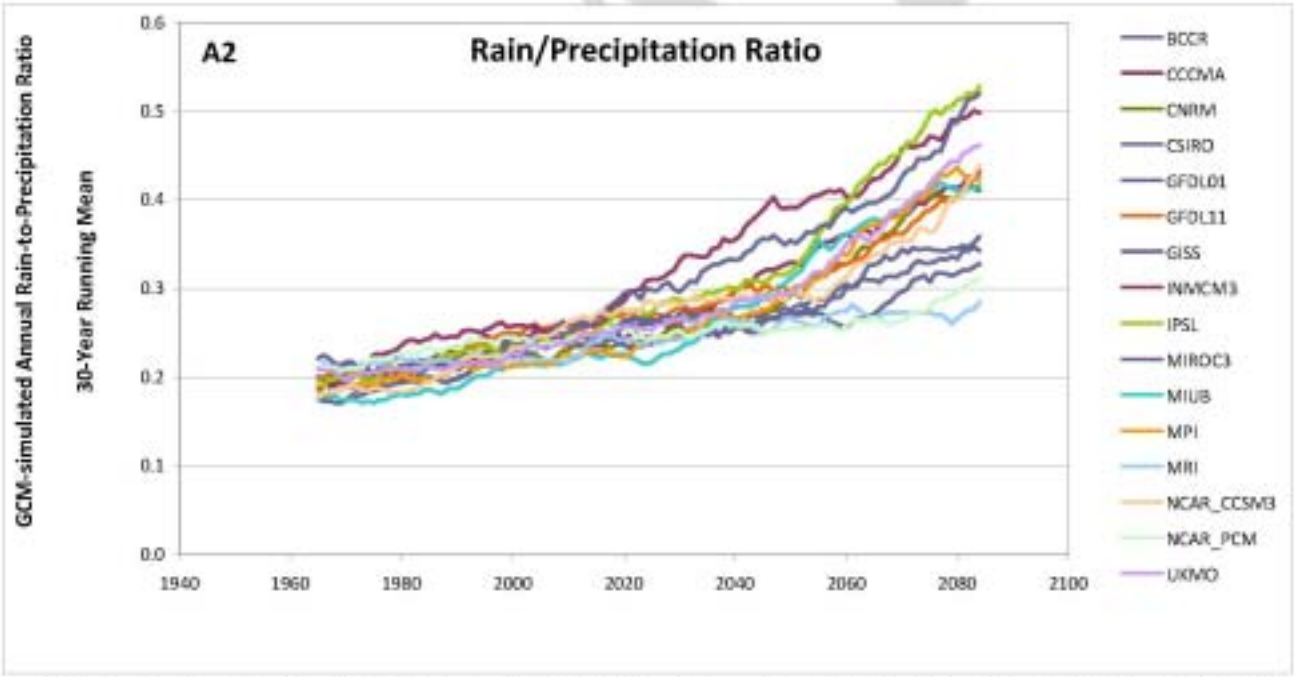
AR0071727

Exhibit 12E
Projected Runoff, Snow-Water Equivalent, and Rain-to-Snow Ratio for Eastern Sierra Nevada Watershed

	Runoff (MAF)	April 1 SWE (Inches)	Rain/Snow Ratio
Baseline (Second Half of 20th Century)	**0.6**	**15.0**	**0.2**
Early 21st-century (2010-2039)	0.5 - 0.85	10.6 - 19.0	0.24 - 0.33
Mid-century (2040-2069)	0.34 - 0.9	7.0 - 19.7	0.25 - 0.43
End-of-century (2070-2099)	0.35 – 1.1	5.0 - 16.0	0.28 - 0.54

Exhibit 12F displays the rain-to-snow ratio based on the projected precipitation and temperature for the 16 GCMs. The rain-to-snow ratio is projected to increase throughout the 21st century, ranging between 0.24 to 0.33 by early 21st century, between 0.25 to 0.43 by mid-century, and between 0.28 to 0.54 by the end-of-century.

Exhibit 12F
Projected Rain to Precipitation Ratio Based on Projected Precipitation and Temperature



The increase of rain-to-snow ratio indicates the shift from snowfall to rainfall, specifically at low to moderate elevations, where the temperature tends to be warmer. This shift indicates more precipitation as liquid, and in turn, leads to loss of the snowpack. The snowpack is critical in providing seasonal storage for water that releases winter precipitation in spring and summer to provide the soil moisture and stream flow needed to sustain both ecosystems and human populations. The climate change study work is still ongoing with remaining analyses to be performed on potential climate change impacts to existing infrastructures, water quality, and recommended adaptation measures.

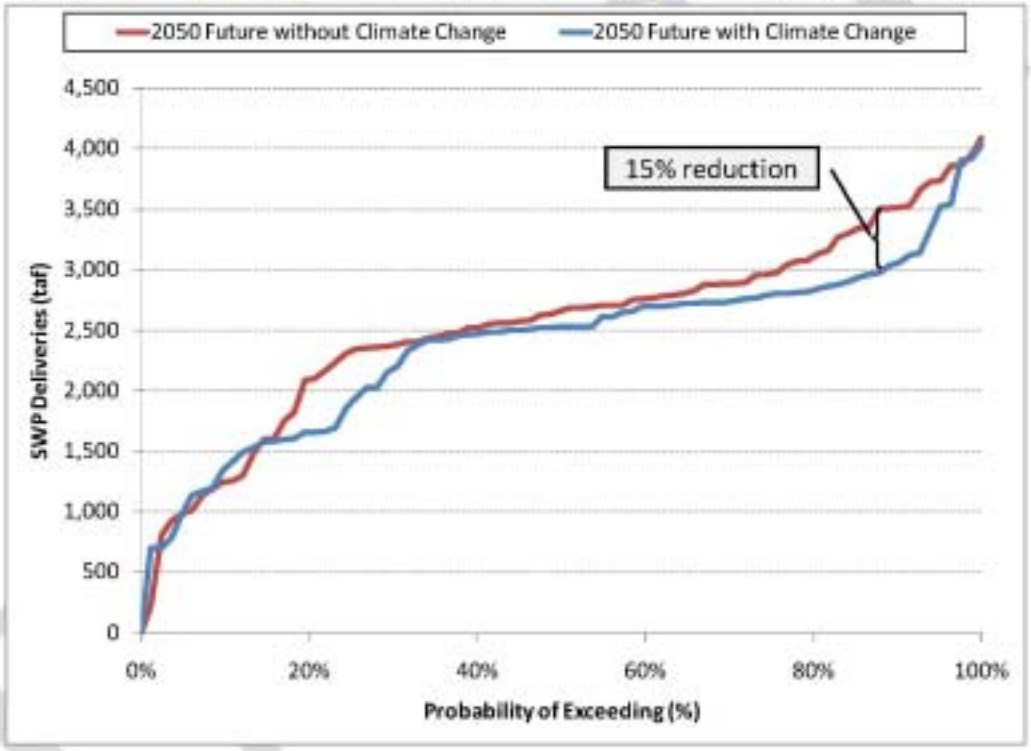
AR0071728

Although the results above are quantitative in nature, it is important to account for the uncertainties inherent in these predictions. The results of this study will help guide the water managers in planning and developing water supply and infrastructure to ensure the reliability and sustainability of adequate water supply and delivery.

12.1.3 State Water Project Impacts

To date, most studies on climate change impacts to California's water supply have been conducted for the Northern California region. In August 2010, DWR released the 2009 State Water Project Delivery Reliability Report, which specifically analyzes changes in volume of water available under various climate change scenarios. DWR projected that SWP deliveries could be reduced by as much as 15 percent in some cases as illustrated in Exhibit 12G.

Exhibit 12G
Projected Rain to Precipitation Ratio Based on Projected Precipitation and Temperature



To incorporate climate change into its reliability reports, DWR reviewed 6 GCMs for year 2050 projections using lower emission and higher emission scenarios contained in *Using Future Climate Projections to Support Water Resources Decision Making in California* prepared in April 2009 by DWR. DWR selected the model most representing median effects on the SWP, the MPI-ECHAM5 model run with a higher greenhouse gas scenario.

Climate change has the potential to disrupt SWP source supplies, impact conveyance, and alter storage levels in reservoir carryover storage. Annual Bay-Delta exports to areas south of the Delta are expected to decline 7 percent for the lower greenhouse gas emissions scenario and 10 percent for the higher emissions scenario. However, it should be noted that for the six GCMs under the lower and higher emission scenarios the range varies from a 2 percent increase to a 19 percent decrease illustrating the variability in the various GCMs.

AR0071729

By 2050, median reservoir carryover storage is projected to decline by 15 percent for the lower emissions scenario and 19 percent for the higher emissions scenario thereby reducing operational options if water shortages were to occur. Furthermore, by 2050 it is projected a water shortage worse than the 1977 drought could potentially occur in 1 out of every 6 to 8 years requiring acquisition of other supplies, reductions in water demands, or a combination. An additional 575 to 850 TAF would be needed to maintain minimum SWP operation requirements and meet regulatory requirements. The main supply reservoirs on the SWP must maintain minimum water levels to allow water to pass through their lower release outlets in the dams. However, the April 2009 report does not consider the SWP vulnerable to a system interruption such as this under current conditions.

The primary effects of climate change on the SWP identified in the 2009 Reliability Report include, among others:

- More precipitation will fall as rain than snow
- Reductions in Sierra snowpack
- Sea level rise threatening the Bay-Delta levee system
- Increased salinity in the Bay-Delta due to sea level rise requiring releases of freshwater from upstream reservoirs to maintain water quality standards
- Shifted timing of snowmelt runoff into streams – spring runoff comes earlier resulting in increased winter flows and decreased spring flows
- Increased flood events

The most severe climate impacts in California are expected to occur in the Sierra watershed, where the SWP supply originates. Therefore, imported SWP water is extremely vulnerable to climate change.

12.1.4 Colorado River Aqueduct Impacts

Although many research efforts are underway, there have not yet been any reports quantifying potential changes in supply to California from the Colorado River via the CRA. At this time, the assumption is that there would be similar patterns as the SWP impacts.

12.2 Water and Energy Nexus

It is widely believed in the scientific community that the increase in concentrations of greenhouse gases (GHG) in the atmosphere is a major contributing factor to climate change. As such, California is leading the way with laws that require reductions in greenhouse gas emissions and requirements to incorporate climate change impacts into long range water resource planning.

Carbon dioxide emissions into the atmosphere and the emissions of other GHGs are often associated with the burning of fossil fuels like crude oil and coal in the generation of energy. As a significant amount of energy is required for the movement of water over long distances and elevations, a link was subsequently realized between water supply conveyance and corresponding GHG emissions through its energy consumption. An assessment of the GHG emissions, sometimes also known as **carbon footprint expressed in units of tons CO_2, could be estimated for water.** Once the size of a carbon footprint is known, a strategy can be developed to better manage and reduce its impact on climate change.

AR0071730

LADWP has taken the initiative to study the nexus between water and energy consumption and to evaluate the associated carbon footprint of its water system. The most energy intensive source of water for LADWP is water purchased from MWD, which imports SWP supplies via the California Aqueduct and Colorado River supplies via the CRA. LADWP also imports water via the LAA, which is a net producer of energy. Local sources of water for LADWP include groundwater and recycled water. Exhibit 12H outlines the sources of LADWP's water supply as well as the energy profiles of each facility that provides water to LADWP. For those sources of water operated by LADWP, the energy intensity has been computed by dividing the total energy consumed/generated by the total water produced or processed by that source.

12.2.1 State Water Project Supplies

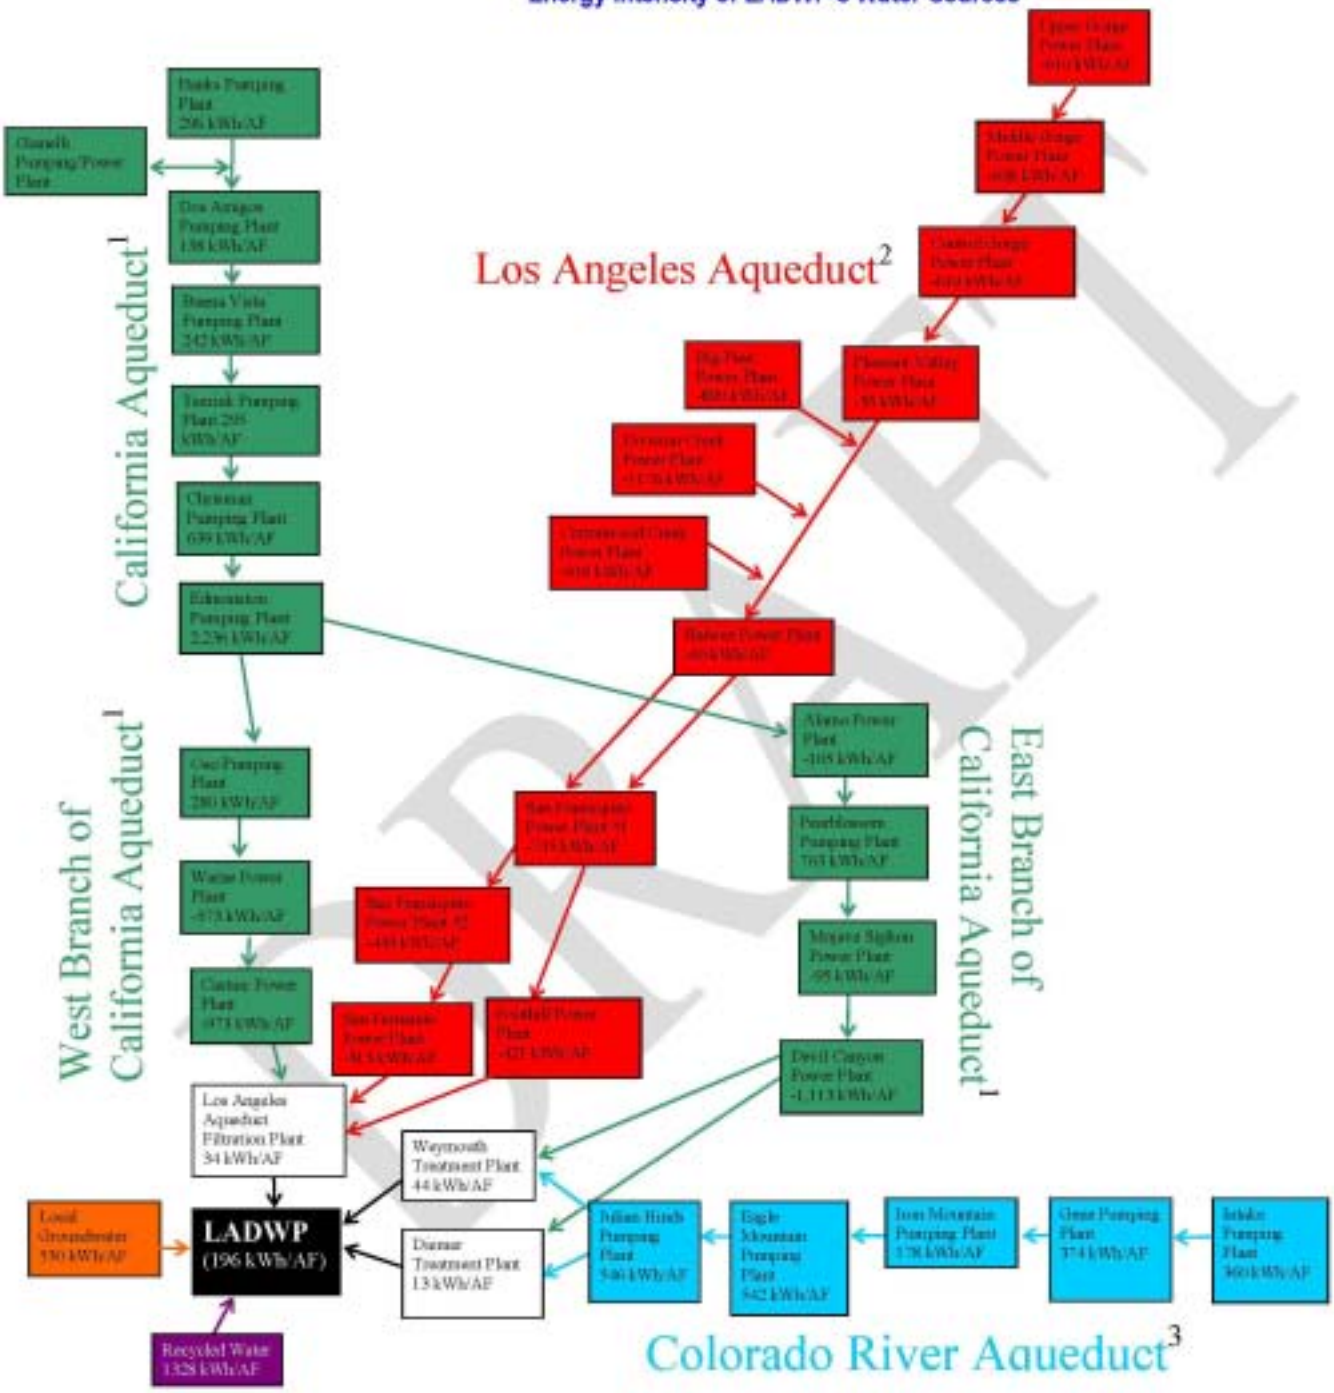
Water Supplied to Los Angeles via the SWP originates from Northern California and the Bay-Delta and is conveyed along the 444-mile long California Aqueduct to southern California. Six pump stations are required to lift the water to the point at which the California Aqueduct splits into two branches. At the zenith of the California Aqueduct in the Tehachapi Mountains, approximately 3,846 kilowatt hours per acre foot (kWh/AF) is required to lift the water from the start of the aqueduct. After the water passes through Edmonston Pumping Plant, the California Aqueduct separates into two branches, the West Branch and the East Branch. Along the West Branch, the water is lifted once more at the Oso Pumping Plant and then energy is recovered through hydro-electric generation at the Warne and Castaic Power Plants. By the time the West Branch reaches its terminus at Lake Castaic, the net energy consumed in transporting the water from the Bay-Delta is approximately 2,580 kWh/AF. Water supplied through the West Branch is provided to the San Fernando Valley, Western Los Angeles, and Central Los Angeles communities.

Along the East Branch, the water generates power at the Alamo Power Plant, is lifted once more at Pearblossom Pumping Plant, and then used for generation at Mojave Siphon and Devil Canyon Power Plants. At the East Branch terminus at Lake Perris, approximately 3,236 kWh/AF of energy has been expended in the transport. Water conveyed through the East Branch is provided to the Eastern Los Angeles and Harbor communities. The water supplied from the SWP is the most energy intensive source of water available to LADWP.

DRAFT

AR0071731

Exhibit 12H
Energy Intensity of LADWP's Water Sources



1. Source: *Methodology for Analysis of the Energy Intensity of California's Water Systems*, p. 27.
2. Generation on the Los Angeles Aqueduct is not considered in LADWP's total energy intensity.
3. Energy intensities for the Colorado River Aqueduct pumping stations were derived by multiplying the total energy intensity for the aqueduct by the proportion of load for each individual pumping station in relation to the total load for all five pump stations.
4. Positive numbers indicate power consumption due to pumping and negative numbers indicate power generation.

AR0071732

12.2.2 Colorado River Aqueduct Supplies

Water supplied from the Colorado River is imported via the 242 mile CRA operated by MWD. From the start of the aqueduct at Lake Havasu to its terminus at Lake Mathews, the water is lifted approximately 1,617 feet. Five pumping stations along the aqueduct lift the water to MWD's service area requiring approximately 2,000 kWh/AF. CRA water is the second most energy intensive water source for Los Angeles and is supplied to the eastern Los Angeles and Harbor communities. Together SWP water and CRA water comprise the total imported provided by MWD to LADWP. MWD imported water is the most expensive water source for LADWP in terms of both cost and energy.

12.2.3 Los Angeles Aqueduct Supplies

The LAA provides water from the Eastern Sierra watershed and is entirely gravity fed. As a result, no energy is required to import LAA water, making it the most desirable source of water in terms of energy intensity. There are twelve power generation facilities along the aqueduct system. On average, the LAA generates approximately 6,848 kWh/AF from water directly used to generate power. This number was determined using the same methodology as was used to determine the energy intensity for the two branches of the SWP. The individual energy intensities for each individual generating facility were summed up to arrive at the total energy intensity for the water used to generate power. However, when considered from the perspective of total amount of water delivered to Los Angeles via the LAA, the energy generated along the aqueduct is approximately 2,456 kWh/AF. The variance between the numbers can be attributed to the fact that not all water wheeled through the aqueduct is used to generate power and the fact that a portion of the water is introduced into the aqueduct system at a point downstream of several of the power plants. For the purposes of determining LADWP's total energy intensity, the energy intensity of the LAA is considered to be zero since the power generated does not directly offset the energy required for other sources of water. However, in terms of supply the LAA is able to offset the more energy intensive sources of water, consequently reducing the overall energy intensity of LADWP's water supplies. As LAA flows to Los Angeles are decreased due to environmental enhancement efforts in the Owens Valley and Mono Basin, LADWP is forced to increasingly rely on energy intensive water purchased from MWD. LAA water currently supplies approximately 37 percent of the demand for Los Angeles.

12.2.4 Local Groundwater Supplies

Groundwater currently accounts for approximately 11 percent of LADWP's water supply and has an average energy intensity of approximately 530 kWh/AF. As LADWP continues with its cleanup of the contaminated water in the San Fernando Basin, groundwater will play an increasingly important role in Los Angeles' water supply. Although there is potential for a future increase in the energy required to produce groundwater due to the introduction of new treatment technologies, groundwater is expected to remain a low energy source of water when compared to imported supplies purchased from MWD. Increasing groundwater production will allow LADWP to offset the energy intensive MWD sources and reduce its overall energy intensity..

12.2.5 Recycled Water Supplies

Recycled water is currently the smallest component of LADWP's water supply portfolio, with municipal and industrial uses accounting for less than 1-percent of total supplies. Currently, LADWP directly receives recycled water from three wastewater treatment plants operated by Bureau of Sanitation (BOS), two of which provide recycled water treated to a tertiary level: LAG and DCT. The TITP performs advanced treatment of recycled water in addition to tertiary treatment. LADWP also directly receives a small portion of recycled water from the West Basin Municipal Water District (WBMWD), which provides additional treatment of wastewater from the Hyperion Treatment Plant (HTP) in El Segundo. Since all water at the plants directly supplying recycled water to LADWP is treated to at least a tertiary level regardless of disposal or reuse, the energy cost to

AR0071733

treat the water to this level is considered a sunk cost because the water would be treated whether it offsets potable use or not. The advanced treatment process at the Terminal Island Treatment Plant (TITP) is beyond the requirements for discharge and is therefore not considered a sunk cost. The incremental energy required to treat water from tertiary levels to advanced treatment levels at TITP requires approximately 2,200 kWh/AF. Since the treatment energy at the other two plants is not considered additional energy, only the pumping energy is included in the overall LADWP recycled water energy intensity. For the Los Angeles Glendale (LAG) Treatment Plant, the pumping requires approximately 690 kWh/AF, and for the Donald C. Tillman (DCT) Treatment Plant, the pumping requires approximately 450 kWh/AF. A weighted average of these values gives recycled water an energy intensity of approximately 1,139 kWh/AF. In the future this number will likely change as the recycled water infrastructure is expanded. In addition to the municipal and industrial recycled water that is considered in LADWP's total supplies, the plants produce significant additional volumes of recycled water that is beneficially used. Beneficial uses include the seawater barrier for the Dominquez Gap using recycled water from TITP and the Japanese Garden and Los Angeles River from DCT.

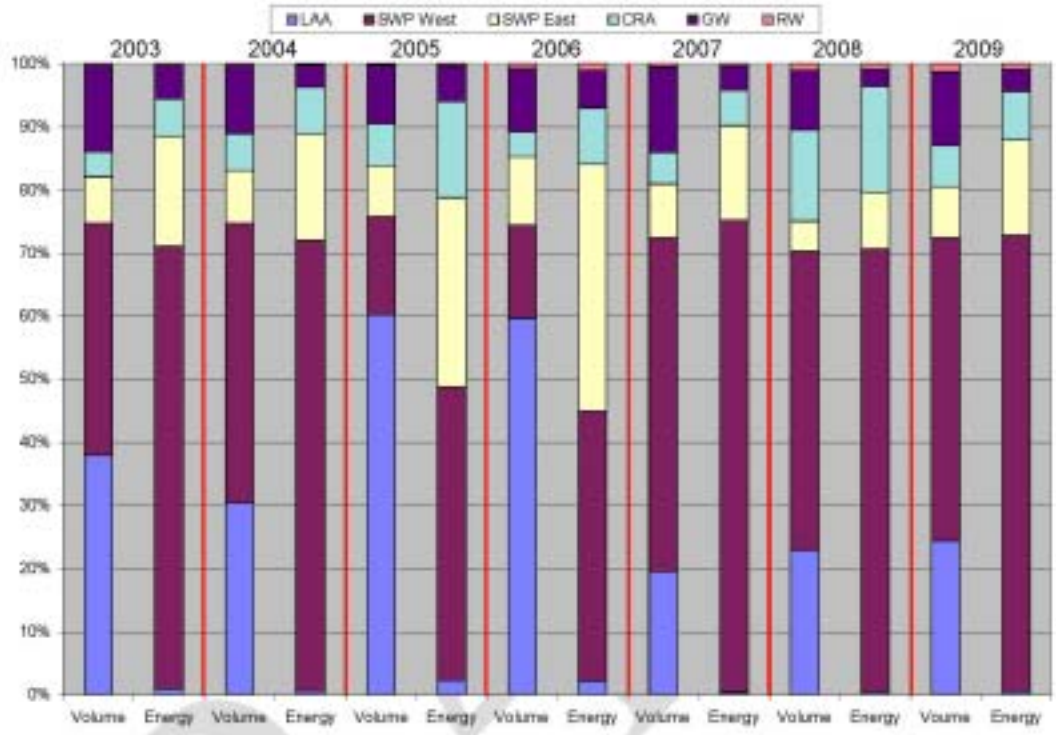
12.2.6 Treatment Energy

Another factor in determining the energy intensity of LADWP's water is the energy required to treat water. All LAA water and nearly all West Branch SWP water purchased by LADWP are treated at the Los Angeles Aqueduct Filtration Plant (LAAFP). For the LAAFP, the average treatment energy intensity is approximately 34 kWh/AF. The East Branch SWP water and the CRA water are primarily treated at the Weymouth Treatment Plant in the San Gabriel Valley and the Diemer Treatment Plant in Orange County. Both of these treatment plants are operated by MWD. The average energy intensity for Weymouth Treatment Plant is approximately 42 kWh/AF and supplies water to the East Los Angeles Community. The average energy intensity for the Diemer Treatment Plant is 13 kWh/AF and supplies water to the Harbor Community. The mix of SWP East Branch water and CRA water that flows through these two treatment plants varies depending on the regional hydrology of the two sources, but on average approximately 55 percent SWP East Branch water and 45 percent CRA water flows through each of these MWD treatment plants.

The proportion that each of the above mentioned sources contributes to the LADWP's total supplies is displayed below in Exhibit 12I. Of note is the relationship that the volume of LAA flow has to the amount of SWP water imported into the system. In this case, the energy free LAA water is replaced by the energy intensive SWP water resulting in an increase in the overall energy intensity.

AR0071734

Exhibit 12I
Proportion of Volume Delivered and Total Energy Intensity (Inclusive of Treatment)



12.2.7 Distribution Energy

LADWP benefits from the topography of its service area in that much of the hydraulic head required for water distribution is provided by gravity. With the major sources of LADWP's water entering the service area at higher elevation than the rest of the City, the energy required for distribution is lower than much of the region. The average energy intensity for LADWP water distribution is approximately 196 kWh/AF.

Exhibit 12J shows the sum of the energy intensities for LADWP from each of the individual sources between 2003 and 2009. Exhibit 12K shows a graphical representation of the total energy intensity for LADWP for the same time period. An important detail is the influence that LAA water has on the total energy intensity for a given year. For those years with large volumes of LAA water, such as 2005 and 2006, the total energy intensity was correspondingly low. Alternatively, those years with low volumes of LAA water have high total energy intensity as a result of the energy requirements for imported MWD supplies

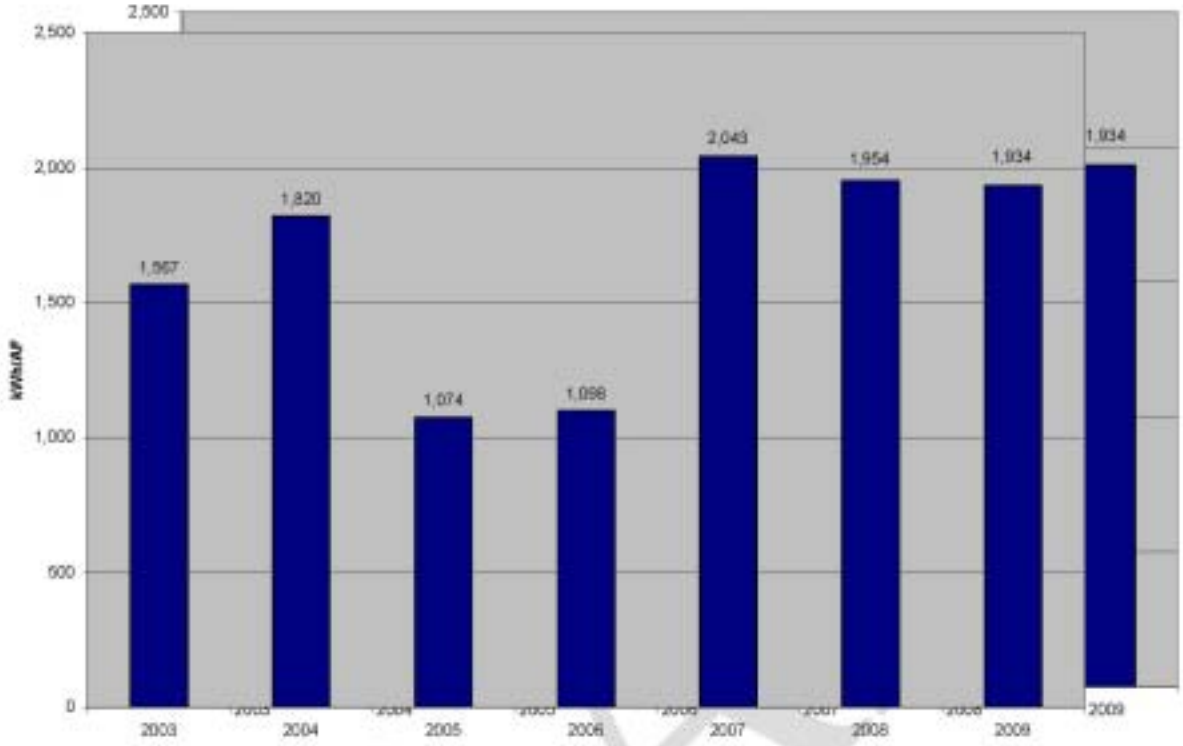
1. Los Angeles Aqueduct and State Water Project West Branch supplies are treated at the Los Angeles Aqueduct Filtration Plant
2. Colorado River Aqueduct and State Water Project East Branch supplies are treated at Weymouth and Diemer Filtration Plants operated by Metropolitan Water District of Southern California. The listed energy intensity is based on an average of the energy intensity for the two plants.
3. Amount of SWP water and CRA water delivered is based on the reported average ratio of the two sources in Weymouth Treatment Plant and Diemer Treatment Plant effluent from MWD annual Water Quality Report
4. Recycled water volume is based on use for municipal and industrial uses, not all beneficial uses. Energy intensity is a weighted average of energy used for pumping to customers and the incremental energy to treat from tertiary to advanced treatment.

AR0071736

Exhibit 12K
LADWP Annual Energy Intensity



12.2.8 Carbon Footprint

All of LADWP's water supply sources have an associated carbon footprint related to the energy required to pump the water. Exhibit 12L provides the annual carbon footprint by water source. Exhibit 12M shows a graphical representation of the total annual carbon footprint for the same time period. For imported sources, the 2007 CAMX California average carbon emission of 0.72412 lbs CO2/kWh was used to estimate the amount of carbon emissions produced per acre-foot of water imported. For local sources the CO2 metric reported to the California Climate Action Registry in 2007 was used to estimate the carbon emissions released in the production of this water. LAA is a net producer of energy and produces only green hydropower. There are no carbon emissions associated with water imported through the LAA.

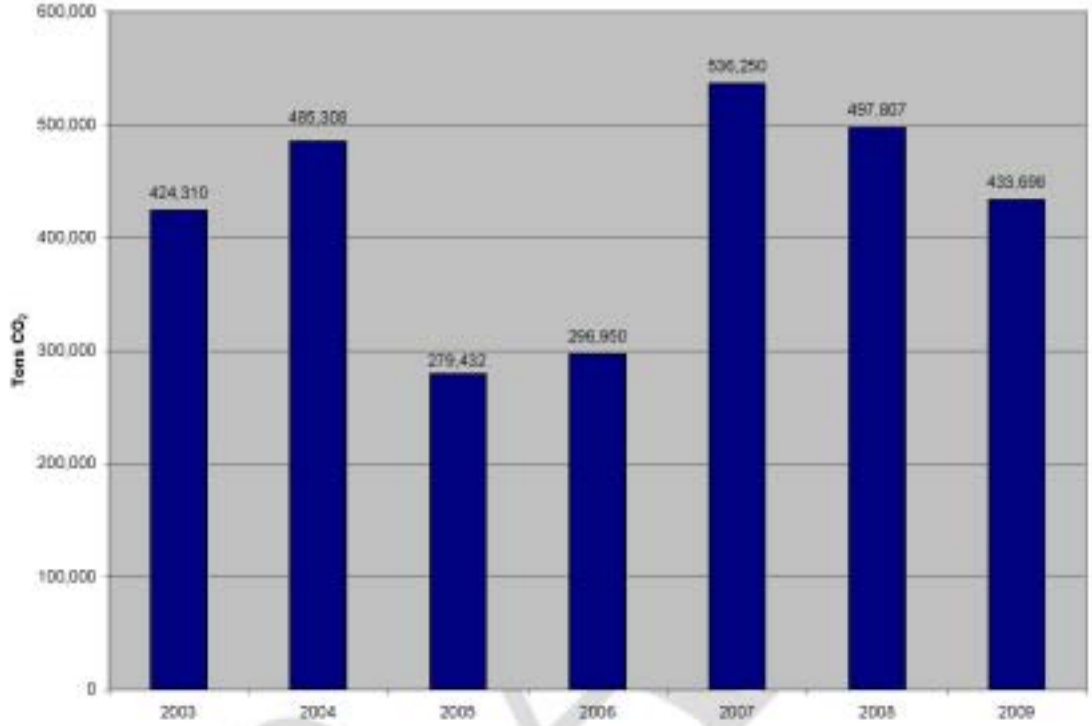
1. Amount of SWP water and CRA water delivered is based on average of the proportion of the two sources delivered to MWD Weymouth Treatment Plant and Diemer Treatment Plant for the calendar year

2. Based on 2007 CO_2 metric of 1.22789 lbs CO_2/kWh reported to the California Climate Action Registry

3. Based on eGRID 2007 CAMX (California Average) of 0.72412 lbs CO_2/kWh

AR0071738

Exhibit 12M
Total Annual Carbon Footprint for Water Supply Portfolio



As Los Angeles increases its reliance on energy intensive imported supplies from MWD, its overall energy intensity will increase. Reductions in LAA flows due to environmental mitigation have the consequence of increasing Los Angeles' reliance on supplies imported through the SWP via the California Aqueduct, and Colorado River through the CRA.

12.3 Climate Change Adaption and Mitigation

Climate change strategies fall under two main categories: adaptation and mitigation. For water resources planning, a climate change adaptation strategy involves taking steps to effectively manage the impacts of climate change by making water demands more efficient and relying on supply sources that are less vulnerable to climate change. A mitigation strategy involves proactive measures that reduce greenhouse gas emissions, such as placing a stronger emphasis on using water resources requiring less greenhouse gas emissions. Both LADWP and its wholesale supplier for imported water, MWD, are implementing adaption and mitigation strategies as they become aware of potential climate change impacts.

It is imperative that supply options are carefully vetted and evaluated against both adaptation and mitigation goals, as they may conflict and work against each other. For example, desalination is a typical supply option that performs quite well in adapting to climate change impacts; however, due to the energy necessary to draw from and manage the supply source, it could result in higher greenhouse gas emissions if conventional energy sources are utilized.

12.3.1 LADWP Adaption and Mitigation

In the 2008 City of Los Angeles Water Supply Action Plan, LADWP and the City have outlined strategies to dramatically increase conservation and water recycling. Increasing conservation and water recycling encompasses both adaption and mitigation goals to address climate change. The Plan calls for reducing potable demands by an additional 50,000 AFY through

AR0071739

conservation by fiscal year 2030 and 50,000 AFY through recycled water use. Additional adaption strategies under investigation by LADWP and the City includes beneficial reuse of stormwater as discussed in Chapters Seven and Nine, Watershed Management and Other Potential Water Supplies, respectively.

Conservation has a double savings in terms of energy intensity because not only does it save energy in importing or producing the water, but it also saves energy through reduction of end use, such as heating water for a shower or for a dishwasher and wastewater treatment. The anticipated conservation savings will not only help to provide Los Angeles a secure and dependable water supply, but it will also reduce the energy footprint of the water supply, and consequently the carbon footprint. A further discussion regarding conservation is provided in Chapter Three, Conservation.

Recycled water use reduces reliance on potable water imported through MWD and provides a year round drought resistant water supply source. While the energy consumption requirements to produce recycled water are greater than local and LAA supply sources, recycled water assists LADWP in bolstering its supply portfolio to address potential supply changes related to climate change. A further discussion regarding recycled water is provided in Chapter 4, Recycled Water.

The climate change study work for the LAA is still ongoing with remaining analyses to be performed on potential climate change impacts to existing infrastructures, water quality, and recommended adaptation measures. Hydraulic models will be performed to determine impacts to the LAA conveyance capacity. Adaptation measures may include upgrades to treatment processes in order to address degradation in water runoff quality, and/or changes in operational procedures to address shifts in runoff timing and quantity.

There is still general uncertainty within the scientific community regarding the potential impacts of climate change for the City of Los Angeles. LADWP will continue to stay abreast of developments in climate change to better understand its potential implications to the City's water supplies to assist in further developing adaption and mitigation strategies.

12.3.2 MWD Adaption and Mitigation

MWD is taking an active approach to adapt and mitigate against climate changes in its operations. Adaption and mitigation measures include:

- Investments in local resources to diversify MWD's water supply portfolio
- Tracking climate change legislation – MWD provides input and direction on legislation
- Collaborating on climate change with state, federal, and non-governmental agencies
- Monitoring state and local climate change actions
- Investigating the water supply and energy nexus
- Coordinating with large water retailers
- Integrating climate change into integrated resource planning as discussed in Chapter 10, Integrated Resource Planning

AR0071740

- Sharing climate change knowledge and providing support – founding member of Water Utility Climate Alliance,
- Adopting energy management policies to support cost-effective and environmentally responsible programs, projects, and initiative

MWD has also taken structural adaption measures including construction of the Inland Feeder. The Inland Feeder completed in 2009 connects SWP supplies with MWD's CRA supplies and allows delivery of SWP supplies to MWD's major reservoir, Diamond Valley Lake. In relation to climate change, the project will increase conveyance capacity allowing more rain to be conveyed as projected snowpack levels decrease and allow MWD to capture rain associated with projected short duration high intensity storms.

Student Generation Factor

In determining the impact of new development, the District is required to show how many students will be generated from the new developments. In order to ensure that new development is paying only for the impact of those students that are being generated by new homes and businesses, the student generation factor is applied to the number of new housing units to determine development-related growth. The District may either use the local student yield rate or the State wide average student generation factor.

The student generation factor identifies the number of students per housing unit and provides a link between residential construction projects and projections of increased enrollment. The State-wide factor used by the Office of Public School Construction is 0.70 for grades K-12. For the purposes of this report we will use the State factors to determine the students generated from new housing developments. Table 3 shows the student generation factors for the various grade groupings.

Table 3

STUDENT GENERATION FACTORS

Grades	Students per Household
K-6	0.4
7-8	0.1
9-12	0.2
Total	0.7

AR0071745

New Residential Development Projections

The Los Angeles Unified District has experienced an average new residential construction rate of approximately 5,121 units per year. Projecting the average rate forward, we would expect that 25,605 units of residential housing will be built within the District boundaries over the next five years.

To determine the impact of residential development, an enrollment projection is done. Applying the student generation factor of 0.7 to the projected 5,121 units of residential housing, we expect that 17,924 students will be generated from the new residential construction over the next five years. This includes 10,242 elementary school students, 2,561 middle school students and 5,121 high school students.

The District is required to use the development-based enrollment projection for the purposes of this study. This is utilized as the cost basis for development impact throughout this study, unless otherwise noted.

Table 4

LOS ANGELES UNIFIED

Totals	664233	17924	682157

AR0071746

IV. Existing Facility Capacity

To determine the need for additional school facilities, the capacity of the existing facilities must be identified and compared to current and anticipated enrollments. The District's existing building capacity will be calculated using the State classroom loading standards shown at Table 6. The following types of "support-spaces" necessary for the conduct of the District's comprehensive educational program, are not included as "teaching stations," commonly known as "classrooms" to the public:

Table 5

Los Angeles Unified School District
List of Core and Support Facilities

Library	Resource Specialist
Multipurpose Room	Gymnasium
Office Area	Lunch Room
Staff Workroom	P.E. Facilities

Because the District requires these types of support facilities as part of its existing facility and curriculum standards at its schools, new development's impact must not materially or adversely affect the continuance of these standards. Therefore, new development cannot require that the District house students in these integral support spaces.

Classroom Loading Standards

The following maximum classroom loading-factors are used to determine teaching-station "capacity," in accordance with the State legislation and the State School Building Program. These capacity calculations are also used in preparing and filing the baseline school capacity statement with the Office of Public School Construction.

AR0071747

Table 6

State Classroom Loading Standards

Kindergarten	25 Students/Classroom
1st-3rd Grades	25 Students/Classroom
4th-6th Grades	25 Students/Classroom
7th-8th Grades	27 Students/Classroom
9th-12th Grades	27 Students/Classroom
Non Severe Special Ed	13 Students/Classroom
Severe Special Ed	9 Students/Classroom

Existing Facility Capacity

The State determines the baseline capacity by either loading all permanent teaching stations plus a maximum number of portables equal to 25% of the number of permanent classrooms or by loading all permanent classrooms and only portables that are owned or have been leased for over 5 years. As allowed by law and required by the State, facility capacities are calculated by multiplying the number of teaching stations at each campus. All qualified teaching stations were included in the calculation of the capacities. To account for activity and changes since the baseline was established, the student grants for new construction projects funded by OPSC have been added. Using these guidelines the District's current State calculated capacity is shown in Table 7

Table 7

AR0071748

LOS ANGELES UNIFIED
Summary of Existing Facility Capacity

School Facility	Permanent Classrooms	Portable Classrooms	Chargable Portables	Total Chargable Classrooms	State Loading Factor	State Funded Projects	District Capacity Added	Total State Capacity
Grades K-6	9326	9407	3485	19312	26	99850	2875	371,125
Grades 7-8	1496	534	432	1929	27	31435	7467	80,903
Grades 9-12	4294	1370	440	5334	37	58238	8261	203,415
SDC N-S	2008	3	0	2008	13	104	0	26,104
SDC Severe	1009	8	0	1016	9	0	0	9,016
Totals	16633	9318	4357	29599		189627	18603	700,663

As Table 7 shows, the total State capacity of the District facilities is 700,663 students.

Unhoused Students by State Housing Standards

This next chart compares the capacity with the space needed to determine if there is available space for new students from the projected developments. The space needed is determined based on the maximum seats needed to house the students within the existing homes. The historic and projected enrollments were reviewed to determine the space needed for each grade grouping.

Table 8

LOS ANGELES UNIFIED
Summary of Available District Capacity

School Facility	State Capacity	Space Needed	Available Capacity
Grades K-6	371,125	364,086	7,039
Grades 7-8	80,903	100,009	(19,046)
Grades 9-12	203,415	208,240	(4,827)
SDC N-S	26,104	21,992	4,112
SDC - Severe	9,016	7,395	1,649
Totals	700,663	701,776	0

AR0071749

Since the enrollment space needed exceeds the District capacity there is no excess capacity available to house students from new development.

AR0071750

V. Calculation of Development's Fiscal Impact on Schools

This section of the study will demonstrate that a reasonable relationship exists between residential, commercial/industrial development and the need for additional school facilities in the Los Angeles Unified School District. To the extent this relationship exists, the District is justified in levying developer fees as authorized by Education Code Section 17620.

School Facility Construction Costs

For the purposes of estimating the cost of building schools we have used the State School Building Program funding allowances. These amounts are shown in Table 9. In addition to the basic construction costs, there are site acquisition costs of $3,347,093 per acre and approximately $1,622,689 per acre for allowable service-site, utilities, off-site and general site development costs.

Table 9

New Construction Costs

Grade Level	Construction Cost Per Student
Elementary	$22,096
Middle	$23,406
High	$28,700
Average	$24,632

Impact of Residential Development:

The next table compares the development-related enrollment projection to the available district capacity for each grade level and then multiplies the unhoused students by the new school construction costs to determine the total school facility costs related to the impact of new residential housing developments.

AR0071751

In addition, the State provides that each District shall be reimbursed for site acquisition costs, including appraisals, surveys and title reports. The District needs to acquire 110.69 acres to meet the needs of the students projected from the new developments.

Table 10

LOS ANGELES UNIFIED
Summary of Residential Impact

Service Facility	Development Projection	Available Space	Net Unhoused	Construction Cost Per Student	Total Facility Costs
Elementary	10,849	0	10,849	$22,606	$228,204,812
Middle	7551	0	2,551	$23,405	$59,947,655
High & Cont.	5121	0	5,121	$20,707	$152,093,700
Site Purchase: 110.69 acres					$369,334,046
Site Development					$179,936,551
			New Construction Needs:		$1,011,518,997
			Modernization Needs:		$0
			TOTAL NEEDS:		$1,011,518,997
			Average cost per student:		$56,434

The total need for school facilities based on the impact of the 25,605 new housing units projected over the next five years totals $1,011,518,997. To determine the impact per square foot of residential development, this amount is divided by the total square feet of the projected developments. As calculated from the historic Developer Fee Permits, the average size home built has averaged 1,585 square feet. The total area for 25,605 new homes would therefore be 40,583,925 square feet. The total residential fee needed to be able to collect $1,011,518,997 would be $24.92 per square foot. Since the State Maximum Fee is currently $3.20 for residential construction, the District is justified in collecting the maximum fee.

AR0071752

Impact of Commercial/Industrial Development

There is a correlation between the growth of commercial/industrial firms/facilities within a community and the generation of school students within most business service areas. Fees for commercial/industrial can only be imposed if the residential fees will not fully mitigate the cost of providing school facilities to students from new development.

The approach utilized in this section is to apply statutory standards, U.S. Census employment statistics, and local statistics to determine the impact of future commercial/industrial development projects on the District. Many of the factors used in this analysis were taken from the U.S. Census, which remains the most complete and authoritative source of information on the community in addition to the "1990 SanDAG Traffic Generators Report"

Employees per Square Foot of Commercial Development

Results from a survey published by the San Diego Association of Governments "1990 San DAG Traffic Generators" are used to establish numbers of employees per square foot of building area to be anticipated in new commercial or industrial development projects. The average number of workers per 1,000 square feet of area ranges from 0.06 for Rental Self Storage to 4.79 for Standard Commercial Offices. The generation factors from that report are shown in the following table.

Table 11

Commercial/Industrial Category	Average Square Foot Per Employee	Employees Per Average Square Foot
Banks	354	0.00283
Community Shopping Centers	652	0.00152
Neighborhood Shopping Centers	369	0.00271
Industrial Business Parks	284	0.00352
Industrial Parks	742	0.00135
Rental Self Storage	15641	0.00006
Scientific Research & Development	328	0.00304
Lodging	882	0.00113
Standard Commercial Office	209	0.00479
Large High Rise Commercial Office	233	0.00431
Corporate Offices	372	0.00269
Medical Offices	234	0.00427

Source: 1990 SanDAG Traffic Generators report

AR0071753

Students per Employee

The number of students per employee is determined by using the 2010 U.S. Census data for the City of Los Angeles. According to the census, there were 1,494,895 employees in the City and a total of 1,739,802 in the district. There were 641,240 school age children in the District. This is a ratio of 0.3686 students per employee. This ratio, however, must be reduced by including only the percentage of employees that worked in their community of residence (73%), because only those employees living in the District will impact the District's school facilities with their children. The actual ratio of students per employee in the district is 0.2691.

School Facilities Cost per Student

State costs for housing commercially generated students are the same as those used for residential construction. The cost factors used to assess the impact from commercial development projects are contained in Table 10.

Residential Offset

When additional employees are generated in the District as a result of new commercial/industrial development, fees will also be charged on the residential units necessary to provide housing for the employees living in the District. To prevent a commercial or industrial development from paying for the portion of the impact that will be covered by the residential fee, this amount has been calculated and deducted from each category. The residential offset amount is calculated by multiplying the following factors together and dividing by 1,000 (to convert from cost per 1,000 square feet to cost per square foot).

- Employees per 1,000 square feet (varies from a low of 0.06 for rental self storage to a high of 4.70 for office building).
- Percentage of employees that worked in their community of residence (73 percent). This was derived from 2010 Census data for the District.
- Housing units per employee (0.9459). This was derived from 2010 census data for the District, which indicates there were 1,413,095 housing units and 1,494,895 employees.

AR0071754

- Average square feet per dwelling unit: (1,585).
- Residential fee charged by the District ($3.20 per square foot).

The following table shows the calculation of the school facility costs generated by a square foot of new commercial/industrial development for each category of development.

Table 12

LOS ANGELES UNIFIED

Summary of Commercial and Industrial Uses

Use	Employees per 1,000 Sq. Ft.	Students per Employee	Students per 1,000 Sq. Ft.	Average Cost per Student	Cost per Sq. Ft.	Revenue to offset per Sq. Ft.	Net Cost per Sq. Ft.
Banks	3.81	0.2691	0.751	$56,434	$42.07	$9.91	$33.06
Community Shopping Centers	1.93	0.2691	0.519	$56,434	$29.22	$5.36	$17.87
Neighborhood Shopping Centers	2.71	0.2691	0.720	$56,434	$41.15	$9.49	$31.66

*Based on 1990 SanDAG Trade Generator Report

Net Cost per Square Foot

Since the State Maximum Fee is now $0.51 for commercial/industrial construction, the District is justified in collecting the maximum fee for all categories.

Verifying the Sufficiency of the Development Impact

Education Code Section 17620 requires districts to find that fee revenues will not exceed the cost of providing school facilities to the students generated by the development paying the fees. This section shows that the fee revenues do not exceed the impact of the new development.

AR0071755

The total need for school facilities totals $1,011,518,097. The amount the District would collect over the five year period at the maximum rate of $3.20 for residential and $0.51 for commercial/industrial development would be as follows.

$3.20 x 35,603 homes x 1,585 sq ft per home = $129,868,960 for Residential
$0.51 x 3,300,000 sq ft per year x 5 years = $8,415,000 for Commercial/Industrial
Total projected 5 year income: $138,283,960

The income is less than the projected needs.

AR0071756

C.1 Residential Student Generation Impacts

In order to analyze the impact on the School District's student enrollment from future residential units, Dolinka Group utilized SGRs calculated in the SGR Study prepared by Dolinka Group. The SGR Study calculated SGRs for SFD units, SFA units (e.g. condominiums, townhomes) and MF units (e.g. apartments, duplexes, triplexes). The SFA and MF categories of the SGR Study were combined to create the MFA category for this Study. The process of calculating SGRs involved cross-referencing the School District's enrollment data against the County Assessor's residential data (see the Residential Study for more information). The resulting SGRs are shown in Table 8.

Table 8
Student Generation Rates

School Level	Single Family Detached Units	Multi-family Attached Units
Elementary School	0.1958	0.1266
Middle School	0.0933	0.0692
High School	0.1062	0.0659
Total	**0.3953**	**0.2617**

To blend the SGRs of the two (2) land uses into a single SGR for each school level, the land uses were weighted in proportion to each type's percentage of the future residential units to be constructed within the School District. Applying these weighting factors yields the following blended SGRs.

Table 9
Blended Student Generation Rates

School Level	Student Generation Factors
Elementary School	0.1400
Middle School	0.0730
High School	0.0737
Total	**0.2876**

C.2 Total Student Generation Impacts

Multiplying net school district household impacts shown in Table 7 by the blended SGRs shown in Table 9 results in the average student generation impacts per 1,000 square feet of GLD. These average student generation impacts are shown by school level in Table 10.

How to Determine Quantities

Print

Tonnage Quantity Calculator

Measuring a Pavement Job

To determine the amount of asphalt you will need for a paving job you first need to know the area to be paved. This may be simple if the area to be paved is square or rectangle and you know the constant width of the road. However, this is rarely the case since there may be portions of the area to be paved, the width of the road may vary or there are curves. This may seem to be impossible in some cases, but by dividing the pavement area into simple geometric shapes and adding and subtracting these areas the area to be paved can be quickly determined. The following are basic formulas for calculating the area of several geometric shapes.

Rectangle		Area = Length x Width
Triangle		Area = Length x Width ÷ 2
Circle		Area = Diameter^2 x 3.14
Half Circle		Area = Diameter^2 ÷ 2 x 3.14
Pipe		Area = 3.14 x Length^2

Let's look at the parking lot in Figure 1, since may often have many features that complicate the calculation of area.

When you first look at this it may seem comparable since it is not a square, triangle or circle. However, it is a combination of squares, triangles and a circle as can be seen in Figure 2.

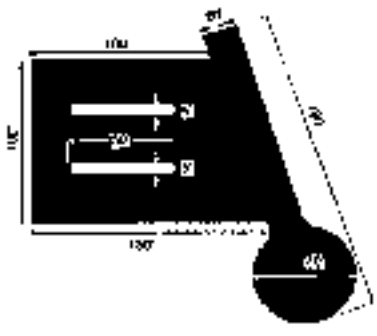

Figure 1 Parking Lot

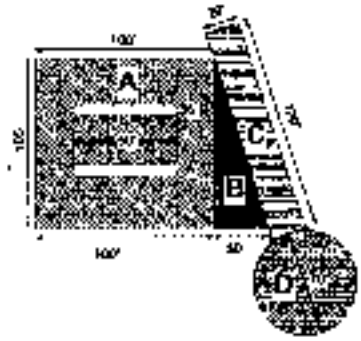

Figure 2 Parking Lot Divided into Geometric Shapes

By dividing a project into these simple shapes you can now easily calculate the area to be paved.

Build Green
BUILDING BETTER COMMUNITIES THROUGH SUSTAINABLE PRACTICES

Area A = a rectangle 100 x 100 = 10,000 square feet

Area B = a triangle 30 x 100 / 2 = 1,500 square feet

Area C = a rectangle 5 x 120 = 2,400 square feet

Area D = a circle 70/2 = 4 x 3.14 = 7,850 square feet

To determine the total area of paving all we have to do is add the areas together with the exception of the planters in the middle of the parking area. All we have to do now is calculate the area of the planters and subtract that area from the sum of the other areas. But for this example we will leave the calculation of the planter areas up to you. Just remember to apply the area of a triangle and semi-circle as shown above.

Therefore the total paving area is:

10,000 + 1,500 + 2400 + 3846.5 = Paving Area = 17,757 square feet

OK... so calculating the planter area, if you wanted to, would only slightly affect the overall area number. This is all the accuracy you will likely ever need on a paving job.

You may notice that there are some areas around the curb returns at the cul-de-sac that were not calculated. In this case the areas are small and will not make a significant difference in the total area. If you have many curb returns on a project, I would probably attempt to draw the area to scale on clean paper and estimate the area by counting the number of squares and multiplying the number of squares by the area of each square. For example if you drew the area at a scale of 1"=20' and the graph paper was divided into 0.1" increments each square would represent an area of 4 square feet (2*2). If you counted 20 squares the total area would be 80 square feet (20*4).

Figure 3 illustrates an example of this. In this case there are approximately 22 squares. One of the keys is to try to find matching areas. For example 1/2 of square A is covering the area and 1/4 of another square is also covered by the area they can be combined and counted as 1 full square.

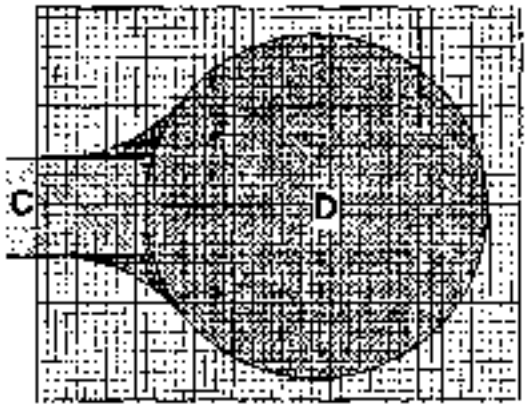

Figure 3 - Graph Paper Method for Calculating Area

Now that you have the area calculated, you next need to calculate the quantities. Quantities are usually specified by weight (tons) or volume (cubic yards). No matter how it is specified you will first need to calculate the volume. Volume is easy to calculate since it is simply Area x Thickness. One of the keys in calculating volume is to always use the same dimension. Therefore, if we measure the area in square feet we have to convert thickness measurement to feet also. For example if you were placing 3" of aggregate base the thickness would be converted to:

3" / 12 feet = 0.3 feet

To calculate the volume we simply multiply the thickness by the area previously computed.

Volume = Area * Thickness = (17,757 square ft.) * (0.3 feet) = 5329.5 cubic ft.

Aggregate base and other materials are often specified or purchased by the cubic yard. therefore, you need to convert cubic feet to cubic yards. 5 mat there are 27 cubic feet per cubic yard (3 yard x 3 yard x 3 yard), you would need to divide the cubic foot volume by 27.

Volume = 3025 cubic ft ÷ 27 cubic feet/cubic yard = 336 cubic yds.

To calculate the weight of material needed for a project you will need to know the compacted density of the material. Density is the weight of material per volume. For example pounds per cubic foot. The density of Hot Mix Asphalt (HMA) does vary depending on the proportions and type of aggregate. If you do not know the in place density of mixes you use ask your supplier.

To determine the weight of material, multiply the volume by the density of material.

Weight = Volume * Density

Using the previous example and assuming an HMA density of 145 pounds per cubic foot (pcf), and 4" (inches of it we would perform the following calculations:

1. Volume = 1,725 sq. ft. x (4" ÷ 12"/ft) = 575.2 cu. ft.
   (note that the thickness was converted from inches to feet)
2. Weight = 575.2 cu. ft. x 145 pcf = 83,404 lbs.
3. Convert to tons = 83,404 lbs. ÷ 2,000 lbs/ton = 41.7 tons

Now it's your turn to try your new skills. Using the paving areas in Figure 2 calculate the cubic yards of aggregate base and tons of HMA needed, assuming the following:

1. Areas A & B are to be paved using 4" of Aggregate Base and 3" of HMA
2. Areas C & D are to be paved using 6" of Aggregate Base and 4" of HMA

Answers: Areas A & B: Agg. Base = 130 cu. yds. HMA = 200 tons
Areas C & D: Agg. Base = 110 cu. yds. HMA = 151 tons

A note about measuring areas of roadways with curves

When determining the area of a roadway with a curve it is important that the length be measured along the centerline of the road. By doing this the area is simply the width of the road along the centerline times the width.

AR0071767

THE NATIONAL ACADEMIES

Advisers to the Nation on Science, Engineering, and Medicine

The **National Academy of Sciences** is a private, nonprofit, self-perpetuating society of distinguished scholars engaged in scientific and engineering research, dedicated to the furtherance of science and technology and to their use for the general welfare. On the authority of the charter granted to it by the Congress in 1863, the Academy has a mandate that requires it to advise the federal government on scientific and technical matters. Dr. Ralph J. Cicerone is president of the National Academy of Sciences.

The **National Academy of Engineering** was established in 1964, under the charter of the National Academy of Sciences, as a parallel organization of outstanding engineers. It is autonomous in its administration and in the selection of its members, sharing with the National Academy of Sciences the responsibility for advising the federal government. The National Academy of Engineering also sponsors engineering programs aimed at meeting national needs, encourages education and research, and recognizes the superior achievements of engineers. Dr. Charles M. Vest is president of the National Academy of Engineering.

The **Institute of Medicine** was established in 1970 by the National Academy of Sciences to secure the services of eminent members of appropriate professions in the examination of policy matters pertaining to the health of the public. The Institute acts under the responsibility given to the National Academy of Sciences by its congressional charter to be an adviser to the federal government and, on its own initiative, to identify issues of medical care, research, and education. Dr. Harvey V. Fineberg is president of the Institute of Medicine.

The **National Research Council** was organized by the National Academy of Sciences in 1916 to associate the broad community of science and technology with the Academy's purposes of furthering knowledge and advising the federal government. Functioning in accordance with general policies determined by the Academy, the Council has become the principal operating agency of both the National Academy of Sciences and the National Academy of Engineering in providing services to the government, the public, and the scientific and engineering communities. The Council is administered jointly by both the Academies and the Institute of Medicine. Dr. Ralph J. Cicerone and Dr. Charles M. Vest are chair and vice chair, respectively, of the National Research Council.

The **Transportation Research Board** is one of six major divisions of the National Research Council. The mission of the Transportation Research Board is to provide leadership in transportation innovation and progress through research and information exchange, conducted within a setting that is objective, interdisciplinary, and multimodal. The Board's varied activities annually engage about 7,000 engineers, scientists, and other transportation researchers and practitioners from the public and private sectors and academia, all of whom contribute their expertise in the public interest. The program is supported by state transportation departments, federal agencies including the component administrations of the U.S. Department of Transportation, and other organizations and individuals interested in the development of transportation. **www.TRB.org**

Author Acknowledgments

These guidelines were developed under NCHRP Project 3-62. The University of North Carolina Highway Safety Research Center (HSRC) was the contractor for this study. Accessible Design for the Blind (ADB) was a subcontractor. Primary authors of this report are Janet Barlow (Principal, ADB), Billie L. Bentzen (Director of Research, ADB), David Harkey (Director, HSRC), and Daniel Carter (Research Engineer, HSRC). Mr. Harkey served as the Principal Investigator for this effort.

The authors wish to acknowledge the assistance and support of others who made this project a success. Several manufacturers of accessible pedestrian signals (APSs) provided invaluable donations of equipment, installation assistance, and technical expertise to this project:

- Campbell Company (Phil Tate),
- Novax Industries (Doug Gubbley),
- Polara Engineering (John McGaffey), and
- Prisma Teknik (Jan Lund and Fredrik Dahlberg).

Field data collection efforts were conducted in Tucson, Arizona; Charlotte, North Carolina; and Portland, Oregon. The authors wish to acknowledge the following city transportation departments and individuals for their support of the project and their tireless efforts to install and maintain the APS equipment through the duration of the project:

- City of Tucson, Arizona Traffic Engineering Department, particularly John Swanson, Bob Burr, Ray Sosa, and Richard Nassi.
- City of Charlotte, North Carolina Transportation Department, particularly Tierney Driver, Sean Lamont, Ken Bostick, Art Siegal, Justin Carroll, and Bill Dilland.
- City of Portland, Oregon Department of Transportation, particularly Bill Kloos, Jason McRobbie, and Dave Gilley.

AR0071769

An expert panel reviewed this guide and provided valuable feedback for its content. Panel members included Jose De Leon, Jana Dugway, Kazessa Hoff, Scott Lamont, Jason McRobbie, Steve Misgen, Linda Myers, Kumar Neppalli, Ed Paulis, and Mike Switzer.

Their able assistance facilitated a smooth and enjoyable research experience for both researchers and participants.

CHAPTER 1

Introduction to Accessible Pedestrian Signals: Definition and Current Guidance

Accessible Pedestrian Signals 2

History of Accessible Pedestrian Signals in the United States 5

U.S. Legislation, Standards, and Guidance Applicable to APS 11

AR0071772

This chapter provides a definition of accessible pedestrian signals and an overview of their use. This chapter also includes an overview of accessible pedestrian signal (APS) standards development in the United States and current guidance on the use of APS devices.

Appendix A includes the portions of the *Manual on Uniform Traffic Control Devices* (1) and the *Draft Public Rights of Way Accessibility Guidelines* (2) that pertain to APS

Accessible Pedestrian Signals

What Is an Accessible Pedestrian Signal?

According to the *Manual on Uniform Traffic Control Devices* (MUTCD), an accessible pedestrian signal (APS) is a device that communicates information about pedestrian timing in nonvisual format such as audible tones, verbal messages, and/or vibrating surfaces (*1*, Section 4A.021).

According to the *Draft Guidelines for Accessible Public Rights of Way* (Draft PROWAG), an APS is a device that communicates information about the "Walk" phase in audible and vibrotactile formats (*2*, R105.5).

Note that the Draft PROWAG definition states that an APS provides information in both audible and vibrotactile formats, while the MUTCD says an APS provides information in audible formats "and/or" vibrating surfaces.

AR0071773

Figure 1-1. Examples of pushbutton-integrated accessible pedestrian signals from various manufacturers.

APS devices are known by different names in different countries, including the following:

- Acoustic signals,
- Audiotactile signals,
- Audible pedestrian signals,
- Audible traffic signals,
- Audible pedestrian traffic signals, and
- Audible crossing indicators.

Major Functions of APSs

APSs can provide information to pedestrians about

- The existence and location of the pushbutton that activates the "Walk" signal (Figure 1-1),
- The beginning of the walk interval,
- The direction of the crosswalk and the location of the destination curb,
- Intersection street names in braille, raised print, or speech messages,
- Intersection signalization with a speech message, and

AR0071774

- Intersection geometry through tactile maps and diagrams or through speech messages.

Benefits of APSs

Research has found that APSs improve crossing performance by blind pedestrians. The devices:

- Allow more accurate judgments of the onset of the walk interval.
- Reduce the number of crossings begun during the "Don't Walk" interval (flashing "Don't Walk").
- Reduce delay, and
- Result in significantly more crossings being completed before the signal changes.

In addition, sighted pedestrians also begin crossing faster at intersections with APSs. (See Appendix C for details of research.)

Use in the United States

Although audible crossing indicators have been available for more than 25 years, they have not been commonly installed in the United States. This is probably attributable to the following two factors:

- Disagreement among blind people on the need for, and effectiveness of, audible pedestrian signals, and
- Noise pollution and consequent community opposition.

In the past 10 years, changes in intersection design and signalization (see Chapter 3) have affected the traditional street crossing techniques used by blind pedestrians, making the pedestrian phase harder to recognize for those who cannot see the visual pedestrian signal. In addition, it has become essential to cross during the pedestrian phase at many intersections. These changes have led to more requests for accessible pedestrian signals and to increased advocacy for their installation in recent years.

In addition, developments in technology have occurred. New types of accessible pedestrian signals, which provide more information and address some of the noise concerns, are now available in the United States.

AR0071775

In Japan, Australia, and some European countries, APS devices have been routinely installed at many intersections for at least 20 years. Information about policies in those countries is included in Chapter 10.

History of Accessible Pedestrian Signals in the United States

Although there are reports of audible pedestrian signals in the United States as early as 1920, they were not included in U.S. standards and regulations until the *MUTCD 2000* (3). Typical devices were bells or buzzers designed by engineers in response to requests from individuals who were blind. The earliest reported installations were near schools for the blind.

Mass marketing of accessible pedestrian signals first occurred in the 1970s, when cuckoo/chirp signals were incorporated on pedestrian signal heads (pedheads) to form APSs. These signals, based on a Japanese system, emitted sound from an overhead speaker only during the walk interval, and the speakers were typically aimed toward the opposite end of the crosswalk (Figure 1-2).

Other types of devices that had been developed in Europe and Australia were not marketed in the United States (see sections on Sweden and Australia in Chapter 10).

AR0071776

Figure 1-2. Pedhead-mounted APS. The speaker is mounted on top of the pedestrian signal head.

Controversy Over the Use of Accessible Pedestrian Signals

Early installations of APSs generated complaints about noise from residents living near the signals. In addition, the two main consumer groups representing blind people—the American Council of the Blind (ACB) and the National Federation of the Blind (NFB)—disagreed about the need for accessible pedestrian signals. Until the early 1990s, ACB supported use of APSs as a means of providing additional information at all intersections, while NFB opposed all use of APSs.

Each of these consumer groups has a membership of approximately 25,000 people, which combined represents less than 1% of people who are blind or who have low vision in the United States. Their disagreement was often very confusing to community officials who were trying to determine the best course of action. Although NFB now states that APSs should be used in some situations, the organization is still opposed to "wholesale" installation at every intersection.

AR0071777

Problems with Pedhead-Mounted APS

Pedhead-mounted APS devices provide limited information. The two-sound system (cuckoo/chirp) provides an ambiguous indication of "Walk", and it requires blind pedestrians to know their direction of travel at all times.

The devices also only provide sound during the walk interval. While the signal sound is loud and is intended to provide directional guidance across the street, the short duration of the walk interval at most locations means that the sound ends before pedestrians have completed crossing.

The devices also fail to provide any information about the presence or location of the pushbutton that activates the signal.

See Appendix C for more information about the research results.

Pushbutton-Integrated Devices

In the mid 1990s, accessible pedestrian signals that were integrated into the pushbutton, similar to European and Australian systems, began to be available in the United States (Figure 1-5). These signals provide audible instructions at a relatively low volume, which are intended to be heard at a distance 6 to 12 ft from the pushbutton.

Additional features of the devices include the following:

- Vibrotactile "Walk" indication, in addition to audible "Walk" indications,
- Pushbutton locator tone, which repeats constantly at once per second to provide information about the presence and location of a pushbutton,
- Tactile arrow that points in the direction of travel on the crosswalk, and
- Automatic volume adjustment, allowing the APS to respond to ambient sound and provide louder indications when the traffic is louder and quieter indications when the traffic is quiet.

AR0071778

Figure 1-3. Pushbutton-integrated APS.

Proper Location

The functioning of a pushbutton-integrated APS is based on proximity to the crosswalk location. The closer the APS is located to the departure location, the quieter it can be. In addition, the vibrotactile indication and tactile arrow are not usable when located too far back from the street. Figure 1-4 illustrates installation recommendations.

AR0071779

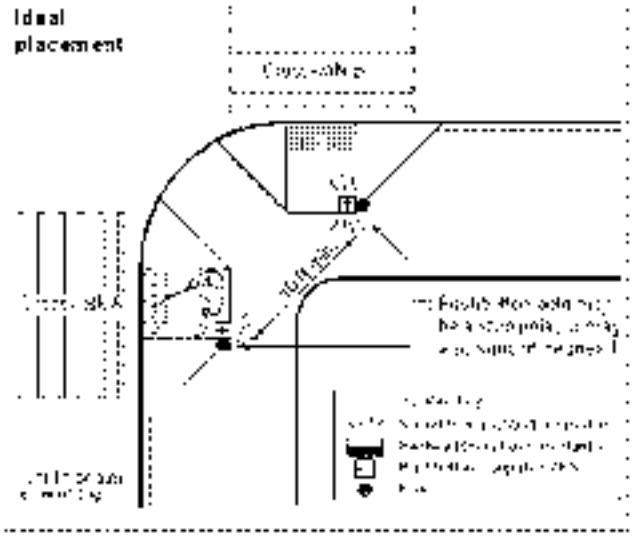

Figure 1-4. Ideal installation of a pushbutton-integrated APS—within 5 ft of the crosswalk extended, within 10 ft of the curb, and separated by more than 10 ft from other APSs on the corner, adjacent to a level landing.

Changes in intersection design, traffic, and signalization have affected the ability of pedestrians who are blind to cross streets using traffic sounds, as discussed in detail in Chapter 2.

Accessible Pedestrian Signals Currently Available in the United States

Accessible pedestrian signals provide an auditory (tone or speech) indication of the walk interval. Vibrotactile indication of the walk interval is required by the Draft PROWAG, but not all APS devices are capable of providing vibrotactile indications. Numerous other features are available, and detailed descriptions of the various features can be found in Chapter 4.

In the previous version of this document, accessible pedestrian signals were described as one of four design types: pedhead mounted, pushbutton integrated, vibrator only, and receiver based (4). These device design types were mainly categorized by the location and type of "Walk" indication provided, although there were characteristic differences in other features at that time. As technology has developed, several combinations of these different types have emerged, and modifications have been made that prevent easy grouping of devices into four "types." A discussion of accessible pedestrian signals and

AR0071780

their features using those terms becomes confusing. This guide, the Draft PROWAG, and the MUTCD all recommend accessible pedestrian signals that have audible and vibrotactile "Walk" indications, which are only available when APS is integrated into the pushbutton. However, other features, such as additional beaconing speakers, may also be provided.

In this guide, the labeling of types of accessible pedestrian signals has generally been dropped, except in this chapter and in Chapter 9. The types are described here for clarification and as background information. Some manufacturers and distributors may continue to use these terms to describe available products.

Pushbutton-integrated APS devices have the following characteristics:

- They are common in Europe and Australia and are rapidly becoming common in the United States.
- The speaker and vibrating surface are located at the pushbutton.
- A regularly repeating quiet locator tone provides information about the presence of the pushbutton and its location during the flashing and steady "Don't Walk" intervals.
- The pushbutton locator tone and "Walk" indication volumes respond to ambient sound.
- The volume is typically adjusted so it can be heard only at the beginning of crosswalks.
- They may provide other information about the name of streets, the geometry of the intersection, or signalization.

Pedhead mounted accessible pedestrian signals can be described as follows:

- They are the most common type installed between 1960 and 2000 in the United States.
- The speaker is mounted on top of the pedestrian signal head.
- A bell, buzzer, cuckoo, chirp, tone, or verbal message is audible during the walk interval only.
- Because it is usually intended to be heard across the street and to act as a beacon, it is thus relatively loud.

AR0071781

Receiver-based APS devices typically have the following features:

- The message is transmitted by infrared or LED technology from the pedestrian signal to a personal receiver held by the individual.
- Blind pedestrians must have and use the appropriate receiver for the technology installed.
- It may provide other information about the name of streets, geometry of the intersection, direction of travel, and address information.

With vibrotactile-only accessible pedestrian signals, either the arrow or the pushbutton housing or the pushbutton itself vibrates during the walk interval. Such devices are no longer available in the United States, and they do not conform to the Draft PROWAG.

U.S. Legislation, Standards, and Guidance Applicable to APS

Transportation Equity Act for the 21st Century

The Transportation Equity Act for the 21st Century (TEA-21) states that pedestrian safety considerations should be included in new transportation plans and projects.

Section 1202(g)(2) of the act directed that safety considerations "…shall include the installation, where appropriate, and maintenance of audible traffic signals and audible signs at street crossings."

TEA-21 also required the Federal Highway Administration (FHWA) to develop guidance on pedestrian and bicycle facility design. The resultant Policy Statement on Accommodating Bicyclists and Pedestrians in Transportation Projects includes the following statement: "Sidewalks, shared use paths, street crossings (including over- and underpasses), pedestrian signals, signs, street furniture, transit stops and facilities, and all connecting pathways shall be designed, constructed, operated and maintained so that all pedestrians, including people with disabilities, can travel safely and independently" (5).

AR0071782

MUTCD

The MUTCD includes two sections on accessible pedestrian signals—Section 4E.06, Accessible Pedestrian Signals, and Section 4E.09, Accessible Pedestrian Signal Detectors. In addition, Section 4D.03, Provisions for Pedestrians, addresses the need for accessible pedestrian signals in the following standards and guidance:

> "*Standard:*
>
> The design and operation of traffic control signals shall take into consideration the needs of pedestrians as well as vehicular traffic. If engineering judgment indicates the need for provisions for a given pedestrian movement, signal faces conveniently visible to pedestrians shall be provided by pedestrian signal heads or a signal face for an adjacent vehicular movement.
>
> *Guidance:*
>
> Safety considerations should include the installation, where appropriate, of accessible pedestrian signals (see Sections *4E.06* and *4E.09*) that provide information in nonvisual format (such as audible tones, verbal messages, and/or vibrating surfaces)." (3)

Section 4E.06 includes standards for APS use, guidance on installation of APSs, and standards and guidance on "Walk" indications and features of APS. Section 4E.09 provides standards and guidelines that address features and locations of accessible pedestrian signal detectors (pushbuttons), pushbutton locator tones, and volume of signals.

The Federal Highway Administration publishes the MUTCD, with revisions made on a regular basis. Major input to the MUTCD is provided by the National Committee on Uniform Traffic Control Devices (NCUTCD), which meets twice a year to consider revisions.

Changes to the MUTCD are published in the *Federal Register* as a Notice of Proposed Rulemaking, which is followed by a comment period and other standard federal rulemaking procedures. The next major revision of the MUTCD is expected to be completed in 2009, and the NCUTCD has recommended major revisions to the sections

AR0071783

on APSs for that edition. A Notice of Proposed Amendments was published in January 2008 (6).

The current MUTCD sections on APSs and the revisions proposed by the NCUTCD are included in Appendix A.

Section 504 of the Rehabilitation Act of 1973

The requirement for nondiscrimination on the basis of disability dates from well before the 1998 TEA-21 or the 1990 Americans with Disabilities Act. Section 504 of the Rehabilitation Act of 1973 prohibits discrimination on the basis of disability in programs and activities receiving or benefiting from federal financial assistance:

> "No qualified handicapped person shall…be denied the benefits of…any program or activity that receives or benefits from Federal financial assistance administered by the DOT." (Rehabilitation Act, 1973)

The act specifically requires the installation of curb ramps on federally funded projects.

Americans with Disabilities Act of 1990

The Americans with Disabilities Act (ADA) is a landmark law that protects the civil rights of persons with disabilities. It prohibits discrimination on the basis of disability in employment, state and local government services, transportation, public accommodations, commercial facilities, and telecommunications. The ADA has five parts, as follows:

- Title I—Employment
- Title II—Public services
- Title III—Public accommodations and commercial facilities
- Title IV—Telecommunications
- Title V—Miscellaneous

The ADA applies to all programs and facilities of state and local government, regardless of funding source. Guidelines for implementation of each part of the ADA were developed by the agencies charged with that responsibility.

AR0071784

The U.S. Access Board (formerly known as the Architectural and Transportation Barriers Compliance Board), an independent federal agency devoted to accessibility for people with disabilities, develops and maintains accessibility guidelines for buildings, facilities, technologies, and transit vehicles covered by Titles II and III of the ADA. These guidelines are known as the *ADA Accessibility Guidelines* (ADAAG) (7).

The ADAAG serves as the basis of enforceable standards issued by the U.S. Department of Justice (DOJ) and the U.S. Department of Transportation (USDOT).

The implementing regulations for Title II of the ADA require state and local government programs and properties to be accessible to persons with disabilities.

ADAAG provides minimum technical provisions for access. The guidelines implementing the ADA were published in 1991 and were adopted as final rule (an enforceable standard) by the DOJ and USDOT in 1992. Section 14, Public Rights-of-Way, was not, however, issued as a final rule at that time.

ADA Standards Development Process

The development of accessibility standards is a long process, with numerous opportunities for public input and comment. The development of public rights-of-way standards is under way, but will probably not be completed for several more years. The following steps are involved in developing accessibility standards for public rights-of-way:

- A Public Rights-of-Way Access Advisory Committee (PROWAAC) was formed by the Access Board in 1999 to develop recommendations for public rights-of-way.
- Recommendations were provided in a 2001 report to the Access Board, *Building a True Community: Final Report—Public Rights-of-Way Access Advisory Committee* (8). Discussion and advisory notes in that document may be helpful in understanding some of the provisions in the Draft PROWAG.
- The Access Board took the PROWAAC recommendations and developed the Draft PROWAG, which was first published on June 17, 2002, for comment. A revised draft was published on November 23, 2005. The APS sections of the Draft PROWAG are included in Appendix A.

AR0071785

- This draft will be followed by a regulatory analysis of the cost of implementing the rule and development of text, commentary, figures, and preamble of guidelines. After approval of a rule by the Access Board, the regulatory analysis and rule will be reviewed by the Office of Management and Budget before release for publication.
- A Notice of Proposed Rulemaking (NPRM) will be published in the *Federal Register*. After publication of the NPRM, comments will be solicited from the public, and staff and the Access Board will evaluate the comments and propose any changes deemed necessary. After that, final guidelines will be approved and issued by the Access Board and eventually adopted as standards by DOJ and USDOT.

Information about the process and progress of development of the guidelines is available at www.access-board.gov, under "Public Rights of Way."

Responsibility under ADA Implementing Regulations

ADA implementing regulations require programs of state and local governments to be accessible. *Barden v. Sacramento*, a 2004 court decision, defined sidewalks and street crossings as programs and facilities of state and local government; thus, they must be accessible under Title II of the ADA.

Several specific sections of the ADA implementing regulations require accessibility.

- Section 35.151, New Construction and Alterations, states that "Each facility ... constructed by, on behalf of, or for the use of a public entity shall be designed and constructed in such manner that the facility ...is readily accessible to and usable by individuals with disabilities ..."
- "Readily accessible to and usable by" means that it can be approached, entered, and used easily and conveniently by individuals with disabilities (including mobility, sensory, and cognitive impairments). As stated in the preamble to the regulation, "To the extent that a particular type or element of a facility is not specifically addressed by the standards, [the above] language...is the safest guide" (9).

AR0071786

- Section 35.160, General, states "A public entity shall take appropriate steps to ensure that communications with... members of the public with disabilities are as effective as communications with others."

The bottom line is that ADA requires newly constructed facilities to be accessible even if there are no specific guidelines covering that type of facility. ADA compliance is a civil rights issue.

Draft PROWAG Sections on APS

Section R208 of the Draft PROWAG requires accessible pedestrian signals be used where pedestrian signals are installed. Section R306 provides specifications regarding walk interval indications, location of devices, volume, pushbutton locator tones, pushbutton operation, size and contrast, signs and tactile arrows, and optional features. Further description and details can be found in Chapter 6 of this guide.

In a memo published January 26, 2006, FHWA states the following:

> The Draft Guidelines are not standards until adopted by the U.S. Department of Justice and the U.S. Department of Transportation. The present standards to be followed are the ADA Accessibility Guidelines (ADAAG) standards. However, the Draft Guidelines are the currently recommended best practices, and can be considered the state of the practice that could be followed for areas not fully addressed by the present ADAAG standards. Further, the Draft Guidelines are consistent with the ADA's requirement that all new facilities (and altered facilities to the maximum extent feasible) be designed and constructed to be accessible to and useable by people with disabilities.*(10)*

Note: The "Draft Guidelines" to which the FHWA memo refers are referred to as "Draft PROWAG" throughout this guide.

AR0071787

CHAPTER 2

Travel by Pedestrians Who Are Blind or Who Have Low Vision

Blindness and Vision Loss 2

Travel Tools and Techniques of People Who Are Blind or Who Have Low Vision 6

How People Who Are Blind or Visually Impaired Cross Streets 9

Changes in the Travel Environment 12

AR0071788

This chapter provides demographic information about individuals who are blind or who have low vision, as well as information about types of vision loss. Travel techniques are explained, and the effect of changes in traffic control and signalization on the travel of pedestrians who are blind or visually impaired is discussed.

Blindness and Vision Loss

Definitions

Visual impairment is defined as a functional limitation in seeing, including "nonsevere limitation" (difficulty seeing words and letters), and "severe limitation" (unable to see words and letters).

Legal blindness is a level of visual impairment defined in law, which is used to determine eligibility for government disability benefits. Legal blindness refers to a central visual acuity of 20/200 or less in the better eye with the best possible correction, as measured on a Snellen vision chart, or a visual field of 20 degrees or less.

Vision correctable to 20/20 with at least 180 degree field is considered "normal" vision. A simplified explanation of visual acuity is that a person who is legally blind with 20/200 vision sees at approximately 20 ft what a person with 20/20 vision sees at 200 ft. A person with a visual field of 20 degrees or less is able to see no more than a 20-degree field without scanning.

Types of Vision Loss

General types of vision loss include

- Reduced acuity,
- Restricted fields (central or peripheral),
- Combination of reduced acuity and restricted fields, and
- Total blindness, or light perception only.

Reduced acuity can refer to a large range of functional vision, from vision tested as 20/20 to totally blind. Lighting and contrast affect functional vision and are not reflected in the clinical measurements.

AR0071789

The general category of restricted fields can be further divided into central field loss and peripheral field loss.

Reduced Acuity

Figure 2-1 represents a street crossing as it might be seen by a person with general reduced visual acuity. An overall loss of acuity, sensitivity to glare, and loss of contrast sensitivity is common in the elderly population.

Figure 2-1. A street crossing as might be seen by a person with general reduced visual acuity.

Central Field Loss

Individuals with a central field loss usually will have difficulty seeing pedestrian signals, some signs, and details directly in front of them (Figure 2-2). Central field loss is typical of macular degeneration, the leading cause of blindness in those over 60.

AR0071790

Figure 2-2. The same street crossing as in Figure 2-1, but now as might be seen by a person with central field loss.

Peripheral Field Loss

Individuals with peripheral field loss, sometimes referred to as tunnel vision, may clearly see details directly in front of them, but have difficulty with objects and signs off to the side. In addition, depth perception is often impaired (Figure 2-3). Glaucoma and retinitis pigmentosa are the main causes of peripheral field loss.

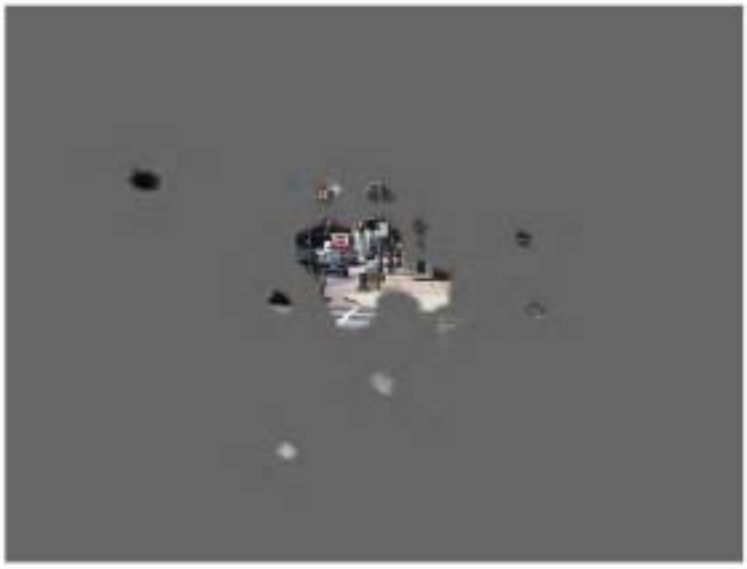

Figure 2-3. A street crossing as might be seen by a person with peripheral field loss.

AR0071791

Decrease in Attentional Field

Research by Bralyn et al. demonstrated that over age 60 the prevalence of problems detecting objects in the peripheral visual field increases dramatically (*17*). This is known as a decrease in attentional field, and it may be present with or without other types of visual impairment. By age 90, 40% of people have an attentional field of less than 10 degrees left and right. Thus, if they are looking at a pedestrian signal head, they are likely to be visually unaware of vehicles that may be turning across their path of travel until it is too late to take appropriate action.

Total Blindness or Light Perception

Individuals who are considered totally blind usually cannot see any differences in light and dark. Individuals who have light perception may be able to tell if it is dark or light and to determine the direction of a bright light source, but they do not have vision that is usable for discerning objects or a travel path.

Prevalence of Blindness

Different sources provide different estimates of the prevalence of blindness in the United States. There is no registry of individuals with vision loss, and different methodologies are used to derive estimates.

Adams et al. estimate that 8.3 million (3.1%) Americans of all ages are affected by some degree of vision impairment (*12*).

According to the Centers for Disease Control and Prevention (CDC), more than 1 million Americans are legally blind, and 12 million are visually impaired. The number of blind and visually impaired people is projected to double by 2030 (*13*).

A Lighthouse National Survey found that 8.7 million (9%) Americans age 45 and older report a severe vision impairment, defined as an inability to recognize a friend at arm's length even when wearing corrective lenses, an inability to read ordinary newspaper print with corrective lenses, poor or very poor vision even when wearing corrective lenses, or blindness in both eyes (*14*).

A survey by Statistics Canada reported that 655,000 Canadians identified themselves as having a "seeing disability" (*15*). Of those Canadians reporting a seeing disability,

- 511,000 were adults living in households.

AR0071792

- 94,000 were adults living in institutions, and
- 30,000 were children age 14 and under.

Area of Residence

Of people with vision impairments, 33% live in cities, 37% live in suburbs, 28% live in nonmetropolitan areas (e.g., small towns), and 1% live in farm areas (16). In comparison with the general population, persons who are visually impaired are somewhat underrepresented in the suburbs (i.e., 48% of the general population lives in suburbs versus 37% of the visually impaired) and overrepresented in cities.

Travel Tools and Techniques of People Who Are Blind or Who Have Low Vision

People who are blind or visually impaired make choices when it comes to traveling. At any given time, they can travel using

- A human guide, which involves holding onto someone's arm;
- A long white cane that identifies and helps avoid obstacles or elevation changes;
- A guide dog;
- Special optical or electronic aids; or
- No additional aid.

The choice of tools depends on the extent and nature of visual impairment, personal preference, lighting, and familiarity with the area.

To travel independently, people with visual impairments use whatever vision they have, auditory and tactile information, and any gathered knowledge of an area to keep track of their location and make travel decisions.

Human Guide

At one time or another, most people who are blind will make use of the human guide technique (sometimes referred to as a sighted guide), in which a person with sight serves as a guide to a person who is blind or visually impaired.

AR0071793

Long White Cane

Many individuals who are blind or visually impaired use a long white cane as a mobility device. In the most common technique, the cane is extended and swung back and forth across their body in rhythm with their steps to provide information about the environment directly in front of them, such as elevation changes or obstacles (Figure 2-4).

In another technique, often used by people with low vision, the cane is held diagonally across their body, with the tip about an inch above the ground. When those individuals are unsure about what they are seeing, they use the cane to check the object or sidewalk surface.

Figure 2-4. Pedestrian with long white cane.

Guide Dogs

Guide dogs are carefully trained service animals used as travel tools by approximately 2% of people who are blind (Figure 2-5). The dog responds to the commands of its handler, such as "right," "left," and "forward." The dog guides the handler around obstacles and stops at curbs or stairs. The handler must, however, know where they are going and must make decisions about the proper time to begin a street crossing. Dog guides move in response to directions from their handlers, but may disobey commands to avoid danger.

AR0071794

Figure 2-5. Pedestrian with guide dog.

No Aid

Not all persons considered blind use a long white cane or a guide dog. People who are visually impaired often rely on their remaining sight and auditory and tactile cues in their surroundings for orientation and travel. Some may also use aids such as telescopes for specific tasks.

Orientation and Mobility Training

Many pedestrians who are visually impaired or blind have received orientation and mobility (O&M) training from an O&M specialist (Figure 2-6). O&M specialists usually have an undergraduate or graduate degree in teaching travel skills to persons who have visual impairments.

Orientation is the ability to understand where one is located in space, and *mobility* refers to being able to travel through that space safely. The goal of most O&M training is to prepare a person who is visually impaired to travel in a variety of environments, both familiar and unfamiliar, and to assess new intersections and travel new routes (Figure 2-6). It is important to note that orientation training and assistance is not provided for every route that a person who is blind needs to travel.

AR0071795

Figure 2-6. Visually impaired pedestrian crossing street with O&M specialist.

How People Who Are Blind or Visually Impaired Cross Streets

Techniques and cues used in crossing streets are diverse and vary by the type of location and by the individual and his or her level of vision. Individuals who are blind or visually impaired often travel to unfamiliar areas and intersections, and they gather information from available sources in order to travel safely.

The following discussion describes typical techniques used at unfamiliar intersections. Although pedestrians who are blind probably travel mostly on routes with which they are familiar, it is not uncommon for bus drivers or taxi drivers to provide incorrect information about a location or to drop off a person at a slightly different location than expected. It is thus necessary for blind pedestrians to regularly confirm location and other information using nonvisual techniques.

Once pedestrians who are blind are familiar with an intersection, they do not usually need to analyze the intersection and traffic control system at length every time. They may still, however, need to listen long enough to determine that they are at the correct location and that the signal is functioning as usual. They will still need to detect the street, align to cross, identify the walk interval, and maintain alignment while crossing. Accessible pedestrian signals can particularly assist with the task of identifying the walk interval both at familiar and unfamiliar locations.

AR0071796

Detecting the Street

The information first needed by pedestrians who are blind is **"Have I arrived at a street?"** People who are blind or visually impaired use a combination of cues to recognize the street edge. These may include:

- Curb or the slope of the ramp,
- Truncated dome detectable warnings, if available,
- End of building line and open sound of the intersection,
- Sound of traffic on the street beside them (the parallel street),
- Sound of traffic stopping on the street they are approaching (the perpendicular street),
- Presence of pedestrians, and
- Presence of an intersecting sidewalk.

Identifying the Street

The information next needed for decision making at unfamiliar intersections is **"Which street is this?"** This information is only occasionally provided in an accessible format.

Pedestrians who are visually impaired develop a mental map and keep track of where they are within that map, usually by counting blocks and street crossings. Where necessary and available, assistance is sometimes sought from other pedestrians.

Analyzing Intersection Geometry

The next information needed is **"What is the geometry of this intersection?"** The pedestrian needs to know the answers to the following questions:

- Is my destination curb straight in front of me, or must I angle to the left or right to reach it?
- How many streets intersect here?
- How wide is this street?
- Should I expect to encounter any islands or medians as I cross this street?
- Am I standing within the crosswalk?

AR0071797

This information may be immediately available to pedestrians having full vision, but pedestrians who are blind may find it impossible to determine this information by listening to traffic patterns. Incorrect or missing answers to any of these questions may result in the pedestrian missing the destination curb or median.

Analyzing the Traffic Control System

Next, pedestrians with visual impairments need to know **"What is the type of traffic control system at this intersection?"** They must be able to determine answers to the following questions:

- Is this a signalized intersection?
- Do I need to push a button to activate the walk interval? If so, where is the button?
- Is the button close enough to the crosswalk that I will have time to push the button, position myself correctly at the crosswalk, and reestablish my alignment facing the destination curb before the onset of the walk interval?
- Which button controls the walk interval for the street I want to cross?
- Does it stop traffic on one street, or all traffic?
- Do cars still turn during the walk interval?
- Is there a second button on the median or crossing island that I must push?
- Will there be a surge of parallel traffic telling me the walk interval has begun? Will I be able to hear it over other, concurrent traffic sounds?

Techniques for gathering this information include listening to traffic patterns through several signal cycles and searching the sidewalk area for poles with pushbuttons. Missing information for any of these questions may result in failure to use pedestrian pushbuttons, not beginning the crossing during the walk interval, not completing the crossing before perpendicular traffic begins moving, and crossing at times other than the pedestrian phase.

Aligning to Cross

Before starting to cross, the pedestrian must align to cross or choose a heading for the crossing. Typical techniques for this task include maintaining the alignment used on the approach to the intersection and listening to parallel traffic through a signal cycle to

AR0071798

constant alignment to parallel traffic. The need to use pedestrian pushbuttons often prevents the use of parallel traffic for alignment. After pushing the button, the pedestrian must cross on the next pedestrian phase, which is usually the next time that traffic begins moving parallel to the pedestrian's crosswalk.

Identifying the Walk Interval

After determining the geometry of the intersection, aligning to face the destination curb, determining that the intersection is signalized, and having pushed a button, where necessary, pedestrians who are blind need to know **"When does the walk interval begin?"**

In the most common technique for crossing at signalized intersections, pedestrians who are blind or visually impaired begin to cross the street when there is a surge of traffic on the street parallel to their direction of travel. This technique is dependent on the presence of traffic and on consistent signal phasing. Various types of phasing and intermittent or low volumes of traffic traveling parallel to the pedestrian may affect the reliability of the technique.

Maintaining Crossing Alignment

Once the pedestrian who is blind has begun to cross the street, the next question is **"Am I headed straight towards my destination curb?"**

Traffic going in the same direction on the parallel street, if present, provides helpful auditory guidance. In addition, pedestrians who are blind may use traffic waiting on the perpendicular street as a partial alignment cue.

Turning traffic can, however, make it difficult to hear and align with the traffic traveling straight through the intersection.

In the absence of traffic on the parallel street, pedestrians who are blind are more likely to veer toward or away from the intersection.

Changes in the Travel Environment

In the past 20 years, significant changes in intersection geometry, signalization, driver behavior, and the automotive technology have affected the ability of blind travelers in the United States to use the above-mentioned techniques.

AR0071799

Intersection Design Changes and Their Effect on Travel Techniques

Intersection design changes have had the following effects on travel techniques:

- Wider streets require more precise alignment.
- Large radius corners make alignment more difficult and increase crosswalk length.
- Curb ramps and depressed corners make street detection and alignment difficult.
- Medians and islands complicate wayfinding and alignment.
- Presence of slip lanes and splitter islands requires crossing in gaps in traffic even at signalized intersections.
- Crosswalk alignment is not consistent.
- Curb extensions, also called bulb-outs or intersection chokers, sometimes complicate wayfinding.
- Raised crosswalks and tabled intersections may obliterate the sidewalk/street boundary.

Driver Behavior and Automotive Technology

Changes in driver behavior and vehicle technology also effect travel techniques, as follows:

- Aggressive and inattentive drivers are moving faster and are less likely to stop for pedestrians.
- Automotive technology, including hybrid and electric cars, has become quieter, making vehicles harder to hear by pedestrians.
- There is less pedestrian traffic in many areas, and drivers are less aware of pedestrians.

Signalization Changes

Intersection signalization has become more complex. Details on signalization and the effect on travel by pedestrians who are blind are provided in Chapter 4.

Intersection Signalization and Timing Plans 6

Vehicular Signals and Timing 15

Pedestrian Signals and Timing 18

Collaboration 23

AR0071801

This chapter provides a description of the terminology and characteristics of traffic signals and intersection design. It is intended to educate O&M specialists who must interact with the travel environment and with traffic engineers, but who may not be familiar with all the terminology and design techniques.

Intersections and signals have become more complex, and it is important that O&M specialists and blind travelers understand these changes. Skills and strategies used by pedestrians who are blind or visually impaired to cross streets at signalized intersections were developed at intersections that had pretimed signals, which meant the signal changed on a regular basis. Signalization has become more complex with the introduction of vehicular and pedestrian actuation and multiple signal phases. This increased complexity has made some previously accessible intersections now inaccessible for pedestrians with visual impairments.

It is essential that O&M specialists understand these changes so that the changes can be incorporated into the curriculum, instructional techniques can be adapted in response to these changes, and O&M specialists can better advocate for their consumers' needs

MUTCD Warrants and Signalization

What Is a Signal Warrant?

A warrant is a condition that an intersection must meet to justify a signal installation. The MUTCD specifies eight "traffic control signal needs studies," known as warrants. The MUTCD advises, however, that "the satisfaction of a traffic signal warrant or warrants shall not in itself require the installation of a traffic control signal." (1A-01). The final decision is to be made based on the traffic engineer's judgment.

Process to Determine if a Signal Is Warranted

To determine whether or not an intersection warrants a traffic control signal, the traffic engineer analyzes vehicle traffic volume, pedestrian activity, intersection crash history, and the physical environment. The intersection analysis may include a review of the following factors:

- Number of vehicles entering the intersection from all directions during 4-hour and 8-hour periods,

AR0071802

- Vehicular volumes during peak hours, classified by vehicle type for traffic movement in all directions.
- Pedestrian volume on each crosswalk in all directions, including children, the elderly, and/or persons with disabilities, during each hour of the day;
- Requests from participants attending nearby facilities and activity centers that serve the young, elderly, and/or persons with disabilities;
- Posted speed limit;
- Physical layout; and
- Crash experience/history.

Different warrants require detailed analysis of different aspects of the above information.

The current *MUTCD* can be downloaded from http://mutcd.fhwa.dot.gov.

Examples of Signal Warrants

Information on two of the signal warrants is included below to illustrate some of the considerations.

Warrant 1—8-Hour Vehicular Volume

Engineers evaluate the number of vehicles traveling through the intersection per hour; a certain volume must be met in order to justify installation of a traffic signal. A complex table is used, which includes the number of lanes of moving traffic for each approach, vehicles per hour on the major street, and vehicles per hour on the higher volume minor street approaches.

According to the MUTCD:

> Standard
>
> The need for a traffic control signal shall be considered if an engineering study finds that one of the following conditions exist for each of any 8 hours of an average day:
>
> A. The vehicles per hour given in both of the 100 percent columns of Condition A in [Table 3-1] exist on the major street and the

AR0071803

higher-volume minor-street approaches, respectively, to the intersection; or

B. The vehicles per hour given in both of the 100 percent columns of Condition B in Table 4C-1 exist on the major-street and the higher-volume minor-street approaches, respectively, to the intersection.

In applying each condition the major street and minor street volumes shall be for the same 8 hours. On the minor street, the higher volume shall not be required to be on the same approach during each of these 8 hours…

Option: If the posted or statutory speed limit or the 85th-percentile speed on the major street exceeds 70 km/h or exceeds 40 mph, or if the intersection lies within the built-up area of an isolated community having a population of less than 10,000, the traffic volumes of the 70 percent volumes in Table 3-1 may be used in place of the 100 percent columns. (V. Section 4C.02)

AR0071804

Table 3-1. Example of Signal Warrant 1.

Condition A—Minimum Vehicular Volume

Number of lanes for moving traffic on each approach		Vehicles per hour on major street (total of both approaches)			Vehicles per hour on higher-volume minor-street approaches (one direction only)		
Major Street	Minor Street	100%[a]	80%[b]	70%[c]	100%[a]	80%[b]	70%[c]
2	1	500	400	350	150	120	105
2 or more	1	600	480	420	150	120	105
2 or more	2 or more	600	480	420	200	160	140
1	2 or more	500	400	350	200	160	140

Condition B—Interruption of Continuous Traffic

Number of lanes for moving traffic on each approach		Vehicles per hour on major street (total of both approaches)			Vehicles per hour on higher-volume minor-street approaches (one direction only)		
Major Street	Minor Street	100%[a]	80%[b]	70%[c]	100%[a]	80%[b]	70%[c]
1	1	750	600	525	75	60	53
2 or more	1	900	720	630	75	60	53
2 or more	2 or more	900	720	630	100	80	70
1	2 or more	750	600	525	100	80	70

[a]Basic minimum hourly volume.

[b]Use for combination of Conditions A and B after adequate trial of other remedial measures.

[c]May be used when the major-street speed exceeds 70 km/h (40 mph) or in an isolated community with a population of less than 10,000

Warrant 4 Pedestrian Volume

Engineers evaluate the level of pedestrian activity at an intersection to see if a signal is warranted. The MUTCD describes Warrant 4 as being "intended for application where

AR0071805

the traffic volume on a major street is so heavy that pedestrians experience excessive delay in crossing the major street" (*I. 40.05*).

As currently written, the warrant requires a fairly large volume of pedestrians crossing at a location:

> The need for a traffic control signal at an intersection or mid-block crossing shall be considered if an engineering study finds that both of the following criteria are met:
>
> A. The pedestrian volume crossing the major street at an intersection or mid-block location during an average day is 100 or more for each of any 4 hours or 190 or more during any 1 hour; and
>
> B. There are fewer than 60 gaps per hour in the traffic stream of adequate length to allow pedestrians to cross during the same period when the pedestrian volume criterion is satisfied. Where there is a divided street having a median of sufficient width for pedestrians to wait, the requirement applies separately to each direction of vehicular traffic (*I. 40.05*)

In addition, "the Pedestrian Volume signal warrant shall not be applied at locations where the distance to the nearest traffic control signal along the major street is less than 90 m (300 ft), unless the proposed traffic control signal will not restrict the progressive movement of traffic" (*I. 40.05*).

However, "the criterion for the pedestrian volume crossing the major roadway may be reduced as much as 50 percent if the average crossing speed of pedestrians is less than 1.2 m/sec (4 ft/sec)" (*I. 40.05*).

Intersection Signalization and Timing Plans

Intersection Signalization

Intersections are generally designed to provide optimal vehicle traffic flow. Timing plans may be of the following two general types:

- Fixed time (or pretimed), or
- Actuated.

AR0071806

A signal at a given intersection may be designed to change from actuated to pretimed to flashing mode depending upon the following factors:

- Time of day (peak periods versus nonpeak periods),
- Day of week, and
- Malfunctions due to power outages.

It is important that O&M specialists understand signal design and terminology so they might teach these concepts to their students.

There is some variability in timing plans in different municipalities and in different locations, depending on the roadway needs and local practices.

Signal Design Terms

Phase—The right-of-way, yellow change, and red clearance intervals in a cycle that are assigned to an independent traffic movement or combination of movements.

Interval—The part of a signal cycle during which signal indications do not change.

- In other words, a phase is the time allotted to a specific movement, such as northbound traffic, whereas an interval is how long the light stays green, yellow, or red for vehicles or "Walk," flashing "Don't Walk," or "Don't Walk" for pedestrians.
- Busier intersections typically have separate phases for left-turn movements (i.e., protected left turns). When a major road intersects a minor road, the green intervals for the major road will be longer than those for the minor road to accommodate the heavier traffic on the major road.
- Although the MUTCD gives specific definitions to "phase" and "interval," these terms are often used interchangeably by traffic engineers.

Cycle—Sum total of all phases at a signal.

- A cycle is timed from the start of one phase to the time when that same phase starts again.
- Larger, busier intersections will commonly have longer cycles.

Pretimed (Fixed Time) Signals

Pretimed intersections operate in predetermined and predictable fashion.

AR0071807

- The sequence of phases (often 30 s or longer) is repeated regularly, regardless of traffic flow.
- The length of phases may change at different times of day. Based on a consistent timing plan for example, one street may have longer phases at peak hours than at nonpeak hours.
- Pretimed signals are still found in many locations, particularly in downtown areas.

Actuated Signals

Actuated signals change the length and/or the order of the phases in response to variations in vehicle or pedestrian traffic. Actuated signals are used where traffic volumes fluctuate or where it is desirable to minimize interruptions to traffic flow on the major street. Detectors are often placed on minor roads and in turn lanes (see Figures 3-1 and 3-2).

- Detectors monitor traffic and send notifications to the traffic signal controller. Detectors are most often inductive loops (electric), though they may also involve magnetic, microwave, video, and other technologies.
- Pushbuttons are most often used for pedestrian detection, although other "pedestrian sensing" technologies (microwave, infrared, piezoelectric) are also used.
- Because vehicular actuation allows the cycle to skip phases, pedestrians with visual impairments cannot accurately predict, based on previous experience, when the pedestrian phase will begin in the cycle.
- Some actuated signals may provide very short phases to accommodate a single vehicle, without provision of a pedestrian phase during that cycle. A pedestrian who is blind and crossing parallel to that vehicle may not realize that a pedestrian phase is not provided during that vehicle's movement.

The extent of actuation is dependent on geometric and operational requirements, but is generally categorized as either semi-actuated or fully actuated.

AR0071808

Figure 3-1. Vehicle detector loops in pavement.

Figure 3-2. Vehicle detector loop in pavement.

AR0071809

Semiactuated Signals

Semiactuated signals are common at the intersection of a main road and a minor side street.

- The main roadway signal stays green until a side-street detection is received, causing the traffic signal to change (the "Walk" signal for crossing the main roadway may not come on unless the pedestrian pushbutton is pressed).
- Vehicle detectors are in place only on the side street; pedestrian detectors are also installed only on the side street.
- Pedestrian activation (usually with a pushbutton) tells the signal to provide a "Walk" interval for pedestrians crossing the major street.
- The pedestrian signal for the side-street crossing may "rest in Walk" (give the "Walk" indication during the green signal for the major street) when no pushbutton is installed.

Fully Actuated Signals

Fully actuated signals are common at the intersection of two main roads (arterials). They are used when traffic volumes on each approach vary by time of day. Because they allow phases within a cycle to be skipped when vehicles are not present, they minimize delay.

- All movements/phases are actuated.
- Vehicle detectors are installed in all approach lanes.
- Pushbuttons are used to activate the "Walk" signal at pedestrian crossings.
- Changing traffic volumes can result in different timing and sequencing of phases for every cycle.

Basic Turning Phases

Protected Turn

A protected turn is made when no opposing through vehicular traffic or pedestrian crossing is allowed. The protected turn is denoted by a green arrow (Figure 3-3).

- It is typically activated by a vehicle detector.

AR0071810

- The signal phasing "protects" vehicles by prohibiting any opposing movements, including pedestrian movements.
- Protected turns require a separate signal phase, which leads to multiphase signalization (more than two phases at the intersection).

Figure 3-3. Protected left-turn signal.

Permissive Turn

A permissive turn is made across an opposing flow of through vehicles and/or pedestrians. This is the most common type of left-turn phasing at signalized intersections, and it is used both when left-turn volumes are not excessive and when adequate gaps of sufficient size exist in the opposing traffic to safety accommodate turns.

- It is typically denoted by a circular green (green ball) signal (Figure 3-4).
- The driver is "permitted" to cross the opposing through flow, but must identify and select an appropriate gap in the opposing traffic stream through which to turn.
- The driver must also yield to pedestrians who are crossing lawfully within the intersection.

AR0071811

Figure 3-4. Permissive green ball signal.

Design of Turning Movements

Concurrent (Dual) Left Turns

Concurrent, or dual, left turns are where two directions of turning traffic (e.g., eastbound and westbound) proceed together while the opposing through traffic (e.g., northbound and southbound) is stopped (protected left-turn phasing).

Concurrent left-turn signals can be activated either before or after the opposing through flows have had their green phase.

- If the left turn comes before the opposing through movement, it is called a "leading left turn." Leading left turns, which are much more common than lagging left turns, can create safety problems for blind pedestrians, since the surging left-turn traffic may be mistaken for the parallel through-traffic surge.
- If the left turn comes after the opposing through movement, it is called a "lagging left turn."

Split or Nonconcurrent Phasing

Split phasing provides separate green time to vehicles on opposing approaches. In typical signal design, the northbound and southbound through movements run simultaneously, as do the eastbound and westbound through movements.

- At offset intersections and locations where there are heavy turn movements, split phasing may be used to allow movements on each approach to move independently of other approaches.

AR0071812

- Pedestrian phases for parallel crosswalks will be activated at different times. The pedestrian phase for a crosswalk will coincide with the through traffic movement immediately adjacent to that crosswalk.
- Where there is split phase timing, the surge of parallel vehicles beside the pedestrian could be mistaken as indicating the onset of the "Walk" interval, and blind pedestrians could thus cross into the path of left-turning vehicles. In addition, the heavy flow of running traffic could be mistaken for the surge of traffic on the street beside the blind pedestrian, when the traffic is actually on the street the pedestrian is crossing.

An example of northbound/southbound movements running under split phasing is shown in Figure 3.5. Northbound traffic, including traffic turning east and west, moves on one signal phase (southbound traffic and all traffic on the east-west street have a red signal at that point). The pedestrian phase usually is provided at this time for pedestrians on the east crosswalk.

Northbound traffic then receives a red light while all southbound traffic, including turning traffic, is allowed to go. The pedestrian phase usually provided at this time is for pedestrians crossing on the west crosswalk.

AR0071813

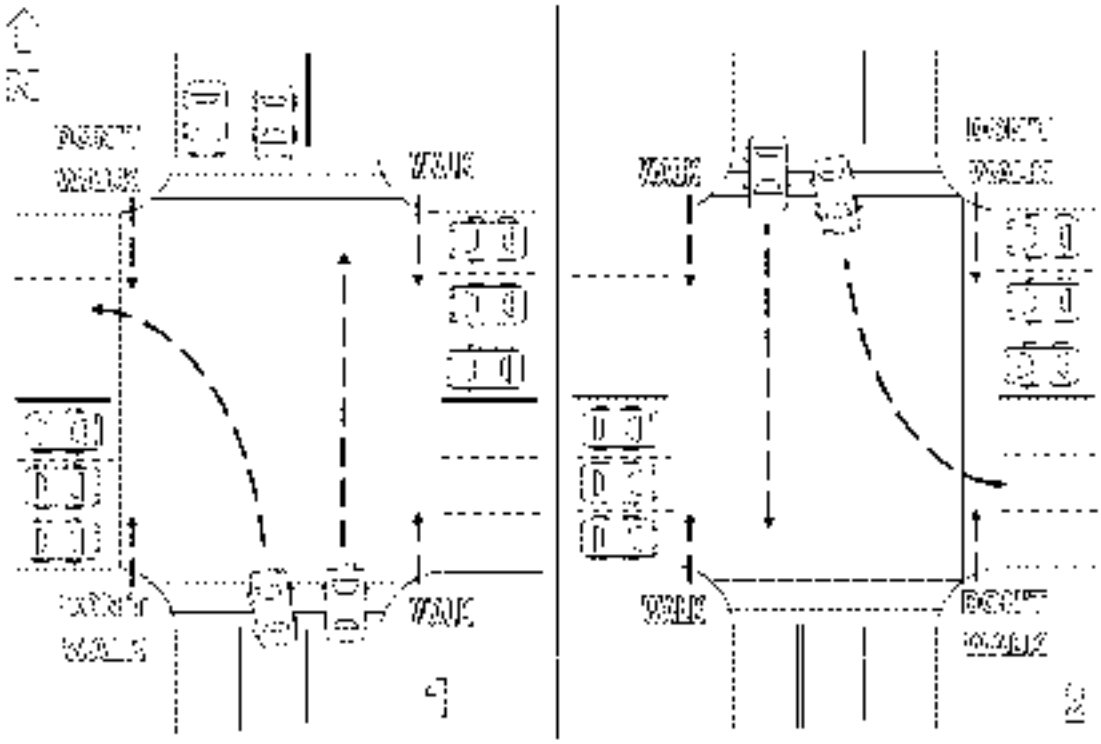

Figure 3-5. Illustration of split phasing.

Flashing Operation

Signals may only operate during peak periods of the day, switching to flashing operation at nonpeak hours, late at night, or in response to a signal malfunction.

- The signals no longer operate under stop-and-go sequencing.
- The signals usually flash red for side streets and flash yellow for the main street, or the signals flash red for both streets.
- The pedestrian signal heads ("Walk/Don't Walk" signs) are dark, and the accessible pedestrian signals are silent.

Coordinated Systems

Coordinated systems provide automated control of signal timing at two or more signalized intersections. Instead of looking at an intersection in isolation, coordinated systems look at an entire arterial or network of intersections and make signal timing adjustments that benefit (optimize) the operation of the entire system.

AR0071814

System changes are a result of traffic volume and travel times. Most often, a central controller computer provides the primary control and communicates with individual controllers located at each intersection.

Coordinated control has a number of advantages from a vehicle perspective:

- Signals can be controlled from a central traffic management center.
- The detection elements of the system can be used to predict future flows within the network and adjust the signal timing proactively instead of reactively.

Signals in a coordinated system can, however, present problems for blind pedestrians.

- The green time given to vehicles on the intersecting road (or the road whose signals are uncoordinated) may be less than normal to fit into the timing scheme of the coordination.
- This shorter time can be insufficient for pedestrians to cross the major road. Pedestrians who are blind will not know that there is insufficient time and may directly conflict with the approaching platoon of traffic on the major road. This demonstrates a need for accessible pedestrian signals at the intersection.

Vehicular Signals and Timing

Meaning of Signals

The use and meaning of particular traffic signal colors and symbols are described in Part 4 of the MUTCD. Signs and pavement marking used at signalized intersections are covered in Parts 2 and 3 of the MUTCD, respectively.

Although this section presents basic traffic laws concerning signals, O&M specialists should be well educated on the specific laws of the state of interest. Some laws, such as right turn on red arrow, vary from state to state. Most states provide a driver handbook that presents this sort of information.

Steady Green Signal

Circular Green (Green Ball)—Traffic, except pedestrians, may proceed straight through or turn right or left except when prohibited by signs or markings. Vehicles

AR0071815

turning right or left shall yield the right-of-way to pedestrians lawfully within the intersection.

Green Arrow—Traffic may make the movement indicated by the green arrow. Opposing vehicle and pedestrian movements will be given a red signal or a "Don't Walk" indication.

Pedestrian Movement—Pedestrians may cross or use a green arrow indicates or if turning traffic will cross into their path or a pedestrian signal indicates they may not cross.

Steady Yellow Signal

A steady yellow signals warns that the green interval has ended and the red signal will begin. Pedestrians should not initiate a crossing as they will not have enough time to complete their crossing before the signal turns red.

Steady Red Signal

At a steady red signal, traffic must stop at the stop line, before the crosswalk lines, or before the intersecting street.

Right Turn on Red—Unless prohibited by local law or a sign, right turn on red is permissible for vehicles, but they must first come to a complete stop before proceeding with the turn if a safe gap in traffic is available. Turning vehicles must yield to pedestrians and to traffic already in the intersection. Right turn on red makes it harder for blind pedestrians to determine the surge of traffic at the onset of the vehicular green phase on the street parallel to the crossing direction. Because blind travelers wait to hear a car traveling straight across the intersection in order to determine if the light has changed, they are frequently delayed in initiating crossing.

Left Turn on Red—This maneuver involves a left turn from a one-way street onto another one-way street on a red signal (same procedure as stated above for right turn on reds). This maneuver is not allowed in all states.

Red Arrow—Vehicles must stop at a stop line, before the crosswalk lines, or before the intersection. Some states allow vehicles to turn right on red after stopping.

Pedestrian Movements—Pedestrians should not enter the roadway in the direction of travel controlled by a steady red signal.

AR0071816

Flashing Yellow

The flashing yellow signal should be treated like a "Yield" sign, and travelers should proceed with caution.

Flashing Red

The flashing red signal should be treated like a "Stop" sign, travelers must come to a complete stop and proceed only when safe to do so.

Flashing Red Arrow and Flashing Yellow Arrow

Flashing red arrows and flashing yellow arrows typically have the same meaning as flashing circular signal indications, except they apply only to vehicular traffic intending to make the movement indicated by the arrow.

- In some states, flashing circular yellow and yellow arrow indications may be used during stop and go traffic signal operations for permissive left turn indications (same control as a green ball for left turns).
- In some states, flashing circular red and red arrow indications may be used during stop and go traffic signal operations for permissive left turn indications.

Other Intersection Terminology

A **channelized turn lane (slip lane)** (see Figure 3-6) is a turn lane that channels turning drivers to a position where they will either yield to oncoming traffic or they will complete a "free flowing" turn, which means the turning vehicles have a dedicated lane on the road they are entering and therefore do not need to stop or yield to traffic.

AR0071817

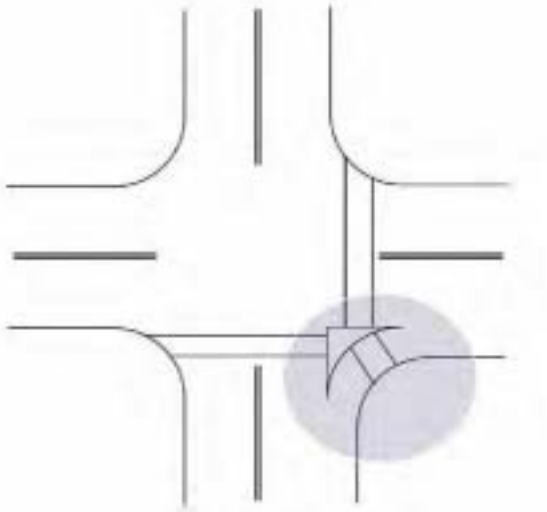

Figure 3-6. Channelized right turn lane.

Pedestrian Signals and Timing

Visual Pedestrian Signals

Pedestrian signal heads instruct pedestrians when it is lawful to cross (see Figure 3-7). Pedheads are typically installed where there is a significant amount of pedestrian activity or when there are safety issues, such as the possibility of pedestrians being confused by the cues from the traffic signal.

Pedestrian signals have three intervals:

- "Walk" interval—A white "Walk" message or a white symbol of a person walking indicates that pedestrians should begin crossing, after yielding to any vehicular traffic still in the street.
- Change interval—An orange flashing "Don't Walk" message or an orange symbol of a flashing hand indicates pedestrians should not begin a crossing because there is not enough time left in the phase for most pedestrians to get all the way across the street. Pedestrians who have already begun to cross should finish crossing.
- "Don't Walk" interval—A steady orange "Don't Walk" message or a steady orange symbol of a hand indicates pedestrians are not supposed to be in the crosswalk.

AR0071818

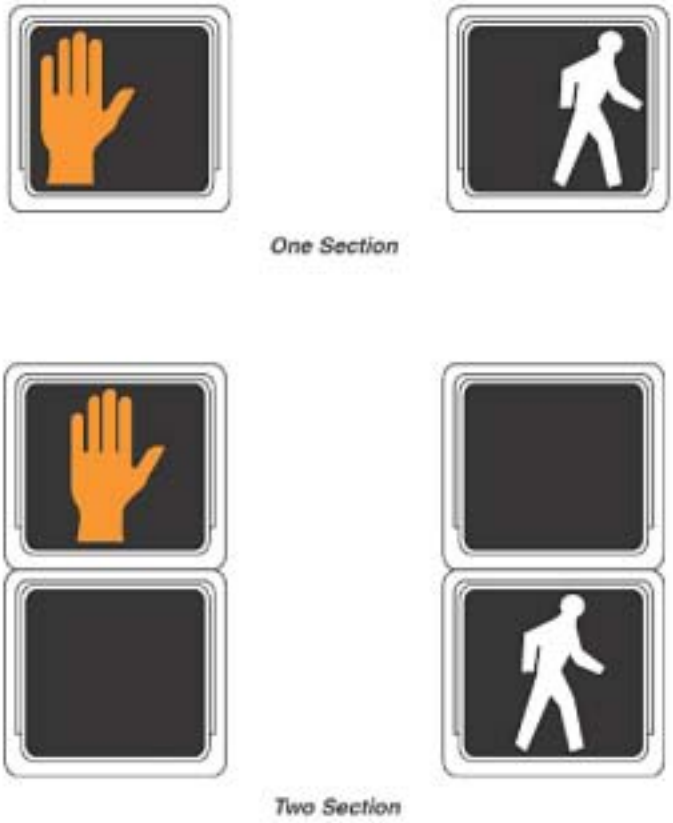

Figure 3-7. Typical pedestrian signal symbols.

Some locations also use pedestrian countdown signals (see Figure 3-8), which provide a countdown, in seconds, of the time remaining in the change interval.

- The countdown signal supplements the "Walk/Don't Walk" signals; it does not replace them.
- MUTCD guidance stipulates that the countdown should only be displayed during the flashing "Don't Walk" interval because of inconsistencies of the countdown during the "Walk" interval at actuated signals. Nonetheless, many cities are still using signals that display the countdown during the "Walk" interval (see Figure 3-9). Pedestrians with low vision have had problems distinguishing the countdown numbers from the orange flashing hand symbol when they are displayed alongside the white symbol of a man walking.

AR0071819

Figure 3-8. Correct display of pedestrian countdown signal (counting down during flashing "Don't Walk").

Figure 3-9. Incorrect countdown display, showing countdown during the "Walk" interval.

Pedestrian Signal Timing

Pedestrian signal timing design deals with the length of the "Walk" and change intervals. The "Walk" interval is typically short (4 to 7 s). The change interval is designed to be long enough for a pedestrian to cross the street. This is typically calculated assuming a walking speed of 3.5 to 4 ft/s. Parking lanes are sometimes excluded from the calculation.

AR0071820

The green time for the parallel traffic movement is calculated based on the time necessary for a pedestrian to cross the street, as in the following equation:

$$\text{Minimum Green Time} = \text{WALK interval} + \frac{\text{Crosswalk Length}}{4.0 \text{ ft/sec}}$$

Flashing DON'T WALK

Figure 3-10, which is a typical signal timing diagram used by traffic engineers in the design of signal timing, illustrates how the vehicle and pedestrian phases overlap. Time is the horizontal axis in the figure.

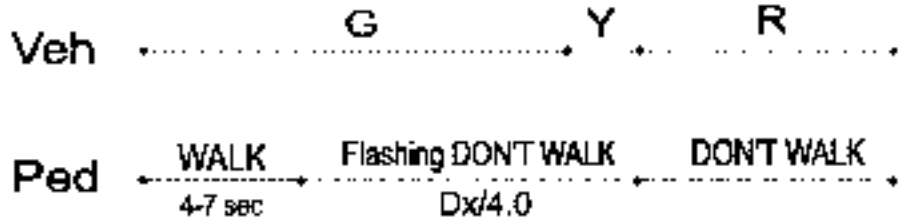

Figure 3-10. Illustration of the overlap of vehicle signal and pedestrian signal timing.

Pedestrian Phase Actuation

Some signals are designed so that the pedestrian phase is actuated by a pushbutton.

- Pressing the pushbutton calls for a pedestrian phase that allows enough time for a pedestrian to cross at average walking pace.
- If the button is not pressed, there may not be sufficient time programmed into the vehicle phase for a pedestrian to cross the street. Once the button is pressed, the pedestrian phase may begin immediately, or it may begin at a certain point during the following cycle.

AR0071821

- The extent of the delay before the beginning of the pedestrian phase will vary depending on the programming of the phases for that intersection and on when the button was pushed within the cycle.
- Blind pedestrians have traditionally waited through a light cycle to assess and refine their location by listening to vehicular trajectories; they then cross on the next pedestrian phase. At a pedestrian-actuated intersection, however, pedestrians have to cross on the next pedestrian phase after pushing the button. If they do not cross at that time, they will have to locate and push the button again (and then re-establish their alignment).

Passive Pedestrian Detection

Pedestrians approaching a crosswalk area can also be detected passively (i.e., without having to push a button) through the use of microwave, infrared, or piezoelectric technologies. Future developments may affect whether an accessible pedestrian signal with a locator tone is necessary at an intersection that uses passive detection. One issue for consideration is whether pedestrians realize they have been detected.

Leading Pedestrian Intervals

Leading pedestrian intervals provide a pedestrian "Walk" interval 2 to 4 s before the vehicular green, giving pedestrians a head start so they are already in the intersection before vehicles begin moving. This can, however, be a disadvantage to blind or visually impaired pedestrians who rely on the surge of traffic to indicate when the signal is green. If these pedestrians want to begin crossing with the surge of parallel traffic at an intersection where a leading pedestrian interval is used, they will have less time to cross than designed. In addition, when pedestrians do not initiate their crossing at the onset of the "Walk" interval, drivers may interpret this to mean that the pedestrians do not intend to cross.

Pedestrians who are blind or visually impaired will have no way of knowing about the leading pedestrian interval at an unfamiliar intersection unless there is an accessible pedestrian signal installed.

AR0071822

Exclusive Pedestrian Phasing

During an exclusive pedestrian phase, all vehicles have a red light during the "Walk" interval, and all crosswalks have the "Walk" signal at the same time. This is typically done to increase pedestrian safety. At some locations, right turn on red is allowed during the pedestrian phase. For efficiency, pedestrian crossings may be made diagonally.

- Exclusive pedestrian phasing may be followed by an extended time for one or more of the crosswalks
- Exclusive pedestrian phasing may be beneficial to pedestrians with mobility impairments and cognitive disabilities as it allows for crossing when few or no vehicles are moving through the intersection. It is, however, a disadvantage for pedestrians who rely on traffic sounds to determine the signal phases. In addition, determining initial alignment and maintaining alignment during crossing may be difficult due to the absence of parallel moving traffic.

Pedestrian Recall

With pedestrian recall, the "Walk" indication is provided every cycle, regardless of whether the button has been pushed.

Rest in "Walk"

When a signal rests in "Walk," the pedestrian signal for crossing the minor street remains in "Walk" as long as the major street has the green signal and there is no call on the minor street.

- When a vehicle approaching on the minor street is detected, the pedestrian signal to cross the minor street changes to flashing "Don't Walk."
- Some APS manufacturers provide a switch on their devices that limits the length of the audible "Walk" indication to 7 or 8 s while the signal rests in "Walk," but recalls the audible and vibrotactile indications of the "Walk" message if the button is pressed when there is adequate clearance time remaining.

Collaboration

O&M specialists should contact local transportation professionals with responsibility for signal design and maintenance. These professionals include traffic engineers, public

AR0071823

works personnel, signal technicians, and transportation planners. The ownership of the signal—whether township, county, city, or state—determines who is in charge of the intersection. In some cases, consulting firms are contracted to provide operation and maintenance control of signalized intersections.

Understand Municipality Structure

The structure varies from one municipality to the next. In some cases, engineering may be part of the public works department, and in other cases it may be a separate department. Intersection signals may be part of a state or county traffic management network, even if they are located within a town or city, or the signals may be managed by a consulting firm.

- New intersection construction may be contracted out to a traffic engineering or electrical contractor.
- Signals may be maintained by a department other than the one that installed them.
- Find out if there is a local jurisdiction or statewide ADA coordinator and/or a DOT/public works department ADA coordinator. This coordinator may be responsible for ensuring that the local jurisdiction's streets, sidewalks, and facilities are accessible to pedestrians with disabilities. The coordinator may also have more influence in getting traffic engineers to install accessible signals than someone from outside the local jurisdiction.

To learn about the structure of a city department, check the city website or a phone directory.

Contact the Traffic Engineering Department

The O&M specialist should call the department that manages traffic signals to find out who to talk to about a specific intersection. The O&M specialist should work collaboratively to develop a productive working relationship.

- Call the transportation professional and explain what you do and why you are inquiring about the intersection (keeping in mind that the persons responsible for the traffic signals may not have considered all travel strategies and may not know that professionals are available to consult with about the travel needs of pedestrians with

AR0071824

visual impairments. Ask for more information about who does what and how to ask for information.

- Ask about signal phasing and timing plans at particular intersections and how pedestrians are accommodated.
- Find out the procedure for requesting changes or modifications to an intersection. Talk with the transportation professional and familiarize yourself with the procedures for handling and accommodating your request.
- Understand that additional parties and factors may be involved in addressing your request (because of funding, politics, etc.).

Attend Meetings

O&M specialists should consider attending the following meetings:

- Local pedestrian advisory/advocacy meetings. Many towns set up these groups to solicit feedback on pedestrian issues and to gather advice on potential solutions.
- Local meetings of the Institute of Transportation Engineers or other engineering organizations.
- Local disability advisory committee meetings. The disability advisory committee reports directly to elected officials (mayor, city council, and county board of supervisors) of the local jurisdiction.

If the disability advisory committee has a physical access subcommittee, an O&M specialist may want to become a permanent member in order to have an opportunity to advocate for and influence future installations of accessible signals.

Participate in Public Hearings

O&M specialists should also consider attending public hearings on state transportation improvement plans. The hearings provide opportunities to meet DOT staff, including traffic engineers, and they also provide opportunities to present comments on the needs of pedestrians.

AR0071825

Educate Yourself

O&M specialists should familiarize themselves with APS installations in their area or nearby areas. They should also

- Learn the language used by traffic engineers;
- Familiarize themselves with state regulations and practices, such as the MUTCD, ADA Title II, and Draft PROWAG;
- Learn the desires of others in the community;
- Remain informed on current APS technology;
- Follow up on any requests for information and not assume someone else is doing everything right; and
- Learn where to report problems or malfunctions.

Educate Students

O&M specialists should teach their students about changes in signalization and intersection geometry.

- Explain the necessity of using pushbuttons at actuated intersections.
- Remind students that timing plans can vary, so the signal timing they identify when crossing the intersection at a specific time of day or day of week may be different the next time they travel the same intersection.
- Assist students in requesting an accessible pedestrian signal.
- Teach students how to use an APS.

Advocate for Accessible Pedestrian Signals

O&M specialists should serve as advocates for APSs, especially at intersections where

- Pedestrians are unable to discern the "Walk" interval;
- A pedestrian pushbutton controls the pedestrian crossing phase;
- Signalization includes a leading pedestrian interval or an exclusive pedestrian phasing; and
- Many electric or hybrid vehicles are present.

AR0071827

This chapter provides a description of APS features, including "Walk" indications. The features currently available on APS devices marketed in the United States and abroad and their use by pedestrians who are blind or who have low vision are discussed.

Intersection geometry, signalization, and installation location can affect the features needed to provide adequate, unambiguous information to pedestrians who are blind or who have low vision. Poor installation can result in ambiguous "Walk" information from an APS. (More information on designing installations and determining needed features is provided in Chapters 6 and 7.)

Because APS technology is changing rapidly, additional choices of features may become available. Those making purchasing decisions should consider the background information provided in this chapter when evaluating new technology.

Criteria for "Walk" Indications

"Walk" Indication Is Critical

The "Walk" indication provides critical safety information. It should be

- Readily detectable in the presence of ambient vehicular sound,
- Highly localizable,
- Uniquely recognizable as a "Walk" signal, and
- Unambiguous with regard to which crosswalk has the walk interval.

Criteria

In the United States, the MUTCD and the Draft PROWAG provide some specific criteria for walk interval indications.

- There shall be audible and vibrotactile indications of the walk interval. Audible indications shall be tone or speech message (2, R306.2, Pedestrian Signals, and R306.2.3, Audible "Walk" Indication).
- The information provided "shall clearly indicate which pedestrian crossing is served by each device" (1, 4E.06).
- The audible tones shall be audible from the beginning of the associated crosswalk (1, 4E.06).

AR0071828

- The volume shall be 2 dB minimum and 5 dB maximum above the ambient noise level in standard operation (2. R306.2.3.2 Volume. *1.* 4E.06)
- The volume should be no louder than the associated pushbutton locator tone unless a louder audible beaconing feature is actuated (*1.* 4E.06: 2, Advisory R306.2.3.2 allows beaconing to exceed volume limits).
- If the tone for the walk interval is similar to the pushbutton locator tone, the "Walk" interval tone shall have a faster repetition rate than the associated pushbutton locator tone (*1.* 4E.06).

Appropriate APS Location

The Draft PROWAG requires accessible pedestrian signals to be located at the pushbutton (i.e., pushbutton integrated) to enable use of the vibrotactile feature. *The material presented in this chapter assumes that the APS device is integrated into the pushbutton, unless another mounting location is specifically discussed.*

There are a number of APS devices available that meet the above listed criteria; however, proper installation is also critical to their effective functioning. Chapter 6 includes a detailed discussion of installation location requirements.

Current Recommendations for "Walk" Indications

Audible and Vibrotactile Indications Required

Audible (speech or tone) and vibrotactile indications of the walk interval are required by the Draft PROWAG.

The MUTCD does not currently provide specifications for audible "Walk" indications, but does caution about the use of tones that could be confused with birds or vehicle back-up beepers.

"Walk" indications can be provided by the use of

- Tones,
- Speech messages (also referred to as verbal messages), and
- Vibrating surfaces.

More information about the use of each is provided on the following pages.

AR0071829

Recent research recommends tones be used in locations where the speakers for APS devices for two different directions of travel can be separated. Speech messages are recommended where the speakers must be located on the same pole or less than 10 ft apart.

Associating Tones with Direction of Travel

In the past in the United States, audible pedestrian signals have utilized two different tones, which are associated with two different crossing directions, broadcast from speakers mounted at the pedestrian signal head. The most common tones used were bird sounds, specifically "cuckoo" and "chirp," with the cuckoo used for north-south crosswalks and the chirp used for east-west crosswalks. Research since 1988, however, has documented that such a system is often ambiguous and confusing (see Appendix C).

Using a different tone for each direction of travel is no longer recommended in the United States.

Use of a Single Tone for Crossings in All Directions

In Europe and Australia, a single tone emanating from speakers located at the pedestrian pushbutton has been used successfully for years to indicate the walk interval. There is some variability in the tones used. Typically, the tone for "Walk" is the same as the pushbutton locator tone, but repeated at a faster rate (usually about 10 times faster). The same tone is used for all crossing directions.

A single tone works because the standardized location of the pushbutton-integrated speaker in relation to the crosswalk provides information about which crosswalk has the "Walk" interval. Pedestrians are beside or within arm's reach of the appropriate APS device when they are wanting to cross and are at some distance from the APS for another crosswalk. Speakers located in this manner are now included in the Draft PROWAG.

See the Chapter 6 discussion of installation decisions for more about the location of APS speakers and vibrotactile "Walk" indications.

AR0071830

"Walk" Indication—Tones

Description

A tone is provided during the walk interval. In the United States, the "Walk" indication for an accessible pedestrian signal has typically been provided by an audible signal, such as a beep, buzz, percussive sound, or cuckoo/chirp. Current recommendations are that the tone used to indicate the walk interval should be a ticking tone that repeats 8 to 10 times per second, otherwise known as a rapid tick. That tone emanates from the pedestrian pushbutton location.

Additional Information

The rapid tick tone repeating at least 8 times per second) has been found to result in faster response than verbal messages or a two-tone system (cuckoo/chirp/cuckoo/chirp). Errors in responding to the correct signal were also reduced with the rapid tick tone, when two APS devices at a corner were separated by at least 10 ft and each was located close to the crosswalk it signaled. For information about the research on tones, see Appendix C.

The walk indication should also have a faster repetition rate than the pushbutton locator tone; the MUTCD specifies the repetition rate and duration of the pushbutton locator tone at once per second (see the section on pushbutton locator tones later in this chapter).

Tones consisting of multiple frequencies, high and low, with a low component at 880 Hz have been found to be highly detectable and localizable in the presence of traffic sound. Frequencies above 1 kHz are difficult for persons with age-related upper frequency hearing loss to detect. For persons with normal hearing, however, the presence of multiple higher harmonics aids localization.

When to Use

An audible "Walk" indication is needed on any APS device.

Tone indications should be used where speakers are separated by adequate distance and are located close to the crosswalk they serve, so that it is clear which speaker is sounding. Generally, tone indications should be provided from pushbutton-integrated speakers, rather than from speakers mounted on pedestrian signal heads.

AR0071831

References

Currently the MUTCD states "When accessible pedestrian signals have an audible tone(s), they shall have a tone for the WALK interval. The audible tone(s) shall be audible from the beginning of the associated crosswalk. If the tone for the WALK interval is similar to the pushbutton locator tone, the WALK interval tone shall have a faster repetition rate than the associated pushbutton locator tone." (4E.06). Revisions to standards and guidance are anticipated in the 2009 edition of the *MUTCD*.

The Draft PROWAG provides information on tones: "Tones shall consist of multiple frequencies with a dominant component at 880 Hz. The duration of the tone shall be 0.15 s and shall repeat at intervals of 0.15 s" (2. R306.2.3.1.1.

It is expected that the Draft PROWAG and the MUTCD will be harmonized in future revisions.

Research has been completed on detectability and localizability of tones and on use of two different tones versus a single tone. See Appendix C for more information.

Use by Pedestrians Who Are Blind or Who Have Low Vision

The audible "Walk" indication provides a clear cue of the beginning of the pedestrian phase. Pedestrians will evaluate traffic and the intersection and listen for the "Walk" indication. Upon hearing the "Walk" indication, they typically check that traffic has stopped and that no cars are turning across their path before beginning their crossing.

"Walk" Indication—Speech Messages

Description

A speech message is provided during the walk interval, usually from a speaker located at the pushbutton. The message should follow the recommended model: "Maple. Walk sign is on to cross Maple." The recommended message for an intersection with an exclusive pedestrian phase is "Walk sign is on for all crossings."

Additional Information

The speech "Walk" message must be detectable, localizable, and recognizable, and it must also be correctly understood by all users. Speech messages from pushbutton integrated APS devices seem very user friendly and have become popular in the U.S.

AR0071832

market. However, the words and their meaning must be correctly understood by all users in the context of the street environment where they are used.

The use of speech messages will not automatically solve all ambiguity problems. In even moderate traffic conditions, people who have age-related or other hearing losses, people who are not native English speakers, and people with cognitive disabilities are likely to miss hearing some words or to misunderstand what they hear, possibly resulting in misinterpreting entire messages.

Model messages have been determined through research (see Appendix C). Recommendations on word order and on wording of messages should be strictly followed. Where complete sentences are used in the models, complete sentences should also be used in actual messages. In the model messages, such words as street, avenue, and road are not used, however, in some locations, these words may be needed to avoid ambiguity.

Pedestrians have to know the names of streets they are crossing in order for speech "Walk" messages to be unambiguous. In getting directions to a new location, travelers do not always get the name of each street to be crossed. They may only know, for example, that they have to cross four streets before looking for their destination. Therefore, the accessible pedestrian signal has to give the user the name of the street controlled by the pushbutton. This can be done by means of a pushbutton information message during the flashing or steady "Don't Walk" intervals.

The user must then combine the information from the pushbutton information message or a braille label, the tactile arrow, and the speech "Walk" message in order to correctly respond to the speech "Walk" message. It may be necessary to have all forms of information for the traveler to correctly identify the street and crossing interval at an unfamiliar intersection. This complex process is much more cognitively demanding and more liable to result in errors or delay than the use of a tone from a speaker located right beside the crosswalk.

A speech and tone "Walk" indication may be combined (i.e., "Maple, Walk sign is on to cross Maple"); and may be followed by rapid tick for the rest of the walk interval.

AR0071833

When to Use

An audible walk indication is needed on any accessible pedestrian signal. Speech "Walk" messages are recommended only where more than one pushbutton speaker must be located on the same pole or where speakers are less than 10 ft apart.

References

The Draft PROWAG allows the "Walk" indication to be provided by speech messages but does not provide additional specifications (2, R306.3.3).

The 2003 MUTCD provides minimal information regarding speech "Walk" messages. It states that "when verbal messages are used to communicate the pedestrian interval, they shall provide a clear message that the WALK interval is in effect, as well as to which crossing it applies. The verbal message that is provided at regular intervals throughout the timing of the WALK interval shall be the term "WALK sign," which may be followed by the name of the street to be crossed" (1, 4E.06).

Revisions and additional language have been approved by the National Committee on Uniform Traffic Control Devices and recommended for inclusion in the 2009 MUTCD. These revisions incorporate recommended messages.

Recent research evaluated localizability and detectability of speech messages, developed recommended message wording, and determined that response to speech messages was more accurate than responses to two different tones when pushbuttons were on the same pole (see Appendix C).

Use by Pedestrians Who Are Blind or Who Have Low Vision

The audible "Walk" indication provides a clear cue to the beginning of the pedestrian phase. Pedestrians who are blind or who have low vision will evaluate traffic and the intersection and then listen for the "Walk" indication. After hearing the "Walk" indication, they typically check that traffic has stopped and no cars are turning across their path before beginning their crossing.

AR0071834

Vibrotactile "Walk" Indication

Description

The pushbutton or a raised arrow on the APS housing vibrates during the "Walk" interval.

Additional Information

Vibrotactile information is useful when pedestrians can be aligned and prepared for crossing while still keeping a hand on the accessible pedestrian signal.

Those who are deaf or hard of hearing must also know where to find the device since the pushbutton locator tone is not helpful.

When to Use

The vibrotactile indication of the walk interval is needed at most locations and is required by the Draft PROWAG. However, it is useful only when the device is located close to the crossing departure location.

It is important to note that Draft PROWAG requires audible information in addition to vibrotactile indications of the walk interval. Without specific training on the device, blind pedestrians may not find or use the vibrotactile indication, particularly if it is not located on the actual pushbutton.

References

The MUTCD standard states that "vibrotactile pedestrian devices, where used, shall indicate that the WALK interval is in effect, and for which direction it applies, through the use of a vibrating directional arrow or some other means" (*1*, 4E.06). Guidance states that the devices should be adjacent to the intended crosswalk.

The Draft PROWAG requires a vibrotactile indication of the walk interval at each crosswalk with pedestrian signal indications (*2*, R306.2).

Use by Pedestrians Who Are Blind or Who Have Low Vision

Pedestrians will stand beside the pushbutton with their hand on the vibrating arrow while waiting to cross (see Figure 4-1). The vibrotactile indication communicates to pedestrians who are deaf-blind that the walk interval is in effect, and at particularly noisy

AR0071835

intersections it may also provide confirmation of the walk interval to pedestrians who are blind.

Figure 4-1. Pedestrian waiting to feel the vibrotactile "Walk" indication.

Pushbutton Locator Tone

Description

A pushbutton locator tone is "a repeating sound that informs approaching pedestrians that they are required to push a button to actuate pedestrian timing and that enables pedestrians who have visual disabilities to locate the pushbutton" (*1*, 4E.09).

The pushbutton locator tone is referred to by different names in manufacturer's brochures, including

- Pole locator,
- Locator signal,
- Locator tone,
- Locating tone, and

AR0071836

- Locator audible.

Additional Information

Pushbutton locator tones typically sound from the pushbutton during the flashing and steady "Don't Walk" signals. The locator tone informs pedestrians of the need to push a button and provides an audible cue to the location of the pushbutton. During the street crossing, the locator tone may be audible in the last lane and thus provide a cue to the direction of the destination.

In available products, the pushbutton locator tone varies from a click sound to a beep tone. Repetition rate and length of tone are standardized by language in the MUTCD. "Pushbutton locator tones shall be easily locatable, shall have a duration of 0.15 seconds or less, and shall repeat at 1-second intervals" (*I*, 4E.09).

Volume of this slowly repeating tone should be adjusted to be heard *no more than 6 to 12 ft (2 to 4 m) from the pushbutton or at the building line, whichever is less* (4E.09). The Draft PROWAG states that the volume of the pushbutton locator tone is to be adjusted to between 2 dB and 5 dB above ambient sound levels in standard operation. (2. R306.3.2). Although these requirements may appear to be in conflict, both can generally be met. Perceived loudness can vary, depending on the environment near the sound source.

Both the MUTCD and the Draft PROWAG allow an increased volume of the locator tone to provide audible beaconing in response to a repeat user actions or extended button press and audible beaconing.

The pushbutton locator tone typically has automatic volume control. A microphone or sensing device is installed in the APS device or in the pedestrian signal head to monitor intersection sound levels and adjust the volume of the locator tone. This technology is also used to adjust the volume of the "Walk" indication. (Sample locator tones are available at www.walkinginfo.org/aps.)

When to Use

The pushbutton locator tone can be useful whenever there is a pushbutton that a pedestrian should use.

AR0071837

References

The Draft PROWAG requires a pushbutton locator tone wherever there is a pushbutton (2. R306.3.2).

The MUTCD states that pushbutton locator tones may be used (7. 4E.09).

Both the Draft PROWAG and the MUTCD have additional information regarding pushbutton locator tone volume.

Use by Pedestrians Who Are Blind or Who Have Low Vision

Pedestrians who are unfamiliar with an intersection will approach the intersection and take the following actions:

- Upon hearing the locator tone, or two locator tones if there are two pushbuttons, they will realize that there is a pushbutton for the crossing.
- They will probably continue to the curb or curb ramp location in order to become familiar with the corner, determine proper alignment, and become familiar with the intersection layout and sounds by listening to traffic.
- They will return to, if they are not already standing next to, the pushbutton locator tone that is believed to be the correct pushbutton for the crossing and check that the tactile arrow alignment is parallel to the desired crosswalk.
- They will push the button and return to the curb to realign themselves for crossing the intersection.
- They may repeat this process if the pedestrian phase begins before they are properly aligned to cross.
- If the pushbutton locator tone for the APS device on the opposite side of the street is audible as they cross the street, they may home in on the sound for verification of alignment.

Tactile Arrow

Description

A raised (tactile) arrow may be part of the pushbutton, as seen in Figure 4-2, may be above the pushbutton (Figure 4-3), or may be on top of the device (Fig 4-4). It is used to communicate to pedestrians which crosswalk is controlled by the pushbutton. The tactile

AR0071838

arrow provides confirmation similar to the printed sign and arrow that are commonly provided for pedestrians who are sighted.

The arrow should contrast with its background. On most APS devices, this arrow also vibrates during the walk interval.

Figure 4-2. This accessible pedestrian signal has a high-contrast, raised tactile arrow on the pushbutton and a high-contrast, recessed tactile arrow on the sign above the button.

AR0071839

Figure 4-3. The tactile arrow above the pushbutton on this accessible pedestrian signal is superimposed on a larger visual arrow.

Figure 4-4. The tactile arrow is located on top of this APS housing (note the lack of required color contrast between the arrow and housing).

AR0071840

Additional Information

It is important that the arrow point in the direction of travel on the crosswalk, as it indicates which crosswalk is controlled by that pushbutton. Tactile arrows provide general alignment information for all pedestrians. However, it is important to note that tactile arrows do not seem to enable the extremely accurate alignment required for blind and visually impaired pedestrians. To align the arrow properly, the installer needs to understand that pedestrians are expecting the arrow to be pointing toward the destination across the street — *not* toward the beginning of the crosswalk or toward the curb ramp location. Misalignment of the arrow may cause a blind pedestrian to be directed into the center of the intersection.

For arrows on the face of the device, the alignment is determined by the installation of the pushbutton on the pole. Arrows on the top of the pushbutton housing are typically glued into place after the pushbutton is installed, and their alignment can be adjusted separately from the pushbutton.

When to Use

Tactile arrows are recommended at all locations with an accessible pedestrian signal.

References

Pushbuttons and arrows should be within 5 ft of the extended crosswalk lines (*7*, 4E.09) and aligned in the direction of pedestrian travel control ed by the pushbutton (*2*, 4E.09; *3*, R306.4.1).

Arrows should have good visual contrast with their background so that all users, including those with low vision, may readily see them (*7*, 4E.09; *3*, R306.4.1).

The Draft PROWAG provides specifications for the arrow: "Include a tactile arrow aligned parallel to the crosswalk direction. The arrow shall be raised 0.8 mm (.03 in.) minimum and shall be 4 mm (1.5 in.) minimum in length. The arrowhead shall be open at 45 degrees to the shaft and shall be 33 percent of the length of the shaft. Stroke width shall be 10 percent minimum and 15 percent maximum of arrow length. The arrow shall contrast with the background" (*3*, R306.4.1).

AR0071841

Use by Pedestrians Who Are Blind or Who Have Low Vision

Pedestrians who are blind use tactile arrows to determine and confirm which crosswalk the pushbutton controls and to determine the general direction of travel. Clues from traffic sounds are also used to confirm alignment and crossing direction.

Blind pedestrians typically proceed in as straight a line as possible from the pushbutton to the curb of the perpendicular street in the direction of the arrow. This means that the APS should be within or as close as possible to the crosswalk lines.

Automatic Volume Adjustment

Description

Automatic volume adjustment is a term for volume control that is automatically responsive to ambient background sound.

- A louder signal is produced when vehicle and other noise at an intersection is high (as during traffic surge or when a truck is passing).
- A quieter sound is produced when background noise volume is lower (as during nighttime hours or a lull in traffic).
- A microphone continuously samples the noise levels and varies the volume in response to the existing sound levels. The microphone may be incorporated into the pushbutton housing or located at the pedestrian signal head.

Automatic volume adjustment is also known as automatic gain control (AGC) or ambient sound adjustment.

Additional Information

Some signals can be preset to vary volume within particular ranges.

Most signals with automatic volume control have a minimum limit placed at about 30 dB and a maximum limit of about 90 dB.

Some APS devices allow the installer to separately set the range of the locator tone and the "Walk" indication, others have one setting for both.

A signal that is 2 to 5 dB above ambient sound, as perceived at the departure curb, is loud enough to be heard by pedestrians waiting at that location. If the microphone is

AR0071842

installed at the pedestrian signal head that is set back from the curb, the traffic volume sensed by the microphone is not as loud as that perceived by pedestrians waiting at the curb. Therefore, the setting may need to be adjusted at each installation, depending on the location of the microphone relative to pedestrians waiting to cross.

Some APS devices have adjustments for microphone sensitivity, as well as "Walk" indication and pushbutton locator tone volume.

When to Use

Automatic volume adjustment is recommended at all locations with access for pedestrian signals.

References

The MUTCD states: "Automatic volume adjustment in response to ambient traffic sound level should be provided up to a maximum volume of 89 dBA. Where automatic volume adjustment is used, tones should be no more than 5 dBA louder than ambient sound" (Ref. 4E.06).

The Draft PROWAG requires devices to be responsive to ambient sound (R306.3.2 and R306.2.3.2).

Use by Pedestrians Who Are Blind or Who Have Low Vision

Automatic volume adjustment provides flexibility and allows APSs to adjust so they will not disturb neighbors at night or during times of low traffic volume. This is also helpful to blind or visually impaired pedestrians, as the accessible pedestrian signal does not drown out the traffic sounds necessary for crossing.

Actuation Indicator

Description

An actuation indicator is a light, a tone, a voice message, or a combination of audible and visual indicators that informs pedestrians that the button has been pressed and that their desire to cross has been communicated to the controller.

Audible indicators include a click, a beep, and the word "wait" when the pushbutton is pushed.

AR0071843

Additional Information

If there is a light, it is at or near the pushbutton and remains illuminated until the walk interval begins (see Figures 4-5 and 4-6). The light is dark during the "Walk" and flashing "Don't Walk" intervals. A light may be helpful to persons with low vision, but persons who are blind require a tone.

Figure 4-5. A red actuation light is near located just above and to the left of the pushbutton.

AR0071844

Figure 4-6. A red actuation indicator light is illuminated directly above the pushbutton.

When to Use

An audible indication is particularly useful to pedestrians who are blind when the pushbutton is a pressure-sensitive electromagnetic button that does not depress when pushed.

References

The MUTCD refers to a pilot light and specifies that the "pilot light or other means of indication installed with a pedestrian pushbutton shall not be illuminated until actuation. Once it is actuated, it shall remain illuminated until the pedestrian's green or WALKING PERSON (symbolizing WALK) signal indication is displayed" (*1*, 4E.08).

Activation indicators are not mentioned in the Draft PROWAG.

Use by Pedestrians Who Are Blind or Who Have Low Vision

The indicator assures all pedestrians that the device is working, thereby encouraging pedestrians to wait until the onset of the "Walk" signal.

AR0071845

Extended Button Press

Description

Extended button press is an option that activates additional accessibility features. The pushbutton must be pushed and held for more than 1 s to activate the features.

Other names for this feature (as listed in manufacturers' literature) include:

- Button activated tutor (BAT), and
- Extended push.

Additional Information

Possible features called by the extended button press include:

- Pushbutton information message,
- Audible beaconing, and
- An extended crossing time.

Any or all of these features could be called by pressing and holding the same button used by all pedestrians.

Recent research (see Appendix C) has standardized the length of the button press at 1 s or longer. Some devices have previously been installed with a 3-s press, but 1 s has been found to be adequate.

When to Use

An extended button press should be used whenever there are optional additional features provided at a crossing that should be available "on request."

References

The Draft PROWAG permits an extended button press to activate additional features (2, R306.3.4 Optional Features).

The MUTCD states that "the audible tone(s) may be made louder (up to a maximum of 89 dBA) by holding down the pushbutton for a minimum of 3 seconds" (1, 4E.09). Draft language changing the minimum length to 1 s has been approved by the NCUTCD and is expected to appear in the 2009 revision of the MUTCD.

AR0071846

Use by Pedestrians Who Are Blind or Who Have Low Vision

Use will depend on the features set called by the extended button press. (See the sections on audible beaconing and pushbutton information messages for further discussion of the use of those features.) The intent is to allow individuals who are blind to have some choice in the use of the accessible features and to provide optional features upon request.

As the extended button press feature becomes more common, pedestrians who are blind or visually impaired will be likely to hold the button longer at unfamiliar intersections in order to determine what features are installed before deciding how they want to cross the street.

The extended button press allows for installation of additional features that are activated only occasionally rather than every time the button is pressed, thus minimizing nuisance to neighbors. For example, individuals who are unfamiliar with an intersection can get intersection street name information (the pushbutton information message), but the message is not played every time the button is pressed. In addition, pedestrians can decide which accessible features they want to use at an intersection. For example, a user may want to use audible beaconing only at certain times and with certain traffic patterns.

Pushbutton Information Message

Description

A pushbutton information message is a recorded message that provides the name of the street and intersection with which that pushbutton is associated. It can also provide other information about the intersection signalization or geometry.

Manufacturers refer to this feature by different names, including:

- Voice or location.
- Informational message.
- Verbal message.
- Additional message, and
- Instructional/location message.

AR0071847

Additional Information

The pushbutton information message is provided from a speaker located at the pushbutton, and it sounds only during the flashing and steady "Don't Walk" intervals. The message is intended to be audible to pedestrians standing at the pushbutton location. Pedestrians may be able to access additional verbal messages by pressing the pushbutton for more than 1 s (see extended button press).

The pushbutton information message, in conjunction with the tactile arrow, can clarify street names and the crosswalk controlled and signaled by the device. This is particularly important if speech "Walk" messages are used. To be effective, the pushbutton information message must indicate which street is actuated by the pushbutton, and the arrow must point in the direction of travel on the described crosswalk.

A message that includes only the intersection street names, without clarifying which street is actuated by the pushbutton, provides ambiguous information. See recommendations below for pushbutton message wording.

A combination of information formats, including raised characters, braille, and audible information, will accommodate the most users.

Message Wording

Pushbutton information messages should be developed according to the following models (7) (see additional information in Appendix C):

- Model pushbutton message: "Wait to cross Howard at Grand."
- Model pushbutton message for intersections having an exclusive pedestrian phase with right turns on red prohibited: "Wait to cross Howard at Grand. Wait for red light for all vehicles."
- Model pushbutton message for intersections having an exclusive pedestrian phase with right turns on red permitted: "Wait to cross Howard at Grand. Wait for red light for all vehicles. Right turn on red permitted."
- Model pushbutton message for angled crosswalks: "Wait to cross Howard at Grand. Crosswalk angles right."

AR0071848

- Model pushbutton message for crosswalks to medians where a second button push is required: "Wait to cross Howard at Grand. Short Walk phase. Raised [or cut through] median with second pushbutton."
- Model pushbutton message for signalized crosswalks to splitter islands: "Wait to cross right turn lane to island for Howard and Grand crosswalks."
- Model pushbutton message for crosswalks at T-intersections: "Wait to cross Howard at Grand." (No different from standard intersection identification message.)

Use "street," "avenue," etc., where needed to avoid ambiguity.

Keep the word order illustrated in the above model messages.

Some model messages have complete sentences for best comprehension.

When to Use

Pushbutton information messages are necessary where speech "Walk" messages are used. If pedestrians do not know the name of the street they are crossing, the speech "Walk" message does not clarify which street is being signaled.

A pushbutton information message can be helpful in providing location information on demand to pedestrians who are blind or who have low vision.

References

The MUTCD states that "pushbuttons should clearly indicate which crosswalk signal is actuated by each pushbutton" [1, 4E.08].

The Draft PROWAG requires APSs to include street name information in braille or in audible format [2, R306.4.2]. Pushbutton information messages can provide information about the street name.

An APS pushbutton should not be used for landmark information or to inform pedestrians with visual impairments about detours or temporary traffic control, according to recent research [71].

Use by Pedestrians Who Are Blind or Who Have Low Vision

Pedestrians who are unfamiliar with an intersection or who wish to confirm their location will

AR0071849

- Locate and depress the pushbutton for 1 s or more.
- Stand beside the pushbutton speaker to listen to the pushbutton information message, and
- Push the button again, if desired, to hear the message repeated.

At a location with two pushbuttons on the same pole and with speech "Walk" messages, it is particularly important that users understand and recognize the street name.

Audible Beaconing

Description

Audible beaconing is the use of an audible signal in such a way that blind pedestrians can home in on a signal coming from the target corner as they cross the street.

Building a True Community defined an audible beacon as "a permanently fixed source emitting sound for directional orientation" (5). The MUTCD and Draft PROWAG include recommendations that the beaconing be called up by special actuation, rather than having the accessible pedestrian signal function in a louder mode all the time. The recommended form of special actuation is an extended button press (holding the pushbutton in for more than 1 s).

Additional Information

A majority of crosswalks require audible beaconing, in which the sound source provides directional orientation. Where audible beaconing is activated, the volume of the "Walk" indication and the subsequent locator tone during the called pedestrian phase is increased and may be operated in one of the following ways:

- Increased sound comes from all speakers for the crossing.
- A louder locator tone comes from the speaker at the far end of the crosswalk during the pedestrian phase.
- The louder audible "Walk" indication and louder locator tone are broadcast from an additional, pedestal-mounted speaker aimed at the center of the crosswalk.
- The audible "Walk" indication alternates back and forth from speakers at each end of the crosswalk.

AR0071850

Audible beaconing speakers must be oriented in line with the relevant crosswalk.

- If the speaker is not carefully oriented, the signal may give ambiguous information about which street has the "Walk" interval and ambiguous information for traveling straight across the street.
- Beaconing is enhanced by the presence of a locator tone that users can home in on as they approach the destination corner, island, or median having an accessible pushbutton.

See Chapter 6, Designing APS Installations, for additional recommendations regarding audible beaconing.

References

The Draft PROWAG does not specifically mention audible beaconing, but provides for optional features (2, R306.3.4).

The MUTCD states: "The audible tones(s) may be made louder (up to a maximum of 89 dBA) by holding down the pushbutton for a minimum of 3 seconds. The louder audible tone(s) may also alternate back and forth across the crosswalk, thus providing optimal directional information" (1, 4E.09).

Revisions have been made in meetings of NCUTCD and are expected to be included in the 2009 revision of the MUTCD. Recommendations are that the beaconing be called up by special actuation, rather than the APS functioning in the louder mode all the time. The recommended form of special actuation is an extended button press (holding the pushbutton in for more than 1 s).

When to Use

Not all crosswalks at an intersection need beaconing. Audible beaconing can actually cause confusion if used at all crosswalks at some intersections. Audible beaconing is probably not appropriate at locations with channelized turns or split phasing due to the possibility of the signal being heard at the wrong crosswalk.

Audible beaconing should only be considered at the following locations:

- Crosswalks longer than 70 ft, unless they are divided by a median that has another accessible pedestrian signal with a locator tone.

AR0071851

- Crosswalks that are skewed.
- Intersections with irregular geometry, such as five or more legs.
- Crosswalks where audible beaconing is requested by an individual with visual disabilities.
- Other locations where a study indicates audible beaconing would be beneficial

Use by Pedestrians Who Are Blind or Who Have Low Vision

Pedestrians may be able to home in on the signal to assist with maintaining alignment while crossing the street.

Alert Tone

Description

An alert tone is a very brief burst of high frequency sound at the beginning of the audible "Walk" indication, which rapidly decays to the frequency of the "Walk" tone. It is intended to alert pedestrians to the beginning of the walk interval.

Additional Information

An alert tone may be useful if the "Walk" tone is not easily audible in some traffic conditions. As used in Australia, the alert tone is 14 dB above the ambient sound level

Australian engineers believe the alert tone encourages faster initiation of crossing, which decreases the likelihood of a conflict between pedestrians and turning vehicles. Also, when crossings are initiated faster, pedestrians exit the intersection faster.

When to Use

In locations with high ambient noise levels, an alert tone may be particularly helpful in alerting pedestrians to the start of a speech "Walk" message or to a tone "Walk" indication.

Reference

The alert tone is not mentioned in the Draft PROWAG or the MUTCD.

AR0071852

Use by Pedestrians Who Are Blind or Who Have Low Vision

The alert tone gets the attention of pedestrians at the beginning of the "Walk" indication.

Tactile Map

Description

A tactile map is a raised schematic map showing what will be encountered as the pedestrian negotiates the crosswalk controlled by that pushbutton (figure 4-7). This feature is currently available from one manufacturer.

Additional Information

Map information may include

- Number of lanes to be crossed,
- Whether the lanes are vehicular or bicycle lanes or trolley tracks,
- Which direction traffic will be coming from in each lane, and
- Whether there is a median.

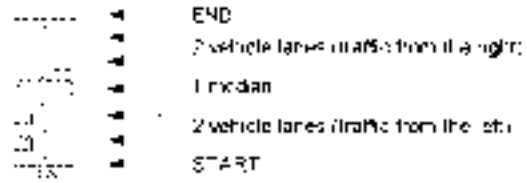

Figure 4-7. This tactile map from a Swedish APS is read from the bottom to the top and indicates lanes as they would be encountered by pedestrians.

Each map is made up of changeable "slugs" inserted into the side of the pushbutton housing. It must be set up for each crosswalk or an intersection. The map information is for the crosswalk controlled by that signal only, rather than the entire intersection.

The symbols used are not standardized in the United States, but one manufacturer has developed a standard set that is used in other countries.

AR0071853

When to Use

A map of the crosswalk may be particularly useful at intersections with medians or islands.

References

The Draft PROWAG states that "where provided, graphic indication of the crosswalk shall be tactile" (2, R306.4.3).

Use by Pedestrians Who Are Blind or Who Have Low Vision

Pedestrians unfamiliar with the intersection or crossing locate the locator tone and locate the pushbutton and map. Standing facing the crossing, they "read" the map and they learn how wide the street is and what they will encounter in the crosswalk before they begin to cross. The map also indicates whether the pedestrian signal controlled by that pushbutton provides a crossing time for the entire crossing or only to a median or island. If the signal is just for a portion of the street, the map will show the crossing ending on a median, indicating that there is another crossing, either controlled or uncontrolled.

Braille Signs

Description

Braille signs should indicate the name of the street that the pushbutton controls on the sign above the pushbutton housing (see Figure 4-8).

AR0071854

Figure 4-8. A braille street name is included on a sign above the pushbutton. The street name is also provided in high contrast large print (but not raised print) at this location.

Additional Information

Although braille signs may be helpful to some pedestrians who are blind, the signs and braille lettering may not be readily found by many blind pedestrians without orientation to the device.

Many individuals who are blind do not read braille; however, those who do would prefer braille information that confirms which street is controlled by the pushbutton

The street name on the device should be the name of the street whose crosswalk is controlled by the pushbutton.

A combination of information formats, including raised characters, braille, and audible information, will accommodate the most users.

References

The MUTCD states: "Name of the street…may also be provided in accessible format: (*1*, 4E.08).

The Draft PROWAG requires street name information in braille or in an audible format. (*2*, R306.4.2)

AR0071855

Use by Pedestrians Who Are Blind or Who Have Low Vision

A pedestrian who is familiar with the installation of braille signs but unfamiliar with a particular intersection would search the sign for braille characters that would indicate or confirm the name of the street whose crosswalk is controlled by the pushbutton.

Braille signs may be helpful to individuals who are deaf-blind and who would not benefit from audible pushbutton information messages.

Raised Print or Large Print Signs

Description

The name of the street that the pushbutton controls is printed in high contrast raised print or large print on the sign above the pushbutton housing or on the pole (see Figure 4-9).

Figure 4-9. Example from Australia: a sign with raised print and braille characters is mounted vertically on a round pole to the right of an accessible pedestrian signal. The sign reads "GEORGE ST. 275-339R."

Additional Information

Some individuals who do not read braille may be able to read large print or raised print. However, raised print must be large enough to be read with fingertips. Imprinting the street name in the area available can be problematic.

The street name on the device should be the name of the street whose crosswalk is controlled by the pushbutton.

A combination of information formats, including raised characters, braille characters, and audible information, will accommodate the most users.

AR0071856

When to Use

Raised print signs may be particularly useful in areas with large numbers of senior citizens.

References

The MUTCD states: "Name of the street ... may also be provided in accessible format (cf. 4E.08)."

The Draft PROWAG provides specifications for raised characters on signs (cf. R409.3). However, at this time, directional information and signs are only required to comply with Section R409.3 (Braille) or provide street name information in audible format.

Use by Pedestrians Who Are Blind or Who Have Low Vision

A pedestrian who is familiar with the installation of raised or large print but unfamiliar with the particular intersection would search the sign to learn or confirm the name of the street that is controlled by the pushbutton.

Passive Pedestrian Detection

Description

Passive pedestrian detection is sometimes used to call the pedestrian phase, and it can extend the clearance interval. The authors are not aware of U.S. installations of passive detection that include audible signals as well as visual signals, but the combination of passive pedestrian detection and audible signals is being used in the United Kingdom, Australia, New Zealand, and the Netherlands (see Figures 4-10 and 4-11).

One available APS device provides the option of triggering the pushbutton locator tone through sensors (piezoelectric, infrared, or microwave) when a pedestrian enters the detection zone. If a pedestrian is not detected, the locator tone is silent.

Additional Information

An example of passive pedestrian detection technology is the "pedestrian user-friendly intelligent" (PUFFIN) crossing in use in England since 1993 (*18*). PUFFIN crossings employ pedestrian detectors for both the pedestrian waiting area and the

AR0071857

crosswalk. Waiting area detectors consist of pressure mats with piezoelectric sensors, infrared or microwave detectors mounted on the signal pole, or video cameras serving remote sensor software.

Figure 4-10. Detail of an APS at midblock crossing in Australia. Sign reads "Push button then wait on red mat."

Figure 4-11. This midblock crossing has sensors in a specific area of the sidewalk. A red mat area is labeled "Push button then wait here."

AR0071858

References

The MUTCD states: "Accessible pedestrian signal detectors may be pushbuttons or passive detection devices" (7–4b.09).

Use by Pedestrians Who Are Blind or Who Have Low Vision

While passive detection of pedestrians for activating the locator tone may be helpful in reducing noise near the intersections, pedestrians who are blind may not approach the crosswalk or intersection within the detection zone. They also may not know about it unless they are familiar with the intersection.

Pedestrians who are blind may also not stand or travel in the exact waiting or crossing area to trigger passive detection for the "Walk" signal or to extend the clearance interval.

Remote Activation

Description

At least one manufacturer offers the option of a handheld pushbutton that sends a message to the APS to call the pedestrian phase. It operates on a limited range radiofrequency (such as used with a garage door opener or car door unlocking device) within 100 ft of the signal.

Additional information

The manufacturer's information does not clarify how the device would differentiate between locations at the intersection or if using the device would place a pedestrian call for all crossings of the intersection.

Reference

Handheld pushbuttons are not mentioned in the MUTCD or the Draft PROWAG.

Use by Pedestrians Who Are Blind or Who Have Low Vision

Pedestrians could place a pedestrian call as they approach the intersection, without having to travel to the pushbutton location. This would make it unnecessary to deviate from the travel path and may be particularly advantageous for wheelchair users.

AR0071859

Tones or Audible Messages During Clearance Interval

Description

A tone or other message sounds during the pedestrian clearance interval at a different rate or tone or with a different speech message than the "Walk" indication or push button locator tone. This can include audible pedestrian countdowns.

APS devices typically revert to the push button locator tone during the flashing and steady "Don't Walk" interval. That is not considered to be a clearance interval indication/tone.

Additional Information

Clearance interval information is sometimes provided by accessible pedestrian signals in Japan and in some parts of Canada

- In Japan, a variety of alternatives are available, including a European emergency vehicle "hee haw" sound and various melodies.
- In Canada, clearance interval information may be provided by a tone that repeats at a faster rate than the "Walk" signal. For example, if the "Walk" signal is a "cuckoo" sounded at 1 time per second, during the clearance interval the "cuckoo" is sounded 2 times per second.

The advantage of tones or audible messages during the clearance interval is that pedestrians who are visually impaired and who have begun to cross the street know that the clearance interval prevails.

Disadvantages include the following

- The clearance interval sound might be mistaken for the "Walk" signal by persons who approach during the clearance interval, leading them to begin crossing during the flashing "Don't Walk" interval
- Pedestrians who are blind generally want to be able to hear traffic while crossing the street. The clearance tone or audible message could distract them from hearing traffic or mask the sound of traffic. The continuous nature of a speech countdown has more potential for masking other sounds than the shorter duration of the push button locator tone.

AR0071860

- Additional cognitive processing may be required to interpret a verbal clearance interval message, such as an audible countdown.
- For a blind person, knowing the remaining length of the flashing "Don't Walk" signal is not useful since they do not have information about the remaining distance to the destination curb.

References

The MUTCD states that the accessible pedestrian signal shall indicate the walk interval and that the word "wait" must precede any message during the clearance interval (FHWA, 2000).

Use by Pedestrians Who Are Blind or Who Have Low Vision

This feature is not currently used in the United States and is not recommended due to the potential confusion of the walk interval with the clearance interval.

As noted in the disadvantages listed above, pedestrian countdown information is unlikely to provide any advantage to the individual who is blind or visually impaired.

Integrated Information Devices

Description

Personal pagers, cellular telephones, and other mobile digital communication devices could potentially receive transmitted pedestrian signal messages. The increased use of these devices suggests that there may be other technologies and methods to provide information to pedestrians and for pedestrians to call the walk interval in the future.

Development is ongoing on an integrated handheld computer type device to provide geographic global positioning system (GPS), intersection layout, and real time signal information to pedestrians who are blind. Communication of a pedestrian call is also being investigated. Such technology is, however, in the very early stages of development.

AR0071861

CHAPTER 5

When to Install Accessible Pedestrian Signals

Where Are Accessible Pedestrian Signals Required? 2

Prioritizing APS Installations 4

APS Prioritization Tool 6

AR0071862

This chapter provides guidance on when and where accessible pedestrian signals should be installed. It contains information on requirements for installation and a tool for prioritizing APS installations.

Where Are Accessible Pedestrian Signals Required?

Current Practice

Currently in the United States, APSs are typically installed upon request along a specific route of travel for a particular individual or group of individuals who are blind or visually impaired. Various states and municipalities have established policies on installation of APS devices, some of which may not be in accordance with ADA requirements.

Section 504 and ADA Requirements

As discussed in Chapter 1, Section 504 of the Rehabilitation Act has since 1973 required nondiscrimination in all programs, services, and activities receiving federal financial assistance. The ADA requirements for state and local governments extend and increase the requirements in the Rehabilitation Act, requiring newly constructed or altered public facilities to be accessible, regardless of the funding source.

Effective Communication

The ADA requirement for effective communication was discussed in Chapter 1. A recent publication by the Federal Highway Administration specifically mentions accessible pedestrian signals as a means to communicate information:

> Implementing regulations for Title II of the ADA, which covers State and local governments, also address "communications and information access," requiring "effective communications" with persons with disabilities. In the sidewalk/street crossing environment, this would include accessible pedestrian signals, markings and signage. [19]

Where there are pedestrian signals, this may require the installation of accessible pedestrians signals to provide access to signal information for pedestrians who are blind or who have low vision.

AR0071863

ADA Standards for Public Rights-of-Way

As discussed in Chapter 1, ADA standards that specifically address the public rights-of-way have not yet been finalized. The Draft PROWAG was published for comment on June 17, 2002, and was revised on November 23, 2005. These minimum technical standards would require accessible pedestrian signals at all newly constructed or reconstructed intersections where visual pedestrian signals are installed.

Accessibility Still Required

ADA accessibility guidelines are minimum guidelines for new construction or reconstruction, and they must be applied to the maximum extent feasible in alterations, renovations, or additions.

While the ADA does not require going back and reconstructing all intersections and locations, it does require improving accessibility when work is performed at a location. When an intersection is being completely reconstructed, the expectation is that new construction guidelines can and will be met. (See the section in Chapter 6 on new construction for a description of the elements covered by the Draft PROWAG.)

When certain elements of an intersection are being upgraded, the accessibility features should also be upgraded to new construction standards to "the maximum extent feasible." The "maximum extent feasible" is explained in the Title II regulations issued by the Department of Justice.

Self-Evaluation and Transition Plans

When the ADA regulations were published in 1992, the Department of Justice extended the Section 504 requirement for transition plans and required a "self evaluation" by all public entities (28 C.F.R. Part 35.105, Self Evaluation). The goal was that each service, facility, and activity of the state or local government, when viewed in its entirety, would eventually be accessible to individuals with disabilities. If structural changes are required to existing facilities to provide program accessibility, a transition plan is required; the elements of a transition plan are discussed in 28 C.F.R., Part 35.150(d). A summary from the FHWA Office of Civil Rights provides a short description of requirements:

> A public entity may not deny the benefits of its programs, activities, and services to persons with disabilities because existing facilities are inaccessible.

AR0071864

- State and local governments of 50 employees or more were required to prepare a self-evaluation plan to identify program access issues (Rehabilitation Act (1973), section 504).
- From this, a transition plan was to be developed to modify inaccessible services, policies and practices. This includes removing barriers and inaccessible features.
- Transition plan work was to have been completed by January 1995.
- If work was not completed by that date, these entities are out of compliance.
- Many states and localities are out of compliance and this makes them more susceptible to lawsuits.
- Ways of complying with the law are to have an ongoing transition plan for improving existing facilities and providing a citizen's request program for accessible parking, curb ramps, Accessible Pedestrian Signals (APS) and removing sidewalk and street crossing barriers. (20)

APSs in Transition Plans

Some municipalities have considered the addition of APSs at intersections part of their ADA transition plan, but many have not. As part of their compliance with ADA, municipalities may need to establish a plan to prioritize and make decisions about installation of APS at "unaltered" intersections

- Where a request for APS is received, and
- Where there is insufficient information for street crossing using non-visual clues

Prioritizing APS Installations

The information regarding prioritizing intersections for installation of APSs is not intended to apply to new or reconstructed intersections. In new construction or reconstruction projects, it is appropriate to consider the Draft PROWAG as the best guidance available at this time (20). In new construction, accessible pedestrian signals should be installed wherever pedestrian signals are installed

Where Are Accessible Pedestrian Signals Needed?

When considering and prioritizing crossings and intersections for retrofit with accessible pedestrian signals, consideration needs to be given to the information available to pedestrians

AR0071865

who are blind and to which crossings are in greater need of an APS. A number of factors enter into that decision.

MUTCD Guidance

The *MUTCD* recommends the following:

> The installation of accessible pedestrian signals at signalized locations should be based on an engineering study, which should consider the following factors:
>
> - Potential demand for accessible pedestrian signals;
> - A request for accessible pedestrian signals;
> - Traffic volumes during times when pedestrians might be present, including periods of low traffic volumes or high turn-on-red volumes;
> - The complexity of traffic signal phasing; and
> - The complexity of intersection geometry. (*Id.*, 4E.06.)

Additional Considerations

Locations that may need accessible pedestrian signals include those with:

- Vehicular and/or pedestrian actuation.
- Very wide crossings.
- Crossings of major streets where minor streets have minimal or intermittent traffic (an APS may be needed for crossing the major street).
- T-shaped intersections.
- Nonperpendicular or skewed pedestrian crossings.
- Low volumes of through vehicles.
- High volumes of turning vehicles.
- Split phase signal timing.
- Exclusive pedestrian phasing, especially where right turn on red is permitted, and
- Leading pedestrian intervals.

Where these conditions occur, it may be impossible for pedestrians who are visually impaired or blind to determine the onset of the "Walk" interval by listening for the onset of parallel traffic. It would also be difficult to obtain usable orientation and directional information about the

AR0071866

crossing from the cues that are available. Too little traffic is as great a problem for pedestrians who are blind as is too much traffic. In the absence of an APS, blind pedestrians must be able to hear a surge of traffic parallel to their direction of travel in order to know when the walk interval begins.

Advisory Committee Involvement

Some jurisdictions may wish to set up a process where ratings are reviewed by an advisory committee of stakeholders, including blind citizens, O&M specialists, and transportation professionals, who can assist the traffic engineering department in the study process.

In many of the current systems used, crossings with the highest number of points are generally considered the highest priority. However, date of request, plans for other construction at the intersection, and other local issues may affect priority of installations.

APS Prioritization Tool

As discussed previously, prioritizing existing intersections for retrofit with accessible pedestrian signals should be done either in response to requests or when updating an ADA transition plan. Prioritization schemes should place only limited emphasis on factors related to frequency or likelihood of use by blind pedestrians. The information provided by an accessible pedestrian signal may be necessary at any time, along any route, by residents, occasional travelers, and visitors. Intersections having high pedestrian volumes are likely to have pedestrians whose vision is sufficiently impaired so as to have difficulty using conventional pedestrian signals.

Of greater importance in prioritizing crosswalks are factors related to determining whether sufficient acoustic information exists — at all times — to permit safe crossing at a particular intersection or crosswalk.

Past Rating Scales

Several rating scales have been developed in cities across the country, some of which have been utilized for more than 20 years. These rating scales have been used in different ways in different cities. In some locations, they were developed as warranting schemes, and APSs were installed only if the intersection met a required minimum number of points. Other cities used rating scales only to aid in prioritization.

AR0071867

Generally, points are assigned to specific intersection features, as well as proximity to services for all pedestrians (such as transit, governmental offices, or shopping). The cities of San Diego, Los Angeles, and Portland and the state of Maryland have used point rating scales as part of their process.

The parties responsible for rating the intersections vary according to the locality. In San Diego, a traffic engineer and an O&M specialist rate separate aspects of the intersections. In Los Angeles and Portland, the rating is conducted jointly by an O&M specialist and a traffic engineering department staff member. In Maryland, the DOT engineer determines the rating.

APS Prioritization Tool Overview

The APS Prioritization Tool was developed as part of this research (*21*). The tool provides traffic engineers and other technical practitioners with the means to take observable characteristics of a pedestrian crosswalk and produce a rating that reflects the relative crossing difficulty for pedestrians who are blind, thus enabling prioritization of crosswalks for installation of accessible pedestrian signals. Practitioners can use this tool to determine these ratings for each crosswalk. The crosswalks with the highest ratings will have the highest priority for APS installation. While an overview of the tool and an example of use are shown in this chapter, the full instruction manual and blank Prioritization Tool forms can be found in Appendix D.

The Prioritization Tool calculates the prioritization score for a crosswalk based on characteristics of the crosswalk itself and the intersection at which it is located. Characteristics that cause a crosswalk to have a greater need for APSs are assigned higher point values.

Intersection characteristics include the following:

- Number of intersection legs.
- Signal design (e.g., pretimed, actuated).
- Proximity of transit facilities.
- Proximity to facilities providing services for people who are blind or visually impaired, and
- Proximity to major pedestrian attractors (e.g., sports arena, downtown area).

Crosswalk characteristics include the following:

- Crosswalk width.
- Street speed limit.

AR0071868

- Approach and crosswalk geometrics (e.g., skewed crosswalks, large curb radii, islands or medians).
- Pedestrian signal control (e.g., pushbutton actuation required for "Walk" signal, leading pedestrian interval).
- Vehicle signal control (e.g., right turn on red, leading protected left turn phase).
- Off-peak traffic presence.
- Distance to alternative APS crosswalk.
- Pedestrian pushbutton location, and
- Requests for accessible pedestrian signals.

APS Prioritization Tool Validation Process

Although prior rating scales included many relevant factors, the point values assigned to these factors were not thoroughly tested in a field validation. The APS Prioritization Tool underwent validation through comparison with expert opinion from O&M specialists and blind pedestrians. The steps in producing and validating the tool were as follows:

1. The research team selected factors (e.g., crosswalk width, signal design) to include in the tool. Factors that made crossing more difficult for blind pedestrians were given higher point values. This produced the initial form of the prioritization tool.
2. The team selected crosswalks in three cities (Cambridge, MA; Tucson, AZ; and Charlotte, NC). Each crosswalk was rated with the initial prioritization tool. The same crosswalks were then rated by O&M specialists and blind travelers, who ranked them in order of difficulty for blind pedestrians.
3. The two sets of rankings were compared. The places where the prioritization tool results differed from the expert results showed where the tool's point values needed to be raised or lowered.

This process produced a tool that was validated by comparison to expert opinion in real-world situations.

AR0071869

Example of the APS Prioritization Tool

The following example shows how the Prioritization Tool would be used to score a crosswalk that would be relatively difficult (an additional example of a relatively easy crosswalk is included in Appendix D).

This example rates a crosswalk at a large intersection of a major arterial and a minor side street. The crosswalk of interest is on the east leg (highlighted in Figure 5-1; shown at street level in Figure 5-2).

Figure 5-1. Overhead view of example crosswalk (reprinted from Google Earth © 2005).

Figure 5-2. Street view of example crosswalk.

The first worksheet deals with the intersection characteristics (Figure 5-3). Points were given for the following reasons:

AR0071870

- The signal is actuated but also uses split phasing, which is a higher point value than actuation, so the intersection gets six points for split phasing. Split phasing is a less commonly used signal design, and the typically heavy turning movements make it harder to effectively use the traffic movement cue to determine signal changes. Accessible pedestrian signals would provide a definitive cue to the onset of the walk interval for pedestrians who are unable to see the pedestrian signal.
- There is a single bus route on the main street, which earns another point. The presence of public transit increases the likelihood that visually impaired pedestrians will travel at this intersection, thereby increasing the priority for an APS.

There are no facilities specifically providing services for individuals who are visually impaired or major pedestrian attractors within 0.5 mi, so no points are given for those categories. The total intersection score is seven points.

AR0071871

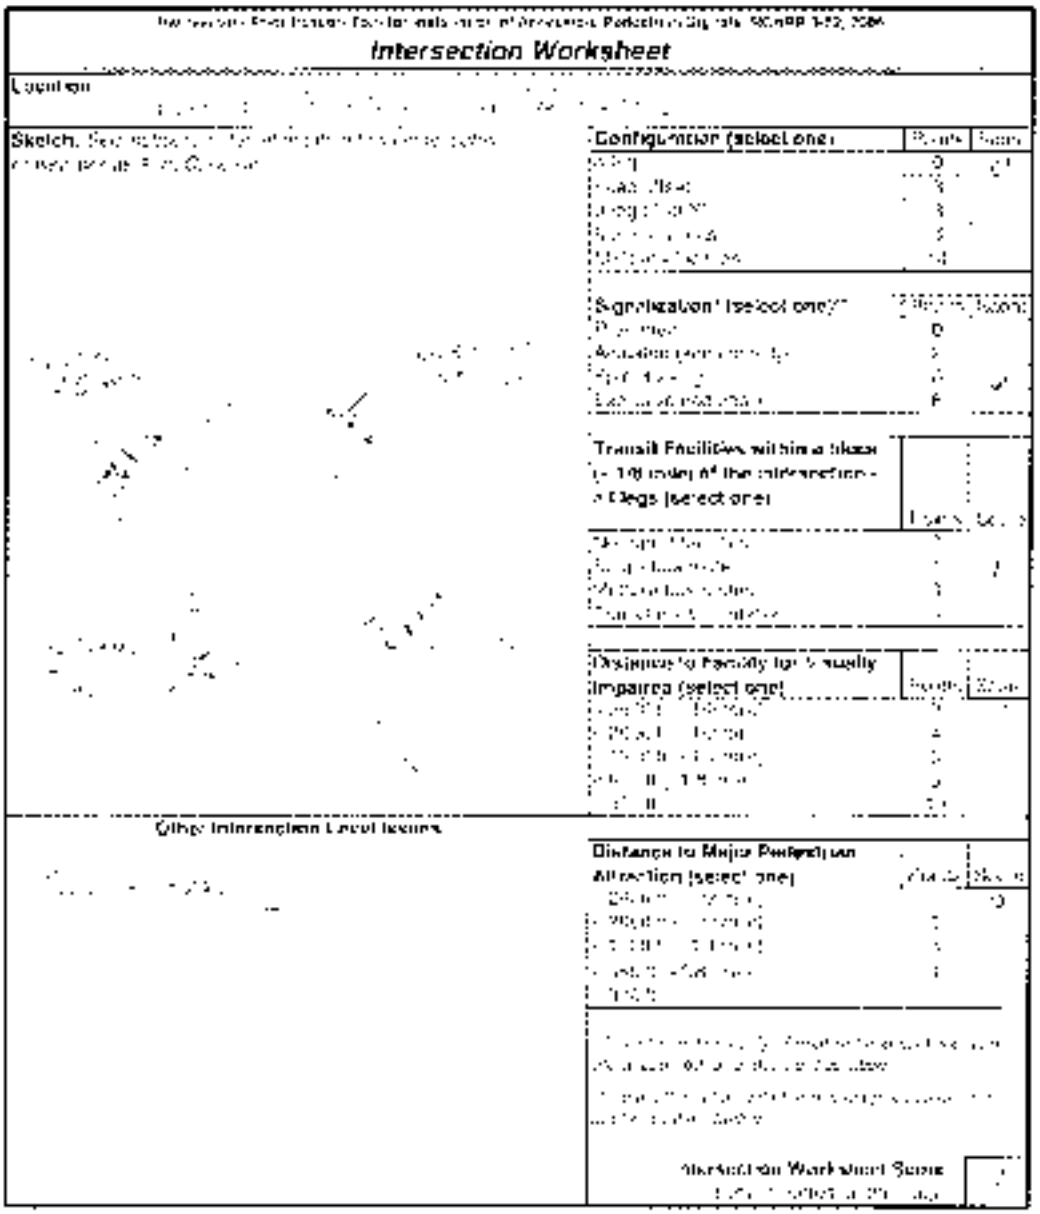

Figure 5-3. Intersection worksheet for example crosswalk.

The second worksheet deals with the crosswalk (Figure 5-4). Points were given for the following reasons:

- The crosswalk width of 120 ft and the speed limit of 45 mph on the main street earn the crosswalk four and five points, respectively. Wider crosswalks and faster traffic increase the

AR0071872

crossing difficulty and risk to visually impaired pedestrians; an APS may help expedite their crossing.

- The curb radius on one of the corners bordering the crosswalk is greater than 25 ft, so one point is given in the geometrics category. Larger curb radii create orientation problems for visually impaired pedestrians that may be decreased with the use of an APS.
- The signal requires pushbutton activation for the pedestrian "Walk" signal, so four points are given for the pedestrian signalization category. An APS locator tone would help a pedestrian who is visually impaired recognize that there is a pushbutton at that crosswalk and help in locating the pushbutton.
- Right turn on red (RTOR) is permitted at the crosswalk, so two points are given in the vehicle signal control category. RTOR may produce misleading traffic cues, and an APS would provide a definitive cue of the appropriate time to cross.
- During off-peak hours, there was enough parallel traffic to provide audible cues (two or more vehicles per cycle) about 75% of the time. This earns two points.
- There is not an alternative APS crosswalk within 0.5 mi, so four points are given toward the prioritization of an APS installation at this crosswalk.
- The pedestrian pushbutton at one end of the crosswalk is located more than 10 ft from the curb, which is contrary to the recommendations in Section 4E.09 of the MUTCD. Three points are given for this drawback, since a correctly installed APS would position the pushbutton closer to the curb, which facilitates orientation alignment for blind and visually impaired pedestrians.

The crosswalk worksheet score is 25 points. When added to the intersection score of 7 points, this yields a total crosswalk score of 32 points. In practice, this score of 32 points would be compared with other crosswalks under consideration for APS installations. Those crosswalks with the highest scores would have the highest priority for installation of accessible pedestrian signals.

Summary of Recommended Features and Installation Practice 57

AR0071875

Accessible pedestrian signal installations require engineering drawings and detailed specifications. Complex intersections require complex decisions and engineering judgment. A number of factors must be considered in designing the installation. This chapter contains guidance on how to design an APS installation that works well for the user and the environment.

Principles

General principles in the decision to install an APS include the following:

- Provide pedestrian signal information to those who cannot see the pedestrian signal head across the street.
- Provide information to pedestrians about the presence and location of pushbuttons, if pressing a button is required to actuate pedestrian timing.
- Provide unambiguous information about the walk indication and which crossing is being signaled.
- Use audible beaconing only where necessary.
  - Put as little additional sound in the environment as possible.
  - Avoid disturbing neighbors.
  - Allow pedestrians who are blind or visually impaired to hear the traffic sounds, as well as the APS.

Features

In many cases, a municipality or state will wish to purchase one style of APS device for all installations. However, there are engineering and design decisions in the installation of an APS, as well as in the choice of equipment.

More latitude in specifications may be applied when the APS is an addition to an existing intersection. The ADA typically requires new construction to meet ADA guidelines, while it requires additions or alterations to existing intersections to meet the guidelines to the maximum extent feasible. Understanding the basic considerations is necessary to designing usable installations in both new and retrofit situations.

In new construction or reconstruction, where the APS can be located consistently, it is likely possible to use standardized device features and mounting locations for all installations. When retrofitting intersections with an APS, it may be necessary to use different features to provide

AR0071876

unambiguous information at different intersections. (See Chapter 4 for a listing and description of APS features.)

Device Location

Device location is critical to the functioning of the APS and needs to be planned. The APS may provide ambiguous information if located incorrectly, just as pedestrian or vehicular signal heads can provide ambiguous, or even dangerous, information if located incorrectly. Engineering judgment is required to determine the best way to install APSs at a given intersection and crossing. Differences in curb radius, width of right-of-way, presence of a parkway (grass buffer), curb ramp design and location, and existing infrastructure on corners make each installation different.

Whenever possible, two poles should be installed for APS speakers to be located close to the pedestrian departure location and crosswalk, as described in detail below. Recommendations about location and the walk indication have been updated as a result of recent research. (See Appendix C for research results.)

Optimal APS Location

The optimal location for a pushbutton-integrated APS is between the edge of the crosswalk line (extended) farthest from the center of the intersection and the side of the curb ramp. The APS should be between 1.5 ft and 6 ft from the edge of the curb, shoulder, or pavement, but no further than 10 ft from the edge of the curb, shoulder, or pavement. The control face and tactile arrow should be carefully aligned with the direction of travel on the associated crosswalk. In order to provide wheelchair users with access to the pushbutton, the pushbutton must be located adjacent to a level, all-weather surface.

AR0071877

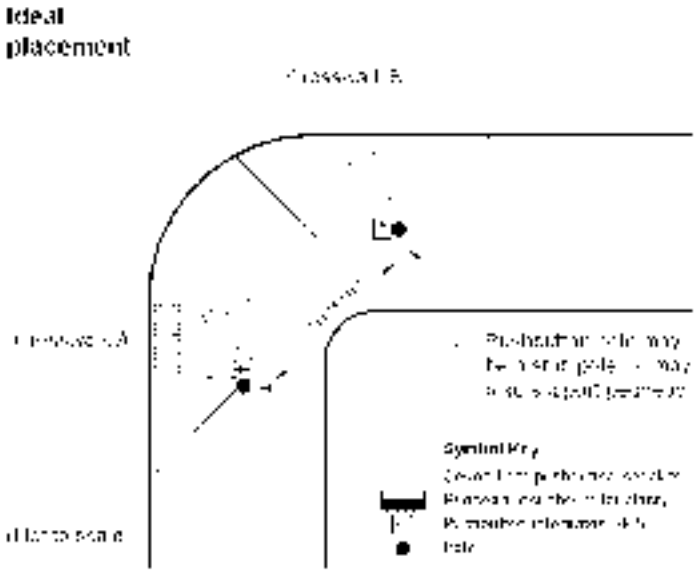

Figure 6-1. Optimal location of pushbutton-integrated APS (two pushbuttons on one corner, mounted on two separated poles; rapid tick "Walk" indication).

The pushbutton and speakers for the APS need to be less than 5 ft from the edge of the crosswalk line (extended) farthest from the center of the intersection. At corners of signalized locations where two pedestrian pushbuttons are provided, the pushbuttons should be separated by a distance of at least 10 ft (see Figure 6-1). A rapid tick "Walk" indication is recommended for installations following these guidelines for location.

When pushbuttons are precisely and consistently located in this way, identification of which crossing is being signaled can be based solely on which pushbutton the "Walk" signal comes from. There is no need to remember a code (such as cuckoo for a north-south crossing and rapid tick for an east-west crossing) or to understand speech messages. Figure 6-2 provides examples of pole arrangements that meet the requirements for corners having different geometries. Figure 6-3 demonstrates acceptable APS placement at a corner with an improper ramp design.

APS Installation Where Two Separated Poles Are Not Possible

Where the only work being done is the addition of APSs to existing poles, or where it is technically infeasible to install two APS devices on separate poles because of limited right-of-way, topography, or the location of other essential equipment, it may be necessary to install two APSs on a single pole. However, the APS features required for this situation are different from those where accessible pedestrian signals and their associated sounds are separated.

AR0071880

When it is necessary to mount two pushbuttons on one pole without a separation of 10 ft or more.

- Speech "Walk" messages, rather than tones, are recommended, and
- Pushbutton information messages identifying the intersection and the street to be crossed are needed to ensure users know the street name to listen for in the "Walk" message.

Research in Portland demonstrated that the pedestrian's identification of which crosswalk had the "Walk" signal was significantly more accurate when the APS provided speech "Walk" signals from both signals than when the APS used two tones—cuckoo and signid tick (see Appendix C).

Need for Audible Beaconing

Audible beaconing is the use of an audible signal in such a way that blind pedestrians can home in on the signal from the opposite corner to aid in alignment during the crossing. The need for audible beaconing may affect the type of device to be installed and the installation location. Not all devices are capable of providing audible beaconing. The need for beaconing should be evaluated and considered early in the design of the APS installation. A minority of crossings is likely to require beaconing; not all crosswalks at an intersection may need beaconing. Beaconing may actually cause confusion if used at some locations. (See Chapter 4 for suggested criteria for audible beaconing.)

Signal Phasing Considerations

Introduction

Some signalization schemes, such as exclusive pedestrian phasing and split phasing, need careful adjustment and consideration to avoid confusing pedestrians who are blind. Crossings with pedestrian signals that rest in "Walk" may need special treatment. These issues must be considered in the design phase in determining type of device and location. In addition, careful adjustment of APS volume after installation is essential.

Split Phasing

Split phasing is a signal design that gives a green phase for all vehicle movements in one direction (e.g., northbound through, right, and left), followed by a phase for all movements in the

AR0071881

opposite direction (e.g., southbound through, right, and left). At a location with split phasing, an APS that can be heard from the parallel crosswalk provides incorrect, confusing, and dangerous information. It is critical that the "Walk" indication be audible only from the ends of the crosswalk being signaled so that pedestrians at other crosswalks do not begin to cross at a time when vehicles are turning across their path in a protected vehicular movement.

This can be accomplished by locating the APS very close to the crossing location so pedestrians can readily determine which signal applies to their crosswalk. Careful adjustment of the APS volume at all times of the day and night, as well as careful aiming of the speakers, is critical. Audible beaconing may not be appropriate at locations with split phasing due to the possibility of confusion of signals.

Possible strategies include the following:

- An APS mounted at the pushbutton location with volume carefully set to be heard only at the crossing location (see photos and further discussion in Chapter 7).
- A pushbutton that actuates the audible "Walk" indication only for the crosswalk that receives the pedestrian call.

Actuated Turn Phasing

In some timing plans for actuated turn phasing, traffic in one direction may be held longer to allow the opposing traffic to complete left turning movements. In many such cases, the pedestrian phases on parallel crosswalks begin at different times. An APS that can be heard from the parallel crosswalk provides incorrect, confusing, and dangerous information and could mislead pedestrians into crossing when vehicles are turning across their path in a protected vehicular movement.

Possible strategies include the following:

- An APS with speakers mounted at the pushbutton or pedestrian signal head, with carefully set volume and very careful placement and adjustment, to be heard only at the crossing location (see photos and discussion in Chapter 7).
- A pushbutton that actuates an audible "Walk" indication only for the crosswalk that receives the pedestrian call.
- Having the audible "Walk" indication sound only during that part of the "Walk" interval that is common to both of the parallel lanes, provided that the pedestrian clearance time remains

AR0071882

long enough to enable pedestrians crossing with audible cues to complete their crossing before the end of the clearance interval.

Exclusive Pedestrian Phasing

Exclusive pedestrian phasing (also known as scramble phasing) is a signal phase in which all vehicle movements are stopped and all pedestrian crosswalks are given the "Walk" signal. This makes it difficult for pedestrians who are blind or visually impaired to recognize the onset of the walk interval, particularly at locations where right turns on red are permitted. In addition, there is no vehicle flow to aid in crossing straight to the destination corner.

In some locations, pedhead mounted accessible pedestrian signals have been installed on all corners, and two different sounds for different crossing directions have been set to sound during the "Walk" indication. This is not recommended, as it is confusing to all pedestrians, and the assumption of pedestrians who are blind may be that the signals are broken.

In a pilot project in Morgantown, West Virginia, a pushbutton information message, followed by a "Walk" tone, was used in an intersection with exclusive pedestrian phasing, in association with a "Walk" tone. The pushbutton information message was recorded after the following phrase: "Want to cross Howard at Grand. Wait for red light for all vehicles. Right turn on red permitted." During the walk interval, all pushbutton integrated devices at the intersection emit the same, rapidly repeating tone. Only one APS may be installed on some corners, with a modified tactile arrow installed on the top of the device, with arrows pointing in two directions. (See the Morgantown case study in Chapter 9.)

Rest in "Walk"

At locations where the pedestrian signal to cross the minor street rests in "Walk," the "Walk" indication would sound constantly for that crossing. In many locations, that might prove to be irritating to neighbors.

Some APS manufacturers provide a limit switch that restricts the length of the audible "Walk" indication to 7 or 8 s, but allows recall of the audible and vibrotactile indications of the "Walk" if the button is pressed when there is adequate clearance time remaining. The availability of that feature should be investigated in the installation planning.

AR0071883

APSs Where Pedestrian Timing Is Pushbutton Actuated

Pushbutton-actuated pedestrian timing requires that a pedestrian locate the pushbutton and push it to request the pedestrian phase. A pedestrian who is blind needs to know a button-press is required to actuate pedestrian timing, and he or she needs to be able to easily find the pushbutton. The most appropriate way to convey that information is with a locator tone at the pushbutton. The Draft PROWAG requires that accessible pedestrian signals have a locator tone when there are pedestrian pushbuttons. Likewise, the MUTCD states that "APS pushbuttons should be audibly locatable" (*1*, 4E.09).

Location of APS Pushbuttons for Actuated Signals

To be useful to pedestrians who are visually impaired, pushbuttons must be installed as near to the crosswalk as possible, preferably on the sidewalk within the width of the crosswalk connection or adjacent to the crosswalk, and as close to the curb as possible.

Pedestrians who are blind must locate and push the pushbutton and then align themselves to cross, as discussed in Chapter 3. Even with an accessible signal, a pedestrian who is blind or visually impaired may not cross on the first "Walk" indication, but rather may need to listen to traffic and the accessible signal for a full cycle to confirm alignment, signal functioning, and traffic direction before pushing the pushbutton again, realigning, and crossing on the following pedestrian phase.

APS Where Pedestrian Timing Is Not Pushbutton Actuated

When pedestrian timing is pretimed, on recall, or called by passive pedestrian detection, pedestrians generally do not need to locate the pushbutton at the intersection. However, accessible pedestrian signals typically have the speakers, a vibrotactile "Walk" indication, and a tactile arrow provided at the pushbutton location. At new or reconstructed intersections, wiring and poles can be added to install the poles and APS in the recommended locations close to the crosswalk and curb ramps.

- When an APS pushbutton with a pushbutton locator tone is installed in a location that is not close to the crosswalk, blind pedestrians may have to deviate from their course of travel to push the button, potentially causing problems in orientation and alignment for the crossing.

AR0071884

- Many downtown areas with wide sidewalks have pretimed pedestrian phases. Poles are rarely located in optimal locations for installation of an APS with audible and vibrotactile "Walk" indications (see location recommendations in Figure 6-2 and 6-3).

Other Options

It may be appropriate to consider other options when the addition of the APS is the only change planned at an intersection with pretimed signals. The following suggestion does not apply at new or reconstructed intersections. If a pushbutton cannot be installed in a location where the tactile arrow and vibrotactile information associated with the pushbutton are usable, it makes little sense to install an APS with those features.

Note, however, that an installation without the tactile arrow and vibrotactile "Walk" indication would not comply with the Draft PROWAG requirements for new construction. Such an installation might be considered to be meeting those requirements "to the maximum extent feasible" where existing conditions and structures prevent installation of additional poles for mounting the APS beside the crosswalk.

In that case, a pedhead-mounted APS without a pushbutton or location tone may be appropriate. However, a "Walk" message or tone and volume levels should be carefully determined to avoid confusion to pedestrians and to prevent disturbance to neighbors. Unless audible beaconing is determined to be necessary, the APS speaker should be oriented down toward the pedestrian waiting location. Use of a small mast arm to locate the APS over the crosswalk location might be appropriate (Figure 6-4).

AR0071885

Figure 6-4. The mast arm is used in this installation in Toronto, Canada, to position the pedestrian signal head and speaker closer to the crosswalk.

Intersection Geometry Considerations

Effect on Accessible Pedestrian Signals

An APS that is audible at the wrong crossing location may lead a visually impaired pedestrian to begin to cross at the incorrect time and place. Geometric features such as unsignalized and signalized right-turn lanes are recognized as situations of concern in the MUTCD.

The type of accessible pedestrian signal may not be as important as the location of the sound source and the volume of the "Walk" indication. These issues must be considered in the design phase, when determining type of device and location. In addition, the APS volume must be carefully adjusted after installation.

Unsignalized Right-Turn Lanes and Splitter Islands

An unsignalized right-turn lane can pose a problem if the APS for crossing the signalized main through lanes of the intersection is too loud. Pedestrians who are unaware of the existence of an unsignalized right-turn lane may reach the curb, hear the APS sounding, and cross the unsignalized lane, thinking that it is signalized.

This concern is the reason that the MUTCD urges careful selection of tones at locations with free right turns (*1*, 4E.06). But tone selection does not really provide a solution; it is the volume of the sound and the placement of the speaker that are the important issues.

AR0071886

The APS must be adjusted so it is heard only from the location where the pedestrian is waiting to cross and is only audible for the crosswalk being signaled. It is generally not appropriate to use audible beaconing where there are splitter islands because the volume cannot be controlled precisely enough. As discussed in the section on split phasing, volume and placement of the sound source are critical considerations in designing and installing the APS.

A pedestrian standing on the corner at location A in Figure 6-5 should not be able to easily hear the APS that is located on the splitter island and that is intended for use by pedestrians crossing the through lanes.

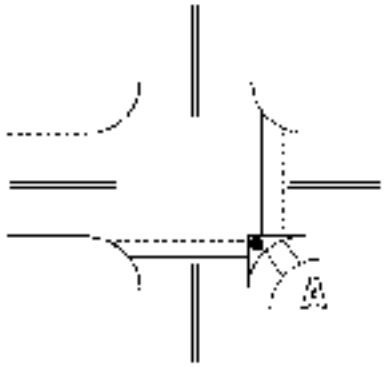

Figure 6-5. APS at channelized turn lane.

Signalized Channelized Right-Turn Lanes

Where crosswalks from corners to splitter islands are signalized, the signals to cross to the island might not, depending on crossing location, be concurrent with traffic movement parallel to the pedestrian who is blind. The APS should be located precisely next to the associated crosswalks, and the volume should be carefully adjusted. Pedestrians waiting on the island must not confuse the "Walk" indication for the turn lane with the "Walk" indication for the through lanes of the intersection. Pedestrians approaching the corner can also be guided to the crosswalk by a locator tone in combination with curb ramp location. Because signalized right turn lanes can be confusing for pedestrians who are blind, installation of APS with pushbutton locator tones at signalized right-turn lanes should be given high priority.

AR0071887

Medians

If the pedestrian clearance time is sufficient only to cross to a median having an additional pushbutton, it is very important that the pushbutton on that median be an APS with a locator tone. This will help inform the pedestrian who is visually impaired that a second button press is needed to complete the crossing, and it will aid in locating the median and the pushbutton. If only one APS device is on the median, the pushbutton should have a double-ended arrow.

If the pedestrian phases for the two halves of the street are timed separately, then two pushbutton-integrated accessible pedestrian signals are needed on the median, separated by as much distance as possible and located as close to each crossing departure location as possible. In European and Australian cities, a fence and offset crosswalks are used, in addition to the locator tone of an APS, to alert all pedestrians about the need to stop on the median and wait for the next pedestrian phase.

Figure 6-6. APS at median midblock crossing.

At the median island in Ireland shown in Figure 6-6, an APS is provided for each crossing, and a fence prevents pedestrians from continuing straight across the street; instead, pedestrians must turn and walk to the location of the other crosswalk and pushbutton.

AR0071888

APS Design in New Construction

Draft PROWAG

The Draft PROWAG was released on November 23, 2005 [21]. Although the Draft PROWAG has not been published as a final rule, it should be considered as the best guidance available at this time [19].

APS Characteristics

The Draft PROWAG requires accessible pedestrian signals with the following features in new construction and reconstruction projects where pedestrian signals are installed (see Figure 6-7):

- APS devices integral with the pushbutton.
- Audible and vibrotactile indications of the walk interval.
- "Walk" indication by tone or speech message.
- Pushbutton locator tone whenever there is a pedestrian pushbutton.
- Pushbutton that is a minimum of 0.5 cm (2 in.) across in one direction and that contrasts visually with its housing or mounting.
- Tactile arrow indicating the direction of travel on the crosswalk, and
- Braille or verbal information about the name of the street.

Optional Features

The Draft PROWAG states that an extended button press shall be permitted to activate additional features. However, no information is provided that specifies what those features may include (see Chapter 4 for discussion of extended button press and possible features).

Location in New Construction

The Draft PROWAG specifies that APS devices shall be located as follows:

- In such a way that the vibrotactile feature can be contacted from the level landing of a curb ramp or from clear ground space in line with the crosswalk line adjacent to the vehicle stop line.
- Within specified reach ranges from a level landing.

AR0071889

- 3 m (10 ft) minimum from other accessible pedestrian signals at the crossing, with an exception to that distance for devices installed on medians, and
- With control face of the device installed facing the intersection, parallel to the direction of the crosswalk it serves.

In addition, clear floor or ground space at the pushbutton shall connect to, or overlap, the pedestrian access route.

Figure 6-7. APS installation in new construction.

MUTCD-Recommended Locations

The MUTCD does not specify locations for new construction in the same manner, but the recommendations are substantially the same as that required by the Draft PROWAG for new construction and reconstruction. The MUTCD states the following:

Pushbuttons for accessible pedestrian signals should be located…as follows:

AR0071890

- Adjacent to a level all-weather surface to provide access from a wheelchair, and where there is an all-weather surface, wheelchair accessible route to the ramp;
- Within 1.5 m (5 ft) of the crosswalk extended;
- Within 3 m (10 ft) of the edge of the curb, shoulder, or pavement; and
- Parallel to the crosswalk to be used. (*Ref.* 4E.09)

See Figures 6-8 through 6-13 for examples of proper positioning of accessible pedestrian signals.

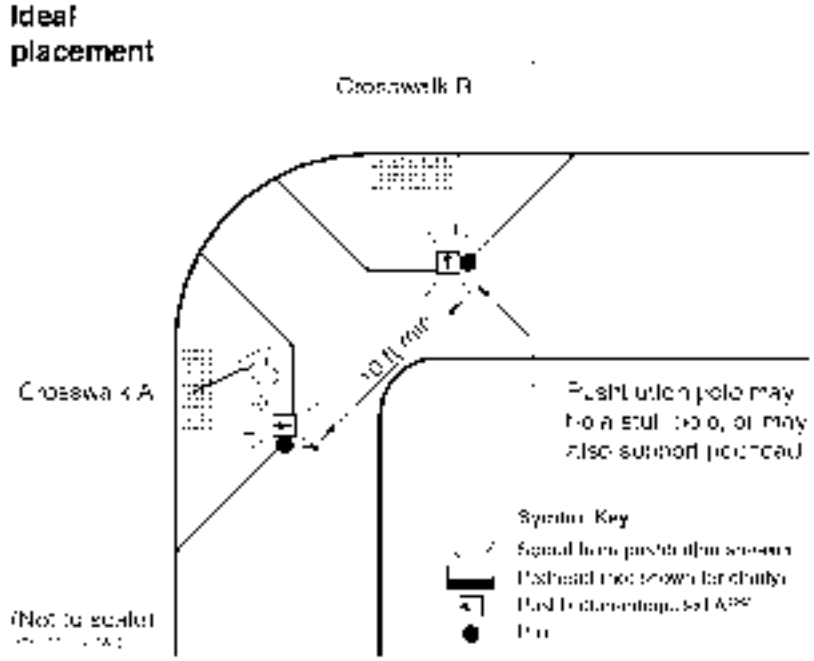

Figure 6-8. Ideal placement for a pushbutton-integrated APS.

AR0071891

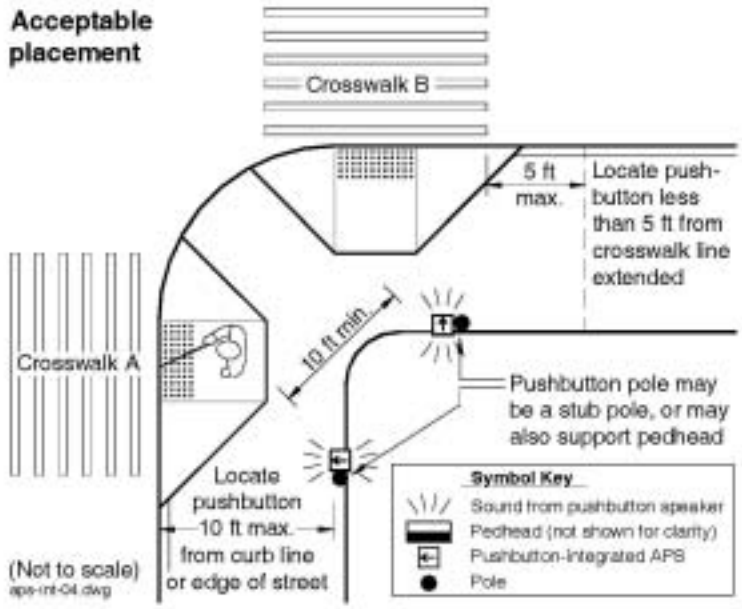

Figure 6-9. Acceptable placement for a pushbutton-integrated APS.

Figure 6-10. The APS should be located on the intersection side of the pole, as shown in this photo.

AR0071892

Figure 6-11. The MUTCD states that the APS should be within 5 ft of the crosswalk line extended.

Figure 6-12. The APS should be within 10 ft of the curb.

AR0071893

Figure 6-13. APSs installed in this reconstruction location are in accordance with the Draft PROWAG in that they are beside a level landing and separated from each other by at least 3 m. Both APS devices are located on the intersection side of their poles.

APS Design at an Existing Intersection

Application of New Construction Guidelines

In retrofit situations, the ADA requires that new construction guidelines be followed to the maximum extent feasible, if compliance with those guidelines is technically infeasible. The determination of technical infeasibility will vary depending on the scope of the project and the existing situation.

The new construction guidelines, as described in the previous section, should be applied as much as possible given the constraints of the project and the site.

The following sections provide guidance to assist the engineer/designer in understanding the effects of location and actuation on the usability of the information provided by APS.

AR0071894

Avoiding Ambiguity

The goal of the new construction location requirements and guidelines is to provide unambiguous information about which crosswalk has the "Walk" indication and to make pushbuttons accessible to and usable by all pedestrians, including those with visual and mobility impairments. Poor location and installation can not only render APSs unusable by a pedestrian who is blind or mobility impaired, but can also provide the pedestrian with dangerously incorrect information.

Pedhead mounted and pushbutton integrated APSs in the United States have typically been mounted on the same pole as the pedestrian signals for that crosswalk, regardless of whether the pedhead is the one closest to that crosswalk. This does not always provide unambiguous audible "Walk" indications.

In Australia and some European countries, it is common to install a separate stub pole so as to mount the APS in a consistent location relative to crosswalks. This consistent location makes it easy to determine which device the "Walk" indication is coming from and therefore provides unambiguous information regarding which crosswalk has the walk interval. The Draft PROWAG implements this strategy in new construction in the United States.

Issues to Consider

In designing retrofit installations, an understanding of the effect of certain intersection features on accessible pedestrian signals use will be helpful in making decisions. Another factor that becomes critical when adding an APS to an existing intersection is the location of existing poles and the possible need for new poles to position the APS close to the crosswalk. Details on these issues and recommended solutions are given in the following sections.

Needs Assessment

Strategies

After an engineering study determines that APSs should be installed at an existing signal, strategies for integrating the APS into the sidewalk environment need to address certain issues and/or questions. Those in charge of installing an APS at an intersection must conduct a needs assessment to determine which features are suitable and to develop detailed installation plans. It is important that the installation designer visit the intersection to gain an understanding of the

AR0071895

particular issues that must be dealt with. Some manufacturers require detailed information about the location and infrastructure of the intersection where the APS will be installed in order to send equipment with appropriate arrows or other features (such as speech "Walk" messages or pushbutton information messages, if needed).

Pushbutton and Pole Locations

A high-priority part of the needs assessment is to determine how much of the existing infrastructure can be used and how much will have to be installed or modified. It is essential to look at each crossing and the anticipated location of the pushbutton in relation to the departure location.

Questions to consider include the following:

- Does the pushbutton and pole location fit within MUTCD and Draft PROWAG recommended locations?
- Is existing wiring adequate for installation of the APS? The manufacturer's devices may have different wiring needs. Some require four wires to be available at the pushbutton, while others require two wires. There may be different requirements where audible beaconing is used.
- Is it possible to separate the pushbuttons for two crossings on the same corner by at least 3 m (10 ft)?
- Is the speaker nearest to the crosswalk it signals than it is to the other crosswalk?
- Are the pushbuttons located adjacent to a level all-weather surface that is free of hazards and obstacles?
- Is there sufficient turning room for a wheelchair if the pedestrian must turn to push the button and then return to the crosswalk?
- If the existing pole is in a "poor" location, can a stub pole be installed? Or are there other poles nearby that are more appropriately located than the signal pole (e.g., utility poles or lamp posts)?
- Depending upon the pushbutton or pole location, should tones or speech messages be utilized? If two pushbuttons must be installed on the same pole, speech messages should be used for the "Walk" indication.)

AR0071896

Intersection Geometry and Need for Audible Beaconing

Audible beaconing is not needed at many intersections, although accessible pedestrian signals in the United States have traditionally been installed with beaconing.

The following questions should be considered:

- Is audible beaconing needed at the intersection? (See discussion of audible beaconing in Chapter 4 for suggested criteria.)
- Would audible beaconing create the potential for confusion? (Confusion is possible at an intersection with channelized right turns or other free-flowing lanes.)

Preference and Requests

When installation is in response to a request for an APS, the needs assessment should consider whether the needs of the individual making the request have been addressed.

Pole Location

Existing Pole Location

When the only change is the addition of an APS at an intersection, the existing pole location at the intersection often restricts the location of the APS components (such as pushbuttons, speakers, and tactile arrows), which can affect the device features needed.

- The location of pushbuttons and tactile arrows and the location of speakers must be carefully engineered to provide accessible and usable information to pedestrians with disabilities.
- These issues must be considered in designing the installation and ordering the devices to ensure that information provided by the APS will not be ambiguous. Before ordering devices, the designer needs to look at the poles available and determine the locations where devices will be installed.
- Pole location may affect the type of "Walk" indication to be used.
  - If two accessible pedestrian signals are located on one pole, separate speech "Walk" indications, additional mast arms, or other provisions will be necessary to separate the sounds.
  - APS loudspeakers may be located at the pushbutton location or on the pedhead. The location of the speakers can be critical.

AR0071897

Location of the Tactile Arrow

If the poles are located too far away from the center of the intersection, outside the extension of the crosswalk lines, a pedestrian who is blind may attempt to cross at a location that is not within the crosswalk area. As discussed in Chapter 4, pedestrians typically align with the tactile arrow and proceed to the curb from that location.

The installation shown in Figure 6-14 is far more than 5 ft outside the extended crosswalk lines. While the arrow does clarify which street the device controls, it provides misleading information, which can be dangerous to pedestrians who cannot see.

Figure 6-14. If pedestrians proceed directly to the curb from the pushbutton in this photo, they will be well outside the crosswalk area when beginning their crossing.

Options for Intersections with No Existing Poles

If there are no existing poles at the recommended locations, options to consider in retrofit situations, in order of decreasing desirability (from the standpoint of minimizing ambiguity), include the following:

- Reposition pedestrian signals and poles, or add stub pole(s) and associated conduit and wiring.
- Install two accessible pedestrian signals with speech messages on a pole (see Chapter 4 for recommended wording of speech messages).

AR0071898

- Mount speakers on the pedestrian signal head, possibly with mast arms or other provisions in order to locate the "Walk" tone speakers as near to the associated crosswalk as possible

Figure 6-15. Well-located pedestrian signal poles provide APS audible indications from the optimal location, close to the pedestrian waiting area.

Reposition Pedestrian Signals and Poles or Add Stub Poles

In some renovation projects, repositioning poles may be considered a major change, but may be less difficult when the addition of the APS is part of an upgrading of the curb ramp. The optimal choice is positioning speakers and pushbuttons on poles that are located close to the crosswalk (Figure 6-15). Possible ways to accomplish this should be strongly considered before other options are explored.

In some locations, the addition of stub poles may be fairly simple (Figure 6-16). Different jurisdictions have different wiring requirements. The wires to pushbuttons are low voltage wires, and it may be possible to run the wires in a saw cut to a pushbutton pole that is mounted with bolts to the sidewalk surface. Looking at the wiring and the use of stub poles in unconventional ways may provide acceptable solutions to problems.

AR0071899

Figure 6-16. APSs are positioned appropriately at this intersection by the addition of a stub pole for one crosswalk. The stub pole holding the APS for the crosswalk at right is simply bolted to the sidewalk. The other APS is mounted on the pole that supports the pedhead.

Installing Two APSs on One Pole

Many jurisdictions use a standard design of two pedestrian signal heads and pushbuttons on one pole. In new or reconstructed intersections, separate poles should be provided at the end of each crosswalk, so that the pushbutton can provide unambiguous APS information and be maximally useful to all pedestrians. Where two APS pushbuttons are mounted on two separate poles at a corner, their arrows can be readily aligned with each crosswalk. Correct alignment can be difficult to accomplish with two APSs on the same pole, particularly at larger radius intersections.

However, if two pushbuttons must be on the same pole, it is essential that speakers be located as close as possible to the pedestrian waiting location and fit the following recommendations for installations of two APSs on one pole.

- A speech "Walk" message is needed, so the user can determine which street has the "Walk" indication (see discussion of "Walk" indications in Chapter 4).

AR0071900

- A pushbutton message and tactile arrow are also needed so that pedestrians can know the direction of the crosswalk served by that pushbutton and the name of the street to be crossed. Without the pushbutton message, the name of the street in the "Walk" message may be ambiguous to pedestrians who are unfamiliar with the intersection.

Positioning Pedhead-Mounted Speakers Near Crosswalk

If the available pole is not close enough to the crosswalk location, pedhead-mounted speakers may be mounted to extend from the pole to provide the appropriate separation of sounds (see Figure 6-4). Provision of the "Walk" information at the proper crossing location, even when pushbutton and poles cannot be relocated, may provide some auditory guidance about the crosswalk location to a pedestrian who is blind. Because this type of installation may not provide the best location for tactile arrows and signs, the pushbutton, if used, should also provide a locator tone and tactile arrow.

In Figure 6-17, the speakers are positioned on the outside of the pedheads, which somewhat separates the sounds, although more separation is preferred. In these photos the speakers are aimed across the street. In most instances, the speakers may be aimed directly down for communicating the beginning of the "Walk" phase to the pedestrian who actuated the signal. When audible beaconing is needed, the speaker may be aimed toward the center of the street.

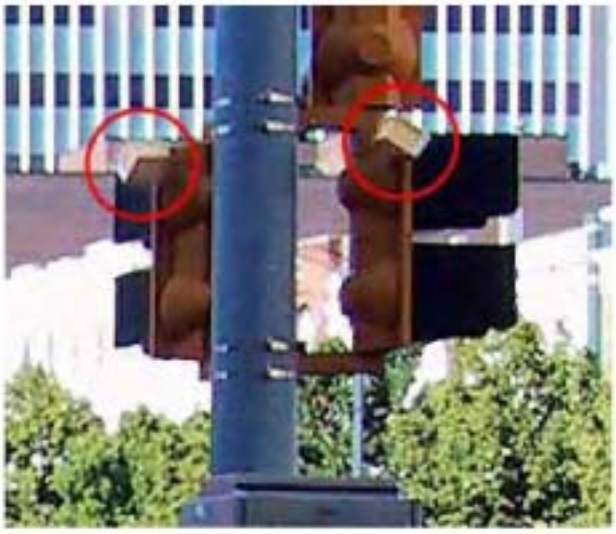

Figure 6-17. Two pedhead-mounted speakers, aimed at right angles to each other, are separated by the width of the pedheads and the mounting pole. More distance is preferred and careful aiming and volume control is important.

AR0071901

Specifications

When ordering APS units from the manufacturer, practitioners will need to be specific about the features and settings they desire or require. The level of detail required by the manufacturer varies depending on the company.

Elements of a specification sheet should inform the manufacturer of the characteristics of the location where the APS will be installed, as well as which APS features will be required by the city or state. The following list contains suggested elements for a detailed specification sheet. APS units do not necessarily need to have all these features, but the practitioner should consider the appropriateness of all features and then specify which ones are required for the selected APS installation.

- Type of "Walk" indication required (tone or speech message).
- Text and name of street for speech "Walk" indication (if used).
- Requirement for "extended button press" function and specification as to what this function would need to do (e.g., provide pushbutton information message, provide louder "Walk" indication).
- Requirement for vibrotactile arrow.
- Requirement for pushbutton information message.
- Text for pushbutton information message (if used).
- Requirement for audible, visual, and/or tactile feedback of pushbutton activation.
- Orientation of tactile arrow for each unit.
- Text to be encoded into braille for imprinting on pushbutton or informational sign.
- Anticipated mounting (wood or metal pole).
- Required location of control unit (pedhead or cabinet).
- Required factory settings for
  - "Walk" indication volume (minimum and maximum and amount over ambient), and
  - Locator tone volume (minimum and maximum and amount over ambient).
- Electrical operating requirements (e.g., voltage).
- Wiring requirements (e.g., number of wires, gauge).
- Required operating temperature range.
- Requirement for built-in "Walk/Don't Walk" conflict detection.

AR0071902

- Warranty duration and coverage
- Follow-up support and assistance available from the manufacturer.

It is also useful to include an intersection diagram showing

- Crosswalks to be controlled,
- Pushbutton locations, and
- Speaker locations and angle (if pedhead-mounted speakers are desired).

Mounting and Wiring Issues

Location of Controller Boards and Wiring

Wiring

Pushbutton integrated devices generally require an extra set of wires to power the audible indications. Those APSs with actuation ind cators may need to receive an actual signal from the controller that the call has been accepted. If the conduit is not adequate for extra wiring, installation plans may require conduit and wiring replacement. However, some manufacturers now provide devices that can replace typical pushbuttons and require only two wires and an additional control unit in the controller cabinet.

Some APSs manufactured abroad initially required 110 V AC power, rather than DC power, to the pushbutton. Those manufacturers now supply APS models to the U.S. market that have been adapted to provide DC power to the pushbutton. It may be necessary to specify that devices meet U.S. requirements.

Traffic Signal Controllers

APS devices work with current controllers used in the United States. In installations made between 2000 and 2003, some controller conflicts were reported, mainly related to a change in voltage that leads to the malfunction management unit (MMU) override. These conflicts have been addressed by the manufacturers and seem to be resolved. In 2002, the Access Board funded a project to investigate problems, which found that many reported issues were due to incorrect installation or sound adjustment problems. The final project report is available on the Access Board website (www.access-board.gov).

AR0071903

Mounting APS Controller Boards

Some APSs have a control board that is completely contained within the device. Other APSs require a separate control board that is mounted in the pedhead (see Figure 6-18), while still others require a control unit mounted in the controller cabinet. The control board often includes voice or sound chips and switches to control volume, microphone response, and other features.

Figure 6-18. APS device with control board in pedhead (speaker opened for illustration).

Some types of pedheads do not have adequate space to mount APS control boards. For example, incandescent, 12-in. over/under pedheads may not have adequate space. These pedestrian signal heads can be replaced. Other options may include the following:

AR0071904

- Manufacturers may be able to supply a separate case for the APS control board (see Figure 6-19).
- APS control boards may be mounted in the signal controller (Figure 6-20). However, the correct gauge wires must be calculated to drive the speakers when wiring is extended across the street/intersection. Included wiring is usually only adequate to drive the speakers when run from the pedhead.

Figure 6-19. External mount for controller board is visible on the left side of the pedestrian signal head.

Figure 6-20. Controller board mounted behind 18-in. pedestrian signal head.

If an area typically experiences high winds, it may be necessary to mount the APS speaker on a strong surface. Engineers in Nova Scotia found that speakers mounted on the plastic pedhead were prone to cracking during times of high wind. Their solution was to mount the speakers directly to the metal pole, as shown in Figure 6-21.

AR0071905

Figure 6-21. APS speaker mounted directly to the metal pole provides more support during high wind.

Vibrating Surfaces

Vibration-only devices are not recommended. However, pushbutton-integrated APS devices should have a vibrotactile arrow that vibrates during the walk interval. The vibrotactile arrow can be useful in confirming the audible "Walk" indication and providing "Walk" signal information to individuals with impaired hearing. Designers/engineers and installers must remember that the vibrating surface will be usable only if it is installed within the width of the crosswalk, or very near the crosswalk, and near the curb line. Pedestrians must be in an appropriate position to begin their crossing while waiting with their hand on the vibrating surface.

Orientation of Tactile Arrow

The tactile arrow must be oriented parallel to the direction of travel on the crosswalk controlled by the pushbutton. Arrows on several manufacturers' devices are positioned by the installer; however, with some devices, the direction of arrow must be specified when ordering the units (Figure 6-22). The pole location in relation to the crosswalk can affect the direction of the arrow.

AR0071906

Figure 6-22. The direction of the cast-in-place arrow on this device must be specified when ordering.

Wooden Poles

In areas where pushbuttons are installed on wooden poles (Figures 6-23 through 6-25), the wiring usually runs within a conduit on the outside of the pole. A mounting bracket is needed on some devices for wiring the pushbutton. This bracket needs to be ordered with the APS.

AR0071907

Figure 6-23. When the APS is mounted on a wooden pole, an additional mounting bracket is installed to allow the wires to run from the conduit into the top of the pushbutton-integrated device.

AR0071908

Figure 6-24. Typical installation without extra mounting plate, with wire running from inside the metal pole into the back of the device.

Figure 6-25. This APS is mounted on a wooden pole by drilling a hole through the pole and running wires through the back of the device.

AR0071909

Pedestrians who are blind have expressed concerns about nails and staples that are common on wooden poles and that present a hazard when they are locating the button with their hands (see Figure 6-26). Innovative solutions include the use of a shield for the pole area near the pushbutton, as shown in Figure 6-27.

Figure 6-26. Wooden pole with nails and staples that are a source of concern.

Figure 6-27. Coated canvas shield used in Charlotte, NC.

Stub Poles

The use of stub poles for mounting pedestrian pushbuttons is common in some areas of the United States. They provide an opportunity to locate the pushbutton where it is most usable to pedestrians and may encourage pedestrians to more frequently use the pushbutton (see Figures 6-28 through 6-31).

AR0071910

Figure 6-28. A stub pole is used to locate the pushbutton beside the sidewalk.

Figure 6-29. Stub pole.

AR0071911

Figure 6-30. Stub pole installed near sidewalk signal box simplifies wiring and locates ped pushbutton by the crosswalk

Figure 6-31. Stub pole example.

Braille Labels and Signs

Before ordering APSs with braille labels on the faceplate, you must know

- The location of the pole, and

AR0071912

- Which side of the pole the APS will be mounted on.

The direction of the faceplate and associated arrow is determined when the braille raised dots are added. The braille characters are generally just punched into the metal plate (see Figure 6-32).

Figure 6-32. Braille label is below the raised print street name.

APS Microphones and Speakers

As part of the automatic sound adjustment feature, some APSs require microphones be installed for monitoring ambient sound. By measuring the sound levels, the microphones can adjust the volume as necessary at the waiting location. If the microphone is mounted too far from the intersection, it will not adequately sample and adjust the volume levels, and the "Walk" indication will likely be too quiet for a pedestrian at the curb to hear above the sound of traffic.

Speakers for APSs may be pedhead-mounted or pushbutton-integrated. There are different issues to be considered, depending on the speaker location, though the majority of APS speakers are pushbutton integrated and the Draft PROWAG requires APSs to be integrated with pushbuttons. Figures 6-33 and 6-34 indicate the different locations of speakers.

Some manufacturers also provide the option of having a speaker at the pedhead in addition to a speaker at the pushbutton location. This may be particularly in focusing the audible beaconing signal.

AR0071913

Pushbutton-Integrated Speakers

Sound Dispersion from Pushbutton-Integrated Speakers

Although the speaker is usually built into the pushbutton-integrated device, different devices have slightly different speaker locations, which can affect the volume settings and the mounting of the device.

If possible, particularly in a location with audible beaconing, the devices should have speakers oriented toward the street, as well as the sidewalk and pedestrian waiting location. Beaconing is unlikely to be successful when provided by a device without speaker openings on the curb side. The addition of a pedhead-mounted speaker may need to be considered in a situation requiring beaconing. Some manufacturers sell optional add-on speakers or baffles to control direction of sound, when needed.

Figure 6-33. Speaker grille on side of APS.

AR0071914

Figure 6-34. Speaker grille on front and side of APS.

H-Frame for Pushbuttons

An H-frame is used for mounting pushbuttons in some northwestern states (see Figure 6-35), but not all APS devices work properly when mounted in this configuration. The type of device and the location of speaker components should be considered before ordering. The arrow of the APS is often part of the pushbutton and may not be oriented properly in the H-frame. In addition, the design of the frame makes it difficult to hear the sound of the locator tone from both the approach direction and the crossing direction.

Figure 6-35. Example of H-frame pushbutton.

It can be helpful for pedestrians who are blind to hear the locator tone as they complete their street crossings, as the "Walk" indication is seldom still sounding by that time. In this type of mounting, the pushbutton locator tone is not audible from the street because the speaker is aimed back toward the building line.

AR0071915

If two pushbutton-integrated APSs in H-frames are mounted on a single pole, they will provide ambiguous "Walk" indications because the APS closest to each crosswalk will be indicating the perpendicular crosswalk, not the closest crosswalk.

Figure 6-36. H-frame APS mounted to pole.

The speaker for the locator tone in Figure 6-36 is oriented toward the building line, rather than toward the street (in the location shown in the photo, the "Walk" indication comes from an overhead speaker). One of the arrows points toward the pole and the other device, as well as toward the street, but it would be hard to use the arrow for direction when standing on the sidewalk side of the pole.

Illustrations of Ideal, Acceptable, and Unacceptable Locations of Pushbutton-Integrated Devices and Speakers

The drawings on the following pages illustrate proper and improper positioning of pushbutton-integrated devices and speakers (Figures 6-37 through 6-42). In the following captions, "retrofit" refers to the installation of APSs at existing intersections. A retrofit might involve some constraints on the installation process, such as the inability to have two separate poles on a single corner. It is assumed that the sidewalk beside the pushbutton is firm and level, as required by the Draft PROWAG.

AR0071916

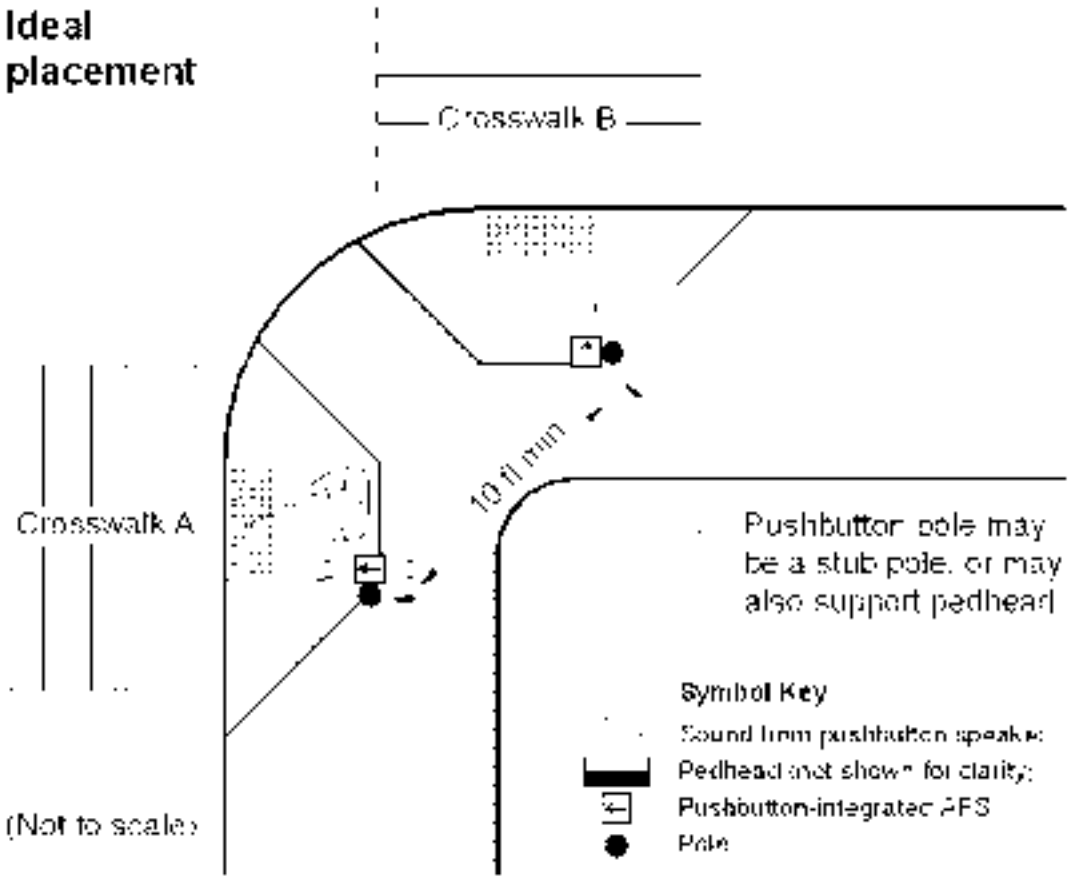

Figure 6-37. Ideal placement for pushbutton-integrated APS.

AR0071917

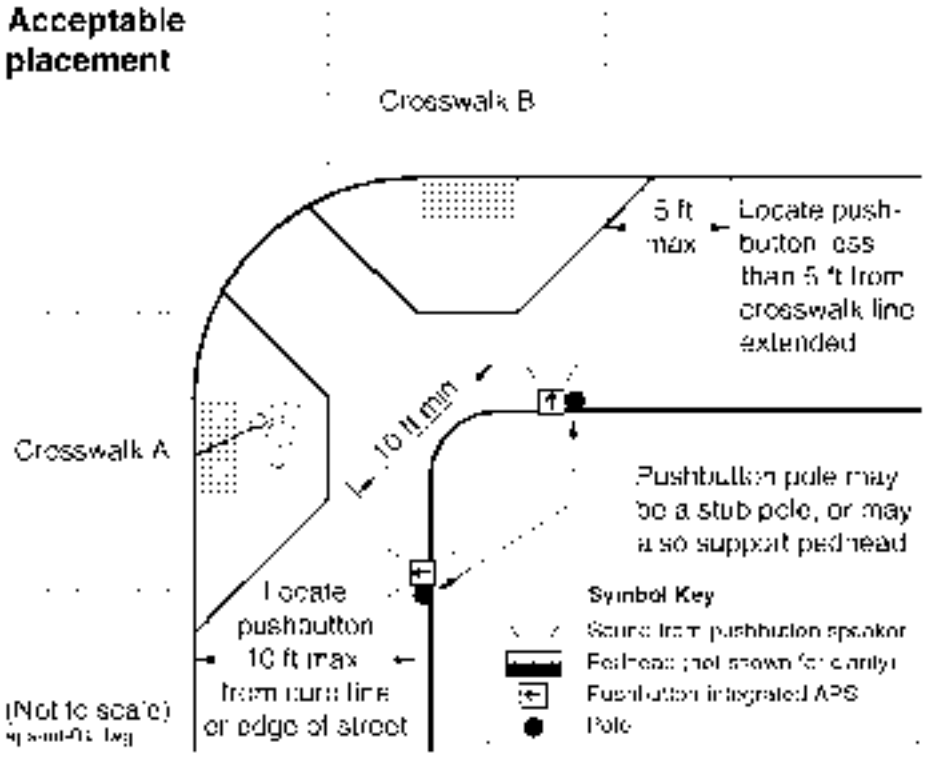

Figure 6-38. Acceptable placement for pushbutton-integrated APS.

AR0071918

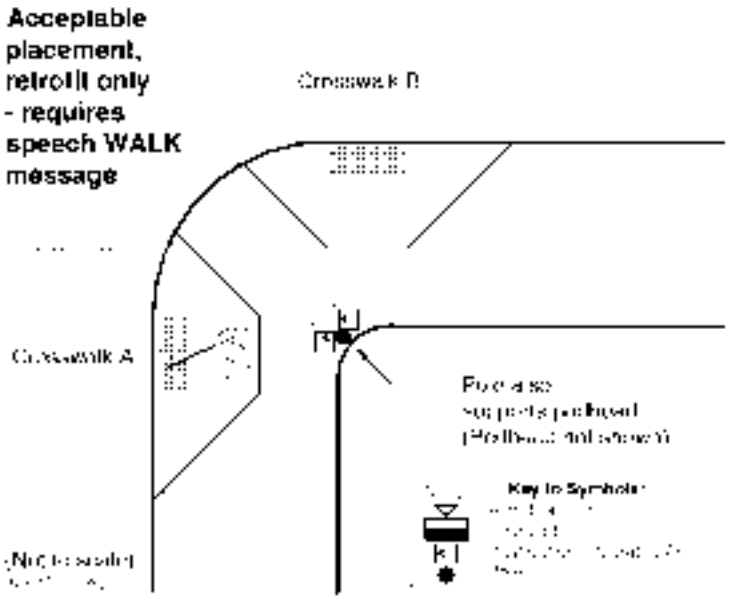

Figure 6-39. Acceptable placement for pushbutton-integrated APS. only when installing in a retrofit situation on an existing pole (if APSs cannot be separated, there will need to be a speech pushbutton information message and speech "Walk" message to prevent ambiguity).

AR0071919

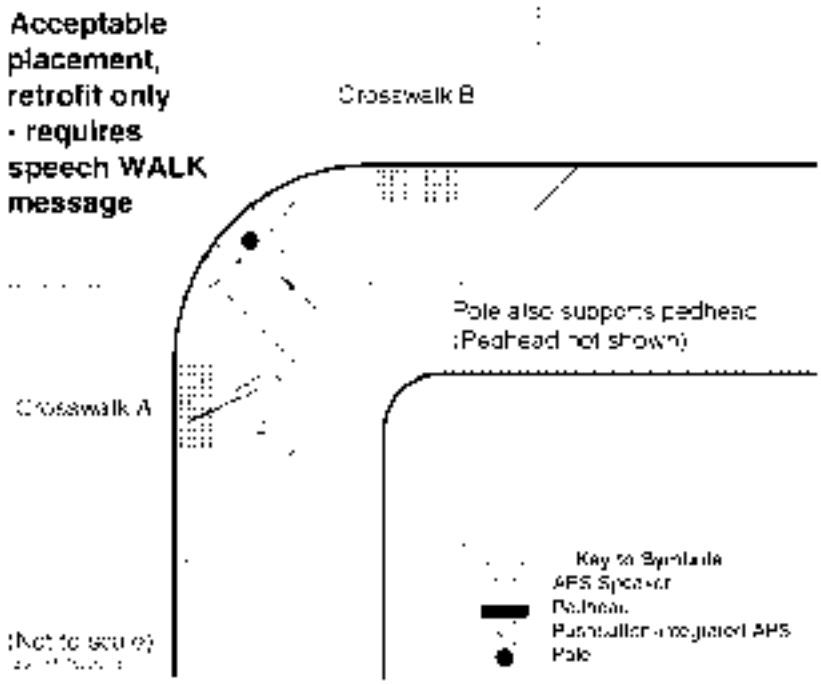

Figure 6-40. Acceptable placement for pushbutton-integrated APS, only when installing in a retrofit situation on an existing pole (if APSs cannot be separated, there will need to be a speech pushbutton information message and "Walk" message to prevent ambiguity).

AR0071920

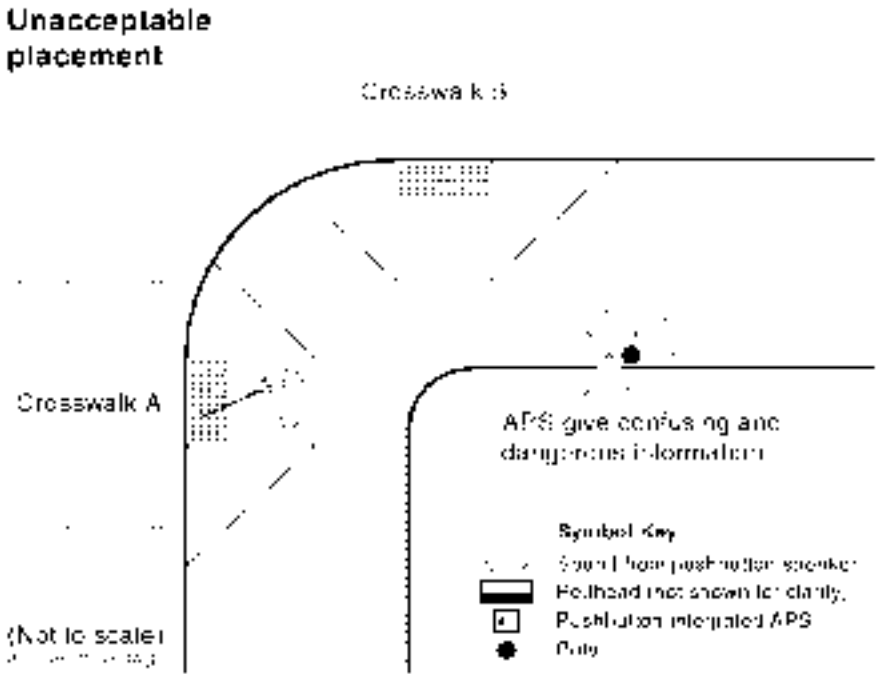

Figure 6-41. Unacceptable placement of APS speakers (the positioning provides ambiguous information).

AR0071921

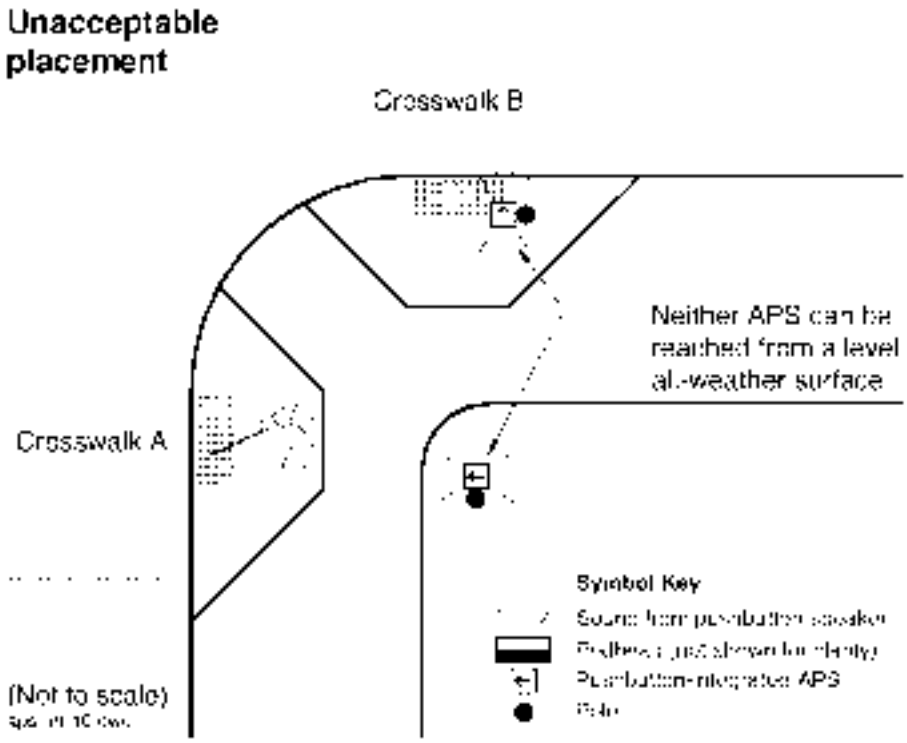

Figure 6-42. Unacceptable placement for pushbuttons and tactile arrows of an APS (not reachable from level all-weather surface).

Pedhead-Mounted Speakers

Sound from Pedhead Mounted Speakers

The sound from pedhead-mounted speakers is not very useful for providing guidance about the location of the opposite curb. Unless audible beaconing is required, speakers should be aimed down, toward the pedestrian waiting location (see Figure 6-43).

Speakers may be aimed toward the center of the street at crosswalks where beaconing is needed. With pedhead-mounted speakers, some will travel farther the more nearly horizontal the radiation pattern of the speaker is.

- Where beaconing is not needed, speakers should be pointed down toward the location of pedestrians waiting to cross the associated crosswalk, which will also minimize noise in neighborhoods.

AR0071922

- Where beaconing is needed, the speaker must be pointed toward the middle of the associated crosswalk (centerline of the road). A side effect of this design is that the APS will produce more noise in the neighborhood.

Figure 6-43. This photo shows a view from below of a speaker attached to the pedhead support and aimed straight down.

Speaker Location

While the direction of the speaker does make a difference, overhead speakers attached to pedheads commonly provide ambiguous information. Figure 6-44 illustrates such a speaker and pedhead placement. In both cases, the mounting is problematic because the speakers are mounted on a pedhead that is not over the departure location of the crosswalk they signal.

AR0071923

Figure 6-44. The pedhead and APS speaker for the north-south crosswalk is located over the pushbutton for the east-west crosswalk.

The speaker in Figure 6-44 is located on the side of the pedhead and sounds for the north-south crosswalk. It is situated directly over the waiting area to cross to the east and some distance from the north-south departure point. This configuration can be very confusing to pedestrians who are blind.

Acceptable and Unacceptable Locations of Pedhead-Mounted Speakers

The drawings on the following pages illustrate proper and improper positioning of pedhead-mounted devices and speakers (Figures 6-45 through 6-51).

Summary of Recommended Features and Installation Practice

APS Installation in New Construction

Recommended Features

- Rapid tick "Walk" indication, no more than 3 to 5 dBA above ambient sound
- Vibrotactile "Walk" indication.
- Speaker and vibrotactile indication located at pushbutton.
- Pushbutton locator tone.
- Tactile arrow on each device aligned in direction of travel on the crosswalk.
- Braille or audible street name.

Recommended Installation

- Precise location of the APS is very important to prevent ambiguity about which crosswalk is being signaled.

AR0071931

- APS should be reachable from the level landing of the curb ramp for the crossing or from a level surface with an accessible path to the ramp (Draft PROWAG).
- APS should be within 5 ft of the extension of the crosswalk lines and within 10 ft of the curb (MUTCD).
- Tactile arrow should be aligned with the direction of travel on the crosswalk.
- Face of the device toward the intersection (APS should be located on the intersection side of the pole).
- APSs on the same corner should be a minimum of 3 m (10 ft) apart.
- Pushbutton should be located within reach range of wheelchair users.

APS Installation at Existing Locations (Not New Construction)

New construction guidelines should be met to the maximum extent feasible.

- Pushbutton-integrated APSs must be located close to the crosswalk (see section in this chapter on optimal APS locations).
- If it is not possible to mount two APSs a minimum of 10 ft apart on the same corner, an APS providing a speech message during the walk interval, as well as a pushbutton message, is recommended.
- If a pedhead-mounted APS speaker is used, it must be above the waiting location of the crosswalk being signaled (see section on pedhead-mounted speakers in this chapter).

Configuration-Specific Recommendations

Below are listed some specific situations in which there are installation recommendations in addition to the ones listed above for new construction and existing construction. The recommendations listed for each situation below are only the areas where they *differ* from the general recommendations listed above. Unless otherwise specified, all other above recommendations apply to each situation.

APS Installations Where Beaconing Is Needed

APSs at intersections where beaconing is needed should have certain features, whether they are used in connection with pretimed or actuated signals.

- Loud locator tone during the flashing "Don't Walk" of the subsequent pedestrian phase only, in response to an extended button press, from speakers at the pushbutton or pedestrian signal

AR0071932

head. If mounted high, speakers should be aimed diagonally down and out into the center of crosswalk indicated by that APS. If possible, beaconing sound should come from the far-side speaker only (this requires special equipment and wiring).

- Sound should be increased *only* over the requested crosswalk.
- Location of all speaker components of the APS within the width of the crosswalk is essential, as users will direct their travel toward the source of the sound (see Figures 6-46 through 6-51 for examples).

APS at Pretimed Intersections Where Beaconing Is Not Needed (Not New Construction)

If a pushbutton-integrated APS cannot be located at the pedestrian waiting area, pedestal-mounted APSs (which do not provide vibrotactile indications) must be above the waiting location of the crosswalk being signaled and should be aimed down toward the waiting location.

APS at Corners Where Two Pushbuttons Must Be Mounted on the Same Pole (Not New Construction)

If two pushbuttons must be mounted on the same existing pole (see Figure 6-52), then

- A speech "Walk" indication should be 2 to 5 dBA above ambient sound.
- A pushbutton-generated information message should provide intersection and crosswalk identification information, and
- Speech messages should follow the recommendations for wording, and the APS should be positioned within 10 ft of the curb (see Figures 6-39 through 6-41 and Figures 6-47 and 6-48).

AR0071933

Lessons Learned from APS Installations 26

AR0071935

This chapter provides guidance for signal technicians who will work directly on the installation of the APS units. In many places, this chapter refers to illustrations in Chapter 6, so readers should have access to both chapters. Lessons learned from project research are included.

Review of Design Guidance

Current Guidance

Section 4E.06 of the MUTCD recommends the following:

> The installation of accessible pedestrian signals at signalized intersections should be based on an engineering study, which should consider the following factors:
>
> - Potential demand for accessible pedestrian signals.
> - A request for accessible pedestrian signals.
> - Traffic volumes during times when pedestrians might be present, including periods of low traffic volumes or high turn-on-red volumes.
> - The complexity of traffic signal phasing.
> - The complexity of intersection geometry. (2)

The Draft PROWAG requires audible and vibrotactile indications of the walk interval when new pedestrian signals are installed (see Chapter 5).

Principles

When installing an APS, there are several guiding principles that should be kept in mind. The APS installation should:

- Provide pedestrian signal information to those who cannot see the pedestrian signal head across the street.
- Provide information to pedestrians about the presence and location of pushbuttons, if pressing a button is required to actuate pedestrian timing.
- Provide unambiguous information about the "Walk" indication, as well as which crossing is being signaled.
- Use audible beaconing only where necessary; and

AR0071936

- Put as little additional sound into the environment as possible to avoid disturbing neighbors and to allow pedestrians who are blind or visually impaired to hear the traffic sounds, as well as the APS.

New Construction—Ideal Installation

Providing audible and vibrotactile indications of the walk interval, as specified in the Draft PROWAG, means that devices should be integrated into a pushbutton unit in order to provide vibrotactile "Walk" indications. The vibrotactile feature is usually a tactile arrow incorporated into the pushbutton device.

The ideal location for a pushbutton-integrated APS is between the edge of the crosswalk line (extended onto the sidewalk) farthest from the corner of the intersection and the side of the curb ramp. If at all possible, the APS should be between 1.5 ft and 6 ft from the edge of the curb, shoulder, or pavement. To allow wheelchair access to the pushbutton, the pushbutton must also be located adjacent to a level all-weather surface. The control face and tactile arrow should be carefully aligned with the direction of travel on the associated crosswalk.

At corners of signalized locations where two pedestrian pushbuttons are provided, the pushbuttons should be separated by a distance of at least 10 ft (see Figure 7-1). A rapid tick "Walk" indication is recommended for installations that follow these location guidelines.

AR0071937

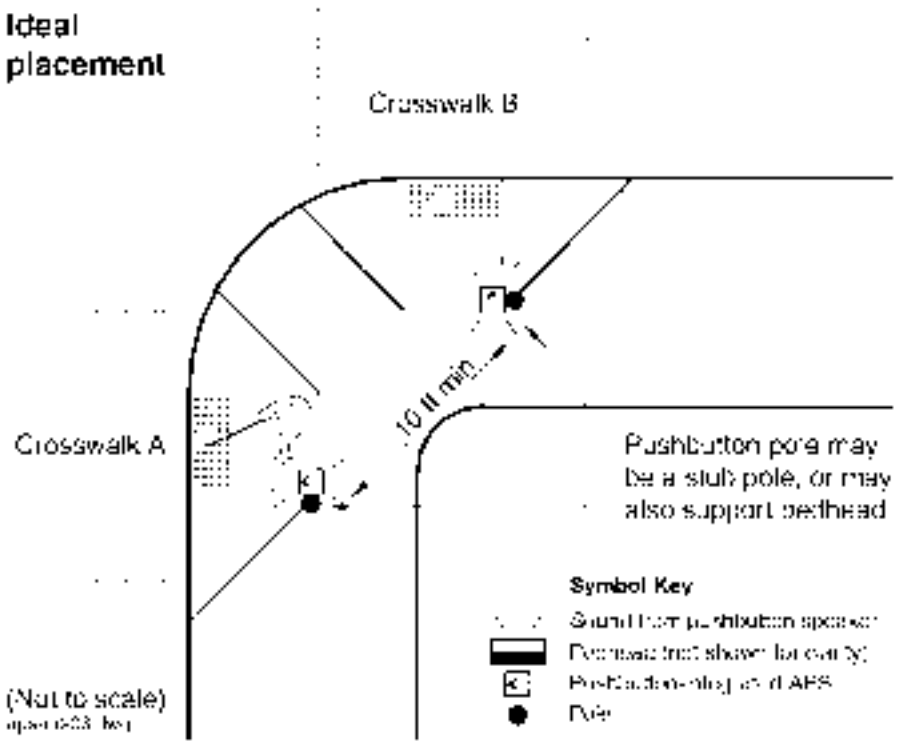

Figure 7-1. Ideal placement for pushbutton-integrated APS in the top corner of the flare of the curb ramp, next to the level landing.

Retrofit Installation—Constraints and Acceptable Solutions

Many APS installations will be a retrofit situation (i.e., they are being installed at an existing signalized intersection that is not being completely reconstructed). There will likely be infrastructure constraints that will make an ideal installation difficult.

If there are no poles at the recommended location, the following options should be considered, in order of decreasing desirability from the standpoint of ambiguity:

- Reposition the pedestrian signals and poles or add a stub pole(s) and associated conduit and wiring.
- Install two APSs on a single pole with speech messages for the "Walk" indication, and provide the additional features that are required with speech messages.
- Use pedhead-mounted speakers, possibly with mast arms or another provision, to locate the "Walk" indication speakers as near to the associated crosswalk as possible.

AR0071938

Installation

Wiring

Wiring needs and availability should be considered before ordering devices because some devices and features require additional wires between the pedestrian signal head, the pushbutton, and the controller. APSs typically require an additional control board in the pedestrian signal head or in the controller cabinet.

The manufacturer's instructions should be reviewed, as wiring may be more complex than expected due to additional features such as the vibrotactile "Walk" indication (vibrating surface) and additional messages or tones. Other potential wiring issues are as follows:

- Additional wire may be needed, beyond what is provided with the APS.
- Wire types may range from phone-type wire to standard wire.
- APSs that require four wires may need to have extra wiring installed at the pushbutton poles.
- Some manufacturers provide a two-wire APS model that uses the existing wiring from previously installed standard pushbuttons. For those installations, a control unit is installed in the controller cabinet. Wiring of this device requires correct connection of wires from pedestrian signal heads, particularly where two parallel crosswalks do not operate concurrently to provide accurate messages. In addition, replacing standard pushbuttons with APSs may not be as easy as it appears. New holes will have to be drilled so that the APS will be mounted in a correct position, if the previous pushbutton was not positioned correctly (e.g., the previous pushbutton was angled toward the center of the intersection instead of parallel to crosswalk).
- APSs that provide audible beaconing from the far side only (opposite end of crosswalk from where the button was pressed) may require additional wiring to provide proper signals between the pedestrian signal and the beacon controller.

APS Control Units

As mentioned above, APSs often have control units that must be installed in the pedhead or in the traffic signal controller. An example of a control board being installed in the pedhead is shown in Figure 7-2. As can be seen in the photo, the technician found a hinged cord to be helpful in holding the pedhead lens while he was installing and adjusting the APS control unit. (Additional photos and information on control units can be found in Chapter 6.)

AR0071939

Figure 7-2. Technician installing APS control board in pedhead.

Traffic Signal Controllers

As stated earlier, APS devices work with current controllers used in the United States. While malfunction management unit (MMU) problems seem to have been solved by manufacturers, functioning of the intersection and devices should be carefully checked after installation.

Pushbuttons, Tactile Arrows, Vibrating Surfaces, and Signs

Height of Pushbuttons

The pushbutton must be within accessible reach range of a level landing to allow it to be used by someone in a wheelchair (see Figures 7-3 and 7-4). The MUTCD specifies 42 in. for the mounting height, which is well within the reach ranges specified by the Draft PROWAG.

AR0071940

Figure 7-3. This pushbutton may be 42 in. from the bottom of the pole, but it is almost 60 in. above the landing, making it inaccessible to a wheelchair user and not likely to be located by a person who is blind.

Figure 7-4. Not only is the pushbutton in the bushes and out of reach range from the sidewalk, but construction barriers have been stored against the pole, preventing all pedestrians from reaching the pushbuttons.

AR0071941

The Draft PROWAG (2. R306.2.2) requires APS pushbuttons to be installed within specified reach ranges of the curb ramp landing or of a level surface with an accessible path to the curb ramp. A level surface is defined as a surface with less than 2% slope in any direction. This allows a person on a wheelchair to push the button without having to hold the wheelchair steady on a slope.

Reach ranges in ADA guidelines are described as forward reach or side reach and unobstructed or obstructed. Forward or side reach refers to the position in relation to a level surface and whether the pushbutton can be approached directly (forward) or must be approached from the side. Obstructed or unobstructed describes whether the wheelchair can be pulled immediately next to the pushbutton mounting surface or whether the user has to reach over an obstruction, such as a wall, pole base, or an uneven or tilt surface, to access the pushbutton from a wheelchair.

Reach depths (distance from level surface) are specified at 25 in. maximum for forward reach and 24 in. maximum for side reach. For unobstructed forward or side reach, the Draft PROWAG allows the pushbutton to be mounted between 15 in. and 48 in. above the level surface. Obstructed high reach varies depending on the depth of the obstacle, but ranges from 42 to 46 in.

Locations that are "convenient" to the installer may not be usable by all pedestrians.

Vibrating Surfaces

Vibrotactile "Walk" indication should be provided during the associated walk interval by each APS equipped with a vibrating surface. The vibrating surface feature will be usable only if it is installed within the width of the crosswalk, or very near the crosswalk, and near the curb line. Pedestrians must be able to wait to cross while keeping a hand on the vibrating surface.

When two APS pushbuttons with vibrotactile indications are installed on the same pole, they may require insulation and a rubber gasket to prevent the user from feeling vibrations generated from the other pushbutton.

Shape and Type of Mounting Pole

Municipalities in the United States use a great variety of poles for mounting pedheads and pushbuttons. When the tactile arrow is part of the pushbutton and located on the face of the pushbutton integrated device, the orientation of the device on the pole determines whether the tactile arrow is aligned with the crosswalk. A new mounting hole may need to be drilled for the

AR0071942

pushbutton in order to be sure the arrow points in the correct direction. A person who is blind may attempt to determine their heading for crossing based on the arrow. The arrow should thus point toward the destination corner.

Figure 7-5. Well-located APS on a square pole.

Most pushbutton-integrated devices are designed to be installed on round poles. Poles that are not round may require a special mounting bracket or shim to orient the arrow correctly (see Figures 7-5 and 7-6).

AR0071943

Figure 7-6. A mounting bracket or shim is needed on this square pole to properly orient the arrow . Without it, the arrow points to the center of the intersection.

Location and Orientation of Tactile Arrows

Before devices are ordered, the pushbutton and tactile arrow (vibrating surface) location should be determined and specified. Any adjustment from the intended design must be carefully considered. If poles are located too far away from the center of the intersection, outside the extension of the crosswalk lines, a pedestrian who is blind may attempt to cross at a location that is not within the crosswalk area. (An example of a poorly placed pole is shown in Figure 6-14 in Chapter 6.)

Pushbuttons should be within reach from a level landing, within 5 ft of the crosswalk lines extended and within 10 ft of the curb. Specifications on pushbutton location are provided in Chapter 6.

The tactile arrow must be oriented parallel to the direction of travel on the crosswalk controlled by the pushbutton. It may be helpful to stand behind the unit and look across the street to check the orientation before and after installation. The arrow should point to a location within the crosswalk along the opposite curb. Arrows on several manufacturers' devices can be turned or repositioned by the installer. However, with other devices the direction of the arrow must be specified when ordering the unit. Pole location in relation to the crosswalk can affect the arrow direction.

Where speech messages are used for the "Walk" indication or where there is a pushbutton information message, the installer should check that arrow direction and speech messages agree.

AR0071944

APSs have accidentally been installed with the message providing notification about the wrong street.

Figure 7-7. A misaligned APS, with the arrow pointing into the bushes.

The fluted pole in Figure 7-7 made correct alignment more difficult. The installer said he had to orient it that way because he did not have any shims. The specifications given to the manufacturer for this unit should have included shims to allow for the necessary angle adjustment.

Wooden Poles

In areas where pushbuttons are installed on wooden poles, the wiring usually runs in a conduit on the outside of the pole. A mounting bracket, which must be ordered with the APS, is needed on some devices for wiring the pushbutton. Other options are discussed in Chapter 6, in the section on mounting and wiring issues.

Braille Labels and Signs

The direction of the face plate and associated arrow is determined when the raised dots of braille characters are added. Braille characters are generally punched into the metal plate. Printed street names may not be provided on the APS, since printed street signs may already be available at the intersection. Typically, the faceplate can be flipped to show a right arrow or a left arrow, and the manufacturer includes a printed label on the faceplate that translates the braille characters

AR0071945

for installers, so that they can install the sign at the appropriate location. The printed label should be installed on the inside of the faceplate (facing the pole), not on the outside (see Figure 7-8). If the braille sign has been installed correctly, the braille dots will be raised to the touch. An example of an incorrect installation is shown in Figure 7-8.

Figure 7-8. The faceplate at this location was mounted backwards, with the braille characters indented rather than raised and the small paper label, intended for translating the braille for the installers, is on the outside rather than the inside.

APS Microphones and Speakers

Microphone Location

Some APSs require microphones be installed to monitor ambient sound as part of the automatic sound adjustment feature. The microphones measure the sound levels to adjust the volume at the waiting location, and they are usually mounted in the pedhead or are part of the pushbutton unit. If the microphone is mounted too far from the intersection, it will not adequately sample and adjust the volume levels, which will result in a "Walk" indication that is too quiet for a pedestrian to hear above the sound of traffic.

AR0071946

APS Speakers

The speakers for an APS may be mounted on the pedhead or located in the pushbutton unit. There are different issues to be considered, depending on the speaker location. If possible, APS devices should have speakers oriented toward the street, as well as the sidewalk and pedestrian waiting location. In locations with audible beaconing, a speaker oriented toward the middle of the crosswalk is needed. The addition of a pedhead mounted speaker may need to be considered in that situation. some manufacturers sell optional add on speakers. One manufacturer provides baffles to better control the direction of sound.

An H-frame is used for mounting pushbuttons in some northwestern states. The design of the frame makes it difficult to hear the sound of the locator tone from both the approach direction and the crossing direction.

Sound from Pedhead-Mounted Speakers

Unless audible beaconing is needed, speakers should be aimed down toward the pedestrian waiting location. Speakers may be aimed toward the center of the street at crosswalks where audible beaconing is needed. For pedhead-mounted speakers, sound will travel farther the more nearly horizontal the radiation pattern of the speaker

Installation of Speakers and Microphones

Confirming Speaker Location and Orientation

Speaker location and orientation should be checked against the specifications. Installers should make no change in speaker location or orientation without checking with the responsible signal engineer. Poorly located speakers can result in

- Ambiguous information about which crosswalk has the walk interval,
- Failure of blind pedestrians to begin or end crossings within the crosswalk, and
- Veering of blind pedestrians outside the crosswalk, possibly into conflicting traffic.

For more information on the effects of speaker location and orientation, see Chapter 6

Speaker Location

Incorrect speaker location can make a difference in the ability of pedestrians who are visually impaired or blind to discern which APS is sounding

AR0071947

- Each APS speaker at a corner must always be closest to the crosswalk it signals
- For pedhead mounted APSs, speakers should not be automatically located on the pedhead that signals the same crosswalk. The pedhead closest to one crosswalk may signal the perpendicular crosswalk. In this case, speakers must be mounted on the pedhead for the perpendicular crosswalk.

Speaker Orientation

The speakers should be adjusted so the pushbutton locator tone can be heard by a pedestrian approaching the corner from both the sidewalk side and the street. However, it is most critical that the "Walk" indication be heard at the beginning of the crosswalk.

Precise orientation of the APS speaker is especially critical at locations with audible beaconing. If a speaker or transmitter is oriented even a few degrees out of alignment with the associated crosswalk, pedestrians may inadvertently travel out of the crosswalk, perhaps into the path of vehicular traffic.

Pedhead mounted speakers in existing installations are often mounted in positions that make the messages more ambiguous. See more information on correct mounting of pedhead speakers in Chapter 6 in "APS Microphones and Speakers."

For pushbutton integrated devices, the speaker is in the pushbutton housing. Location of the pushbutton and orientation of the speaker can be critical to hearing the "Walk" indication at the crosswalk. If the speaker is located too far from the crosswalk location, pedestrians who are blind may not hear the "Walk" indication.

Adjustments

Introduction

Devices should be carefully adjusted in the field and evaluated after installation to be sure they are working properly from an engineering perspective and from the perspective of pedestrians who are visually impaired.

- If the APS has been added in response to a request from a pedestrian who is blind or visually impaired, that individual should also be involved in the post-installation evaluation.
- Because installers may be unfamiliar with new types of APS devices, extra attention and supervision will be required during the first few installations by any crew or contractor

AR0071948

- Even when carefully specified, installations sometimes do not match the specifications because installers do not understand that failure to exactly follow specifications may lead to an installation that cannot be accessed by pedestrians who use wheelchairs or that could cause a pedestrian who is blind to push the wrong pushbutton, veer from the crosswalk, or mistake which crosswalk has the walk interval and start crossing at an unsafe time.

The sound level of the speakers must be carefully set and evaluated at the time of installation and then checked when traffic volumes are different to ensure that the settings are correct. It is better to install an APS with volumes that may be too low and adjust upwards as needed. If volumes are set too high initially, problems can arise with neighboring residents and businesses that could lead to the removal of the APS and difficulties for future installations.

Setting and Evaluating Sound Levels

How to Adjust APS Sound Levels

The controls for adjusting the settings of the APS vary among the different manufacturers. The settings may be adjusted by

- Screws on a control board, which may be mounted in the pedhead or in the APS speaker unit, or
- A remote handheld device, using infrared communication, which must be used in close range to the APS (Figure 7-9).

Figure 7-9. Resetting APS settings with handheld device supplied by manufacturer.

AR0071949

Settings

Most devices require the following controls be set:

- Microphone sensitivity or automatic gain control (AGC) sensitivity.
- Volume of the pushbutton locator tone.
- Volume of the "Walk" indication.

The microphone sensitivity or AGC controls how the other tone/message volumes respond to ambient noise levels. The setting must be adjusted by the installer to provide output at one of a number of ranges between the maximum and minimum. The number and width of ranges varies by manufacturer.

How Loud Should the Sound Be?

In general, installers have a tendency to set volume levels too loud. Loud overhead audible signals have caused problems for neighbors of APS installations. In addition, the loud sound of the signal may prevent pedestrians who are visually impaired from:

- Hearing critical traffic sounds used for alignment.
- Determining that cars have stopped.
- Hearing cars that may be turning across their path, and
- Localizing on the signal source.

Installers should set volume levels according to the following guidance:

- The "Walk" indication must be audible from the beginning of the associated crosswalk (Z. 4E.06 Standard).
- The MUTCD states that the locator tone and the "Walk" tone of an APS should be at the same volume (except by special actuation, providing a louder tone for a single pedestrian phase) and specifies that the locator tone should be audible 6 to 12 ft from the pushbutton or to the building line, whichever is less (Z. 14E.06 and 4E.09 Guidance).
- Manufacturers typically set a default maximum and minimum output level on APS devices. The settings should be checked to ensure that the device is set for 30 dB minimum and 80 dB maximum.

AR0071950

- At no time should the sound be more than 5 dB above ambient sound (except by special actuation for audible beaconing). The sound level should be between 2 and 5 dBA above ambient sound (*cf.* 4E.06 and 4E.09 Guidance: and 2. 2.5.2.2 Gt.

Volume Level Considerations

The correct setting will vary depending on whether there are buildings close to the APS and whether there is split phasing or slip lanes.

- When buildings are close to the APS, the sound reflected from the buildings will make the sound seem louder. The reflected sound may also influence the microphone and AGC such that the APS will sound louder than if the APS, at the same setting, was in an open area.
- At intersections having split phasing, APSs at parallel crosswalks must not be audible across the street (at the other parallel crosswalk), else users may begin crossing with the wrong "Walk" signal. Check this at times of low ambient sound, as well as at times with normal sound. In Figure 7-10, the APS giving the "Walk" indication on corner B should not be heard by someone standing on corner A.
- APSs at intersections having channelized turn lanes must not be audible from the corners of the intersection. If an APS on the splitter island is too loud, pedestrians who are blind may believe the turn lane is signalized or that the intersection crosswalk extends all the way to the corner. If the volume is too loud, pedestrians might assume that they have a "Walk" indication to begin crossing, when, in fact, they may be entering an uncontrolled slip lane, yield or stop sign controlled slip lane, or a separately signalized turn lane. In Figure 7-11, a pedestrian standing on the corner at location A should not be able to easily hear an APS located on the splitter island.

AR0071951

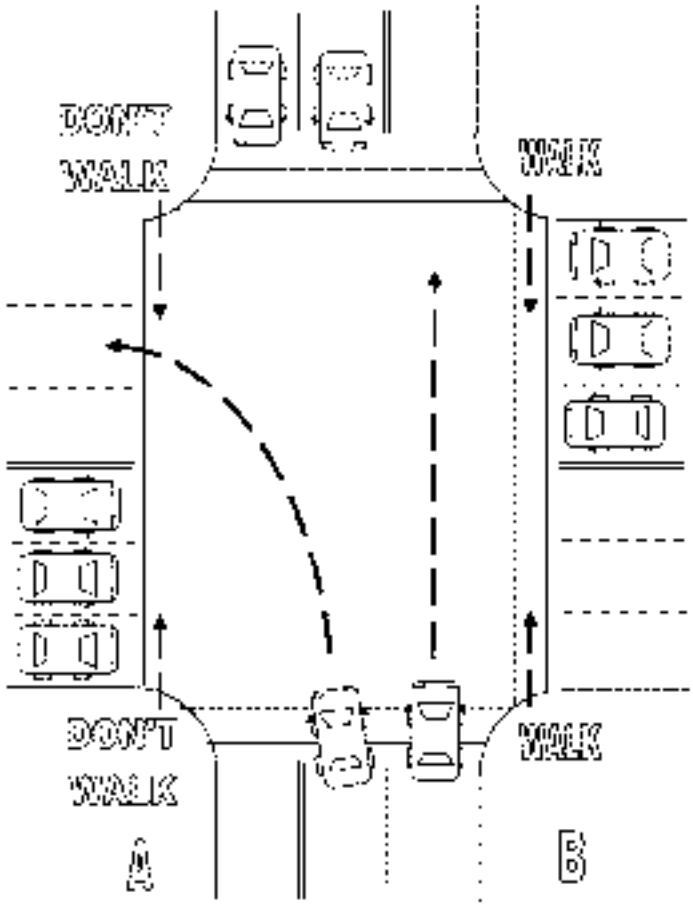

Figure 7-10. Illustration of pedestrian signals at an intersection with split phasing.

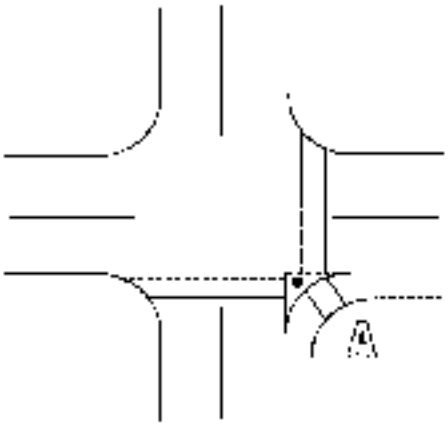

Figure 7-11. Channelized turn lane illustration.

AR0071952

Automatic Volume Adjustment

Preset automatic volume adjustment or automatic gain controls cannot ensure that the volume meets the criterion for distance at which the APS should be audible. Similar automatic volume adjustment settings on APS devices by different manufacturers may seem to provide quite different levels of loudness, as judged by listeners.

- Automatic volume adjustment technology used by different manufacturers varies in the rate of sampling of ambient sound and in the speed with which output adjusts to changes in ambient sound
- Some APS devices and some installations will be more subject to responding to their own noise than others. For example, as the "Walk" signal continues throughout the walk interval, the signal may get louder and louder in response to its own noise.
- Different tones or speech will seem louder or quieter depending on their frequency content, although they may measure the same on the dBA scale.

Measuring the Sound Level

Due to the short duration of the pushbutton locator tone and "Walk" tone pulses, conventional analog or digital sound level meters are not able, in the crosswalk environment, to accurately measure the absolute sound level (dBA) of APS tones or the sound level of APS tones relative to ambient sound.

At present, setting and evaluating APS sound level is typically done by ear. There can be errors in making the sound too quiet or too loud. It is critical that the "Walk" indication be loud enough to be audible at the crosswalk waiting location. Both the locator tone and "Walk" indication should be audible within 10 to 12 ft of the device, but not beyond that distance. It has been the authors' experience that many APS installations have been set louder than was optimal either for blind pedestrians or nearby neighbors.

Measuring Sound Where Audible Beaconing Is Needed

At crosswalks where audible beaconing is needed, the sound level should be evaluated from the middle of the street, when the loud "Walk" indication has been called, to be sure beaconing will be provided throughout the crossing. However, current MUTCD language limits the maximum output of an APS to 89 dB, and most manufacturers preset this maximum. Therefore, at exceptionally wide crossings, and when and where there is high ambient sound, there may be a

AR0071953

point in the middle of the crosswalk where the beaconing is not readily heard. Changes to the MUTCD limits have been recommended by NCUTCD and may be incorporated into the 2009 edition.

Microphone Location and Effect on Perceived Loudness

APS devices that respond to ambient sound have microphones to pick up ambient sound.

- Microphones for pedhead-type devices are typically in or on the pedhead, incorporated into the APS.
- Pushbutton-integrated devices may have microphones at the pedhead, or the microphones may be incorporated into the pushbutton housing.

An APS microphone should be mounted as close as possible to the position of the pedestrian who is waiting to cross the associated crosswalk, because sound pressure is halved for each doubling of the distance from the sound source in a free field.

The farther from that ideal position the microphone is for a given APS device, the greater will be the following problems.

- The ambient traffic sound when a microphone is located on a signal pole 10 ft from the curb line will be quieter at the microphone than at the street; therefore, the resulting output will be quieter than it would be if the ambient sound were measured near the street.
- The "Walk" indication, if it comes from the same pole location, may already be too quiet because the ambient sound level has been measured too far from waiting pedestrians, and it will be quieter still when its sound reaches the ears of pedestrians waiting at the crosswalk because the sound has traveled farther to reach them.
- If the microphone is closer to the intersecting street than to the street the pedestrian is waiting to cross, or if the microphone is oriented toward the intersecting street, it will respond to the traffic sound on that street instead of the street the pedestrian is waiting to cross. This may result in "Walk" signals that are too loud or too quiet, as perceived by pedestrians waiting to cross.

Ideal Microphone Location

The best location for the microphone is as close as possible to the position of pedestrians who are waiting to cross the associated street. This results in pedestrians being clearly able to hear

AR0071954

APS signals with no need to set the automatic volume adjustment so high that sound levels will be too high or that APS neighbors will be annoyed.

Post-Installation Checklist

Checklist

Once installation is complete, the installer should perform the following steps (detailed in sections below). A checklist is shown in Figure 7-12).

- Evaluate and adjust the locator tone volume.
- Evaluate and adjust the "Walk" indication volume.
- Evaluate and set the sensitivity level of the automatic volume adjustment.
- Confirm proper functioning of the "Walk" indicators.
- Check height and location of pushbutton.
- Check the tactile arrow.
- Check optional features.
- Check audible beaconing.
- Recheck the functioning at a later time.

Locator Tone Volume

Evaluate and adjust locator tone volume.

- Approach the intersection from both directions along the sidewalk and note where the pushbutton locator tone is audible. If there are two pushbutton locator tones at the corner, each should be audible. The pushbutton locator tone should be audible 6 to 12 ft from the pushbutton or at the building line, whichever is closer to the pushbutton.
- Approach the corner from the crosswalk and note where the pushbutton locator tone is audible. The pushbutton locator tone should be audible at 6 to 12 ft (or approximately one lane) from the pushbutton.
- Listen through several cycles at times when traffic is noisy and at times when traffic is quiet.
- Adjust the locator tone volume as necessary.

"Walk" Indication Volume

Evaluate and adjust the volume of the "Walk" indication.

AR0071955

- Stand at the curb-cut end of the curb ramp at the crosswalk and listen for the "Walk" indication. It should be audible from the crossing location.
- Confirm that the "Walk" indication for each crosswalk sounds closer than the "Walk" indication for the perpendicular crosswalk.
- Listen through several cycles at times when traffic is noisy and at times when traffic is quiet.
- Adjust the "Walk" indication volume as necessary.

Automatic Volume Adjustment

Evaluate and set the sensitivity level of the automatic volume adjustment.

- If volumes are adequate in quiet conditions, but do not increase enough or quickly enough when ambient noise increases, the microphone sensitivity, or automatic gain control, may need to be increased.
- Increase the microphone sensitivity in 10% to 20% steps until the response is as desired.
- It might be necessary to readjust the volume of the locator tone and "Walk" indications after the microphone is adjusted.

Confirm Proper Functioning of the "Walk" Indication

Determine if the vibrating surface, speech messages, or other features of the "Walk" indication work properly.

- Press the button and wait for the "Walk" indication. The tactile arrow or vibrating surface should vibrate rapidly only during the walk interval.
- The "Walk" indication (tone or speech message) should sound for the duration of the walk interval, unless there is a special setting due to a rest in "Walk" situation.
- If the "Walk" indication is a speech message, confirm that it refers to the correct street and is appropriately worded and understandable.

Check Height and Location of the Pushbutton

Confirm that pushbutton height and location conform to specifications and can be reached by a person in a wheelchair, from a level landing.

Check Tactile Arrow

Examine the tactile arrow.

AR0071956

- Check that it is aligned in the direction of travel on the crosswalk
- Confirm that it points to the street that is controlled by that pushbutton

Check Optional Features

Confirm that optional features, if ordered, are present and functioning correctly

- Confirm that braille dots are raised to the touch. If possible, have a person who reads braille confirm that it is the correct label.
- Press the pushbutton for an extended button press to see if the pushbutton information message plays and that it accurately identifies the crossing controlled by the pushbutton and that other information, if provided, is accurate.
- Confirm that a tactile map accurately represents the crossing features.

Check Audible Beaconing

If the intersection requires audible beaconing.

- Press the pushbutton for an extended button press and confirm that the sound is boosted during the following pedestrian phase for the "Walk" tone and for the locator tone, and
- Walk across the street during the pedestrian phase and evaluate placement and aim of devices for providing sound in the crosswalk area.

Recheck Device Functioning at a Later Time

Follow up during the first few weeks after installation, checking device and volume at different times of day to ensure proper functioning.

Designate a person and phone number to call and report any malfunctioning device. Share that information with agencies serving individuals who are blind and with community organizations of individuals who are blind.

Maintenance

When and How Often the APS Installation Should Be Checked

As with any complex device, an APS has many features that could malfunction or fail in the course of its operation. If features such as "Walk" indication, locator tone, or signal interaction fail to work correctly, the resulting lack of information or misinformation can be dangerous for pedestrians who are blind. It is important that municipalities who have taken steps to install these devices also take steps to ensure correct functioning through the years.

The overseeing agency should conduct an audit or checkup of the APS installations on a regular basis. Checkups should be conducted frequently if factors such as harsh weather may have affected the devices. At the very least, the APS should be checked

- Every 6 months.
- After any repairs to the intersection signals, poles, or controller, and
- After any changes to signal timing.

What Should Be Checked

On each regular visit to conduct a checkup of the APS units, the evaluator should recheck *each of the items on the original post-installation checklist* (see previous section). The following list comprises some of the most common failures that have been observed on installed APS devices:

- Vibrating arrow/button—may stop working or have very weak vibration
- "Walk" indication—tone or speech message may have stopped working or be delayed in sounding after the walk interval begins.
- Raised arrow—may be missing or pointing in the wrong direction
- Pushbutton—may be jammed or malfunctioning.
- Ambient noise response—may be slow to respond or have ceased responding at all.

These items should be specifically checked since some may not be obvious in a cursory glance.

AR0071959

Other Operation and Maintenance Issues

Repairing an APS After a Crash

It is essential that all maintenance personnel understand the functioning of the APS and consider it when making any repairs to the APS location.

One municipality had a problem when the pole holding the APS was knocked down in an accident and the repair team that replaced the pole oriented the APS toward the wrong street (see Figure 7-13). Because the speech message and arrow did not match up; pedestrians heard "Walk sign is on to cross Harford Road" (at the correct time), but the arrow on the device pointed toward Taylor Avenue.

In another instance, an APS was damaged by a car that left the roadway. The APS was just strapped back onto the pole with no attention to the alignment of the tactile arrow. The APS continued to function, but was pointing to the center of the intersection, rather than being aligned with the appropriate crosswalk.

Figure 7-13. The APS was temporarily replaced on the pole, but the tactile arrow points to the center of the intersection, rather than being aligned with the direction of travel on the crosswalk.

Lessons Learned from APS Installations

New Technology

Not unlike any new technology, the first installations of new types of APS devices did not always operate flawlessly. There were sometimes issues that had to be resolved. In addition,

AR0071960

reports from older installations sometimes brought up recurring problems that had to be addressed in the installation. All of the issues were easily solvable.

The following list of issues should provide information that will prevent such problems from reoccurring:

- Wiring to pedhead and/controller,
- Pushbutton installation,
- Signal phasing,
- Volume adjustment,
- Use and wording of speech messages,
- Pushbutton and pole location,
- Tactile arrow location and position,
- Speaker positioning and volume, and
- Braille signage and correct installation.

Wiring

Some minor problems have been experienced with wiring and color code.

- Prisma, a Swedish company, uses a European wire color standard. Since this standard is not consistent with the U.S. NEMA color code standard, some wiring problems were created. Installers of these products should take care to be certain the devices are wired correctly.
- Prisma APSs have also drawn concern from signal technicians over the voltage (120 V AC) sent to the pushbutton location. Technicians are concerned about pedestrian safety if the pushbutton is damaged or removed by a passing vehicle and a pedestrian comes in contact with the live wires or the electrically charged metal pole. Step-down transformers for mounting in the pedhead are provided upon request for U.S. installation.

Other problems may be related to incorrect wiring of the pushbutton units.

- In one location, the technician attached the vibrator wire to the speech "Walk" indication instead of the speech "Walk" indication and the vibration of the arrow that were expected. there was a rapid buzzing sound from the unit during the walk interval and no vibration of the arrow. This was easily corrected by switching the wires, once the problem was noticed and diagnosed.

AR0071961

- At another location, wires from the parallel crosswalks were switched when attached to the control unit in the controller. Those units were programmed for the extended button press to call audible beaconing on the crosswalk, but the sound came from the APS on the parallel crosswalk, rather than from the other end of the called crosswalk. This problem could lead blind pedestrians to cross the intersection diagonally.

Pushbutton Installation and Vibrotactile Indication

When two APS pushbuttons with vibrotactile indications are installed on the same pole, they may require insulation and a rubber gasket to eliminate vibrations generated from the other pushbutton.

A problem was experienced when two pushbuttons were on the same pole with no vibratory insulation (Figure 7-14). Pedestrians were unable to determine which pushbutton was vibrating, since it appeared that both were. Proper insulation of the pushbutton will prevent this problem from occurring.

Figure 7-14. Incorrect installation of two APSs on a single pole (no vibratory insulation).

Phasing

An installation had a problem when the signals went into flash mode and the APS device remained in "Walk" mode. This scenario presented an unsafe condition and message for pedestrians. This problem was resolved by correctly wiring the APS device into the

AR0071962

controller/signal system so the controller logic and conflict monitor detected and changed the pedheads to the appropriate indications.

Volume Adjustment

Although current standards call for the APS volume to only be 2 to 5 dB above ambient sound and for the locator tone to be heard at a distance of 6 to 12 ft from the pushbutton, the volume is often set much louder than that.

- Installers used to devices using audible beaconing think that APSs are supposed to be loud enough to hear across the street.
- There is no easy way to measure the volume of the locator tone and the "Walk" indication because of the short duration of the tones or messages, the requirement to measure relative to ambient sound, and the signal's quick response to ambient sound.
- For pushbutton-integrated devices, the speaker is in the pushbutton housing. Location of the pushbutton and orientation of the speaker can be critical to hearing the "Walk" indication at the crosswalk.

One installation experienced a different problem in adjusting the volume of an APS unit. They had used the pushbutton control units that install in the cabinet (as opposed to those that install in the pedhead). The wiring was too small of a gauge to drive the speaker to provide a loud enough message (compensated by the pole and speaker being more than 10 ft back from the crosswalk).

The manufacturer's guidelines and specifications should be followed for proper operation. Speakers can be provided for each control unit.

Speech Messages

The speech messages used for the "Walk" indication, as well as the descriptive pushbutton message, must be understandable.

- In one case, poorly recorded "Walk" messages, by an individual with a strong accent, made the street names indistinguishable ("Plant" and "Calvert").
- Use of a standard message, "Walk sign is on," at locations with two pushbuttons on the same pole can be confusing, as a pedestrian waiting to cross and who is unable to see the "Walk" signal cannot tell which "Walk" message is being conveyed.

AR0071963

- A speech message that does not have additional information clarifying which street the pushbutton applies to can be confusing to pedestrians unfamiliar with the intersection. For example, at the intersection of Harford and Taylor Streets, the pushbutton information message for all devices said "Harford" and "Taylor." If the pedestrians do not know which street they are facing, the message "Walk sign is on for Taylor" is ambiguous.
- One jurisdiction wanted to use a male voice for one crossing direction and a female voice for the other direction to distinguish crossing directions and add to the safety of the crossing. Most APS devices provide only a male voice; however, all APS devices use messages recorded on speech chips, and a different voice can be specified. Most devices now provide capabilities for self-recording messages. However, care should be taken to provide clear and understandable messages.
- Speech "Walk" indications should be in the form "Maple, Walk sign is on to cross Maple." Some problems have resulted from using different message wording.

Pushbutton and Pole Location

Some problems have been observed with pushbutton and pole location for APS devices:

- Poles that are more than 10 ft from the curb line create real problems for blind pedestrians who must find the pushbutton and then realign to cross the street.
- Pushbuttons are often placed where they are not reachable from the sidewalk area, are in the bushes, or are behind a fence.

Tactile Arrow and Position

The tactile arrow is supposed to point in the direction of pedestrian travel on the crosswalk, and the face of the device is supposed to be parallel to the crosswalk it controls.

Installation issues include the following:

- If the pole is in a poor location, the arrow may be pointing at the street and crosswalk direction, but may not be within the crosswalk area.
- If installers do not understand the purpose of the arrow, they may install it angled in the wrong direction. For example, if they use the holes from a previous pushbutton, the arrow may be pointing diagonally across the intersection rather than in line with the crosswalk.

AR0071964

Speaker Positioning

Pedhead-mounted speakers in existing installations are often mounted in positions that make the messages more ambiguous. (See examples in Chapter 6 and also earlier in this chapter.)

For pushbutton-integrated devices, the speaker is in the pushbutton housing. Location of the pushbutton and orientation of the speaker can be critical to hearing the "Walk" indication at the crosswalk. If the speaker is located too far from the crosswalk location, pedestrians who are blind may not hear the "Walk" indication.

Figure 7-15. APS pushbuttons installed incorrectly.

As shown in Figure 7-15, the pushbuttons are installed incorrectly; as a result, the APS is too far from the crosswalk it signals, and the sound for the other crosswalk at the intersection comes from a speaker closer to the crosswalk.

AR0071965

Figure 7-16. APS pushbuttons installed correctly.

In Figure 7-16, the APSs are installed correctly (close to the crosswalk they signal) and provide accurate information through proximity to the crosswalk.

Braille Signing and Location

Braille indications on pedestrian signals have sometimes been mounted backwards; in other cases, the braille sign has been installed at the wrong street.

- Manufacturers ship braille signs with a label to clarify positioning for nonbraille-readers. However, technicians might later make adjustments to the sign and reverse or mix up the braille plaques.
- When a braille message is added, the sign cannot later be turned around without reversing the braille, which would make the braille dots depressed, rather than raised. The braille characters must remain raised to the touch. If the original specification was not correct, the arrow cannot be turned without making the braille characters unreadable.

Providing Information to the Public 3

One-Page Flyer about APS Installation 4

Techniques to be Used by Pedestrians Who Are Blind at Intersections Equipped with APSs 5

Requesting an APS 7

AR0071967

This chapter provides instruction on methods and materials for providing the public with appropriate educational information about APSs.

Need for Education

Many people in the United States have had no experience with the newer types of APSs. It is important that pedestrians, both blind and sighted, have some understanding of the functioning of an APS, as well as the various features of the APS installed at a location. In particular, it is important that pedestrians know and understand the difference between the pushbutton locator tone and the "Walk" indication.

Individuals who live close to newly installed APSs may not be aware of how useful an APS is for pedestrians who are visually impaired. Advance publicity about the APS to be installed will help people understand the need for the device and may result in a higher level of neighborhood acceptance. Many individuals are not familiar with pushbutton locator tones and may benefit from an explanation of how they are used by pedestrians who are blind or who have low vision.

Education Needs Documented by Research Project

Research completed as part of this project indicates that education is needed to give blind pedestrians a better understanding of pushbutton locator tones, response to ambient sound, and "Walk" indications.

Some participants thought that the increase in volume of the locator tone, in response to ambient sound, was a new kind of "Walk" indication.

In addition, most participants were not familiar with the need to use pushbuttons. Most of the pedestrians who were blind stated that they did not use pushbuttons, unless they knew the pushbuttons were present and knew where they were located. They were unclear on the purpose or function of the pedestrian pushbuttons. Pushbutton locator tones should provide more information. All pedestrians seem to need more education about the use and function of pushbuttons.

It is important that pedestrians who are blind understand the placement of an APS. The MUTCD 2000 (3, 41[08]) provided more specific location guidance for APS pushbuttons. It was noted in this research project that many of the blind pedestrians were unfamiliar with arrows and were unable to immediately determine which direction the tactile arrow was pointing. An

AR0071968

explanation that includes actual hands-on experience with the APS and pushbuttons can be helpful.

Providing Information to the Public

Information about APSs is commonly distributed through **radio and TV publicity**, which reaches many people, including those who are blind or who have low vision. Newspaper articles, in contrast, may not reach individuals who are blind or visually impaired, particularly those in the growing elderly blind population.

Radio reading services, which provide live spots and informational programs aimed at individuals who are blind or who have low vision, [illegible] in many cities. Radio reading services broadcast the reading of newspapers and books and magazines to the blind, physically impaired, and those who have difficulty reading small print. Because of copyright law, reading service radio broadcasts are restricted to a closed channel that is not available to the general public. Listeners can usually hear the service only by ordering a special "subchannel" radio through special cable service, or through a subscription webstream service.

The radio reading service serving a specific area can usually be found through an internet or phone book search.

Rehabilitation centers that provide services to individuals who are blind or who have low vision are located in many cities. These centers may have telephone- or email-based bulletin boards providing news of interest to individuals who are blind. Usually the posting information or notices is free. Centers may also provide meeting space or facilitate regular support group meetings.

There are two main **consumer groups** of individuals who are blind and who have low vision—American Council of the Blind and National Federation of the Blind. Each organization has affiliate groups and local chapters that usually meet monthly. Speaking at a group meeting is an excellent way to reach a number of individuals who are blind or who have low vision. Information about local chapters and contact information for each chapter is available from the national office and is usually listed on the national organization web pages (www.acb.org and www.nfb.org).

Offering to provide information and speakers at various **community organizations**, ranging from Parent Teacher Association meetings to business association meetings, can be another

AR0071969

avenue for educating individuals in the community where APSs are being installed. Individuals who are blind or who have low vision are often members of these groups as well.

One-Page Flyer about APS Installation

Public agencies may find it useful to distribute flyers to inform the public about APSs. The following sections list important information to include on the flyer, as well as some suggested text for each topic. Notes in italics are for the flyer designer and should not be included on the flyer.

[SAMPLE FLYER]

New accessible pedestrian signals are being installed at *[list intersections]*

[Insert a photo of an APS of the type being installed.]

The accessible pedestrian signals provide audible and vibrotactile "Walk" indications that help people who have trouble seeing the pedestrian signal. The sounds come from the pushbutton and automatically adjust to ambient sound so they will be louder when the traffic is loud and quieter when traffic is quiet.

Audible and vibrotactile "Walk" indications tell a visually impaired pedestrian that the "Walk" signal is on, but it is still important that they check traffic before crossing to be sure that cars are not running the red light or turning across the crosswalk.

Each accessible pedestrian signal has the following features:

- Pushbutton locator tone—a tone that constantly sounds once per second from each pushbutton to help people who are blind or who have low vision find the pushbutton.
- Audible and vibrotactile "Walk" indications—a sound and vibration during the "Walk" signal.

[Insert applicable "Walk" indication description.]

- Rapid tick "Walk" indication—a rapidly repeating tick from the pushbutton location to indicate that the "Walk" signal is on.
- Speech "Walk" message—provides the name of the street to be crossed, then "walk sign is on to cross" and the street name again. For example, "Haywood. Walk sign is on to cross Haywood."

AR0071970

- A tactile arrow either on the pushbutton or above the pushbutton points in the direction of travel on the crosswalk. The arrow vibrates during the "Walk" signal.
- Actuation indicator—a tone, a click, or a spoken "wait" that is generated when the pushbutton is pushed to confirm the button has been pushed.
- Braille street name—the name of the street with the crosswalk that the pushbutton controls is listed in braille on the plate above the pushbutton.

[If optional features are installed, add the applicable text below:]

- Optional features when you hold the pushbutton in for more than 1 second:
  - Pushbutton information message—names the street that the pushbutton controls and the other streets at the intersection. Example: "Wait to cross Vermont at Haywood."
  - Audible beaconing—The volume of the locator tone is boosted during the flashing "Don't Walk" interval to allow a person who is blind to home in on the opposite corner of the street.

[Provide contact information for questions or concerns.]

Techniques to be Used by Pedestrians Who Are Blind at Intersections Equipped with APSs

The following section, intended for O&M specialists, is adapted from *Crossroads: Modern Interactive Intersections and Accessible Pedestrian Signals* (22).

It is particularly important to recognize that the APS information is supplemental to traffic and environmental cues and only provides information about the status of the signal. The APS "Walk" indication indicates that the "Walk" signal is on, not that it is safe to cross. Cars can still be turning across the crosswalk or might be running a red light. The APS "Walk" sound can be compared to the "on your mark" instruction at the beginning of a race, though it means that the signal has changed, it is still important to "get set" (assess the traffic) and then "go" (begin to cross).

Suggested Techniques in Using APS

The only place in the O&M literature where specific techniques are suggested for crossing at intersections using APSs is a section in a curriculum on APS developed for Easter Seals Project ACTION (22). Based on the experience of the authors and the Project ACTION curriculum, the following techniques are suggested:

AR0071971

- Approach the intersection and stop at the curb ramp/street edge, maintaining initial alignment; check alignment for crossing by listening to traffic. Even if a pushbutton locator tone is noticed during approach, continue to the curb or edge of street first.
- Determine the starting location for crossing and identify tactile cues for use in realigning after pressing the pushbutton, because once the button is pushed, there may be insufficient time to listen for parallel traffic and realign before the next "Walk" signal.
- Listen and evaluate the intersection. Determine traffic patterns and intersection geometry and listen for a pushbutton locator tone or for a tone or speech "Walk" information. It is important that students/clients understand and can recognize the difference between a pushbutton locator tone and typical "Walk" indications.
- Search for a pushbutton using a systematic pattern. Even where there is a pushbutton locator tone, a systematic search pattern is needed to maintain orientation. Because guide dogs/guides are trained to avoid obstacles, they may be reluctant to approach a pole supporting a pedestrian pushbutton. It may be more efficient for the handler to initially use a cane to search before teaching the dog to locate the pole.
- Once the APS is located, explore the device and its functioning, including locating the tactile arrow to confirm that the arrow is pointing in the direction of the street being crossed.
- Hold the pushbutton down for more than 3 s and listen if more information is provided.
- Listen to APS and traffic for a full cycle to make sure that the tones or speech messages correspond with traffic information.
- Press the button and return to the predetermined spot at the curb, realign, and prepare to cross.
- When the "Walk" indication is heard, confirm that traffic on the perpendicular street is stopping or stopped and listen for initial parallel traffic movements, when available. Traffic may still be legally clearing the crosswalk when the "Walk" begins, so careful listening is important.
- Cross the street using typical alignment techniques (traffic, straight line travel, etc.) while continuing to listen for turning cars. In many cases, cars can turn right and left across the crosswalk during the pedestrian phase. Although drivers are supposed to yield to pedestrians, they often do not.

AR0071972

- Be aware that a locator tone on the destination curb may provide additional wayfinding information.
- Continue to be vigilant of traffic even though the "Walk" indication is on.

Requesting an APS

The following was copied from the website of the Environmental Access Committee of the Orientation and Mobility Division of the Association for Education and Rehabilitation of the Blind and Visually Impaired (23). A sample letter for requesting an APS is also reprinted.

- Educate yourself about types of APS available and the applicable regulations.
- Find out who controls the intersection where you're making the request. Sometimes it's a city department of traffic engineering, sometimes it's the county, and sometimes, if it's a state or federal highway, it's the state Department of Transportation. You can just call the number listed in the phone book for traffic engineering or public works and ask who you need to contact about the traffic signals at that intersection. Get a name, address and phone number. If you get to talk to someone on that phone call, ask what their policy is on APS.
- The request for an APS is strongest if it comes from a consumer who is blind or visually impaired. So, the consumer should make the actual request for modification in a letter to the individual in the traffic engineering department that manages that intersection. (A sample letter is below.)
- Include wording in the first letter about the need for "access to information" about the status of the pedestrian signal. If you have to, you can refer back to the ADA and requirements to make the right of way accessible if they refuse or delay installation.
- With the consumer's permission, follow their letter with a letter of support on your professional letterhead, restating the reasons for the need for the APS at that intersection.
- Follow up with a phone call about a week later to the person who is responsible for that intersection. Remember that most traffic engineers will never have heard of an Orientation and Mobility Specialist and O&M in traffic engineering

AR0071973

terminology is Operations and Maintenance, so don't shorten your title) and may not have thought about a blind person crossing an intersection independently. Remind them of the letter of request and see how they respond. If they have no idea about APS and where to get them, share that you have a list of manufacturers and would like to meet with them to discuss solutions.

- If you can get the engineer to meet you and the consumer on the street corner, and discuss it there, do it. Be sure to include the consumer at that time. Demonstrate the problems and talk about what the APS would do to help.
- If you have not talked to the engineer within two weeks after they should have gotten the letter, you or the consumer should send a follow-up letter asking them to contact you.
- If you need to send a third letter, it needs to be copied to the department head, the city ADA coordinator, and a local elected official.
- If they refuse to meet with you or refuse to put in the APS, ask them to send a letter to that effect to the client with a copy to you. Say it nicely, but they'll know why you're asking and don't settle for a non-response. Documentation can be useful if you have to file an ADA complaint. You and the client should document any phone conversations (date, who, what they said, etc.). Hopefully, you won't need that information later, but just in case, keep track. (2.5)

Sample letter requesting an APS:

[Date]

[Address to traffic engineer in charge of the intersection]

This letter is to request the installation of an Accessible Pedestrian Signal (APS) at the intersection [insert street names]. As a pedestrian who is blind, I am unable to use the visual pedestrian signals currently installed at this location and need access to the information in order to cross the street. As you may be aware, there is a bus stop at this intersection. I must cross the street safely to reach the bus stop. [change that last sentence to fit the specifics of the intersection, particularly if there are some

AR0071974

issues that make it particularly hard to cross such as poor traffic sounds, lots of right turning traffic, T-intersection, etc.].

I would like to meet with you or someone from your department at the intersection in question to discuss appropriate modifications. I would also like for [insert O&M instructor name], an orientation and mobility specialist at [insert agency name] to join us. You may contact me at [insert phone number or address] or [insert O&M instructor name] at [insert phone number] to set up an appointment. Thank you for your attention to this matter.

Sincerely,
[signature]

cc: [O&M specialist name, agency affiliation]

AR0071976

Case Study—Montgomery County, Maryland

Date: May 2002

History and Background

The intersection of Fenton Street and Wayne Avenue is the first of 11 locations in the Silver Spring central business district (CBD) to be equipped with APS under a pilot program initiated by the county executive.

Process and Procedure

There is no formal procedure to request an APS. A committee was formed, in coordination with the Montgomery County Commission on Persons with Disabilities, to make decisions about type and features of APS to be installed.

Most signalized intersections in the county are on state roads, so final decisions of the State Highway Administration on APS policy will affect installation at those locations.

Funding

Costs for the pilot project are absorbed as part of the traffic engineering department budget. An additional line item for APS installation was requested in the budget but was not funded.

Description of Intersection

These traffic signals are being rebuilt as part of the redevelopment of the CBD. Fenton Street and Wayne Avenue was the first one to be rebuilt and hence the first to receive APSs. All intersection legs are four lanes wide. Fenton Street runs approximately north-south and Wayne Avenue runs east-west. There is a leading left turn phase from westbound Wayne to southbound Fenton.

Date Installed

September 2001

APS Type and Features

Pushbutton integrated devices from Polara Engineering.

AR0071977

The intersection is pretimed, with walk intervals associated with each crossing being provided each cycle, but the APSs are actuated (audible and vibrotactile "Walk" indications are not provided unless the pushbutton is pushed).

APS features:

- Speech "Walk" message.
- Vibrotactile "Walk" indication.
- Pushbutton locator tone.
- Tactile arrow.
- Pushbutton information message called by extended button press.
- Automatic volume adjustment in response to ambient sound.
- Speech "Walk" message: "Walk sign is on to cross Fenton Street" for Wayne Avenue).
- Pushbutton information message, provided after an extended button press (3-s depression of pushbutton):
  - Includes both street names.
  - Clarifies to which crossing the button applies.
  - Example: "Crossing Wayne Ave at Fenton St."

APS Installation

Devices are installed on all four corners, using stub poles for all in order to place the pushbuttons and APS at the top of the ramp for each direction, separated by at least 10 ft (see Figures 9-1 and 9-2).

AR0071978

Figure 9-1. Pushbutton-integrated APS located on a stub pole beside the level landing of the curb ramp.

Figure 9-2. Pedestrian with guide dog at an APS located in line with crosswalk.

Each pole is approximately 5 ft tall with a substantial base; locations vary somewhat but are generally

- Within 5 ft of the crosswalk lines extended, and
- 6 to10 ft from the curb (except on the northwest corner, where further construction is planned; thus those poles were located farther from the curb).

AR0071979

The Polara control unit and the microphone, which monitors sound for the automatic volume adjustment, are typically installed inside 18-in. pedestrian traffic signal heads. At this location, which has 12-in. pedestrian signal heads, the control units were installed in an exterior box attached to the top of the pedestrian traffic signal heads. The microphone was attached to the box, which located it much higher than usual; however, that placement seems acceptable.

Installation Issues

There were no real problems with the installation. However, locating the poles and APS properly in relation to the curb ramp and as recommended in the MUTCD is difficult. While it may be less of a problem in new construction, it requires thought and planning, as well as extra poles, conduit, wiring, and construction in retrofit situations.

Maintenance

Except for some minor adjustments after installation, there have been no maintenance issues or failures.

Evaluation

No formal evaluation has been conducted. Committee members visited the installation and were generally pleased with the functioning.

Case Study—Portland, Oregon

Date: July 2003

AR0071980

History and Background

The City of Portland has had some form of audible pedestrian signal for over 20 years. In installing these devices, staff worked closely with the requester to identify specific needs.

- In the late 1970s, city staff installed buzzer-like devices at three intersections on request basis. These buzzers were inexpensive devices purchased from a local electronics store. The buzzer was only activated with a normal pedestrian pushbutton call.
- During the late 1980s the city began using an inexpensive Mallory chime as an audible device. It was installed in some fixed time intersections, as well as actuated intersections.
- By 1995 the city had 10 signalized intersections with audible devices.
- In 1996 the city decided that a more formal policy was necessary and a process was implemented, which was revised by a Citizens Advisory Committee in 1999.

During the past 5 years the city has greatly expanded its program. By mid-2003, Portland had 53 signalized intersections with some form of audible signal (Figure 9-3).

The City of Portland was awarded a Pedestrian Project Award for 2003 from the Institute of Transportation Engineers and the Partnership for a Walkable America. The award, in the elderly and mobility category, recognized Portland's project to retrofit existing signals with APSs.

Figure 9-3. An APS mounted over 12 ft high on the pole broadcast speech messages at this location in Portland. City engineers expressed concerns about intelligibility of the message.

Process and Procedure

A formal policy was established in 1996.

AR0071981

- City staff assembled a stakeholders group, which included representation from the Oregon Council of the Blind, the National Federation of the Blind, the Oregon Commission for the Blind, Independence Living Resources, and other groups representing both the visually impaired community and mobility instructors.
- The policy was developed over a series of three meetings.

Key points of that policy include the following:

- Audible signals are installed only on a request basis.
- The intersection has to have some unique or unusual characteristics that warrant the addition of an audible signal.
- Referral to a mobility specialist is required; this service is provided through an agreement with Oregon Commission for the Blind. In some instances the crossing problems may be related to a lack of user skills that might be better addressed by further training.

In mid-1999 the requests for audible signals outstripped city resources for the program. A citizens advisory committee (CAC) was activated to review and rank the requests.

- The CAC and city staff started with a ranking process similar to that used by the City of Los Angeles.
- Staff applied the criteria to 10 intersections on the request list. The CAC made some revisions to the scoring criteria (see Appendix D).
- Scoring materials were developed. The electrician responsible for the installations and a mobility instructor from the Oregon Commission for the Blind meet with the requester at the candidate intersection to better understand the user's needs and concerns. After agreeing that some sort of audible signal is a viable solution, the city staff person and the mobility instructor complete field aspects of the scoring form. Information such as volumes and accidents is gathered by office staff from existing city records and added to the scoring form.
- The CAC meets semiannually to rank the requests.

Funding

From 1996 through 2000, the city used approximately $150,000 in general transportation funds to install APSs. That funding source for APS has since been lost. To continue with new

AR0071982

installations, the city received over $200,000 in transit mobility funds from the local transit agency. However, that grant expires in July 2004 and no replacement funding source has yet been identified.

APS Types and Features

Pedhead mounted at numerous intersections. Pushbutton-integrated at two intersections.

Pedhead-mounted devices manufactured by Novax and Mallory.

Pedhead-mounted APS features include

- "Walk" indication—cuckoo/chirp, beep, or chime, and
- Extended button press to call accessible features on some devices (no locator tone is used.).

Pushbutton-integrated devices, manufactured by Polara Engineering and Campbell Company, have been installed recently with locator tones and additional features.

The City of Portland has also evaluated the Vibrawalk pushbutton manufactured by Novax Industries (see Figure 9-4).

Figure 9-4. Vibrawalk pushbutton installed in Portland includes a locator tone. The arrow vibrates during the walk interval and a "Walk" indication is provided from the pushbutton or speaker mounted on the pedhead.

Special Features

Portland staff has worked with manufacturers on developing device features.

- After 1996, in deference to requests of members of the National Federation of the Blind, a technology was used that requires the user to hold the button for at least 1 s to place a call for an audible signal to make the technology "refusable." The button actuated timer, from Novax

AR0071983

Industries of British Columbia, requires that the button be depressed for at least 1 s to call the audible indication.

- Staff worked with Novax and McCain to take the speaker and electronics out of the exterior Novax housing and mount them directly on the pedhead to afford more protection from vandalism and to place the speaker closer to the users' ears

In 1999, the CAC and city staff expressed a desire to find lower cost options so that more intersections could be treated. City staff received approval from the CAC to install lower cost Mallory devices. Since the Mallory device has neither automatic volume adjustment nor the button activated timer, city staff is careful to use the device only in locations that are that are not close to residences.

Date Installed

Between 1970s and present.

Installation

Installation varies greatly from intersection to intersection. Portland transportation engineering staff report that the largest problem faced is with existing infrastructure. The aging transportation system makes installing new wires in old, undersized conduits a challenge. The location of existing poles also poses a problem. As intersections evolve throughout their life span, poles for pushbutton locations are often located in areas that are less than desirable for accessible pedestrian installations.

Obstructions, such as utility and sign poles, are also a significant challenge. These obstacles often make placement of pushbutton locations difficult, translating into higher installation costs.

Proximity of poles, in relation to one another, also has to be taken to account. Volume level of the "Walk" cue and locator tone must be loud enough to tell pedestrians to go, but quiet enough to not give a false "Walk" cue to someone at a conflicting pedestrian lane. This can be difficult at intersections with odd configurations, such as islands with separately actuated pedestrian lanes.

AR0071984

Maintenance

Maintenance of equipment has been almost a nonissue. There have been few maintenance problems, although it should be noted that most of the equipment with electronics mounted in the pedhead or pushbutton is relatively new. These installations are only 1 to 6 years old, so there is not a long maintenance history on those devices.

Evaluation

Portland tested a variety of "Walk" indications.

- The earliest sounds for the walk interval were a buzzer and Mallory chime.
- A trial installation used voice messages. The voice message typically said "The Walk light is now on to cross 81st Street." Although equipped with ambient sound adjustment to increase the output as background noise increased, the voice message was often difficult to hear.
- Tones seem to be better for cutting through background noise in an urban street environment. After the initial test with voice and tones, the city decided to use the cuckoo and chirp sounds.

The community had the following reactions to the APS:

- Buzzer—Staff received some calls regarding the annoying sound and usually responded by placing some sort of baffling material around the buzzer.
- Mallory chime—The chime was a more pleasing sound and the city seldom received any noise complaints, even though the chime was installed in some fixed time intersections.

Case Study—Newton, Massachusetts

Date: July 2003

History and Background

Accessible pedestrian signals were installed at major intersections in Newton, Massachusetts, in 2001, as part of a major signalization upgrade project and at the recommendation of the Mayor's Committee for People with Disabilities (Mayor's Committee). This is Newton's first experience with this signal type.

Process and Procedure

New Construction and Signal Upgrades

When new signals are installed in Newton, the Mayor's Committee considers whether they should have accessible pedestrian signals. Their recommendation is then referred to the Departments of Public Works and Planning. For example, when signalization at an intersection is being upgraded from a flashing beacon to full signalization, input is obtained from the Mayor's Committee.

Handling Individual Requests

Individual requests are referred simultaneously to the Mayor's Committee and to the Traffic Council. The Traffic Council is required to respond to requests by making a decision within 12 weeks.

Consultation with Local Agency for the Blind

The City Traffic Engineer also consults with the orientation and mobility specialist at the Carroll Center for the Blind regarding the need for APS and for suggestions regarding the most appropriate type of APS for a particular intersection.

AR0071986

Funding

APS installations in Newton were funded jointly by the Departments of Public Works and Planning, with a portion of the cost being covered through the Community Development Block Grant program.

The City of Newton currently has $10,000/year earmarked for APS installations.

Description of Intersection

The APSs were installed at a complex intersection with high pedestrian and vehicular traffic volumes. At this intersection, three crosswalks share the same exclusive pedestrian phase timing:

- One is a midblock arterial crossing (Figure 9-5);
- One is a minor street intersecting the arterial in a "T," near the mid-block crossing (Figure 9-6).
- The other is across a third street that enters the arterial diagonally, close to the T-intersection of the minor street.

Because of abundant turning traffic during all vehicular phases, there is no safe crossing time for pedestrians, except during the exclusive pedestrian phase.

APS Type and Features

Pushbutton-integrated APS manufactured by Bob Panich Consultancy.

APS features include the following:

- "Walk" indication – audible rapidly repeating tones;
- Vibrotactile "Walk" indication;
- Pushbutton locator tone;
- Alert tone;
- Tactile arrow; and
- Automatic volume adjustment in response to ambient sound.

AR0071987

Figure 9-5. Panich APS at midblock crossing, Newton, MA. The APS should have been mounted on the side of pole closest to the crosswalk, with the arrow parallel to the crosswalk rather than pointing up.

Figure 9-6. Panich APS for crossing the stem of a T-intersection.

APS Installation

At another intersection at which APS devices were added, a stub pole was installed in order to locate the pushbutton properly for one crosswalk (Figure 9-7).

AR0071988

Figure 9-7. Panich APS on stub pole in Newton, MA. Arrow oriented parallel to crosswalk.

Installation Issues

Installation presented no technical difficulties.

Initially, the APS volume was set so loud at one location that the "Walk" signal was audible from a nearby intersection, possibly leading pedestrians at that intersection to incorrectly believe they had the walk interval. The volume was turned down several months after the APSs were installed.

Although the basic requirement for conduit in public rights-of-way in Newton is a 36-in. trench, actual construction may be less than 36 in. depending on site conditions. It is important that such an installation be based on direct field knowledge, rather than be designed in the shop.

Maintenance

No maintenance, except for volume adjustment, has been necessary since the audio-tactile pushbuttons were installed. Weather does not seem to affect their performance, and there has been no vandalism.

Evaluation

The APSs have been well-received by blind users, and there have been no objections from neighbors.

The APSs are located in a small business area, not close to any residences.

Case Study—New Jersey DOT—Washington, New Jersey

Date: July 2003

History and Background

The New Jersey Department of Transportation (NJDOT) has been sensitive to the needs of the visually impaired. The first vibratory pushbuttons (with raised directional arrow) in New Jersey were installed in 1992 at the Rowan College signalized pedestrian crossing across Route 322. As of August 2000, NJDOT had installed APS devices at four intersections. The devices at the location described here and pictured in Figure 9-8, Route 31 and Route 57, were installed in the fall of 2000. NJDOT has recently installed APS devices at other intersections and expects to install more devices.

A project involving the installation and evaluation of four types of APS devices at intersections in Morristown, NJ, was funded by NJ Highway Traffic Safety and was conducted by Edwards and Kelcey in cooperation with The Seeing Eye. (More information is provided in the Appendix.)

Process and Procedure

There is no formal process for deciding to install an APS.

These APS devices were installed at the request of a blind person in conjunction with reconstruction of the intersection. An O&M specialist provided information useful in making the decision about the type of APS selected.

Funding

The APSs are funded under the general state fund, with no special funding sources.

The devices cost $400 per device to NJDOT, plus installation by NJDOT forces. NJDOT went out to bid for the devices.

AR0071990

Date Installed

Fall 2001

Description of Intersection

Route 31 and Route 57 is a major intersection of a four-lane undivided road and a two- and three-lane road with a parking lane at the edge of small downtown CBD. There are four traffic islands, with signalized crossings to the islands. Pushbuttons were installed at all crossings for a total of 12 devices at the intersection.

APS Type and Features

Pushbutton-integrated APS manufactured by Polara Engineering.

APS features include

- Vibrotactile "Walk" indication,
- Pushbutton locator tone,
- Tactile arrow,
- Braille street name, and
- Actuation indicator—tone.

APS Installation

Figure 9-8. Installation of two pushbuttons on a single pole (only a single pushbutton is visible in the photo). Although the pushbutton is in line with the crosswalk, the pedestrian must travel more than 10 ft before reaching the street and the beginning of the crosswalk.

AR0071991

APS devices were installed at all crosswalks to provide the signal information at all possible crossings used by the blind person. It is a state standard to put two pushbuttons on the same pole with no standalone pole for the APS. This meant that some devices were located a distance from the beginning of the crosswalk. Because the only "Walk" indication was vibrotactile, the walk interval was lengthened to provide time for a pedestrian who is visually impaired to reach the departure curb after the "Walk" signal began.

These devices were installed as a retrofit before various recommendations and guidelines were issued. Currently, recommendations of PROWAAC and the Draft PROWAG state that devices should provide audible and vibrotactile information about the walk interval. These APSs are vibrotactile only and thus do not conform to those recommendations. The MUTCD and Draft PROWAG recommendations also encourage installation of devices on two poles separated by at least 3 m. If separation is not possible, the Draft PROWAG recommends speech messages for the walk interval; vibrotactile indication was used here.

Installation Issues

No major installation issues.

Maintenance

There have been no reported maintenance problems, except for the vibrating arrows on a couple of devices that got stuck and stopped vibrating.

There has been no vandalism.

Evaluation

There are no reports of complaints or comments received from the general public or individuals in the community. With other installations, there have been complaints due to the locator tone increasing in response to the traffic noise and bothering persons who live close to the intersection.

There were complaints at first from a blind woman regarding placement of the devices and inability to line up and cross while keeping her hand on the vibrating arrow. After she was trained by an O&M specialist, however, she was able to adequately use the APS (see Figure 9-9).

AR0071992

Figure 9-9. APS mounted on signal pole for crossing signalized right-turn lane. A pedestrian who is blind is waiting with her hand on the pushbutton for the vibrotactile "Walk" indication. After the "Walk" indication begins, she must turn and cross the sidewalk before beginning to cross the street.

Placement is problematic for a device that is vibrotactile only. In order to keep her hand on the device, the user must stand back from the crosswalk and then turn toward the crosswalk after the "Walk" indication begins.

There has been no research or evaluation regarding the APS either before or after installation.

Case Study—West Virginia Division of Highways—Morgantown, West Virginia

Date: July 2003

History and Background

APSs were installed in 2002 at the request of blind citizens. These are the first APSs that have been installed in the state.

Process and Procedure

Morgantown does not have a process or procedure for determining which intersections will be equipped with APS. Typically, all traffic signal installations in West Virginia are done by contractors working under the purview of the West Virginia Division of Highways.

Funding

This demonstration project was fully funded by the West Virginia Division of Highways.

Description of Intersections

APSs were installed at two downtown intersections that have pedestrian actuation and exclusive pedestrian phasing with right turns on red permitted.

APS Type and Features

Pushbutton-integrated APS manufactured by Precise Traffic (model TS-903).

APS features include:

- Tone "Walk" indication—fast tick, a rapid repetition of the pushbutton locator tone for crossing in both directions.
- Pushbutton locator tone.
- Tactile arrow.
- Actuation indicator.
- Tactile map of crossing, and

AR0071994

- Automatic volume adjustment in response to ambient sound.

Signals are being modified to include pushbutton information messages modeled after "Wait to cross Willey St. at High St. Wait for red light for all vehicles. Right turn on red permitted."

APS Installation

Two pushbuttons have been mounted on some corners so the standard single arrow can be correctly oriented in the same direction at each crosswalk (Figure 9-10). This was necessary where the two crosswalks at a corner were not at right angles to each other.

Since these locations used exclusive pedestrian phases, a right-angle, double-ended arrow was installed so that a single pushbutton could be located on one corner or quadrant, controlling the "Walk" signal for two crossing directions. The right angle arrow will be installed where both crossings are 90 degrees from a particular quadrant.

Figure 9-10. Mounting of two Prisma pushbutton units on a single pole. See arrows on insert detail for the orientation of the tactile arrow on the top of each unit. Both devices make the same sound during the "Walk" indication, which is acceptable in this installation since there is exclusive pedestrian phasing.

AR0071995

Installation Issues

Wiring of the APS was little different than typical (non-APS) pushbuttons. APSs are mounted to signal uprights using two 0.25-in. stainless steel screws. In the future, stainless steel bands may be placed at the top and bottom sections of the APS in high-vandalism areas.

Diligence is needed in the initial design of a complete intersection so as to correctly locate APS according to the MUTCD.

Maintenance

No weather-related maintenance issues have been reported.

Cabinets and signals are well guarded against transient voltage surges, including high speed surges that are accompanied by lightning.

To date, APSs have been installed at six intersections in West Virginia. At one intersection in downtown Charleston in a high vandalism area, three APSs have been knocked off the signal upright.

Evaluation

The APSs have performed as expected according to manufacturer's literature.

Negative comments have been received from nearby businesses about the noise level of the locator tone. The entrance to one business is less than 10 ft from the pole on which two APSs are mounted.

Blind users have objected to the location of some APS units (in some cases at a distance of about 20 ft from the crosswalk).

Positive comments have been received about the protective installation of APS.

Case Study—Dunedin, Florida

Date: July 2003

History and Background

There are two downtown intersections and one at Patricia Avenue and Beltrees in Dunedin where APSs have been installed at the request of citizens who are blind.

The City of Dunedin received the Inspired Leadership Award for 2003 from the Florida Alliance for Assistive Services and Technology (FAAST) for their APS installations.

Process and Procedure

Requests for APSs are received by the City of Dunedin ADA coordinator and reviewed and recommended by the ADA Committee appointed by the city manager.

APSs were requested by one person who is blind and who also has limited hearing in one ear. She consulted with an O&M specialist and requested pushbutton-integrated devices, and she also worked with the engineer on installation details.

Funding

The intersection modifications were part of a redevelopment project.

Description of Intersections

One of the downtown intersections, Douglas and Main Streets, is a fairly small square intersection of two-lane streets with a pushbutton-actuated exclusive pedestrian phase

AR0071997

The other downtown intersection is at Broadway and Main, which is a more complex intersection where a very busy state road intersects with the city's Main Street.

The third intersection, at Patricia and Beltrees, is a T-intersection of a minor street with very busy street with a right turn lane.

APS Type and Features

Pushbutton-integrated devices from Polara Engineering.

APS features include the following:

- Speech "Walk" message:
  - At Douglas and Main (with exclusive pedestrian phasing): "Walk sign is on."
  - At Broadway and Main: "Walk sign is on to cross Main" or "Walk sign is on to cross Broadway."
- Vibrotactile "Walk" indication.
- Pushbutton locator tone.
- Actuation indicator—tone.
- Tactile arrow.
- Automatic volume adjustment in response to ambient sound.
- Extended button press—increases the volume of the "Walk" indication and locator tone.

Figure 9-11. Two pushbuttons are located on fluted pole at this location with exclusive pedestrian phasing. Tactile arrow of each device points in the direction of travel on the crosswalk.

AR0071998

APS Installation

Two APSs were mounted on each pole.

At one crossing the APSs were about 15 ft back from the crosswalk location and approximately 5 ft toward the intersection from the extension of the crosswalk lines. The volume of the locator tone and the "Walk" message was quite loud.

At the Patricia and Belcrest location, APSs were installed on only one crosswalk, for crossing the through street, as needed and requested by the person who lived near the intersection.

Installation Issues

Installers stated that they had difficulty figuring out the new devices, but that the devices seemed to work fine after they figured them out.

Fluted poles were used in the redesign, which made it difficult to align the tactile arrow (see Figure 9-11).

Maintenance

No maintenance issues have been reported except for the need to adjust volume levels.

Evaluation

The installation generated complaints from patrons of a restaurant/bar with outdoor seating at one corner of the intersection. The locator tone was loud enough to hear from more than 30 ft away.

The woman who requested the installation was initially unhappy with some parts of the installation. The original plans included a stub pole close to the crosswalk, but the stub pole was not installed at first. Even with the signal adjusted to the maximum volume, the woman was unable to hear the "Walk" indication when she was standing at the crosswalk location. A stub pole was later installed that allows a reduction in volume of the device and diminishes problems for neighbors as well.

Case Study—Maryland DOT

Date: July 2003

History and Background

During the 1980s and 1990s, Maryland installed APSs of the cuckoo/chirp type at some locations throughout the state, including in Montgomery County, Frostburg, Cutherville, and Towson.

In response to concerns about mobility for persons who are visually impaired traveling through unique intersections, such as roundabouts, and the addition of the APS section in the MUTCD, Maryland DOT convened a committee in November 2000 to develop criteria for installation and prioritization plans for installation of APSs.

The committee consisted of representatives of the visually impaired community, traffic engineers, O&M specialists, local ADA coordinators, and DOT staff. The goals of the committee included

- Identifying factors affecting mobility of the visually impaired through intersections.
- Identifying and reconciling differences of approach to mobility issues within the visually impaired community, and
- Developing a rating and prioritizing process for APS.

AR0072000

Process and Procedure

The committee developed a prioritization checklist. This checklist has been used at approximately 60 intersections to date, with scores ranging from 14 to 46 out of a possible total of 60. While each crossing receives a rating, the highest rating for any crossing is used for the intersection.

At this time, Maryland is considering any intersection with a rating greater than 36 to be a high priority. Eleven intersections are rated at this level and either have had APS installed or are under design for installation.

Funding

Maryland considers an APS to be a traffic control device, and as such, funding comes from traffic control, highway construction, and federal funds.

Type of APS Used

Pushbutton integrated APS manufactured by Polara Engineering.

APS features include:

- Speech "Walk" message, with option of cuckoo/chirp if desired for a specific location;
- Vibrotactile "Walk" indication;
- Pushbutton locator tone;
- Tactile arrow;
- Actuation indicator;
- Pushbutton information message in response to extended button press; and
- Automatic volume adjustment in response to ambient noise levels.

Maryland is also testing and evaluating equipment from other manufacturers.

First Intersection with APS Example

The first installation example, Lord Raven and Taylor, is a large intersection with right-turn islands, heavy traffic volumes, and left-turn lanes on all approaches (Figures 9-12 and 9-13).

Existing poles were used at this location with channelizing islands and uncontrolled right-turn lanes in three of the four quadrants.

AR0072001

The "Walk" indication is a speech message. The volume levels of the APS were carefully adjusted to prevent the "Walk" indication from being audible to pedestrians before they crossed the right-turn lane. The speaker is blocked on the side away from the intersection. However, wind, humidity, and large trucks can affect the sound levels, and the signals may be audible from the sidewalk under certain conditions. In this case, the person who requested the signals is familiar with the geometry.

Figure 9-12. Two APSs are mounted on the existing pole on this island.

Figure 9-13. APS as seen from right-turn lane crossing.

Second Intersection with APS Example

The second installation, Loch Raven and Glen Keith, is an intersection with low side-street volumes. The APS is for crossing the major street (Loch Raven) only. There are no pedestrian indications to cross the minor street (Glen Keith); thus, APSs were not installed for those crossings. The major street is quite wide, with a median island and a stop sign controlled service road along the west side of Loch Raven. Again, the volumes needed to be carefully adjusted. A

AR0072002

vehicular signal pole was used for one APS, but others were located close to the crosswalk on pedestrian signal poles (Figures 9-14 through 9-16).

Figure 9-14 APS installed on pedestrian signal pole.

Figure 9-15. View across Loch Raven toward two median islands and stop sign controlled service road.

AR0072003

Figure 9-16. APS installed on signal pole beside crosswalk waiting location.

Installation Issues

Edward Paulis of the Office of Traffic and Safety states that the location of pushbuttons and other APS equipment is of high importance in providing a properly operating system for pedestrians who are visually impaired. In many cases, it is not desirable to use only existing poles for the installation of APS. The installation of additional pedestal poles is often necessary to ensure the proper location of APS relative to crosswalks and curb cuts.

Adjusting the initial volume levels has been an issue. Obtaining the proper balance between the needs of the persons who are visually impaired and the surrounding community, while not presenting misleading information to pedestrians, has proved to be difficult. Complicating the process are uncontrollable factors—namely, traffic noise and weather conditions, such as wind and rain.

Maintenance

There have been some failures of the control boards, but these may not be excessive when considering that the equipment is a new and of relatively recent design, and that new technology often has growing pains.

Evaluation

No formal evaluation has been conducted of installations. Most individuals who have requested the installations seem to be pleased.

Case Study—Charlotte, North Carolina

Date: July 2003

History and Background

Charlotte began installing pushbutton-integrated APSs in 1999 after discussions with the Charlotte/Mecklenburg Advocacy Council of People with Disabilities Committee. Approximately 12 intersections are now outfitted with 42 pushbutton-integrated APS devices. Before that, pedhead-mounted APSs had been installed upon request; current staff are not sure when those devices were installed or how the decision was reached to install them. They state that they are replacing current "chirpers" with pushbutton-integrated devices.

O&M specialists helped evaluate APS products in advance and made recommendations to engineers.

Figure 9-17. An early Polara installation in Charlotte.

AR0072005

Process and Procedure

APSs are requested by citizens and installed after review by staff of Metrolina Association for the Blind. In general, devices are installed in the order of request, depending on how much construction is involved.

The Charlotte/Mecklenburg Advocacy Council for People with Disabilities Committee and the Metrolina Association for the Blind serve as liaisons between the person who is visually impaired and the city.

Funding

The city council approved $95,000 in a restricted fund that is earned over year to year for purchase of equipment. The installation cost is covered in the normal budget. The public and individuals who are blind were involved in making the request for funding and getting it approved.

APS Type and Features

Pedhead mounted devices before 1999

Pushbutton-integrated devices from Polara Engineering since July 1998 (see Figure 9-17).

APS features (pushbutton-integrated device installations) include

- Speech "Walk" indication,
- Vibrotactile "Walk" indication,
- Pushbutton locator tone,
- Tactile arrow,
- Actuation indicator,
- Pushbutton information message in response to an extended button press, and
- Automatic volume adjustment in response to ambient sound

Installation Issues

The first generation Polara device did not accommodate pretimed or "ped recall" locations. It was designed to look for a logic common signal from the controller. Using instructions provided by Polara, city technicians in the signal shop modified the printed circuit board, including adding a resistor and two jumpers. This being done, the devices were usable in those situations.

AR0072006

A simple jumper setting has addressed this problem with the newer Polara product. The first generation Polara (installed at four locations) was also more labor intensive to install. Installers drilled holes in the top of the device to accept conduit on wood pole locations.

The newer version Polara Navigator has addressed all installation concerns (Figure 9-18).

Figure 9-18. Recent Polara Navigator installation.

When it is necessary to install new poles to locate the device more appropriately, it takes longer and requires more funds because traffic engineering has to coordinate with various departments to fix curb ramps and work around other utilities. Installation can be time-consuming when a new pole is needed.

Maintenance

No problems reported.

In early installations where two devices were on the same metal pole, it was possible to feel the vibration during the "Walk" signal on both devices at the same time (separate walk phases). This was solved by insulating between the device and pole. A speaker problem was resolved by improving the installation method through the efforts of the city electronics tech and the manufacturer.

AR0072007

Evaluation

The Public Service Department has no complaints regarding the devices. However, the staff of Metrolina Association for the Blind received some complaints about the noise level of the locator tones, especially in residential areas. The volume can easily be adjusted.

The City of Charlotte placed in the top 10 U.S. cities in the Accessible America contest a year ago and in the top seven this past year. Metrolina Association for the Blind has provided very favorable input and review of this project. Communication between all agencies involved has made this project a success.

Case Study—Atlanta, Georgia

Date: May 2003

History and Background

Atlanta has installed APSs upon specific request since 1992. Until April 2003, all devices installed had been pedhead-mounted devices. The city is evaluating pushbutton-integrated devices as part of a research project. There have been requests from citizens who are blind for devices with pushbutton locator tones at pushbutton actuated locations; however, the city has not generally installed them to date.

Process and Procedure

Individuals who are blind or visually impaired make a request to the traffic engineering department. The engineer evaluates the intersection and current timing and signalization. He may meet the blind person and an O&M specialist (usually from the Center for the Visually Impaired) at the intersection to discuss the problems.

Requests are prioritized by date of request and volume of traffic.

AR0072008

If the request is for an APS at a signalized intersection and devices are in stock, they can usually be installed in less than a month.

Funding

Funding comes from city traffic engineering funds; however, some private developers have paid for street improvements as part of a development project.

APS Type and Features

Pedhead-mounted devices from IDC/US Traffic are installed at approximately 15 intersections (Figure 9-19).

APS features include

- "Walk" indication—cuckoo/chirp,
- No pushbutton locator tone, and
- No automatic volume adjustment.

Atlanta has recently installed pushbutton-integrated APSs from Polara Engineering and a receiver-based system from Relume as part of a research project.

Figure 9-19. Pedhead-mounted speaker mounted on the pole as typically installed in Atlanta.

Date Installed

1992 to present

Installation Issues

Pedhead-mounted devices are simple to wire and install on the pole or on the pedhead.

AR0072009

The signal shop found the pushbutton-integrated device to be very difficult to install, requiring additional wiring and careful adjustment. After installation, the control unit of one APS was malfunctioning and the device was not sounding; the manufacturer replaced the unit.

Maintenance

Many pedhead-mounted units have been functioning for 5 to 10 years or more without problems. Recently, two units failed two consecutive times until engineers found that water was getting into the devices, probably through the speaker holes. They recommend rechecking the seals and mounting the speakers under the pushbuttons to protect them from the impact of heavy rain.

In general, Atlanta's traffic engineering department considers pedhead mounted devices very reliable and serviceable. Vandalism has not been a problem.

Evaluation

The traffic engineering department has received some complaints about the noise levels of pedhead mounted speakers (ones currently installed do not have automatic volume adjustment), but complaints have usually stopped a couple weeks after installation. At times, the department has adjusted the volume after installation.

The city looked at pushbutton-integrated devices with locator tones to address concerns about finding the pushbuttons by persons who are blind. However, the signal maintenance department prefers to install the pedhead-mounted devices, as long as there are no complaints.

Case Study—Halifax, Nova Scotia

Date: April 2005

AR0072010

History and Background

Halifax has been using pedhead-mounted APSs since 1998. Pushbutton-integrated units were introduced in 2003 and are now in operation at five intersections. The APS units were installed in response to requests from the Canadian National Institute for the Blind (CNIB). All installations were retrofits to existing signals and were performed by a contractor.

Process and Procedure

Requests for APS installations come from the CNIB, which typically provides the city with a list of intersections where they would like APS installed. The city reviews the list and selects intersections for APS installations based on design of the intersection and available funding. If an intersection is suitable for pushbutton integrated units, Novax Vibrawalks are installed in addition to the overhead speaker. Factors that affect the decision about pushbuttons include suitability of pole location and availability of wiring.

Funding

APS installations in Halifax were funded by the capital budget from a specified fund for pedestrian safety issues. There was also a federal 50-50 funding match in 2004 for APS installations.

APS Type and Features

Pedhead mounted and pushbutton integrated devices from Novax Industries (DS2000 for overhead speaker units and Novax Vibrawalk for pushbuttons).

APS features on installations where pushbutton-integrated devices are installed) include:

- Vibrotactile "Walk" indication,
- Audible "Walk" indication only in response to an extended button press;
- Pushbutton locator tone;
- Tactile arrow;
- Actuation indicator; and
- Automatic volume adjustment in response to ambient sound.

Installation Issues

The APS speaker is mounted on top of the pedestrian head and faces across the street. A typical configuration for a crossing in Halifax involves two APS speakers, one at each end of the

AR0072011

crossing. The volume is adjusted so the sound only reaches three-fourths of the way across the street; this is intended to enable the user to detect the second APS when part way across the street, which will provide guidance on the proper direction. Setups with only one APS per crossing generated numerous noise complaints because the volume has to be higher to be heard across the street.

Most APSs are installed on aluminum poles, but some locations have wooden poles, as shown in Figure 9-20. The overhead APS devices on wooden poles are clamped to the signal arm or pedestrian head. Novax pushbuttons typically are wired through the back of the device. To wire the pushbuttons, 0.5-in. PVC conduit is strapped to the wooden pole, and an LB or liquid tight flex pipe runs into a hole drilled into the bottom of the pushbutton.

The overhead speakers are typically mounted to the pedestrian signal head. When the APS speakers were mounted into plastic (polycarbonate) signal heads, strong winds would push on the speaker and crack off the thin plastic of the signal head into which the speaker was mounted. Where there were plastic pedestrian signal heads, the speaker was mounted on the pole or some other metal or wood surface, as shown in Figure 9-21. Pedestrian signal heads made of aluminum did not have this issue. In areas with less of a problem with strong winds, this may not be a concern.

Availability of wiring at the pole is an important issue. If sufficient wiring is installed with the signal, installing an APS later is much easier. Pulling wire later can become prohibitively expensive.

AR0072012

Figure 9-20. APS pushbutton mounted on wooden pole, showing conduit installed into the bottom of the pushbutton device.

Figure 9-21. APS speaker mounted on signal head support arm.

Maintenance

The city handles the maintenance of the devices. As the city is near the ocean, moisture and salt in the air is a problem, as is salt placed on the roads for deicing. The overhead speakers generally start having problems at the 5-year mark as a result of salt and moisture. The speakers usually last from 5 to 10 years. The Vibrawalk pushbutton devices have not evidenced any problems during the 2 years they have been in service.

AR0072013

Cold Weather Issues

Snow is a constant problem in the Halifax climate. Snow banks, when not cleared properly, can prevent access to the pushbuttons. Pole placement is an important issue at intersections where pushbuttons are used, so that all pedestrians can reach the pushbutton. If pushbuttons are located to the immediate left or right of the crosswalk, there is a better chance pedestrians will be able to reach the button and that the sidewalk near the button will be cleared properly. Because Halifax uses miniplows for clearing sidewalks, the city believes the action of clearing snow could cause problems for stub poles (e.g., knocking them over); the use of stub poles is thus generally avoided.

Other problems are caused by freezing temperatures. Pulling additional wire for a retrofit installation cannot be done in the winter due to ice in the wire conduits. Extreme cold can cause some signals cabinets to fail and thus the APS to fail.

Evaluation

The initial installations of pedhead-mounted APS installations were configured to give the audible "Walk" tone at every cycle. The city received complaints about noise, especially in the summer months when people had their windows open. Because of concerns about noise, these units were set to be off (give no audible indication) from 11:00 pm to 6:00 am.

The pushbutton integrated installations, as installed in Halifax, can be accessed 24 hours per day; the "Walk" indication is provided only when the button is held for 3 s or more. No feedback on the pushbutton integrated devices was reported.

Traffic Signal Supervisor
City of Halifax, Nova Scotia
Phone: 902-490-4971
Email: filippm@halifax.ca

Case Study—Waukesha, Wisconsin

Dates: April 2005

AR0072014

History and Background

Waukesha has been using pushbutton-integrated APS devices with speech messages since 2002. Prior to that, they used overhead speaker units that provided a cuckoo or chirp, but that were not activated by pushbutton. There are approximately 84 pushbutton-integrated APSs in service in Waukesha, most of which were installed during summer 2004. The move to pushbutton integrated devices was motivated by requests from the local Blind community and the Sight Loss Network Support Group, who introduced the city to the speech message capability of new types of APSs.

Process and Procedure

The initial APS installations were done in one large campaign in the summer of 2004. These installations were scattered about town, but mainly focused on center city intersections. Another installation campaign—of approximately 100 units—is planned, which will focus on installing devices at the rest of the center city intersections and moving outward from there. Current Waukesha policy states that any new signal installation will include an APS.

Funding

APSs in Waukesha are currently fully funded by the Waukesha County Community Development Block Grant Program, up to a specified amount per year. This funding includes time and materials.

APS Type and Features

Pushbutton-integrated devices from Polara Engineering (Navigator four-wire devices with remote configuration capability).

APS features include:

- Speech "Walk" indication;
- Vibrotactile "Walk" indication;
- Pushbutton locator tone;
- Tactile arrow;
- Actuation indicator—click and light;
- Pushbutton information message, called by extended button press; and
- Automatic volume adjustment in response to ambient sound.

AR0072015

Installation Issues

Installation of the devices is done by city staff. If a signal to be retrofitted already has pushbuttons, this greatly facilitates the APS installation. However, the four-wire models still necessitate pulling extra wire.

Most of the signal poles are steel and accommodate the APS devices fairly easily. The city attempts to have two poles per corner for every intersection. Sometimes stub poles are necessary, if the signal poles are not close enough to the crosswalk. In one case, a lamppost was used successfully as a mount for an APS unit (Figure 9-22), since aesthetics of the area placed restrictions on installing additional poles.

All but one of the existing APS installations were retrofits. However, all new signals will include APS devices.

Figure 9-22. APS mounted on lamppost.

Maintenance

There have been no maintenance issues for the APS units in their first year of service.

AR0072016

There have been no significant issues related cold weather. Waukesha uses miniplows for removing snow from sidewalks, and the manager of city snow plowing has, however, expressed concern that stub poles may be damaged by these plows.

Evaluation

Devices in residential areas initially drew noise complaints. The city had been leaving the sound settings at the factory default. Once the volume was turned down, there were no complaints.

Email: cshook@ci.waukesha.wi.us

Case Study—Ann Arbor, Michigan

Date: April 2005

History and Background

Ann Arbor has been using pushbutton-integrated APSs since 2001. Five were installed that year, and some have been added since then.

Process and Procedure

APSs are installed on the basis of recommendations from the Ann Arbor Commission on Disability Issues.

Funding

Funding approval for APS devices comes through the City Council. The money is budgeted from the Major Street Fund, which is a non-transportation fund. Currently, $50,000 is designated for the purchase, installation, and maintenance of five APS devices.

APS Type and Features

Pushbutton integrated devices (Navigator) from Polara Engineering.

AR0072017

APS features include

- "Walk" indication—speech message.
- Vibrotactile "Walk" indication.
- Push-button locator tone.
- Tactile arrow.
- Actuation indicator—tone and light.
- Push-button information message called by extended button press; and
- Automatic volume adjustment in response to ambient sound levels

Installation Issues

All APS installations were retrofits to existing signals on steel poles, and existing wiring was sufficient to accommodate the APS installations. Some units are installed on pedestrian signal poles, and some are mounted on the vertical pole of a signal mast arm.

Maintenance

When many of the APS units began to malfunction in 2004, the city sent them back to the manufacturer for repair/replacement. The problem was observed to be rusting of the devices.

Vandalism was also an issue. There were several instances where the unit was knocked off the pole. The attachment bolts were replaced with bigger diameter bolts.

Locator tone effect was seen from cold weather conditions. However, the use of salt may have contributed to rust that was experienced. The city engineers do not believe that the winter conditions contributed much to the problems.

Evaluation

There were several complaints about the noise of the locator tones, especially in the summer when people keep windows open. The locator tone volume was lowered in response, and where there were two APS units on a single pole, one of the locator tones was switched off to control noise. To explain how the APS devices work, the city publicized the devices through a newspaper article and local cable broadcast.

CHAPTER 10

International Practice

Japan 3

Australia 9

Sweden 14

Denmark 18

AR0072020

The information in this chapter is based primarily on visits Janet Barlow and Billie Louise Bentzen made during 2001 to four countries whose use of APSs has been long term, extensive, systematic, and positively accepted by blind pedestrians and traffic engineers. Many other countries have a long history of using accessible pedestrian signals. This chapter is not an attempt to review all international experience.

During trips to Japan, Sweden, Australia, and Denmark, the authors met with traffic engineers, O&M specialists, APS manufacturers, and representatives of consumer groups to discuss APSs. Installations were observed and photographed. At times Barlow and Bentzen, both of whom have unimpaired vision, traveled under blindfold and crossed intricate intersections using typical O&M techniques and APSs.

AR0072021

Japan

Functioning of Pedestrian Signals

- A "red man, green man" signal is used (Figure 10-1).
- Pedestrian signal timing:
  - "Walk" or "green man" timing is figured based on walking time of 1 m/s and is calculated to the centerline of the intersection.
  - Flashing "Don't Walk" timing was reported to be based on a walking speed of 1 m/s; however, this timing seemed to average about 3 s regardless of the width of streets.

Figure 10-1. "Red man, green man" type signal used in Japan.

- Mr. Sugimoto at the Japanese National Police Agency (JPNA), which manages all intersections, stated that intersection timing always includes a pedestrian phase, and at locations with vehicular actuation, pedestrian buttons are provided to lengthen the phase and/or actuate an audible signal.
- Many intersections have pretimed signalization.

AR0072022

Intersection Geometry

Streets are generally wide. Driving is on the left.

Even where there is a very wide median, it is not considered or used as a pedestrian refuge.

Most intersections have pedestrian crosswalks; a fence is typically used where crossing is prohibited.

At areas with high levels of pedestrian traffic, there may be exclusive pedestrian phasing. Most intersections with exclusive pedestrian phasing have audible signals.

Japan has very few nonsignalized turn lanes or pork-chop-type islands.

Tactile walking surface indicators, such as "dot tiles" (called detectable warnings in the United States) are ubiquitous in urban areas and have been in use since the 1960s to indicate danger or a need to make a travel decision. Dot tiles are used in combination with "bar tiles," a directional surface (Figure 10-2). Together they provide a continuously demarcated route for pedestrians who are blind.

Figure 10-2. At this intersection, a chain fence is used where crossing is prohibited, and bar tiles indicate a travel route.

Number of APSs

Japan has 170,000 signalized intersections, 10,570 of which have APSs.
There are a variety of APS systems, most with sound broadcast from the pedestrian signal head (pedhead). A number of melodies and tones are used to indicate the walk interval.

AR0072023

The tone or melody varies from municipality to municipality; each is allowed to choose its own. JPNA has also developed a receiver-based system called PICS.

- 7,978 intersections have cuckoo or chirp sounds from the pedhead during the walk interval (Figure 10-3).
- 2,592 intersections have melodies from the pedhead during the walk interval.
- 300 intersections in 20 cities have an infrared APS system (PICS-A) compatible with the Smith-Kettlewell/Talking Signs standard, as developed and evaluated under the direction of JPNA.

Figure 10-3. Pedhead with APS speaker is mounted on a mast arm overhanging the crosswalk below.

Functioning of Broadcast APSs

Cuckoo/Chirp

- Cuckoo and chirp are the most common sounds for a walk interval.
- An alternating signal is now the recommended signal and costs a "trivial amount" more than a nonalternating signal. The signal usually uses birdcalls. They are beginning to install alternating signals with different sounds (chirp and chirp-chirp) on different sides of the street, to improve beaconing.

AR0072024

Melody

- A variety of melodies is broadcast into the intersection, with a change in melody during the clearance interval.
- The sound was often quite loud; sometimes it is possible to hear the melody of one intersection from a block away.

Speech Message

- The speech message was "Walk" followed by the street name in Japanese.
- The speaker in the pedestrian signal head may be pointed straight down toward the pedestrian below (Figure 10-4).

Other Characteristics

- Some APSs in Tokyo used increased repetition rate of cuckoo or chirp during the clearance interval.
- Very few APSs had locator tones at the pushbutton.
- The APS may have a sound for the pedestrian clearance interval. Yokohama used a sound like that of an emergency vehicle.
- It is fairly common in Tokyo to center the APS speaker over the crosswalk on a mast arm extending from the pole.
- The APS sound is usually turned off at 8:00 p.m. because nearby residents are bothered by the noise.

Figure 10-4. Japanese pedhead with APS speaker pointing straight down toward the pedestrian below.

AR0072025

Functioning of PICS System

The PICS system is being developed, evaluated, and installed under the direction of JPNA.

- The system communicates from an infrared transmitter called an "IR station" and a short-range radio transmitter installed at the intersection to a receiver carried by pedestrians.
- There are two types of PICS systems: PICS-A and PICS-B.

PICS-A Speech System

The PICS-A speech system (Figure 10-5) provides visually impaired pedestrians with pedestrian traffic signal information and location information about bus stops and public facilities. As the traveler approaches within 10 m of the intersection where the PICS-A system is installed, an FM radio message is received by the hybrid radio/IR receiver in either a speech or vibration mode. The vibration alerts users to the presence of the transmitted signal. The speech message identifies the intersection. When pedestrians arrive at a corner and are within the crosswalk, they aim the receiver aimed toward the infrared transmitter on the opposite corner to receive IR-transmitted speech information about the status of the pedestrian signal. A third function extends the pedestrian phase when a button on the receiver is pushed.

Figure 10-5. The PICS-A system is shown with four infrared transmitters mounted on a horizontal mast arm.

AR0072026

PICS-B Image System

The PICS-B image system extends green lights and provides route guidance and information about the surrounding area on a visual display for people with mobility or hearing impairments. Portable receivers (transceivers) are pointed at IR stations located near pedestrian traffic signals to extend the pedestrian signal timing, make emergency contacts, and obtain route guidance and information about the surrounding area.

Comments

The authors found the variety of audiotactual speakers (loudly broadcasting musical sounds or birdcalls) to be confusing and distracting. Although these systems have been in use in Japan for about 40 years, there is growing concern in Japan about the noise pollution they cause.

The PICS-A system provided signal and directional guidance quite efficiently. Radio-transmitted information was useful for general intersection information on approach. A large array of transmitters is required for this system, as shown in Figure 10-5.

- A head-mounted receiver has now been developed by Mitsubishi Precision Corp. Barlow and Bentzen used this receiver at one intersection and found it effective.
- The standard receiver is handheld and can hang on a neck cord or be stowed in a pocket when not in use.

AR0072027

Australia

Functioning of Pedestrian Signals

Pedestrian Signals

- Red and green man signals are used, with the red man set to flash during the flashing "Don't Walk" interval.
- All pedestrian pushbuttons were located in very standardized locations, on the side of the crosswalk away from the parallel street, aligned with the crosswalk line, about 0.5 to 1.0 m from the curb line (Figure 10-6). Most fixed time intersections in downtown Sydney had pushbuttons with audible and vibrotactile features.

Pedestrian Signal Timing

The "Walk" and flashing "Don't Walk" were similar to the U.S. system, with clearance interval timed at 1 m/s.

Intersection Geometry

Streets can be wide and complex, sometimes having narrow medians and channelized turn lanes, which were signalized in some locations.

Roundabouts are used extensively, and O&M specialists and blind travelers state that roundabouts are a barrier to travel.

Detectable warnings or "TWSIs" (tactile walking surface indicators) are used to define the edge of the street on the curb ramp, but they are not consistently installed from state to state. The edge of the TWSI is intended to be aligned perpendicular to the crosswalk direction, to provide additional directional information to blind pedestrians.

AR0072028

Figure 10-6. Signalized left-turn lane with APS mounted close to the crosswalk locations. Three APSs are on the splitter island, one for each crossing.

Number of APSs

Each state is responsible for its own area.

The overall number was not available.

Since the 1980s, APSs have been fairly extensively installed in areas where there is pedestrian traffic.

APS Functioning

A pushbutton integrated type of signal is used. The pushbutton and sound are standardized nationally.

There are several APS manufacturers in the Australian market, but the pole mounted control box overhead was the only visible difference. All pushbuttons looked identical, whether they had APS or not, except that those with APS features had an additional raised bar on the arrow to indicate that they had APS (Figure 10-7). All pushbuttons with audiotactile features functioned identically.

AR0072029

Figure 10-7. This APS has a tactile arrow within a larger visible arrow. A raised bar on the tactile arrow indicates that this is an APS. Other features include a locator tone and audible and vibrotactile "Walk" indication.

Locator Tone

The locator tone has a repetition rate of once every 2 s.

The "Walk" indication has the following characteristics:

- Fast repetition of low-frequency thumping sound during the walk interval.
- May have the capability to be set so that the "Walk" sound is limited to 8 s even when the "Walk" indication is longer.
- The alert tone at the beginning of the "Walk" indication is set to sound at 14 dB above ambient sound.
- All devices respond to ambient sound, both for the locator tone and the "Walk" indication.
- Vibrotactile information at the arrow panel pulses at the same rate as the audible tone.
- Placement has been standardized at the line of the crosswalk away from the center of the intersection. The orientation of the face of the APS varied (Figure 4-9). The speaker for the APS is at face of the arrow, so sound emanates from the face of the unit. Orientation of the device can make a difference in hearing the APS when approaching or from the street.

AR0072030

- APSs are sometimes turned off at night due to neighbors' complaints about noise.

Comments

The standard location of the pushbutton, located beside the waiting location for the crossing, provided a clear indication of which crossing the APS was signaling (Figure 10-8). There was no need for different sounds for different directions of travel. Even on pork-chop-type islands with three devices sounding, it was possible to distinguish the location and crossing being signaled.

The placement of the tactile arrows was inconsistent, which caused confusion in some cases (Figure 10-9).

Figure 10-8. Typical APS location in relation to the crosswalk and sidewalk. Australian curb ramp standards allow a steeper slope than allowed by U.S. standards.

AR0072031

Figure 10-9. Installation of tactile arrows was not consistent and provided misleading information in some cases.

AR0072032

Sweden

Functioning of Pedestrian Signals

Pedestrian Signals

- Sweden uses a "red man, green man" symbol signal.
- Use of a flashing or clearance interval seems to be a local decision. In Göteborg, there is no flashing interval, while in Skövde, a flashing "red man" is used. Pedestrian actuation is common, and the location of the pushbutton is fairly standard, approximately 0.5 to 1.0 m from the curb line and near the farthest crosswalk line from the center of the intersection.

Pedestrian Signal Timing

- Pedestrians rarely had to cross more than two lanes without coming to an island or median.
- The walk interval is timed according to the width of the street, using 1 m/s, with a change interval of about 4 s.

Intersection Geometry

In cities, streets were generally narrow, with lots of islands. In general, medians or islands separated traffic. Most channelized turn lanes were signalized.

Arterials typically have bicycle lanes on both sides of the street (Figure 10-10). Bicycle lanes are usually signalized separately, using small ball signals and separate pushbutton actuation.

AR0072033

There are no curb ramps as such; all curbs at corners are typically 3 to 4 cm high, which is said to be acceptable to persons with mobility impairments.

Figure 10-10. This intersection in Göteborg, Sweden, has a bike lane (seen on left side of photo) with its own signal head, and an APS is mounted on the same pole.

Number of APSs

The overall number of APSs was not available. APSs have been in use in Sweden since the 1960s and are APSs are fairly extensively installed in downtown areas. In suburban areas, signals are installed at the request of persons who are blind or visually impaired and may be installed only at some crosswalks of the intersection, depending on the request.

APS Functioning

There is no Swedish standard for APSs, but most APSs have a ticking sound that repeats at 60 pulses per minute for the locator tone and 600 pulses per minute for the "Walk" interval.

The APS is typically placed on a signal pole or stub pole near the edge of the crosswalk furthest from the intersection, about 0.5 m from the curb.

Signal volume is typically set to be audible 3 m from the pole. Signals respond to ambient sound, within a range set by the installer. APS can also be set to a constant volume.

AR0072034

Each intersection had a number of APSs and pedestrian signal heads because there was an APS on each island/median; many medians had an additional pedhead as well (Figure 10-11).

The APS is differentiated from the standard pedestrian pushbutton by different colored panels on the side of the device.

A raised tactile arrow on top of the device points across the crosswalk (Figures 10-12 and 10-13). At median locations where the signal actuated a simultaneous "Walk" for pedestrians crossing in both directions from the median, arrowheads were on both ends of the shaft.

Signals were of a type that could include vibrotactile information through a separate button on the bottom of the device. However, that feature was not commonly provided.

Figure 10-11. This street crossing in Göteborg, Sweden, includes two islands and numerous APSs (indicated in the photo by circles or half-circles).

AR0072035

Figure 10-12. The Swedish APS displays a tactile map on one side.

Figure 10-13. A pedestrian uses the tactile map.

Additional information

Most devices had a crosswalk map feature on the side of the device, indicating the number of vehicular or bicycle lanes to be crossed and, where present, the locations of islands or transit rails across the crosswalk. However, Kaj Nordquist of the Swedish Blind Association stated that most blind people in Sweden only travel on familiar routes so the tactile maps are not used much. He stated that orientation to new routes is generally available to blind citizens of Sweden.

AR0072036

Comments

Although there were a number of APSs at each intersection, it was possible to locate the devices and use the "Walk" indication of the device to cross efficiently.

Because of the precise location of each APS, the information provided was unambiguous as to which crosswalk had the walk interval.

A pedestrian waiting to cross could always be within arm's reach of the APS, so there was no question regarding which APS was sounding during the walk interval.

Sources of Information

Jan Lund, Prisma Teknik, Tibro

Roger Peterson, Prisma Teknik, Tibro

Bengt Ekdahl, Traffic Engineering, Göteborg

Kay Nordquist, Swedish Blind Society, Stockholm

Denmark

Functioning of Pedestrian Signals

Denmark uses a "red man, green man" symbol signal.

The length of the walk interval varies by time of day. The walk interval is usually calculated using a walking speed formula of 1.3 m/s, but up to 1.5 m/s can be used.

There is no flashing clearance interval.

Most of the central business district has fixed time signals.

AR0072037

Intersection Geometry

Streets typically were narrow (by U.S. standards) with a great deal of pedestrian and bicycle traffic. Streets included wide bike lanes, often slightly raised from the street level.

There are no unsignalized right-turn lanes for cars, but there are right-turn lanes for bicycles.

Curbs are typically 3 to 4 cm high, which is said to be acceptable to persons with mobility impairments.

Detectable warning surfaces are installed in some locations at the curb, usually in a 1-ft band. There are no detectable warnings at edges of cut-through medians.

Number of APSs

APSs are very common in central business districts; outside of the central business district, APSs are installed at the request of the Danish Blind Association and only at requested crosswalks.

Tactile arrows are installed on the top of the APS (Figures 10-14 and 10-15).

Figure 10-14. Illustration of tactile arrow.

AR0072038

Figure 10-15. The tactile arrow on the APS in Denmark was on top of the device, which was located on a pole near the crosswalk line. Most intersections were pretimed, so no pushbutton was included on this device.

APS Functioning

Most installations have audible signals coming from devices at pushbutton height, whether they have pushbuttons or the signals are fixed time; overhead beaconing speaker devices are currently installed in combination with pushbutton locator tones at a few trial locations.

Signals must conform to a national standard.

The locator tone and "Walk" indication have the following characteristics:

- Both are 880-Hz square or sawtooth wave tones. The locator tone is pulsed at 30/min, and the "Walk" indication pulsed faster.
- The Danish standard requires that the "Walk" indication be five times the rate of the locator tone.
- The pulse length of the locator tone is 400 ms, and the pulse length of the "Walk" tone is 200 ms.

Volume

All APSs respond to ambient sound, unless special permission is received to set the signal to a constant low level.

AR0072039

- Although the standard for setting the volume is that the signal should be audible 3 m from the pole, the signal was quite often audible as far as 10 m from the pole.
- The installer determines the volume by listening.

Additional Information

Location

The APSs were located consistently at the end of the crosswalk line so the location tone could be used to line up for crossing.

The consistency of location is considered very important: the APS is installed no more than 0.6 m from the curb line, and the horizontal distance from the crosswalk line is not more than 0.3 m.

Stub poles are installed if signal poles are not available in the appropriate location.

Crosswalk Information

A knob on the end of the bar indicates the far side of the street, and additional knobs indicate the number of islands or medians that will be encountered prior to the far side.

All APS devices have a bar aligned with the crosswalk, which functions as an arrow, on top of the device (Figure 10-16).

Other

Where there is a pushbutton, it is usually located on the backside of the APS, toward the pole, with sufficient space for fingers to reach between the APS and the pole.

In general, there is no need to push a button, as most intersections have pedestrian phases.

AR0072040

Figure 10-16. Danish APS with tactile bar (arrow) mounted on the top. The bar is aligned with the crosswalk, and two knobs at the end of the bar indicate a median and the far side of the street.

Comments

The locator tone was same tone as the "Walk" interval tone and of the same intensity. Repetition rates at some locations in Copenhagen did not seem to conform to the published standard.

At a multileg intersection, the APSs were very useful for crossing and alignment.

- APSs were very consistently located in relation to the crosswalk.
- The directional bar (arrow) was useful, as were the crosswalk maps on the side of the signals.
- Medians were cut through, without detectable warnings, but the sound of the APS at the median gave some information about the median location.

The representative of the Danish Blind Association mentioned that some people have expressed concerns that the signals were too loud, causing noise pollution.

Appendix A—Current Guidelines

For the convenience of the reader, this appendix contains excerpts from the MUTCD (current and proposed language) and Draft PROWAG concerning guidance on accessible pedestrian signals (7, 2). The organization of this appendix is as follows.

Document	Dated	Sections Included in this Appendix	Starting Page in this Appendix
MUTCD 2003	November 2004	sections 4D.03, 4E.06, and 4E.09	A-2
NCUTCD approved changes to the next version of the MUTCD	June 30, 2006	sections 4A.02, 4D.03, 4E.06, 4E.08, and 4E.09	A-9
Draft PROWAG	November 25, 2005	Chapters R1 through R4	A-26

AR0072046

Excerpts from MUTCD - 2003 Edition with Revision No. 1 Incorporated, dated November 2004

Section 4D.03 Provisions for Pedestrians

Support:

Chapter 4E contains additional information regarding pedestrian signals.

Standard:

The design and operation of traffic control signals shall take into consideration the needs of pedestrian as well as vehicular traffic.

If engineering judgment indicates the need for provisions for a given pedestrian movement, signal faces conveniently visible to pedestrians shall be provided by pedestrian signal heads or a signal face for an adjacent vehicular movement.

Guidance:

Safety considerations should include the installation, where appropriate, of accessible pedestrian signals (see Sections 4E.06 and 4E.09) that provide information in nonvisual format (such as audible tones, verbal messages, and/or vibrating surfaces).

Where pedestrian movements regularly occur, pedestrians should be provided with sufficient time to cross the roadway by adjusting the traffic control signal operation and timing to provide sufficient crossing time every cycle or by providing pedestrian detectors.

Option:

It is desirable to prohibit certain pedestrian movements at a traffic control signal, a PEDESTRIANS PROHIBITED (R9-3) or No Pedestrian Crossing (R9-3a) sign may be used (see Section 2B.44).

AR0072047

Section 4E.06 Accessible Pedestrian Signals

Support:

The primary technique that pedestrians who have visual disabilities use to cross streets at signalized locations is to initiate their crossing when they hear the traffic in front of them stop and the traffic alongside them begin to move, corresponding to the onset of the green interval. This technique is effective at many signalized locations. The crossing environment is often sufficient to provide the information that pedestrians who have visual disabilities need to operate reasonably safely at a signalized location. Therefore, many signalized locations will not require any accessible pedestrian signals.

Guidance:

If a particular signalized location presents difficulties for pedestrians who have visual disabilities to cross reasonably safely and effectively, an engineering study should be conducted that considers the safety and effectiveness for pedestrians in general, as well as the information needs of pedestrians with visual disabilities.

Support:

The factors that might make crossing at a signalized location difficult for pedestrians who have visual disabilities include: increasingly quiet cars, right turn on red (which masks the beginning of the through phase), continuous right turn movements, complex signal operations, traffic circles, and wide streets. Further, low traffic volumes might make it difficult for pedestrians who have visual disabilities to discern signal phase changes.

Local organizations providing support services to pedestrians who have visual and/or hearing disabilities can often act as important advisors to the traffic engineer when consideration is being given to the installation of devices to assist such pedestrians. Additionally, orientation and mobility specialists or similar staff also might be able to provide a wide range of advice. The U.S. Access Board's Document A-37, "Accessible Pedestrian Signals," provides various techniques for making pedestrian signal information available to persons with visual disabilities (see Addresses for the address for the U.S. Access Board).

AR0072048

Accessible pedestrian signals provide information in nonvisual format (such as audible tones, verbal messages, and/or vibrating surfaces).

Information regarding detectors for accessible pedestrian signals is found in Section 4E.09.

Standard:

When used, accessible pedestrian signals shall be used in combination with pedestrian signal timing. The information provided by an accessible pedestrian signal shall clearly indicate which pedestrian crossing is served by each device.

Under stop-and-go operation, accessible pedestrian signals shall not be limited in operation by the time of day or day of week.

Guidance:

The installation of accessible pedestrian signals at signalized locations should be based on an engineering study, which should consider the following factors:

A. Potential demand for accessible pedestrian signals;
B. A request for accessible pedestrian signals;
C. Traffic volumes during times when pedestrians might be present, including periods of low traffic volumes or high turn-on-red volumes;
D. The complexity of traffic signal phasing; and
E. The complexity of intersection geometry.

Support:

Technology that provides different sounds for each nonconcurrent signal phase has frequently been found to provide unambiguous information.

Standard:

When choosing audible tones, possible extraneous sources of sounds (such as wind, rain, vehicle back-up warnings, or birds) shall be considered in order to eliminate potential confusion to pedestrians who have visual disabilities.

AR0072049

Guidance:

Audible pedestrian tones should be carefully selected to avoid misleading pedestrians who have visual disabilities when the following conditions exist:

A. Where there is an island that allows unsignalized right turns across a crosswalk between the island and the sidewalk.
B. Where multileg approaches or complex signal phasing require more than two pedestrian phases, such that it might be unclear which crosswalk is served by each audible tone.
C. At intersections where a diagonal pedestrian crossing is allowed, or where one street receives a WALKING PERSON (symbolizing WALK) signal indication simultaneously with another street.

Standard:

When accessible pedestrian signals have an audible tone(s), they shall have a tone for the walk interval. The audible tone(s) shall be audible from the beginning of the associated crosswalk. If the tone for the walk interval is similar to the pushbutton locator tone, the walk interval tone shall have a faster repetition rate than the associated pushbutton locator tone.

Support:

A pushbutton locator tone is a repeating sound that informs approaching pedestrians that they are required to push a button to actuate pedestrian timing, and that enables visually impaired pedestrians to locate the pushbutton (see Section 4E.09).

Guidance:

The accessible walk signal tone should be no louder than the locator tone, except when there is optional activation to provide a louder signal tone for a single pedestrian phase.

Automatic volume adjustment in response to ambient traffic sound level should be provided up to a maximum volume of 89 dBA. Where automatic volume adjustment is used, tones should be no more than 5 dBA louder than ambient sound. The A-weighted sound pressure level should conform to the requirements of "ISO 1996-1:1982" and "ISO

AR0072050

1996-2:1987" (see Addresses for the address for the International Organization for Standards).

Standard:

When verbal messages are used to communicate the pedestrian interval, they shall provide a clear message that the walk interval is in effect, as well as to which crossing it applies.

The verbal message that is provided at regular intervals throughout the timing of the walk interval shall be the term "walk sign," which may be followed by the name of the street to be crossed.

A verbal message is not required at times when the walk interval is not timing, but, if provided:

A. It shall be the term "wait."

B. It need not be repeated for the entire time that the walk interval is not timing.

Option:

Accessible pedestrian signals that provide verbal messages may provide similar messages in languages other than English, if needed, except for the terms "walk sign" and "wait."

Support:

A vibrotactile pedestrian device communicates information about pedestrian timing through a vibrating surface by touch.

Standard:

Vibrotactile pedestrian devices, where used, shall indicate that the walk interval is in effect, and for which direction it applies, through the use of a vibrating directional arrow or some other means.

Guidance:

When provided, vibrotactile pedestrian devices should be located next to and on the same pole as, the pedestrian pushbutton, if any, and adjacent to the intended crosswalk.

AR0072051

Section 4E.09 Accessible Pedestrian Signal Detectors

Standard:

An accessible pedestrian signal detector shall be defined as a device designated to assist the pedestrian who has visual or physical disabilities in activating the pedestrian phase.

At accessible pedestrian signal locations with pedestrian actuation, each pushbutton shall activate both the walk interval and the accessible pedestrian signals.

Option:

Accessible pedestrian signal detectors may be pushbuttons or passive detection devices.

Pushbutton locator tones may be used with accessible pedestrian signals.

Guidance:

At accessible pedestrian signal locations, pushbuttons should clearly indicate which crosswalk signal is actuated by each pushbutton. Pushbuttons and tactile arrows should have high visual contrast as described in the "Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (ADAAG)" (see Section 1A.11). Tactile arrows should point in the same direction as the associated crosswalk. At corners of signalized locations with accessible pedestrian signals where two pedestrian pushbuttons are provided, the pushbuttons should be separated by a distance of at least 3 m (10 ft). This enables pedestrians who have visual disabilities to distinguish and locate the appropriate pushbutton.

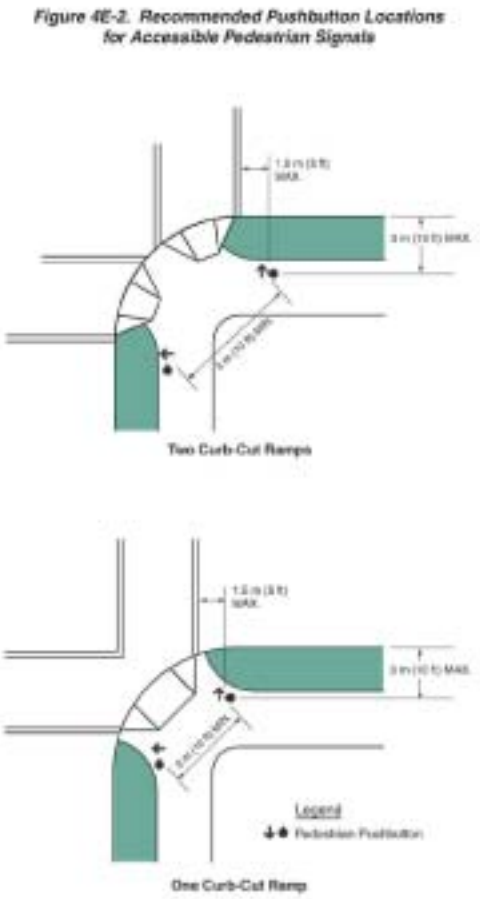
Pushbuttons for accessible pedestrian signals should be located (see Figure 4E-2) as follows:

A. Adjacent to a level all-weather surface to provide access from a wheelchair, and where there is an all-weather surface, wheelchair accessible route to the ramp,
B. Within 1.5 m (5 ft) of the crosswalk extended,
C. Within 3 m (10 ft) of the edge of the curb, shoulder, or pavement, and

AR0072052

D. Parallel to the crosswalk to be used.

Figure 4E-2 Recommended Pushbutton Locations for Accessible Pedestrian Signals



If the pedestrian clearance time is sufficient only to cross from the curb or shoulder to a median of sufficient width for pedestrians to wait and accessible pedestrian detectors are used, an additional accessible pedestrian detector should be provided in the median.

Standard:

When used, pushbutton locator tones shall be easily locatable, shall have a duration of 0.15 seconds or less, and shall repeat at 1-second intervals.

AR0072053

Guidance:

Pushbuttons should be audibly locatable. Pushbutton locator tones should be intensity responsive to ambient sound, and be audible 1.8 to 3.7 m to 16 to 12 ft) from the pushbutton, or to the building line, whichever is less. Pushbutton locator tones should be no more than 5 dBA louder than ambient sound.

Pushbutton locator tones should be deactivated during flashing operation of the traffic control signal.

Option:

At locations with pretimed traffic control signals or nonactuated approaches, pedestrian pushbuttons may be used to activate the accessible pedestrian signals.

The audible tones may be made louder (up to a maximum of 89 dBA) by holding down the pushbutton for a minimum of 3 seconds. The louder audible tones may also alternate back and forth across the crosswalk, thus providing optimal directional information.

The name of the street to be crossed may also be provided in accessible format, such as Braille or raised print.

AR0072054

National Committee on Uniform Traffic Control Devices (NCUTCD) approved changes to the next version of the MUTCD

As approved by the National Committee June 30, 2006.

TECHNICAL COMMITTEE RECOMMENDATION

TECHNICAL COMMITTEE:	Signals Technical Committee
DATE OF ACTION:	January 19, 2006
TOPIC:	**Sections 4A.02 Definitions Relating To Highway Traffic Signals, Section 4D.03 Provisions for Pedestrians, Section 4E.06 Accessible Pedestrian Signals, Section 4E.08 Pedestrian Detectors, and Section 4E.09 Accessible Pedestrian Signal Detectors**
ORIGIN OF REQUEST:	Signals Technical Committee

DISCUSSION:

The STC has been working for over six years to incorporate the results of research and practice regarding accessible pedestrian signals (APS) into the MUTCD. The 2000 MUTCD included new sections on APS (4E.06) and Accessible Pedestrian Detectors (4E.08 – now 4E.09). The language in these sections was revised in the 2003 MUTCD, based on research results available at that time. Recommended modifications to the 2003 MUTCD have been reviewed and approved by the NCUTCD. Additional changes are now proposed based on results of research, practice, and technical development on APS.

Both the Rehabilitation Act of 1973 (Section 504) and the Americans with Disabilities Act of 1990 require that facilities, programs and services be accessible to persons with disabilities. Both require that all new construction and alterations be

AR0072055

accessible to persons with disabilities. This requirement means that pedestrian signals at new construction and alterations must be accessible to persons with disabilities, including vision impairment, vision and hearing impairment, cognitive impairment, and mobility impairment. Pedestrian signals are required to communicate WALK signal information in both audible and vibrotactile modes so they are usable by pedestrians with vision, and vision and hearing impairment. Pushbuttons to actuate pedestrian signals must be able to be located by persons with vision impairments and able to be actuated by persons with mobility impairments. Proposed changes have been demonstrated to result in accurate communication of pedestrian signal information to pedestrians having vision, vision and hearing, or cognitive disabilities. Proposed changes also result in making accessible pedestrian detectors easy to locate and actuate by persons with visual or mobility impairments.

Proposed changes to 4A.02, 4E.06, 4E.08, and 4E.09 are based primarily on additional research conducted under NCHRP 3-62 Accessible Pedestrian Signals, and a 5-year project sponsored by the National Institutes of Health, National Eye Institute, Blind Pedestrians' Access to Complex Intersections. Major changes are the following.

- Standards for the nature of audible and vibrotactile WALK indications
- Change from Guidance to Standard for volume of audible WALK indications
- Guidance on accessible pedestrian signal timing when pedestrian signals rest in walk
- Standard restricting the use of speech WALK indications to locations in which it is not technically feasible to locate two accessible pedestrian signal devices on separate poles at a corner
- Guidance on the use of audible beaconing to aid users in maintaining a straight direction of travel across a crossing
- Standards for ways to provide audible beaconing; Standard for location of tactile arrows on devices
- Change from Guidance to Standard requiring an additional accessible pedestrian detector on a median where pedestrian timing is sufficient only to cross from a curb or shoulder to a median
- Options for an alert tone at the onset of the walk interval and for a tactile map of the crosswalk

AR0072056

Additional changes clarify the intent of existing language, reduce redundancy, or provide a more logical organization.

Since the 2000 MUTCD, 4E.06 has required that "The information provided by an accessible pedestrian signal shall clearly indicate which pedestrian crossing is served by each device." However at that time there were no Standards and little Guidance on how this should be accomplished. Research has documented that requirements for both the nature of the tone or speech message provided by an accessible pedestrian signal, and the location of accessible pedestrian signal devices are needed to avoid ambiguity in determining which crosswalk has the WALK signal. Further, a tactile arrow is necessary for pedestrians who are blind to determine which pushbutton should be used to actuate the WALK signal at a particular crossing.

Under NCHRP 3-62, research was conducted to determine which device features best facilitated safe and independent street crossings by pedestrians who are blind. Four different types of pushbutton-integrated APS were used at one intersection in each of two cities. (Only pushbutton integrated APS make pedestrian signal information accessible to the large proportion of people who are blind and who also have hearing impairments.) All devices had a pushbutton locator tone, an audible actuation indicator, an audible WALK indication, a tactile arrow that vibrated during the walk interval, and automatic volume adjustment. Acoustic characteristics of the locator tone, the WALK signal, and the actuation indicator varied across devices, as did style of pushbutton and tactile arrow. In each city, 20 blind participants made two or three crossings using each device. Objective data included participants' location at the onset of crossing and at the end of crossing, with relation to the location and direction of the crosswalk; heading at the onset of crossing; intervals during beginning and ending of crossing; starting delays; searching for, locating and using pushbuttons; use of particular device features; and independence in crossing.

Results of NCHRP 3-62, supplemented by research sponsored by the National Eye Institute, demonstrate that for pedestrians with varying amounts of visual impairment and varying types of cognitive impairment, the least ambiguous information was provided when two APS on a corner were located on separate poles close to the curb that were separated by a distance of at least 10 feet. Both speed and accuracy in determining which

AR0072057

crosswalk had the walk interval were also significantly better when both APS on a corner, located as described above, had the same rapid tick tone as compared with two different tones. Although subjective preference for WALK indications revealed that speech WALK signals were preferred, in the interest of minimizing the occasions on which pedestrians who have visual or cognitive impairments begin crossing with the wrong signal, the Final Report for NCHRP 3-62 recommends that the WALK indication should be a rapid tick.

Nonetheless, it is not always possible to locate APS on two different poles at a corner. NCHRP 3-62 results indicated that where two pushbuttons were located on a single pole, speed and accuracy in determining which crossing has the WALK signal were greater when the WALK indication was a speech message providing the name of the street being crossed than when a different WALK tone was provided by each of the two APS on one pole. While it is technically infeasible to locate APS on two different poles, the only way to provide unambiguous information regarding which crossing has the WALK signal is a speech message. However, speech messages are not understandable to all pedestrians under all ambient sound conditions. Therefore the use of speech WALK indications should be restricted to those situations in which it is necessary to locate two pushbuttons on a single pole.

Devices having the vibrating tactile arrow located on the pushbutton were used more quickly and accurately, and were preferred over devices in which the vibrating arrow was not incorporated into the pushbutton.

Research on APS sponsored by the National Eye Institute indicates that safety and independence of pedestrians with visual impairments at street crossings is enhanced by some form of audible beaconing at some crossings having complex geometry. Sixteen blind pedestrians in each of four cities made crossings at two complex signalized intersections before and after installation of APS having different means of providing beaconing. Objective measures included participants' accuracy in locating the crosswalk, aligning for crossing, crossing within the crosswalk, starting within the walk interval, and completing crossings within the pedestrian phase, as well as completing crossing independently.

AR0072058

Based on results of this research, Guidance is proposed for identifying those crossings where audible beaconing should and should not be used. There are currently four potential ways of providing audible beaconing. Thus a Standard requiring the use of one of these four ways to provide beaconing is proposed, where audible beaconing is needed. All of the ways to provide beaconing require increased signal volume. To minimize the impact of increased signal volume on neighbors, while making it available to persons who need it, audible beaconing is provided only in response to an extended button press.

Also, the use of the term "speech" instead of "spoken" or "verbal" is recommended when referring to accessible pedestrian signals and has been incorporated into the proposed changes.

The Signals Technical Committee recommends that the National Committee submit the following proposed MUTCD changes to sponsors for comments.

AR0072059

Section 4A.02 Definitions Relating to Highway Traffic Signals

Standard:

Accessible Pedestrian Signal—a device that communicates information about pedestrian timing in nonvisual format such as audible tones, ~~verbal~~ speech messages, and/or vibrating surfaces.

Pedestrian Change Interval—an interval during which the flashing UPRAISED HAND (symbolizing DONT WALK) signal indication is displayed. ~~When a verbal message is provided at an accessible pedestrian signal, the verbal message is~~ "wait."

Pushbutton Locator Tone—a repeating sound that informs approaching pedestrians that ~~they are required to push~~ there is a pushbutton to actuate pedestrian timing or to receive additional information and that enables pedestrians who have visual disabilities to locate the pushbutton.

Vibrotactile Pedestrian Device—~~a device~~ an accessible pedestrian signal feature that communicates, by touch, information about pedestrian timing using a vibrating surface.

Section 4D.03 Provisions for Pedestrians

Guidance:

Safety considerations should include the installation, where appropriate, of accessible pedestrian signals (see Sections 4E.06 and 4E.09) that provide information in nonvisual format (such as audible tones, ~~verbal~~ speech messages, and/or vibrating surfaces).

AR0072060

Section 4L.06 Accessible Pedestrian Signals

Support.

The primary technique that pedestrians who have visual disabilities use to cross streets at signalized locations is to initiate their crossing when they hear the traffic in front of them stop and the traffic alongside them begin to move corresponding which often corresponds to the onset of the green interval. ~~This technique is effective at many signalized locations.~~ The existing environment is often not sufficient to provide the information that pedestrians who have visual disabilities need to operate safely cross a roadway at a signalized location. ~~Therefore, many signalized locations will not require any accessible pedestrian signals.~~

Guidance.

If a particular signalized location presents difficulties for pedestrians who have visual disabilities to cross safely and effectively the roadway, an engineering study should be conducted that considers the safety and effectiveness for needs of pedestrians in general, as well as the information needs of pedestrians with visual disabilities. The engineering study should consider the following factors:

A. Potential demand for accessible pedestrian signals;

B. A request for accessible pedestrian signals;

C. Traffic volumes during times when pedestrians might be present, including periods of low traffic volumes or high turn on red volumes;

D. The complexity of traffic signal phasing (such as split phases, protected turn phases leading pedestrian intervals, and exclusive pedestrian phases); and

E. The complexity of intersection geometry.

Support.

AR0072061

The factors that ~~might~~ make crossing at a signalized location difficult for pedestrians who have visual disabilities include: increasingly quiet cars, right turn on red which masks the beginning of the through phase, combination right turn movements, complex signal operations, traffic circles, and wide streets. Further, low traffic volumes might make it difficult for pedestrians who have visual disabilities to discern signal phase changes.

Local organizations providing support services to pedestrians who have visual and/or hearing disabilities can often act as important advisors to the traffic engineer when consideration is being given to the installation of devices to assist such pedestrians. Additionally, orientation and mobility specialists or similar staff also might be able to provide a wide range of advice. The U.S. Access Board's **Document A-37, "Accessible Pedestrian Signals"** (www.access-board.gov) provides various techniques for making pedestrian signal information available to persons with visual disabilities (see **Page** i for the address for the U.S. Access Board).

Accessible pedestrian signals provide information in nonvisual format (such as audible tones, ~~spoken~~ speech messages, and/or vibrating surfaces).

Information regarding detectors for accessible pedestrian signals is found in Section 4E.09.

Standard:

When used, accessible pedestrian signals shall be used in combination with pedestrian signal timing. The information provided by an accessible pedestrian signal shall clearly indicate which pedestrian crossing is served by each device.

Under stop-and-go operation, accessible pedestrian signals shall not be limited in operation by the time of day or day of week.

~~Guidance:~~

~~The installation of accessible pedestrian signals at signalized locations should be based on an engineering study which should consider the following factors:~~

AR0072062

~~A. Potential demand for accessible pedestrian signals;~~

~~B. A request for accessible pedestrian signals;~~

~~C. Traffic volumes during times when pedestrians might be present, including periods of low traffic volumes or high turning movement volumes;~~

~~D. The complexity of traffic signal phasing; and~~

~~E. The complexity of intersection geometry.~~

Support:

Accessible pedestrian signals that are located as close as possible to pedestrians waiting to cross the street provide the clearest and least ambiguous indication of which pedestrian crossing is served by a device. Technology that provides different sounds for each nonconcurrent signal phase has frequently been found to provide unambiguous information.

~~Some~~ Research indicates that a rapid tick tone for each crossing on separated poles located close to each crosswalk provides unambiguous information to pedestrians who are blind or visually impaired. Vibrotactile indications provide information to pedestrians who are blind and deaf and are also used by pedestrians who are blind or who have low vision to confirm the walk signal in noisy situations.

Standard:

~~**When choosing audible tones, possible extraneous sources of sounds (such as wind, rain, vehicle back-up warnings, or birds) shall be considered in order to eliminate potential confusion to pedestrians who have visual disabilities.**~~

Accessible pedestrian signals shall have both audible and vibrotactile walk indications.

AR0072063

Accessible pedestrian signals shall have an audible walk indication during the walk interval only. The audible tone(s) shall be audible from the beginning of the associated crosswalk.

Accessible pedestrian signals shall not provide an audible pedestrian change interval indication.

Audible walk indications shall be a percussive tone. Audible tone walk indications shall repeat at 8 to 10 ticks per second. Audible tones used as walk indications shall consist of multiple frequencies with a dominant component at 880 Hz.

Vibrotactile walk indications shall be provided by a tactile arrow on the pushbutton which vibrates during the walk interval (see Section 4E.09).

Guidance

The sound level of audible pedestrian tones indications should be adjusted to be low enough ~~centrally-elected~~ to avoid misleading pedestrians who have visual disabilities when the following conditions exist:

A. Where there is an island that allows unsignalized right turns across a crosswalk between the island and the sidewalk.

B. Where multiple approaches or complex signal phasing require more than two pedestrian phases, such that it might be unclear which crosswalk is served by each audible tone

C. At intersections where a diagonal pedestrian crossing is allowed, or where one street receives a WALKING PERSON (symbolizing WALK) signal indication simultaneously with another street

~~Standard~~

AR0072064

When accessible pedestrian signals have an audible tone(s), they shall have a tone for the walk interval. The audible tone(s) shall be audible from the beginning of the associated ~~crosswalk. If the tone for the walk interval is similar to the pushbutton locator tone, the walk interval tone shall have a faster repetition rate than the associated pushbutton locator tone.~~

Support:

A pushbutton locator tone is a repeating sound that informs approaching pedestrians that ~~they are required to push~~ there is a pushbutton to activate pedestrian timing or to receive additional information, and that enables ~~visually impaired~~ pedestrians who have visual disabilities to locate the pushbutton (see Section 4E.09).

Guidance **Standard**:

~~The accessible walk signal tone should be no louder than the locator tone, except where there is optional activation to provide a louder signal tone for a single pedestrian phase.~~

~~Automatic volume adjustment in response to ambient traffic sound level should be provided up to a maximum volume of 80 dBA.~~ **Where automatic volume adjustment is used,** Tones **should** shall be set to be no more than 5 dBA louder than ambient sound except when a louder signal is provided in response to an extended button press. Automatic volume adjustment in response to ambient traffic sound level shall be provided up to a maximum volume of 100 dBA. ~~The A-weighted sound pressure level should be measured according to "ISO 1996-1:2003" and "ISO 1996-2:1987" at a distance of 1 m (3.3 ft) from the transmitter (see Page i for the address for the International Organization for Standards).~~

The accessible walk signal shall have the same duration as the pedestrian walk signal except when the pedestrian signal rests in walk.

Guidance:

When the pedestrian signal rests in walk, the accessible walk signal should be limited to the first 7 seconds of the walk interval. The accessible walk signal should be repeated by a button

AR0072065

press during the walk interval provided that the crossing time remaining is greater than the pedestrian change interval.

Option

An alert tone, which is a very brief burst of high frequency sound at the beginning of the audible walk indication which rapidly decays to the frequency of the walk tone, may be used to alert pedestrians to the beginning of the walk interval. An alert tone may be particularly useful if the walk tone is not easily audible in some traffic conditions.

Support

~~Spoken~~ Speech messages communicate to pedestrians which street has the walk interval. ~~Spoken~~ Speech messages might be either directly audible or transmitted, requiring a personal receiver to hear the message. To be a useful system, the words and their meaning must be correctly understood by all users in the context of the street environment where they are used. Because of this, tones are the preferred means of providing audible walk indications.

Where speech messages are used, pedestrians have to know the names of streets they are crossing in order for ~~spoken~~ speech walk messages to be unambiguous. In getting directions to travel to a new location, pedestrians who are blind do not always get the name of each street to be crossed. Therefore, it is desirable to give users of accessible pedestrian signals the name of the street controlled by the pushbutton. This can be done by means of a speech pushbutton information message during the flashing or steady don't walk intervals, or by raised print and Braille labels on the pushbutton housing.

Users must combine the information from the pushbutton message or Braille label, the tactile arrow aligned in the direction of travel on the relevant crosswalk, and the ~~spoken~~ speech walk message in order to correctly respond to ~~spoken~~ speech walk messages, particularly if there are two pushbuttons on the same pole.

Standard:

AR0072066

When spoken speech messages are used to communicate the pedestrian interval, they shall provide a clear message that the walk interval is in effect, as well as to which crossing it applies. Speech walk messages shall be used only at intersections where it is technically infeasible to install two accessible pedestrian signals at one corner separated by a distance of 3 m (10 ft).

When spoken speech messages are used during the walk interval at intersections having concurrent pedestrian phasing they shall be patterned after the model: "Broadway. Walk sign is on to cross Broadway."

When spoken speech messages are used at intersections having exclusive pedestrian phasing they shall be patterned after the model: "WALK sign is on for all crossings."

Walk interval messages shall not contain any additional information, except they shall include designations such as "Street or "Avenue" where this information is necessary to avoid ambiguity in a particular locale.

~~The spoken message shall be repeated for the first 7 seconds of the walk interval, unless the walk interval is less than 7 seconds in which case the spoken message shall be repeated for the duration of the walk interval. Pedestrian actuations occurring during walk intervals of longer than 7 seconds shall cause the spoken message to be repeated for up to 7 seconds.~~

Guidance:

Messages should not be worded in a way that seems to provide a command to the pedestrian, such as "cross Broadway Street now". Messages should not tell users that it is "safe to cross." It should always be the pedestrian's responsibility to check actual traffic conditions.

Standard:

A spoken speech message is not required at times when the walk interval is not timing, but, if provided:

A. It shall begin with the term "wait."

AR0072067

B. It need not be repeated for the entire time that the walk interval is not timing.

Support

Section 4E.09 contains additional ~~material~~ information regarding ~~spoken~~ speech pushbutton information messages when the walk interval is not timing.

Option

Accessible pedestrian signals that provide ~~spoken~~ speech messages may provide similar messages in languages other than English, if needed, except for the terms "walk sign" and "wait."

~~Support:~~

~~A vibrotactile pedestrian device communicates information about pedestrian timing through a vibrating surface by touch.~~

~~Standard:~~

Vibrotactile pedestrian devices, where used, shall indicate that the walk interval is in effect, and for which direction it applies, through the use of a vibrating directional arrow or some other means.

~~Guidance:~~

~~When provided, vibrotactile pedestrian devices should be located next to, and on the same side as, the pedestrian pushbutton, if any, and adjacent to the intended crosswalk.~~

~~Option:~~

Pedestrians may be provided with additional features such as increased crossing time, audible beaconing, or a pushbutton information message as a result of an extended pushbutton press.

AR0072068

Standard:

If an extended pushbutton press is used to provide any additional feature(s), such as audible beaconing, a pushbutton press of less than one second shall actuate only the pedestrian timing and any associated accessible WALK signal, and a pushbutton press of one second or more shall actuate the pedestrian timing, any associated accessible WALK signal, and any additional feature(s).

Support:

Audible beaconing is the use of an audible signal in such a way that blind pedestrians can home in on the signal from the target corner as they cross the street.

Not all crosswalks at an intersection need audible beaconing; audible beaconing can actually cause confusion if used at all crosswalks at some intersections. Audible beaconing is not appropriate at locations with channelized turns or split phasing, because of the possibility of confusion.

Guidance:

Audible beaconing should only be considered following an engineering study at:

A. Crosswalks longer than 21 m (70 ft), unless they are divided by a median that has another accessible pedestrian signal with a locator tone;

B. Crosswalks that are skewed;

C. Intersections with irregular geometry such as multiple legs;

D. Crosswalks where audible beaconing is requested by an individual with visual disabilities; or

E. Other locations where a study indicates audible beaconing would be beneficial.

AR0072069

Option:

Audible beaconing may be provided in several ways, any of which are initiated by an extended button press.

Standard:

If audible beaconing is used, the volume of the locator tone during the pedestrian change interval of the called pedestrian phase shall be increased and operated in one of the following ways:

A. The louder locator tone comes from the target corner, as pedestrians cross the street; or

B. The louder locator tone comes from both ends of the crosswalk; or

C. The louder locator tone comes from an additional pedestrian-signal-head-mounted speaker aimed at the center of the crosswalk.

Section 4E.08 Pedestrian Detectors

Support:

The following guidance places pushbuttons within easy reach of pedestrians who are intending to cross each crosswalk and makes it obvious which pushbutton is associated with each crosswalk. This location also positions pushbutton poles optimally for subsequent installation of accessible pedestrian signals. Guidance regarding reach ranges can be found in the "Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (ADAAG)," (see Section 1A.11).

~~Guidance~~ Standard:

AR0072070

When pedestrian actuation is used, pedestrian pushbutton detectors ~~should~~ shall be capable of easy activation and conveniently located near each end of the crosswalks. Except as described in the ~~Option~~ Guidance below, pushbuttons ~~should~~ shall be located to meet all of the following:

A. Unobstructed and adjacent to a level all-weather surface to provide access from a wheelchair;

B. Where there is an all-weather surface, a wheelchair accessible route from the pushbutton to the ramp;

C. Between the edge of the crosswalk line (extended) farthest from the center of the intersection and the side of a curb ramp (if present), but not greater than 1.5 m (5 ft) from said crosswalk line;

D. Between 0.45 m (1.5 ft) and 1.8 m (6 ft) ~~, but not greater than 3 m (10 ft)~~ from the edge of the curb, shoulder, or pavement; ~~and~~

F. With the ~~control surface~~ face of the pushbutton parallel to the crosswalk to be used; and

E. At a maximum mounting height of 1.2 m (4 ft) above the sidewalk.

Guidance:

Where there are constraints that make it infeasible to place the pedestrian detector adjacent to a level all-weather surface, the surface should be as level as feasible.

Where there are constraints that make it infeasible to place the pedestrian detector between 0.45 m (1.5 ft) and 1.8 m (6 ft) from the edge of curb, shoulder, or pavement, it should not be further than 3 m (10 ft) from the edge of curb, shoulder, or pavement.

A mounting height of approximately 1.1 m (3.5 ft) above the sidewalk should be used for pedestrian pushbutton detectors.

AR0072071

At corners of signalized locations where two pedestrian pushbuttons are provided, the pushbuttons should be separated by a distance of at least 3 m [10 ft] (see Figure 4E-2).

Option:

Where there are constraints that make it impractical infeasible to meet the Guidance on pedestrian detector separation in this Section, on a corner requiring pedestrian actuation of signals for two crosswalks, a single pole may be used.

Guidance:

Where two accessible pedestrian ~~detectors~~ pushbuttons are used ~~at corners having~~ on a single pushbutton pole, the accessible pedestrian detectors pushbuttons should have the features described in Section 4E.09 for this situation.

Option:

Pedestrian signal detectors may be pushbuttons or passive detection devices.

Standard:

Signs (see Section 2B.44) shall be mounted adjacent to or integral with pedestrian pushbutton detectors, explaining their purpose and use.

Option:

At certain locations, a sign at a more visible location may be used to call attention to the pedestrian detector.

Guidance Standard:

AR0072072

If two crosswalks, oriented in different directions, end at or near the same location. The positioning of pedestrian detectors and/or the legends on the pedestrian detector signs ~~should~~ shall clearly indicate which crosswalk signal is actuated by each pedestrian detector.

Standard:

If the pedestrian clearance time is sufficient only to cross from the curb or shoulder to a median of sufficient width for pedestrians to wait and the signals are pedestrian actuated, an additional pedestrian detector shall be provided in the median.

Guidance:

The use of additional pedestrian detectors on islands or medians where a pedestrian might become stranded should be considered.

~~A mounting height of approximately 1.1 m (3.5 ft) above the sidewalk should be used for pedestrian pushbutton detectors.~~

If used, special purpose pushbuttons to be operated only by authorized persons should include a housing capable of being locked to prevent access by the general public and do not need an instructional sign.

Standard:

If used, a pilot light or other means of indication installed with a pedestrian pushbutton shall not be illuminated until actuation. Once it is actuated, it shall remain illuminated until the pedestrian's green or WALKING PERSON (symbolizing WALK) signal indication is displayed.

If a pilot light is used at an accessible pedestrian signal location, each actuation shall be accompanied by the speech message "wait".

Option:

AR0072073

At signalized locations with demonstrated need and subject to equipment capabilities pedestrians with special needs may be provided with additional crossing time by means of an extended pushbutton press.

Section 4E.09 Accessible Pedestrian Signal Detectors

Standard:

An accessible pedestrian signal detector shall be defined as a device designated to assist the pedestrian who has visual or physical disabilities in activating the pedestrian phase.

At accessible pedestrian signal locations with pedestrian actuation, each pushbutton shall activate both the walk interval and the accessible pedestrian signals.

An accessible pedestrian pushbutton shall incorporate a locator tone.

Pushbutton locator tones shall have a duration of 0.15 seconds or less, and shall repeat at 1-second intervals.

Pushbutton locator tones shall be intensity responsive to ambient sound, and be audible 1.8 (6 ft) to 3.7 m (12 ft) from the pushbutton, or to the building line, whichever is less. Pushbutton locator tones shall be no more than 5 dBA louder than ambient sound.

Pushbutton locator tones shall be deactivated during flashing operation of the traffic control signal.

Option:

Accessible pedestrian signal detectors may be pushbuttons or passive detection devices.

Standard:

AR0072074

At accessible pedestrian signal locations, pushbuttons shall clearly indicate by means of tactile arrows which crosswalk signal is actuated by each pushbutton. by means of Tactile arrows shall be located on the pushbutton, ~~having~~ have visual contrast (light on dark or dark on light), and Tactile arrows shall be aligned parallel to the direction of travel on the associated crosswalk.

Guidance:

At corners of signalized locations with accessible pedestrian signals where two pedestrian pushbuttons are provided, the pushbuttons should be separated by a distance of at least 3 m [10 ft] such that they clearly indicate which crosswalk has the WALK indication.

Pushbuttons should be located as close as possible to the crosswalk line farthest from the center of the intersection and as close as possible to the curb ramp.

Standard:

Where it is impractical to install accessible pedestrian detectors on two separate poles at a corner, each accessible pedestrian detector shall have the following features, in addition to the pushbutton locator tone and tactile arrow: ~~pushbutton locator tone,~~ a verbal speech walk message for the WALK indication (see Section 4E.06), tactile arrow aligned parallel to the direction of travel on the crosswalk, and a speech pushbutton information message.

Guidance:

If the pedestrian clearance time is sufficient only to cross from the curb or shoulder to a median of sufficient width for pedestrians to wait and accessible pedestrian detectors are used, an additional accessible pedestrian detector should shall be provided in the median.

~~Standard:~~

~~When used, pushbutton locator tones shall be easily localizable, shall have a duration of 0.15 seconds or less, and shall repeat at 1-second intervals.~~

AR0072075

~~Guidance:~~

~~Pushbuttons should be audibly locatable. Pushbutton locator tones should be intensity responsive to ambient sound and be audible 1.5 to 3.7 m (5 to 12 ft) from the pushbutton or to the building line, whichever is less. Pushbutton locator tones should be no more than 5 dB(A) louder than ambient sound.~~

~~Pushbutton locator tones should be deactivated during flashing operation of the traffic control signal.~~

Option:

At locations with protected traffic signals or unmarked approaches, pedestrian pushbuttons may be used to activate the accessible pedestrian signals.

~~Pedestrians may be provided with~~ Additional features may be provided for pedestrians such as increased crossing time, audible beaconing, or a spoken pushbutton information message as a result of an extended pushbutton press.

Standard:

If an extended pushbutton press is used to provide any additional feature(s), a pushbutton press of less than one second shall actuate only the pedestrian timing and any associated accessible WALK signal, and a pushbutton press of one second or more shall actuate the pedestrian timing, any associated accessible WALK signal, and any additional feature(s).

Option:

The name of the street to be crossed may also be provided in accessible format, such as Braille or raised print.

Tactile maps of crosswalks may be provided.

AR0072076

Spoken Speech pushbutton information messages may be made available by actuating the accessible pedestrian signal detector when the walk interval is not timing. These messages may provide intersection identification, as well as information about unusual intersection signalization and geometry, such as notification regarding exclusive pedestrian phasing, leading pedestrian intervals, split phasing, diagonal crosswalks, and medians or islands.

Standard:

If ~~spoken~~ speech pushbutton information messages are made available by actuating the accessible pedestrian signal detector, they shall only be actuated when the walk interval is not timing. They shall begin with the term "Wait," followed by intersection identification information modeled after: "Wait to cross Broadway at Grand." If information on intersection signalization or geometry is also given, it shall follow the intersection identification information.

Guidance:

Spoken Speech pushbutton information messages should not be used to provide landmark information or to inform pedestrians with visual impairments about detours or temporary traffic control situations.

Support:

Additional information on structure and wording of pushbutton messages is included in ITE's "Electronic Toolbox for Making Intersections More Accessible for Pedestrians Who Are Blind or Visually Impaired," which is available at ITE's website.

AR0072077

Excerpts from Draft Public Rights-of-Way Accessibility Guidelines (Draft PROWAG)

CHAPTER R1: APPLICATION AND ADMINISTRATION

R101 Purpose

R101.1 General. This document contains scoping and technical requirements for accessibility to facilities for pedestrian circulation and use located in the public right of way. Advisory notes are for informational purposes only. These requirements are to be applied during the design, construction, additions to, and alterations of facilities in the public right-of-way to the extent required by regulations issued by Federal agencies.

Advisory R101.1 General. Access requirements are also addressed in the Manual on Uniform Traffic Control Devices (MUTCD) [HWA/FHS DOT, 2003 (http://mutcd.fhwa.dot.gov). MUTCD is a reference standard in this guideline.

Key transportation industry guidance documents also address accessibility in the public right-of-way and can provide useful information on design and construction. They include 'Guide for the Planning, Design, and Operation of Pedestrian Facilities', American Association of State Highway and Transportation Officials, July 2004 (www.aashto.org) and 'Designing Sidewalks and Trails for Access', FHWA/FHS DOT September 2001 (http://www.fhwa.dot.gov/environment/sidewalk2/index.htm).

R101.2 Effect on Existing Facilities. This document does not address existing facilities unless they are included in the scope of an alteration undertaken at the discretion of a covered entity. The U.S. Department of Justice and U.S. Department of Transportation

AR0072078

have issued and enforce separate regulations for existing facilities subject to their requirements for program accessibility under the Americans with Disabilities Act.

Advisory R101.2 Effect on Existing Facilities. The U.S. Department of Justice ADA regulations require that the usability of accessible features be maintained (28 CFR 35.133 and 36.211).

Federal agencies and entities receiving federal funds may also have an obligation for program accessibility under section 504 of the Rehabilitation Act of 1973 as amended. For example, state departments of transportation that receive Federal-aid Highway funds must comply with program accessibility requirements issued by the U.S. Department of Transportation at 49 CFR part 27.

R102 Equivalent Facilitation Nothing in these requirements prevents the use of designs, products, or technologies as alternatives to those prescribed, provided they result in substantially equivalent or greater accessibility and usability.

R103 Conventions R103.1 Dimensions. Dimensions that are not stated as "maximum" or "minimum" are absolute.

R103.1.1 Construction and Manufacturing Tolerances. All dimensions are subject to conventional industry tolerances except where the requirement is stated as a range with specific minimum and maximum end points.
Advisory R103.1.1 Construction and Manufacturing Tolerances. Conventional industry tolerances recognized by this provision include those for field conditions and those that may be a necessary consequence of a particular manufacturing process. Recognized tolerances are not intended to apply to design work.

Information on specific tolerances may be available from industry or trade organizations, code groups and building officials, and published references.

AR0072079

[Sections R103.2 – R103.4 not included]

R104 Referenced Guidelines and Standards

R104.1 General. The guidelines and standards listed in R104.2 are incorporated by reference in this document and are part of the requirements to the prescribed extent of each such reference. The Director of the Federal Register has approved these guidelines and standards for incorporation by reference in accordance with 5 U.S.C. 552(a) and 1 CFR part 51. Copies of the referenced guidelines and standards may be inspected at the Architectural and Transportation Barriers Compliance Board, 1331 F Street, NW, Suite 1000, Washington, DC 20004; at the Department of Justice, Civil Rights Division, Disability Rights Section, 1425 New York Avenue, NW, Washington, DC; at the Department of Transportation, 400 Seventh Street, SW, Room 10424, Washington DC; or at the National Archives and Records Administration (NARA). For information on the availability of this material at NARA, call (202) 741-6030, or go to **www.archives.gov/federal_register/code_of_federal_regulations/ibr_locations.html**

R104.2 Referenced Guidelines and Standards. The specific edition of the guidelines and standards listed below are referenced in this document. Where differences occur between this document and the reference, this document applies.

R104.2.1 MUTCD Manual on Uniform Traffic Control Devices for Streets and Highways (MUTCD), 2003 edition. Copies of the referenced standard may be obtained on-line from the Federal Highway Administration at **mutcd.fhwa.dot.gov** (see R305 and R302.4).

[Sections 104.2.2 – 104.2.3 not included]

R105 Definitions

R105.1 General. For the purpose of this document, the terms defined in R105.5 have the indicated meaning.

R105.2 Terms Defined in Referenced Guidelines and Standards. Terms not defined in R105.5 or in regulations issued by Federal agencies, but specifically defined in a

AR0072080

referenced guideline or standard, shall have the specified meaning from the referenced guideline or standard unless otherwise stated.

R105.3 Undefined Terms. The meaning of terms not specifically defined in R105.5 or in regulations issued by Federal agencies or in referenced guidelines and standards shall be as defined by collegiate dictionaries in the sense that the context implies.

R105.4 Interchangeability. Words, terms and phrases used in the singular include the plural and those used in the plural include the singular.

R105.5 Defined Terms.

Accessible. Describes a facility in the public right-of-way that complies with this part.

Accessible Pedestrian Signal. A device that communicates information about the WALK phase in audible and vibrotactile formats.

[Rest of Section 105.5 not included]

CHAPTER R2: SCOPING REQUIREMENTS

R201 Application

R201.1 Scope. All newly designed and newly constructed facilities located in the public right-of-way shall comply with these requirements. All altered portions of existing facilities located in the public right-of-way shall comply with these requirements to the maximum extent feasible.

Advisory R201.1 Scope. This document (see R101.1 General) covers facilities for pedestrian circulation and use in the right of way. Examples of facilities include, but are not limited to, walkways and sidewalks, street or highway shoulders where pedestrians are not prohibited, crosswalks, islands and medians, overpasses and underpasses, on-street parking spaces and loading zones, and equipment - signals, signs, street furniture, and other appurtenances provided for pedestrians. Examples of facilities not included are manholes and utility vaults.

AR0072081

These requirements are to be applied to all areas of a facility within the scope or limits of the planned project unless expressly exempted or limited with respect to the number of multiple elements required to be accessible. For example, not all benches are required to be accessible; those that are not required to be accessible are not required to comply with these requirements or to be served by a pedestrian access route.

R201.2 Temporary and Permanent Facilities. These requirements shall apply to temporary and permanent facilities.

Advisory R201.2 Temporary and Permanent Facilities. Temporary facilities covered by these requirements include, but are not limited to, temporary routes around work zones, portable toilets in the public right-of-way, sidewalk vending facilities, street fair booths performance stages and reviewing stands, and the pedestrian access routes that serve them. As presumed in R203.1.1, structures and equipment directly associated with the actual processes of construction are not required to be accessible.

[rest of 201.2 advisory and section 201.3 not included]

R202 Alterations and Additions to Existing Facilities

R202.1 General. Additions and alterations to existing facilities shall comply with R202.

Advisory R202.1 General. Alterations include, but are not limited to, remodeling, rehabilitation, reconstruction, historic restoration, resurfacing of circulation paths or vehicular ways, or changes or rearrangement of structural parts or elements of a facility.

[Rest of sections R202 – R207 not included]

R208 Accessible Pedestrian Signals (APS) Where pedestrian signals are provided at pedestrian street crossings, they shall comply with R306.

[Sections R209 – R222 not included]

CHAPTER R3: TECHNICAL PROVISIONS

AR0072082

[Sections R301 – R305 not included]

R306 Accessible Pedestrian Signals (APS)

R306.1 General. Pedestrian signals shall comply with R306.

R306.2 Pedestrian Signals. Each crosswalk with pedestrian signal indication shall have an accessible pedestrian signal which includes audible and vibrotactile indications of the WALK interval. Where a pedestrian pushbutton is provided, it shall be integrated into the accessible pedestrian signal and shall comply with R306.2.
Advisory R306.2 Pedestrian Signals. Signals should generally sound and vibrate throughout the WALK interval. Where signals rest in WALK, audible operation may be limited to a repetition at short intervals rather than continuous sounding for several minutes.

R306.2.1 Location. Accessible pedestrian signals shall be located so that the vibrotactile feature can be contacted from the level landing serving a curb ramp, if provided, or from a clear floor or ground space that is in line with the crosswalk line adjacent to the vehicle stop line.

R306.2.1.1 Crossings. Accessible pedestrian signal devices shall be 3.0 m (10.0 ft) minimum from other accessible pedestrian signals at a crossing. The control face of the accessible pedestrian signal shall be installed to face the intersection and be parallel to the direction of the crosswalk it serves.

R306.2.1.2 Medians and Islands. Accessible pedestrian signals located in medians and islands shall be 1.5 m (5.0 ft) minimum from other accessible pedestrian signals.

R306.2.2 Reach and Clear Floor or Ground Space. Accessible pedestrian pushbuttons shall be located within a reach range complying with R404. A clear floor or ground space

AR0072083

complying with R402 shall be provided at the pushbutton and shall connect to or overlap the pedestrian access route.

R306.2.3 Audible Walk Indication. The audible indication of the WALK interval shall be by tone or speech message.

R306.2.3.1 Tones. Tones shall consist of multiple frequencies with a dominant component at 880 Hz. The duration of the tone shall be 0.15 s and shall repeat at intervals of 0.35 s.

Advisory R306.2.3.1 Tones. Many new accessible pedestrian signal installations in the US use speech messages, which are perceived as being more user-friendly than tones. However, such messages may not be intelligible under high-ambient-noise conditions or to non-English speakers. Electronic tones are more universal and unambiguous. Section 4E.06 of the MUTCD specifies content of speech messages.

R306.2.3.2 Volume. Tone or voice volume measured at 92 cm (3.0 ft) from the pedestrian signal device shall be 2 dB minimum and 5 dB maximum above ambient noise level in standard operation and shall be responsive to ambient noise level changes.

Advisory R306.2.3.2 Volume. Where additional volume or beaconing features are available on pedestrian actuation, these will momentarily exceed volume limits.

R306.3 Pedestrian Pushbuttons. Pedestrian pushbuttons shall comply with R306.3.

R306.3.1 Operation. Pedestrian pushbuttons shall comply with R405.4.

R306.3.2 Pushbutton Locator Tone. Pedestrian pushbuttons shall incorporate a locator tone at the pushbutton. Pushbutton locator tone volume measured at 92 cm (3.0 ft) from the pushbutton shall be 2 dB minimum and 5 dB maximum above ambient noise level and shall be responsive to ambient noise level changes. The duration of the locator tone shall be 0.15 s maximum and shall repeat at intervals of one second. The locator tone

AR0072084

shall operate during the DON'T WALK and flashing DON'T WALK intervals only and shall be deactivated when the pedestrian signal is not operative.

R306.3.3 Size and Contrast. Pedestrian pushbuttons shall be a minimum of 0.5 cm (2 in) across in one dimension and shall contrast visually with their housing or mounting.

R306.3.4 Optional Features. An extended button press shall be permitted to activate additional features. Buttons that provide additional features shall be marked with three braille dots forming an equilateral triangle in the center of the pushbutton.

R306.4 Directional Information and Signs. Pedestrian signal devices shall provide tactile and visual signs complying with 306.4 on the face of the device or its housing or mounting to indicate crosswalk direction and the name of the street containing the crosswalk served by the pedestrian signal.

R306.4.1 Arrow. Signs shall include a tactile arrow aligned parallel to the crosswalk direction. The arrow shall be raised 0.8 mm (.03 inch) minimum and shall be 4 mm (1.5 in) minimum in length. The arrowhead shall be open at 45 degrees to the shaft and shall be 33 percent of the length of the shaft. Stroke width shall be 10 percent minimum and 15 percent maximum of arrow length. The arrow shall contrast with the background.

R306.4.2 Street Name. Accessible pedestrian signals (APS) shall include street name information aligned parallel to the crosswalk direction and shall comply with R409.3 or shall provide street name information in audible format.

R306.4.3 Crosswalk Configuration. Where provided, graphic indication of crosswalk configuration shall be tactile.

[Sections R307 – R309 not included]

AR0072085

Sections referenced in R306.2.2 Reach and Clear Floor or Ground Space:

R402 Clear Space

R402.1 General. Clear space at accessible pedestrian signals (APS), street furniture, and operable parts shall comply with R402.

R402.2 Surface Characteristics. Surfaces of clear spaces shall comply with R501.5 and shall have a slope and cross slope of 2 percent maximum.

R402.3 Size. The clear space shall be 760 mm (30 in) minimum by 1220 mm (48 in) minimum.

R402.4 Knee and Toe Clearance. Unless otherwise specified, clear space shall be permitted to include knee and toe clearance complying with R403.

R402.5 Position. Unless otherwise specified, clear space shall be positioned for either forward or parallel approach to an element.

R402.6 Approach. One full unobstructed side of the clear space shall adjoin a pedestrian access route or adjoin another clear space.

R402.7 Maneuvering Space. Where a clear space is located in an alcove or otherwise confined on all or part of three sides, additional maneuvering space shall be provided in accordance with R402.7.1 and R402.7.2.

R402.7.1 Forward Approach. Alcoves shall be 915 mm (36 in) wide minimum where the depth exceeds 610 mm (24 in).

R402.7.2 Parallel Approach. Alcoves shall be 1525 mm (60 in) wide minimum where the depth exceeds 380 mm (15 in).

AR0072086

R404 Reach Ranges

R404.1 General. Reach ranges shall comply with R404.

R404.2 Forward Reach.

R404.2.1 Unobstructed. Where a forward reach is unobstructed, the high forward reach shall be 1220 mm (48 in) maximum and the low forward reach shall be 380 mm (15 in) minimum above the finish surface.

R404.2.2 Obstructed High Reach. Where a high forward reach is over an obstruction, the clear space shall extend beneath the element for a distance not less than the required reach depth over the obstruction. The high forward reach shall be 1220 mm (48 in) maximum where the reach depth is 510 mm (20 in) maximum. Where the reach depth exceeds 510 mm (20 in), the high forward reach shall be 1120 mm (44 in) maximum and the reach depth shall be 635 mm (25 in) maximum.

R404.3 Side Reach.

R404.3.1 Unobstructed. Where a clear space allows a parallel approach to an element and the side reach is unobstructed, the high side reach shall be 1220 mm (48 in) maximum and the low side reach shall be 380 mm (15 in) minimum above the finish surface. An obstruction shall be permitted between the clear space and the element where the depth of the obstruction is 255 mm (10 in) maximum.

R404.3.2 Obstructed High Reach. Where a clear space allows a parallel approach to an element and the high side reach is over an obstruction, the height of the obstruction shall be 865 mm (34 in) maximum and the depth of the obstruction shall be 610 mm (24 in) maximum. The high side reach shall be 1220 mm (48 in) maximum for a reach depth of

AR0072087

255 mm (10 in) maximum. Where the reach depth exceeds 266 mm (10 in), the high side reach shall be 1170 mm (46 in) maximum for a reach depth of 610 mm (24 in) maximum.

Section referenced in R306.3.1 Pedestrian Pushbuttons, Operation:

R405.4 Operation. Operable parts shall be operable with one hand and shall not require tight grasping, pinching, or twisting of the wrist. The force required to activate operable parts shall be 22 N (5 lbsf) maximum.

Section referenced in R306.4.2 Street Name

R409.3 Braille. Braille shall be contracted (Grade 2) and shall comply with R409.3 and R409.4.

R409.3.1 Dimensions and Capitalization. Braille dots shall have a domed or rounded shape and shall comply with Table R409.3.1. The indication of an uppercase letter or letters shall only be used before the first word of sentences, proper nouns and names, individual letters of the alphabet, initials, and acronyms.

R409.3.1 Braille Dimensions

Measurement Range	**Minimum in Millimeters** **Maximum in Millimeters**
Dot base diameter	1.5 mm (0.059 in) to 1.6 mm (0.063 in)
Distance between two dots in the same cell	2.3 mm (0.090 in) to 2.5 mm (0.100 in)
Distance between corresponding dots in adjacent cells	6.1 mm (0.241 in) to 7.6 mm (0.300 in)
Dot height	0.6 mm (0.025 in) to 0.9 mm (0.037 in)
Distance between corresponding dots from one cell directly below	10 mm (0.395 in) 10.2 mm to (0.400 in)

AR0072088

* Measured center to center

R409.3.2 Position. Braille shall be positioned below the corresponding text. If text is multi-lined, braille shall be placed below the entire text. Braille shall be separated 9.5 mm (.375 in) minimum from any other tactile characters and 9.5 mm (.375 in) minimum from raised borders and decorative elements. Braille provided on elevator car controls shall be separated 4.8 mm (.1875 in) minimum and shall be located either directly below or adjacent to the corresponding raised characters or symbols.

R409.4 Installation Height and Location.
Signs with tactile characters shall comply with R409.4.

R409.4.1 Height Above Finish Floor or Ground. Tactile characters on signs shall be located 1.2 m (4.0 ft) minimum above the finish floor or ground surface, measured from the baseline of the lowest tactile character and 1.5 m (5.0 ft) maximum above the finish floor or ground surface, measured from the baseline of the highest tactile character. Tactile characters for elevator car controls shall not be required to comply with R409.4.1.

Appendix B—Product Information

Campbell Company 2
Mallory Sonalert 5
Novax Industries 6
Bob Parlen Consultancy 9
Polara Engineering 11
Prisma Teknik 14
U.S. Traffic Corporation 17
Wilcox Sales 18

Introduction

Information on accessible pedestrian signal (APS) manufacturers was obtained directly from manufacturers and manufacturers' websites and is accurate as of May 2007. Be sure to confirm features, functioning, and installation requirements of APS with the manufacturer before purchase, as APS product offerings are constantly changing. New manufacturers may enter the U.S. market at any time; this appendix lists ones that authors of this report are aware of at the time of publication.

Leader Dogs for the Blind in Rochester, Michigan, has plans to develop an APS based on the previously available Relume system. Talking Signs and Mitsubishi are continuing development and testing of their product for street crossings devices in Japan. Talking Signs is working with Polara on a combined system for U.S. installation. There are a number of companies manufacturing and distributing APS in other countries, and more development can be expected.

The descriptions of features of APS, as well as how these features are used by pedestrians who are blind and visually impaired, can be found in Chapter 4. If the manufacturer uses a term different from the terms commonly used in this document for a feature, the manufacturer's term is listed in parentheses.

In the descriptions of each product, "Standard features" refer to features that are included in the standard price of on all models. "Optional features" refer to features that

AR0072090

must be ordered extra or need special specifications on ordering (i.e., speech messages or pushbutton information messages that may need to be recorded by the manufacturer).

Campbell Company

221 West 37th Street, Suite C

Boise, Idaho 83714

Models

- Advisor Fully integrated Pedestrian Station – Advisor FIPS
- Advisor Base Broadcast Unit – BBU
- Vibrotactile Only – VTO

Photos

Figure B-1. Advisor FIPS 57.

AR0072091

Figure B-2. Advisor FIPS H.

Figure B-3. VTO Unit.

Figure B-4. BBU, showing speaker mounted on bottom of pedestrian signal head.

Standard Features

Advisor FIPS

"Walk" Indication:

AR0072092

- Speech Message or Cuckoo/Chirp.
- Vibrotactile Arrow

Other:

- Speaker at pushbutton.
- Pushbutton Locator tone.
- Tactile arrow.
- Automatic volume adjustment.
- Actuation indicator, tone, message, acknowledgement tone or message, LED (visual feedback).

BBU

"Walk" Indication:

- Cuckoo/chirp

Other:

- Speaker in pedestrian signal head

VFO

"Walk" Indication:

- Vibrating arrow

Other:

- No speaker: vibrotactile only.

Optional Features:

- Also available in H frame style (used mainly in Northwest U.S. states).
- Custom tones and messages.
- Fixed audible walk time for use with rest in "Walk".
- Braille street names.
- Extended button push functions:
  - Pushbutton information message (pushbutton message).

AR0072093

- Volume increase, and
- APS actuation

Installation Notes:

- Advisor control unit/driver typically mounts in the pedestrian signal head or separate enclosure (available on request) to existing screws, or with industrial hook and loop
- Volume adjustments are on the control unit board which mounts in the pedestrian signal head
- Sound dish mounts to pedhead and plugs into driver board
- Factory made cable plugs into driver and back of pushbutton.

Comments

Advisor PIPS provides both audible and vibrotactile indications and other features as required in Draft PROWAG.

BBU provides an audible "Walk" indication only, and VTO units provide vibrotactile indications only.

Mallory Sonalert

Models

- VSB 120

Photo

Figure B-5. Mallory Sonalert unit.

AR0072094

Standard features

VSB 110

"Walk" indication:

- Cuckoo – 800 Hz and 1200 Hz, every 1.5 s.
- Chirp – 2000 Hz, every 1 s.

Other:

- Speaker intended for mounting in pedestrian signal head.

Optional Features

None

Installation Notes

Usually mounted inside the pedestrian signal head and directly wired to the "Walk" indication.

Comments

No pushbutton locator tone, vibrotactile indication, or automatic volume adjustment, which are features required by Draft PROWAG 12.

Mallory also sells sound generators in various beeps, siren and chime sounds; these are not recommended sounds for use as APS.

Models

- DS100

AR0072095

- DS3000

Additional components for DS3000: Vibrawalk, with functions of pushbutton and vibrating arrow integrated.

Photos

Figure B-6. The DS100 mounted on pedestrian signal heads.

Figure B-7. The Vibrawalk2 unit for use with the DS3000 to provide a pushbutton locator tone and a vibrotactile arrow.

AR0072096

Figure B-8. DS3000 is the company's newest product.

Standard Features

DS100

"Walk" indication:

- Two or four tones standard, cuckoo and chirp (peep-peep) and two additional custom tones.

Other:

- Speaker unit mounts on pedestrian signal head.

DS3000

"Walk" indication:

- Two or four tones standard: cuckoo, chirp, short beep, and long beep.
- Dip switch setting to provide either concurrent sound from both ends of the crosswalk or sound that alternates from each end of the crosswalk.
- Optional additional unit (VibraWalk) to provide vibrotactile indication.

Other:

- Typically mounted on pedestrian signal head.
- Automatic volume adjustment (dynamic proportional volume compensation).
- Separate volume settings for locator tone and "Walk" signal.
- External sound adjustment screws.

AR0072097

- Separate circuit to drive the optional vibrating tactile feature.

Optional Features

- VibraWalk2 unit, which provides pushbutton locator tone, actuation indicator (button lamp indicator), RUI, pushbutton information message (pedestrian acknowledge), and vibrotactile arrow at pushbutton
- Custom speech messages for DS100 (up to 1.5 s) and DS3000 (up to 3.2 s).
- Sound inhibit interacts with traffic signal controller to disable audible indications as required.
- Maximum walk timer for rest in "Walk" intersections.
- DS3000i option provides a control board, which is mounted inside the pedestrian signal head, to drive VibraWalk2 unit and provide all sounds from pushbutton, or for use with optional additional loudspeaker.

Installation Notes

4 wire 20 gauge.

120 VAC derived from "Walk" and "Don't Walk" indicator

Comments

Optional VibraWalk unit is needed to provide pushbutton locator tone, tactile arrow and vibrotactile "Walk" indications, as required by Draft PROWAG.

Models

- BPC

AR0072098

Photos

Figure B-9. Panich BPC.

Figure B-10. Driver unit for Panich BPC.

Standard Features

"Walk" indication:

- Tone—500 Hz with a repetition rate of 8.5 Hz—series of rapid thump sounds.
- Vibrating arrow.

Other:

- Pushbutton locator tone (locating tone)—880 Hz with a repetition rate of 1 Hz for US market or 1000 Hz with a repetition rate of 0.55 Hz for Australian market.
- Tactile arrow.
- Automatic volume adjustment, with three standard settings for response.

AR0072099

- Alert tone (transitional tone) – brief burst of 3500 Hz tone, decreasing exponentially to 700 Hz, and then going to 500 Hz "Walk" tone.

Optional Features

- Cuckoo and chirper other sounds
- Fixed "Walk" message length of 8, 16, or 32 sec "Walk" message can be cut during the full "Walk" interval
- Actuation indicator (steward indicator/demand tone) – light and tone.
- Long button press – allows pedestrians to request a "Walk" tone at 12 dB above the sound of the locator tone (higher volume demand, HVD).

Installation Notes

Driver unit is mounted in a housing on the pole near the pedhead, wired to the pedhead.

Automatic gain control level is set during installation.

Comments

Complies with specifications of the Australian standard; standard pushbutton in Australia.

Models

Navigator

Photos

Figure B-11. Polara Navigator APS mounted on pole.

Standard Features

"Walk" indication:

- Speech message or cuckoo/chirp
- Vibrating tactile arrow

Other:

- Speaker at pushbutton.
- Pushbutton locator tone (locating tone).
- Tactile arrow.
- Automatic volume adjustment—60 dB range.
- Separate minimum and maximum volume settings for pushbutton locator tone (locate sound), clearance, and "Walk" sounds.
- Actuation indicator – tone, LED light, and tactile bounce back.
- Depression in the arrow enables pushbutton operation with a head stick.
- Push button failures or system failures default to transmitting a constant pedestrian call.

AR0072101

Optional Features

- Custom speech messages.
- Fixed "Walk" message timing or "Walk" message can be on during full interval
- Braille street name on the faceplate
- Face plate with informational sign.
- Optional clearance sounds or audible countdown of remaining seconds during clearance available.
- Direction of travel message.
- Extended pushbutton functions:
  - Pushbutton information message (pushbutton message)
  - Audible beaconing – volume increase of "Walk" indication and pushbutton locator tone during the subsequent pedestrian phase
  - Extended push priority (mutes entire intersection except selected crosswalk to minimize confusion caused by other sounds).
- Talking Signs receiver-based system available as additional option.

Installation Notes

Two-Wire System

Operates with only two wires from the intersection traffic control cabinet to the pushbutton and is programmable after installation by the installer using a handheld PDA type device. Control unit is mounted in the signal controller. Numerous options programmable with PDA.

Four Wire System

Used when pushbutton wires from the traffic control cabinet to each button location do not exist. Two pair of 18-22 gauge wires run from the control unit that mounts in the pedestrian signal head to the pushbutton unit. All features programmed after installation by the installer using a handheld PDA type device.

AR0072102

If Navigator is used in combination with Talking Signs transmitter, the transmitter must be carefully positioned to provide information only within the width of the crosswalk.

A PDA-type device called a Configurator is an additional piece of equipment that is needed for setting the features and volume of their two-wire and four-wire APS. Jurisdictions will need to purchase one or two for technician use. (See Figure 7-9 in Chapter 7 for an example of use of the PDA.)

Comments

Combination of Polara Navigator with Talking Signs transmitter can transmit messages to a handheld receiver to provide orientation and alignment information.

Figure B-12. Prisma TS-907F.

Figure B-13. Prisma TS-995 pedhead-mounted beaconing loud speaker.

Standard Features—TS-903F, TS-904F, TS-907F, TS-908F

"Walk" indication:

- Rapidly repeating percussive tone.
- Vibrating arrow on TS-907 and TS-908 only.

Other

- Speaker at pushbutton.
- Pushbutton locator tone.
- Tactile arrow.
- Automatic volume adjustment within range of 55-95 dB.

AR0072104

- Actuation indicator—light and tone—on TS 903 and TS 907 only.
- Crosswalk tactile map (braille map).
- Fault indicator.

Optional Features

- 10 different tones available.
- Night switch to deaden sound
- Double-ended arrow available for use on medians and right-angle arrow available for use with exclusive pedestrian phasing, where there is a single pushbutton on a corner

Standard Features - DAPS

"Walk" indication:

- Rapidly repeating percussive tone.
- Vibrating arrow.

Other

- Speaker in pushbutton
- Pushbutton locator tone.
- Tactile arrow.
- Automatic volume adjustment within range of 55-95 dB.
- Actuation indicator—light and tone.
- Crosswalk tactile map (braille map).
- Fault indicator.

Optional Features

- 10 different tones available by setting with PDA
- Custom speech "WALK" messages, recorded and programmable with PDA.
- Additional beaconing speaker (TS 9951) for mounting at overhead location
- Night switch to deaden sound
- Double-ended arrow available for use on medians and right-angle arrow available for use with exclusive pedestrian phasing, where there is a single pushbutton on a corner.

AR0072105

- Extended button press features:
  - Pushbutton information message 1.2 s.

Installation Notes

Numerous features of D-APS model are programmable with PDA.

Volume min/max levels are adjustable by installer.

Step-down transformer available for mounting in the pedestrian signal head for U.S. installation.

Tactile arrow is mounted horizontally on top of device, allowing some latitude in placement of APS on pole, while still making it possible to align the arrow parallel with the associated crosswalk.

Wiring colors may conform to European standards rather than U.S. standards.

Introduction

Throughout the preceding chapters of this guide, references were made to various studies to support the recommendations given in those chapters. Interested readers may wish to see more details on the studies underlying these recommendations. This appendix was designed for such readers. This appendix reviews the research literature on APS including

- Research on problems of blind pedestrians,
- Effects of APSs on particular street crossing tasks,
- Effects of APSs on independence and confidence,
- Effects of "Walk" signal characteristics,
- Accuracy and speed in identifying "Walk" indications for a given crossing,
- Research on source of the "Walk" signal,
- Research on other APS features,
- Other concerns and needs, and
- Need for additional research.

Research on Problems of Blind Pedestrians

Introduction

Although APSs have been widely used in Japan and Sweden since the 1960s, the early development of APS in these countries was not, as far as these authors have been able to ascertain, based on research. Nor was there any research basis for the "cuckoo/chirp" APS that has been most commonly used in the U.S.

The first substantial research on APS appears to have been done in 1976 by Frank Bulsher, an electrical engineer with the Department of Motor Transport, New South Wales, Australia. Bulsher's research was the basis for the well developed, fully standardized, and highly successful APS system in use in Australia today.

Substantial research on APS in the U.S. began with a project undertaken by the San Diego Association of Governments in 1988. The results of this project were the basis for a policy of implementing standard signals at intersections in San Diego where audible access committee recommended them, following a systematic evaluation.

AR0072111

Since 1996, there has been a concerted research effort related to APS. Several research studies and surveys have documented problems of pedestrians who are blind or who have low vision at signalized intersections without APSs (Barlow, Bentzen, and Bond, 2005; Bentzen, Barlow and Bond, 2004; Bentzen, Barlow, and Franck, 2000; Carroll and Bentzen, 1999; Murakami, Ishikawa, Ohkura, Sawai, Takano and Tanchi, 1998; San Diego Association of Governments, 1988). Several studies in the United States have contrasted travel by blind pedestrians with and without APSs (Barlow, Bentzen, Bond and Guthie, 2006; Crandall, Bentzen and Myers, 1998; Crandall, Brabyn, Bentzen, and Myers, 1999; Crandall, Bentzen, Myers and Brabyn, 2001; Marston and Golledge, 2000; Ponam, Peck and Waddell, 1988; Williams, Van Houten, Ferraro, and Blasch, 2005). In these studies, some of the APSs have been signals mounted on the pedestrian signal head, while others have been receiver-based systems, and others been pushbutton-integrated devices. Information in this section is drawn from these studies. A brief summary of each follows.

Surveys of Blind Pedestrians and Orientation and Mobility Specialists

The San Diego Association of Governments (1988, and Szatos, Valerio, and Nowak, 1991a, b, c, hereafter referred to collectively as San Diego research) surveyed 71 national, regional, and local organizations representing and/or serving elderly persons and persons who were visually impaired to determine their involvement in installation of audible signals and the level of support for audible signals; 36 responses were received. A separate survey was also sent to members of California Association of Orientation and Mobility Specialists to gather information about their experience with audible signals. Surveys were mailed to 67 members, and 27 responses were received.

In 1998, the American Council of the Blind (ACB) and the Association for Education and Rehabilitation of the Blind and Visually Impaired (AER) conducted similar surveys to determine problems experienced by blind pedestrians during street crossings. Problems with audible signals currently installed were also identified by the surveys.

- ACB survey (Carroll and Bentzen, 1999, hereafter referred to as ACB survey) – Surveys were administered orally, in groups, to 158 pedestrians who were visually impaired.
- AER survey (Bentzen, Barlow, and Franck, 2000, hereafter referred to as AER survey) – Surveys were mailed to 1000 orientation and mobility specialists; 349 surveys were returned.

AR0072112

Murakami et al. (1998) conducted a survey of 80 blind pedestrians in Japan.

More details about the survey results, and references to studies which support the results, are provided in the section on crossing problems.

Crossing Data

Ustan, Peck, and Waddell (1988) compared crossings by 27 legally blind pedestrians at three intersections in Huntington Beach, California, having "chirp call" signals and one control intersection without APS.

In research by the Smith-Kettlewell Eye Research Institute (Crandall, Bentzen, and Myers, 1998; Crandall, Bentzen, Myers and Brabyn, 2001; Crandall, Brabyn, Bentzen, and Myers, 1999; hereafter referred to collectively as SKERI research), 20 blind participants made a total of 80 crossings at four fixed-time signalized intersections in downtown San Francisco, both with and without Talking Signs, which are receiver-based APSs. Intersection signal phases were permissive, so no pushbutton was required. There were nine measures, including measures of crossing timing (safety), orientation (precision), and independence.

Marston and Golledge (2000) compared crossings by blind participants with and without APSs, using the receiver based APS system, Talking Signs, in a study investigating the use of Talking Signs to provide infrared audible signs for a number of transit tasks.

The effects of a pushbutton integrated APS, a receiver based APS manufactured by ReZume, and typical visual pedestrian signals without APS on the street crossing behavior of 24 totally blind participants were compared by Williams, Van Houten, Bertamo, and Blasch (2005).

As part of a project on blind pedestrians at complex intersections, which was funded by the National Eye Institute of the National Institutes of Health, a series of studies on crossings by blind pedestrians with and without APS is in progress in four cities -- Portland, Oregon; Charlotte, North Carolina; Tucson, Arizona; and Cambridge, Massachusetts. Objective data on measures of street crossing performance by 16 participants who were blind was obtained at two complex signalized intersections in each city. Measures were similar to those used in the SKERI research, including nine broad measures of crossing timing, orientation, and independence.

Results from all four cities are not yet analyzed, but slightly different analyses have been reported in several articles. Results from preinstallation testing in two cities, Portland and Charlotte, are reported by Bentzen, Barlow, and Bond (2004), hereafter referred to as NCHRP

AR0072113

cities, and reports on three cities—Portland, Charlotte, and Cambridge—are reported by Barlow, Bentzen, and Bond (2005), hereafter referred to as NEI-3 cities. Barlow, Bentzen, Bond, and Gubbe (2006), hereafter referred to as NEI Portland pre-post, compare results of testing with and without APS in Portland.

Problems with Specific Tasks at Signalized Intersections

Locating the Crosswalk

Pedestrians who are visually impaired use a variety of nonvisual cues and strategies to locate crosswalks, none of which is absolutely reliable. Cues include proximity to the corner or to traffic on the street parallel to the pedestrian's direction of travel, location of curb ramps when present, location of idling cars on the street to be crossed, and presence of other pedestrians. When APSs are present, they may also be used as an indication of the location of crosswalks.

ACB and AER surveys did not include specific questions about locating the crosswalk. In the Japanese survey, 78% of individuals indicated that locating the crosswalk was difficult at intersections without APSs.

In the SKERI research, at locations without an APS, participants requested assistance in locating the crosswalk at 19% of street crossings. Participants were permitted to begin a crossing from any location that satisfied them, whether or not it was actually within the crosswalk lines. On 30% of trials, subjects who located the crosswalk independently began crossing from outside the crosswalk. (Participants were permitted to start crossing from any location so long as they were in no immediate danger.)

The NEI-3 cities results indicated that participants started from outside the crosswalk area on 28.3% of crossings and requested or required assistance locating the crosswalk on 15% of crossings.

Orientation (Aligning to Cross and Maintaining Alignment While Crossing)

Pedestrians who are visually impaired typically use a number of clues to help them align to face the direction of travel on the crosswalk before beginning to cross. These include vehicular sounds such as the detection of parallel traffic flow and the location of idling traffic on the street to be crossed. Another good cue, or strong predictor, of the direction of the destination corner is the direction pedestrians are traveling before they arrive at the starting corner. Additional cues

AR0072114

that are useful in familiar locations are walls, fences, hedges, grass lines, and objects near the curb that have a straight surface that is either parallel or perpendicular to the direction of travel across the crosswalk. The direction of slopes of the curb ramp and the alignment of a truncated dome detectable warning near the bottom of the curb ramp are not reliable indicators of the direction of travel on the crosswalk, and when used either intentionally or inadvertently, they may lead pedestrians who are visually impaired into the center of an intersection. Although there are numerous clues to the direction of travel on the crosswalk, none of them alone or in combination provide a definitive direction to pedestrians who are crossing at unfamiliar crosswalks.

Two clues used to help pedestrians who are blind maintain their alignment while crossing are the distance and direction of parallel traffic flow and the location of idling vehicles on the perpendicular street. Even at familiar crossings these clues may not be sufficient to provide positive guidance to pedestrians who are blind as they are crossing a street.

In the ADR survey, 97% of O&M specialists who responded indicated that their students had difficulty aligning to cross the street, while 66% indicated that their students sometimes had difficulty knowing when the destination corner was. The most important reasons stated were that traffic was intermittent or the intersection was offset. In the ACB survey, 79% of respondents indicated that they sometimes have difficulty figuring out where the destination corner is.

Respondents to the Japanese survey indicated that "direction facing at the starting position" and "keeping direction while walking in the crosswalk" were a problem, even with an APS.

The broadcast sound from speakers mounted on the pedestrian signal head has not seemed to provide usable directional information. ACB and ADR surveys indicated that pedestrians who are blind are sometimes not able to localize the sound of an APS in order to use it for guidance across the street (ACB, 6%; ADR, 39%). Eighty-five percent of ACB respondents indicated that they were sometimes confused by unexpected features such as medians or islands, while 64% of O&M respondents indicated that their students had difficulty with medians or islands.

In the SKERI research, participants started crossing from an aligned position at 48% of crossings without an APS and completed their crossings within the crosswalk on 58% of crossings. In the NEI-3 cities research (without APS), participants started from an aligned position on 73.4% of crossings. Participants requested assistance or required intervention for

AR0072115

safety while aligning to cross on 10% of crossings. Of participants who aligned independently, 58.1% completed their crossings within the crosswalk.

Using Pushbuttons

At 90% to 95% of signalized intersections today, signal timing is constantly adjusting to accommodate current vehicular and pedestrian traffic, and pedestrians are required to push a button to actuate a pedestrian timing to cross the street. Unless a pedestrian pushes the button, the "Walk" signal will not come on, and, when there is a green signal for parallel traffic, it is timed to accommodate vehicular traffic, not pedestrians. A pedestrian who does not push the button and who crosses with the green signal for parallel traffic may not have enough time to cross the street. The vehicular signal timing may be as much as 20 s less than the pedestrian signal timing (Barlow and Bentzen, 2003). Therefore it is very important that pedestrians who are visually impaired use pushbuttons.

Blind pedestrians experience a number of problems with pushbuttons.

In the ACB and AER surveys, many respondents indicated that they or their students had difficulty with pushbuttons (ACB, 90%; AER, 94%). The following reasons were given:

- Users couldn't tell whether they needed to push a button.
- Users had difficulty locating the button.
- Users couldn't tell which crosswalk was activated by the button.
- The pushbutton was so far from the crosswalk that users couldn't push the button and then return to the crosswalk and align to cross before the walk interval began.

Ulfan et al. (1998) also found that, with "bird call" type APSs, 27 legally blind participants had major problems locating the pole and the pushbutton and determining which pushbutton was for which crosswalk. Participants traveling with guide dogs experienced the most difficulty locating the pole. Sometimes participants first located the incorrect button and subsequently located and pushed the correct button after waiting and listening through one or more cycles.

The San Diego research also identified problems with locating the pushbuttons and poles (Szlyk et al., 1995). Gallagher and Montes de Oca (1998) also noted this in research on vibrotactile only APSs.

AR0072116

In the NEI-2 cities results, at crossings where pushbutton activation was required, participants looked for, found, and pushed the button on only 16.3% of these crossings in Portland and none (0%) of the crossings in Charlotte.

In research under NCHRP 3-62 (see NCHRP 3-62 Final Report and Bentzen, Scott and Barlow, 2006), blind participants crossing at signalized intersections with APS in Tucson, but without having any instruction in use or purpose of the APS, failed to even search for pushbuttons at 29% of crossings.

Identifying the Onset of the Walk Interval

In the absence of an APS, pedestrians who are visually impaired rely on the stopping of perpendicular traffic, followed by the onset of parallel traffic, to indicate the onset of the walk interval. Pedestrians who do not quickly and accurately identify the onset of the walk interval are likely to be delayed in starting to cross, may miss crossing on the first pedestrian phase, or may begin crossing when the walk interval is not in effect. Complex geometry and intersection signalization make the use of traditional clues to the onset of the walk interval unreliable.

Many respondents to the surveys indicated that they or their students sometimes had difficulty knowing when to begin crossing (ACB, 91%; AER, 98%). The following reasons were identified:

- The surge of traffic was masked by right turning traffic.
- Traffic flow was intermittent.
- The intersection was too noisy.
- The surge of traffic was too far away.

In the AER survey, 79% of respondents indicated that blind students sometimes had difficulty determining the onset of the walk interval at intersections having exclusive pedestrian phasing.

In the Japanese survey, 46% of respondents stated that "to take a timing to start" was difficult without APS.

Ulzan found that, at the control intersection without APS, which was considered the easiest to cross without APS, 4 out of 15 participants began crossing during the "Don't Walk" interval.

AR0072117

In the SKERI research, on 24% of trials when APS information was not available, blind pedestrians requested assistance in knowing when to start crossing. On 34% of trials on which they independently initiated crossings, participants began crossing during the flashing or steady "Don't Walk."

The NCHRP cities research found that pedestrians who were blind began crossing independently during the walk interval on only 48.6% of crossings and completed crossings after the onset of perpendicular traffic on 26.9% of crossings. The need for pushbutton actuation of the walk interval affected the likelihood that participants would begin crossing during the walk interval. On the pedestrian actuated crossings, participants began crossing during the walk interval on only 19.5% of the crossings, compared with 71.7% of crossings where the pedestrian phase was on recall (i.e., the pedestrian phase was actuated in every cycle).

Mean latency in beginning crossing (the time between onset of the "Walk" signal or near-side parallel traffic and the participant beginning to cross) was 6.41 s.

Problems with APS

The ACB and AER surveys were not limited to information about crossings that did not have APS; they also had questions about APS volume and about confusion of tones.

Volume The 1998 ACB and AER surveys reported the experience of pedestrians with visual impairments in using APS that had "bird call" signals, bells and buzzers. There were problems both with APS being considered too quiet and too loud. In the ACB survey, 45% of participants considered signals to be too loud, while 71% considered them too quiet. In the AER survey, 24% of participants considered signals to be too loud, while 32% reported that the signals were too quiet.

When APS are too loud, and are at intersections that are close together, the APS for one intersection may be heard from another, leading some pedestrians to incorrectly think they have the walk interval. The surveys noted this problem (ACB—19%; AER 25%).

In addition, complex phasing can contribute to problems with APS volume. Ustan et al (1988) found that at one intersection with split phase timing, where the bird call signals for parallel crosswalks had separate timing, three of 15 blind participants initiated their crossings with the signal for the parallel crosswalk, walking into the paths of left-turning vehicles.

AR0072118

Problems with APS: Knowing Which Street Has the "Walk" Signal—Researchers particularly evaluated data from the AER and ACB surveys of blind pedestrians and O&M specialists from California, whose experience with APS is almost exclusively with "bird call" signals that are intended to provide unambiguous information regarding which street has the walk interval. Many respondents indicated that they or their students sometimes did not know which crosswalk had the walk interval (ACB, 68%; AER, 72%). The reasons cited included the following:

- Users forgot which signal was associated with which crossing direction.
- Users didn't know which direction they were traveling, and
- The intersection was not aligned with primary compass directions.

The San Diego research also indicated that blind pedestrians had difficulty remembering which sound was for which crossing direction.

Recent research in the NIH project and the NCHRP Project 3-62 addressed this issue. (See Chapter 5 in this guide.)

Problems with APS: Confusion of Tones with Other Sounds—Anecdotal evidence has existed for some time that some birds in the United States have calls that are like the chirp sound of some APSs, and that other birds may mimic this sound. This has led to confusion between APS sounds, particularly the chirp sound and the sounds of birds.

AER and ACB surveys confirmed that blind pedestrians really do confuse the sounds of birds with APS sounds. In the AER survey, 11% of respondents stated that their students had crossed the street with an actual bird, and 10% stated that their students had not crossed because they thought the signal was a bird. Lasky et al. (1988) and the San Diego research also noted this as a problem.

Pedestrian Crashes

To obtain a rough measure of the incidence of intersection crashes and near crashes for pedestrians who are visually impaired, the ACB survey asked respondents whether they had been struck by a car at an intersection or whether their long canes had been run over. In the ACB survey, 12 of 158 (8%) of respondents had been struck by a car at an intersection, and 45 (28%) had had their long canes run over.

AR0072119

Effect of APSs on Specific Crossing Tasks

Introduction

Since it is known that pedestrians with visual impairments have difficulty with many of the tasks that, taken together, compose the action of crossing a street, it would be desirable to think that APSs improve all measures of crossing at signalized intersections. To determine the extent to which this is true, a number of research projects have obtained objective data comparing street crossing with and without APSs on one or more of the following measures:

- Locating the crosswalk,
- Aligning to cross and maintaining alignment while crossing,
- Use of pushbuttons,
- Identifying the walk interval,
- Delay before beginning to cross, and
- Independence in any or all crossings tasks

Projects that have already been mentioned are SKERT research, NEI Portland pre-post, Uslan et al. (1988), Marston and Golledge (2000), and Williams et al. (2005).

There are several additional studies that shed light on this topic. As part of NEI research, in three different experiments, blind and blindfolded sighted participants made crossings at a simulated intersection, in the presence of recorded traffic sound, to determine the effect on crossing accuracy with signals composed of bird calls, percussive "ticks," a chirp train, or a female voice (Wall et al. 2004). The signals, all of which were mounted at a height of 8 ft, came either simultaneously from both ends of a crosswalk (typical practice), alternated from one end to the other, or came from the far end of the crosswalk only. These researchers also compared crossing accuracy when signals came from two parallel crosswalks (typical practice) or from a single crosswalk. A further comparison was between "Walk" signals with a typical 7 s duration versus a 7 s "Walk" signal followed by a locator tone.

Hulscher (1976) reported an estimate by Leith (personal communication) comparing starting delay pre- and post-APS installation.

Wilson conducted a pre- and post-APS installation study of behavior of adult, non-assisted pedestrians at one intersection.

AR0072120

Further, the research undertaken for NCHRP 3-62 contributed to the understanding of the effects of APSs on specific crossing tasks.

Results of Research

Locating the Crosswalk

SKERI research found that starting crossing from within the crosswalk increased from 70% to 97% with use of an APS.

NEI Portland pre-post research found significant increases in participants' ability to begin crossings from within the crosswalk at locations where pushbutton use was required and pushbutton locator tones were installed. Preinstallation, 77% of crossings began from within the crosswalk; post-installation, 97% of crossings began within the crosswalk, indicating that locating the crosswalk was significantly improved by the presence of a pushbutton-integrated APS (Barlow, Bentzen, Bond and Gubbe, 2006).

Orientation (Aligning to Cross and Maintaining Alignment While Crossing)

APSs have some affect on aligning to cross, but results have not been as positive as desired.

On 48% of crossings in the SKERI research, where APS information was not available, blind pedestrians were not facing directly toward the opposite corner when they started their crossings; rather, they were facing somewhat toward or away from the center of the intersection. With the use of receiver-based APSs, participants were well aligned when beginning 80% of crossings.

However, in NEI Portland pre-post research, alignment showed only a very small trend toward improvement, with 70% of independent crossings starting from an aligned position preinstallation and 84% postinstallation.

NEI research (Wall et al. 2004) found the presence of a locator tone during the second half of the crossing had a positive effect on alignment.

In the NCHRP 3-62 research on device features, statistical analyses revealed no differences in orientation attributable to device in Tucson, and only a few minor differences in Charlotte. These differences are easily explained by unique characteristics of the given intersection or pole placements, and taken together with the lack of findings in Tucson they suggest that none of the differences in APS device features on different manufacturer's APS had an important impact on pedestrian orientation. (See NCHRP 3-62 Final Report, and Bentzen et al. 2006.)

AR0072121

Various means of beaconing and providing directional information to blind pedestrians are being investigated in the NEI research, including increasing the volume of the locator tone and providing it from a directional speaker, and providing an orientation tone that involves increasing the volume of the locator tone on the opposite end of the crosswalk before the crossing interval, in response to a request. Data collection and analysis of results from these experiments are not complete.

Using Pushbuttons

Data reported in NEI pre-APS installation testing (NEI 2 cities, NEI-5 cities) indicated that blind pedestrians typically didn't search for and use pedestrian pushbuttons at unfamiliar intersections. In Portland, after installation of APS with locator tones (NEI Portland pre-post), participants were not instructed to use the pedestrian pushbuttons, nor were they provided with instruction about the fact that pushbuttons were needed to call the walk interval at some of the crossings. However, the addition of pushbutton locator tones and the knowledge that an APS might be installed resulted in participants looking for the pushbuttons on over 98% of crossings, although looking for the pushbutton did not always result in finding and using the correct pushbutton. Participants independently looked for and used the pushbuttons on 93% of the crossings after pushbutton locator tones were installed. In the pre-test situation, pedestrians had looked for and used pushbuttons on only 16% of crossings.

NCHRP 3-62 research (see NCHRP 3-62 Final Report and Bentzen et al., 2006) reported that while pedestrians who are blind do not typically use pushbuttons when making unfamiliar crossings, after being made aware of the function of the pushbuttons to call the walk interval, and hearing the demonstration locator tones, 100% of participants in Tucson and Charlotte searched for the pushbutton. Participants in both cities said they used the locator tone when locating the pushbutton on most trials, regardless of device. However, the presence of a pushbutton locator tone did not guarantee that participants would find and push the correct pushbutton. Errors in finding the correct pushbutton were reported, leading to recommendations for instruction in understanding and using tactile arrows, as well as maintaining orientation while looking for pedestrian pushbuttons.

AR0072122

Initiating the Crossing

APSs have been found to positively affect measures of delay in beginning to cross, starting crossing during the walk interval, and completing crossings before the onset of perpendicular traffic.

Delay in Beginning to Cross - Ulusche (1976) cites a personal communication from Leith (1975) in which Leith estimated that, following APS installation, delay in beginning crossings was reduced an average of 2 to 3 s for all pedestrians.

Watson (1980) in a pre- and post-APS installation study of adult nonestablished pedestrian behavior at one intersection, found the following results:

- For pedestrians using the pushbutton, delay in beginning crossings was reduced by 20%, from 2.7 s to 2.1 s.
- The time taken to cross by persons who started during the walk interval decreased by about 5%; crossing time for other pedestrians was unchanged.
- For pedestrians who arrived at the crossing during the flashing or steady "Don't Walk" and who waited to cross until the onset of the walk interval, the proportion who failed to complete their crossings before the onset of opposing traffic was reduced by one-half, from 32% to 17%.

Williams et al. (2005) found that mean latency in beginning crossing without APS was more than 5 s, which was reduced to 2.2 s with a receiver-based APS device with a tone "Walk" indication and 3.8 s with a pushbutton-integrated APS using speech messages.

In NCHRP/Portland pre-post research, in 144 crossings at two intersections, the weighted mean starting delay for blind pedestrians without APS was 5.1 s, and after APS installation, the delay was reduced to 2.9 s. Ulstan et al. (1988) also found significant differences between speed of crossing at control intersections and intersections where APS were installed; crossings at locations with APS were completed faster.

Williams et al. (2005) assessed participants on total number of signal cycles missed before crossing. Without APS, mean wait time was almost 2 full cycles, while with either type of APS, the mean wait time was just over half a cycle.

In NCHRP research, different "Walk" indications have been found to affect latency to begin crossing. (See NCHRP 3-62 Final Report, Chapter 2.)

AR0072123

Starting During "Walk" and Completing Crossing Before the Onset of Perpendicular Traffic—In SKERI research, participants began crossing during the walk interval on only 66% of crossings without APS, but on 99% of crossings with APS.

In NE Portland pre-post research, without APS the pedestrian actuated crossings were highly problematic for pedestrians who are blind. Preinstallation, participants began crossing during "Walk" on only 25% of crossings. Postinstallation, there was dramatic improvement in participants correctly determining the appropriate time to start crossing, with 84% of crossings initiated during "Walk." Similarly, participants completed crossing after the onset of perpendicular green on 56% of crossings preinstallation, with a significant decrease, postinstallation to 12% of crossings completed after the onset of perpendicular green.

Furthermore, only 37% of decisions about when to start crossing were made independently preinstallation, as opposed to 95% postinstallation. Preinstallation, the total number of crossings where the individual independently determined a start time and actually began crossing during the walk interval was less than a quarter of crossings. Postinstallation, with the addition of the APS, there was a significant increase both in independence and in beginning to cross at the appropriate interval.

For crosswalks where the pedestrian phase was on recall, the APS activated at the beginning of the walk interval, regardless of whether the pushbutton was used or not. The "Walk" indication only sounded for the first 7 s of the walk interval, unless the pushbutton was pushed again. Preinstallation, 70% of independent crossings began during the walk interval; postinstallation, this increased to 100%.

Marston and Golledge (2000) found that at crossings without an APS, almost half (48%) of the participants attempted to cross during the steady "Don't Walk" interval, a time recorded as unsafe by the researcher. With access to the pedestrian signal information provided by an APS, no participant started crossing at an unsafe time.

Effect of APSs on Independence and Confidence

Both independence and confidence affect the likelihood that people who are blind will cross streets independently. Lack of independence and low confidence in ability to cross safely result in lack of participation in normal community life.

AR0072124

Independence

Both the NEI research and the earlier SKERI research on which the method was based measured independence on three street-crossing tasks both with and without APS—i.e., locating the crosswalk, starting to cross within the walk interval, and completing the crossing. The NEI research also measured independence on aligning to cross. The percent of crossings on which participants were independent on each task is shown in Table C-1.

Task	Without APS		With APS	
	SKERI	NEI	SKERI	NEI
Locating crosswalk	81%	81%	99%	95%
Aligning to cross	NA	94.5	NA	97%
Starting to cross during WALK	76%	79%	100%	92%
Completing the crossing	81%	86%	97%	96%

Table C-1. Percentage of crossing tasks on which participants were independent.

Confidence

Marston and GeDodge (2000) measured confidence in street crossing at intersections with and without APSs. The range of responses for the no APS condition, by street crossing task, was 2.7 to 3.5 (5 point scale: 1 = no confidence, 5 = very confident), while the range of responses by task for the APS condition was 4.8 to 5.0.

Effect of "Walk" Signal Characteristics

Introduction

Both the Access Board Draft Guidelines for Accessible Public Rights-of-Way (revised 2005) and this APS Guide recommend using a rapid tick "Walk" indication. Research on "Walk" signal characteristics, described in this section, formed the basis for that recommendation.

It is important that any audible "Walk" signal be detectable and localizable, and, if it is a speech message, it must also be intelligible. Two factors make it difficult to satisfy these requirements. First, both detection and localization are influenced by ambient sound, especially the sounds of vehicles. Second, any degree of hearing impairment makes it more difficult to

AR0072125

detect and localize sounds and to understand speech. One might think that simply making the "Walk" signal loud enough would overcome both problems. However, the problems are much more complex.

Not only volume, but also the nature of the sound (that is, the spectral and temporal characteristics) must also be taken into account. A body of research, reported below, describes efforts to identify the characteristics of sounds or messages that make them detectable, localizable, and intelligible. Some of this research particularly addresses detectability, localizability, and intelligibility for people with hearing impairments.

There are also important limits to the amount of "Walk" signal noise that will be tolerated in neighborhoods, and limits to signal volume that are based on Occupational Health and Safety Administration (OSHA) requirements. Furthermore, if the "Walk" signal is too loud, it may make it difficult for pedestrians who are blind to hear the sound of vehicles that are about to cross their path.

APS devices available today respond to ambient sound, providing "Walk" signals that are louder when the ambient sound is high, such as when a large truck accelerates, and quieter when the ambient sound is low, such as at night. This greatly increases the public's acceptance of APSs.

APS users must not only be able to detect the "Walk" signal and localize it, they must also be able to quickly and unerringly determine which crosswalk the signal is for. The nature of the signal and its location are critical to the performance of this important part of the street-crossing task.

Results of Research

Hearing Loss and Blind Pedestrians

A majority of persons who are severely visually impaired are age 65 or older, and they typically also have some amount of upper frequency, age-related hearing loss. In addition, the incidence of hearing loss in people with visual impairments is higher than for the general population because a number of causes of blindness also result in hearing loss.

Upper frequency hearing loss results in a decrease in the ability to localize sound and to understand speech, particularly in noisy environments (Wiener and Lawson, 1969).

AR0072126

Characteristics of Traffic Sounds

The sound produced by vehicular traffic is concentrated in the low frequencies, especially for vehicles that are accelerating from a stop. The noise produced by accelerating vehicles is approximately 10 dB louder than that of vehicles traveling at a constant rate of speed. The mean intensity of accelerating traffic, measured from the position of a pedestrian waiting to cross streets in residential and small business areas, was found by Wiener and Lawson (1997) to be 89 dB, equal to the maximum APS volume currently permitted by the MUTCD. (The 89 dB maximum in the MUTCD was based on OSHA 8-hour exposure limits.) This means that signals at their maximum permitted volume will sometimes be difficult to hear.

Detectability

Hulscher (1976) found that, because of the masking of high frequency signals by predominantly low frequency traffic noise, and because a majority of blind pedestrians have some upper frequency hearing loss, the optimal fundamental frequency of the "Walk" tone is between 500 Hz and 1000 Hz, and the tone should be composed of multiple short bursts of sound to aid localization.

Staffeldt (1968), in research cited by Hulscher (1976), conducted extensive testing of APSs at crossings where they were mounted on the pedestrian signal head and found that an 880 Hz signal was most detectable in a background of traffic noise.

Hulscher's recommendation and Staffeldt's result was supported by Poulsen (1982), who compared the noise spectrum of traffic as attenuated by windows to arrive at a recommended signal frequency (880 Hz) that would not be largely masked by traffic noise, but would also not transmit through windows and become a public annoyance.

In San Diego research, laboratory measurements of "chirpcall" signals from Nagoya Electric Works of Japan found that neither signal was highly directional. However, the cheep was more detectable than the cuckoo. The cheep was produced by a continuous frequency variation with a fundamental frequency base of 2800 Hz, and the cuckoo consisted of two frequencies with a combined frequency base of 1100 Hz. (Currently available "cuckoo/cheep" signals may vary from this manufacturer's standard.)

Hall, Rabelle, and Zabihaylo (1996) worked with audiologists to develop a signal that provided the most localizable melody for an accessible signal and recommended a melody that

AR0072127

was composed of fundamental frequencies between 300 Hz and 1000 Hz, but including harmonics extending to 7000 Hz.

In NEI research unpublished data, Wall, Ashmead, Barlow, and Bentzen carried out a series of experiments on detectability of "Walk" signal indications in a laboratory setting. Experiment 1 evaluated the detectability of signals in white noise. Experiment 2 evaluated the detectability in traffic noise, and Experiment 3 evaluated detectability in traffic noise for subjects with age-related hearing loss. Signals evaluated were an 880-Hz square wave, a bird chirp, a cuckoo, two click trains, two percussive signals ("chink" and "tok"), a four-tone melody, and female and male voice signals.

Results indicated that audible signals of a more percussive nature with predominantly lower frequencies were best heard in background traffic noise. In addition to one of the percussive signals, participants with age-related hearing loss were better able to detect male voice signals. Signals with a simple percussive nature tended to need less gain to be heard in noise, relative to the levels necessary to be heard in quiet. In other words, percussive signals were more detectable at lower volumes.

When asked their preference, most participants liked voice signals best, but all of the voice signals needed more gain to be heard. Note that the measurement in these studies was the point at which the signal was detected, not the point at which the message was easily understandable. Intelligibility of voice messages was not evaluated or assessed by participants. The cuckoo and chirp, most commonly used in the U.S. as an audible signal at the time of the study, required the most gain to be detectable amidst background noise.

Localizability of "Walk" Signal

An additional factor of audible pedestrian signals are to be used as beacons to guide pedestrian with visual impairments across a street, is how well signals can provide directional information. Laroche, Gigure, and Poirier (1999) compared localization of cuckoo and chirp signals to localization of 4-four note melodies varying in fundamental frequencies, harmonics, note duration, and temporal separation between notes. In combined objective and subjective testing, the chirp and a melody with minimal harmonics were found to be less localizable than the cuckoo and the other three melodies. In a follow-up study, Laroche, Laroux, Giguere and Poirier (2000) compared the typical cuckoo-chirp sounds used in Canada with a cuckoo having a

AR0072128

lower fundamental frequency and the melody that was recommended as a result of their 1999 research. In both studies, the signal was 30 s long (much longer than typical U.S. "Walk" indications) and the measurements were in a simulated pedestrian corridor in a quiet environment. In situations with actual traffic sounds, the chirp was found to result in significantly greater veering and longer crossing times than any of the other signals, which did not differ from each other.

In NLI research, Wall, Ashmead, Bentzen, and Barlow (2004) found no significant differences in localizability among several disparate signals including cuckoo, chirp, "cos," and voice messages when tested in research that involved multiple crossings on a simulated street, in the presence of recorded vehicular sound. The five signals used were representative of signals in wide use or that showed promise for directional beaconing. None of the analyses indicated any systematic differences between the five signals. Further experiments focused on presentation mode and signal location, rather than signal sound characteristics.

Speech "Walk" Indications

Several APS systems used in the United States are capable of producing directly audible speech messages, either from a speaker that is integrated into the pushbutton housing or from a speaker at the pedestrian signal head. When demonstrations are given indoors, to an audience for whom English is the predominant first language, APSs with speech messages are considered by many people to be especially user friendly. However if messages are not correctly understood by users, APSs with speech messages, especially speech "Walk" indications, can lead to catastrophe.

Intelligibility of speech messages is influenced not only by the relationship between signal volume and ambient sound, but also by the nature of the message, how familiar the hearer is with the English language, and any kind of hearing impairment that the user may have.

Understanding Speech in Noise Listeners with "normal" hearing require that speech be 15 dB louder than background noise for intelligibility to reach 90% (Killion 1999). This means that, in order to be intelligible, speech messages should be louder than tone indications. The effect of that louder sound level on the ability of blind pedestrians to hear other sounds in the intersection, or the effect of the louder sound level on nearby neighbors, may limit the acceptability of speech messages. At this time, the MUTCD and Draft PROWAG limit the output of APSs to 5 dB

AR0072129

above ambient sound, except when special actuation requests a louder pedestrian signal for a single pedestrian phase. As noted in the section on detectability, speech messages can be detected in traffic sounds, but that does not guarantee that they can be understood.

Speech "Walk" Message Structure and Wording—Bentzen, Barlow and Franck (2000) conducted research to obtain information from stakeholders regarding the structure and content of speech messages for APS "Walk" messages and for "pushbutton information messages" that are available only during flashing and steady "Don't Walk." "Walk" messages convey that the "Walk" signal is on and provide the name of the street being crossed. Pushbutton messages provide intersection and crosswalk identification information, and may also provide information about unusual intersection signalization and geometry.

The research utilized an expert panel of stakeholders, who prepared a survey composed of sample messages to rate, as well as items to determine respondent understanding of messages. The survey was administered to people who are visually impaired, O&M specialists, transportation engineers, and APS manufacturers.

Speech "Walk" messages should provide pedestrians who are blind with information that is similar to the information being provided to pedestrians who are sighted. The message should not be worded in a way that seems to provide a "command" to the pedestrian. For example, "Cross Howard Street now" would not be an appropriate message.

Messages also should not tell users that it is "safe to cross."

Research resulted in recommended messages for the walk interval, which include beginning with the name of the street being crossed — for example, "Broadway. Walk sign is on to cross Broadway." Recommended messages are included in Chapter 4 of this guide.

Effect of Speech Messages on All Pedestrians—Van Houten, Malenfant, Van Houten, and Retting (1997) found that redundant information conveyed by audible pedestrian signals increases the attention of all pedestrians to turning traffic and may contribute to a reduction in pedestrian-vehicular conflicts and crashes at signalized intersections. Their research in Clearwater, Florida, used prototype speech message technology in which speech messages were broadcast from the pedestrian signal head. When the pedestrian pushbutton was pressed, the message was "Please wait for 'Walk' signal." The message "Look for turning vehicles while crossing [street name]" began 200 ms before "Walk" signals were illuminated.

AR0072130

The signal also gave participants who were blind precise information about the onset of the walk interval and about which street had the walk interval.

Accuracy and Speed in Identifying "Walk" Indication for a Given Crossing

Introduction

Both the Access Board Draft PROWAG and this guide emphasize the importance of installation location for APS. Installation location is critical for accurate and fast identification of which crosswalk has the "Walk" signal. Research on the "Walk" signal location and tone, described in this section, was the basis for that recommendation.

APSs must provide unambiguous information regarding which crosswalk has the "Walk" indication. A pedestrian who mistakes the signal for one crossing as a cue for a signal for the other crossing is at risk of making a crossing when vehicular traffic has the right of way and pedestrian crossing is not permitted. A two-tone system such as cuckoo/chirp has long been assumed to provide unambiguous information; however, San Diego surveys and Uslan et al. (1988) noted problems with such systems. ACB and AER surveys confirmed that there were numerous problems with it.

Speed in identifying the "Walk" signal for the desired crossing is related to delay in starting to cross. The most desirable signal from this perspective is one that is quickly identified, enabling users to initiate crossings promptly, and to finish crossing before the onset of perpendicular traffic.

Results of Research

In NEI research, Ashmead, Wall, Bentzen, and Barlow (2004) investigated the effects of location of APS speakers on accuracy and speed in identifying the correct crosswalk (see Figure C-1 for APS positioning used in research), using typical placements seen in the United States.

AR0072131

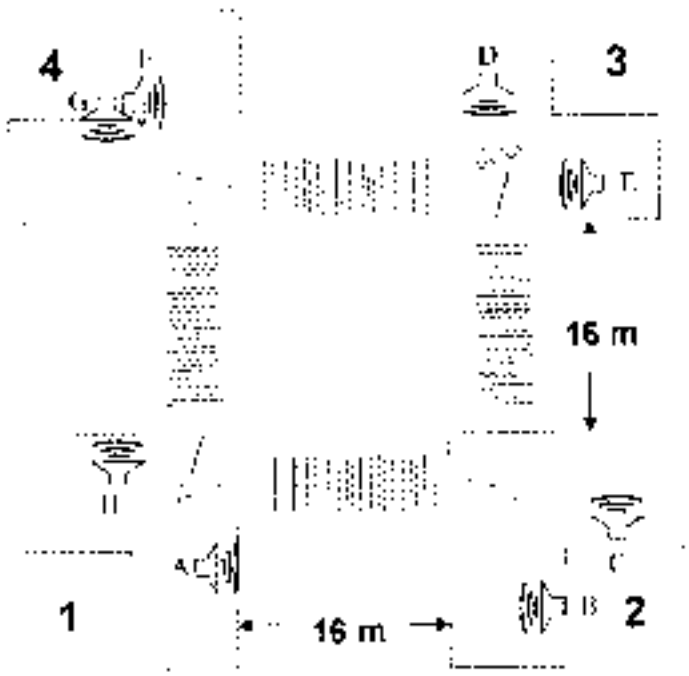

Figure C-1. Positions and headings of loudspeakers and pedestrians at each corner in NEI research. (Figure from Ashmead et al., 2004) Note: The question to the pedestrian always was, "Which has the "Walk" signal, the crosswalk straight in front of you or the one to your right?" Corner 1: loudspeakers near curb, on outside of crosswalk line. Corner 2: loudspeakers near back edge of sidewalk, on outside of crosswalk line. Corner 3: loudspeakers near curb but facing across pedestrian's position. Corner 4: loudspeakers near back edge of sidewalk mounted on the same pole. (Figure is not drawn to scale.)

Under the most typical signal mode, simultaneous presentation from both ends of the crosswalk, the most accurate performance occurred when signals were placed close to the curb line, near the side of the crosswalk that was furthest from the center of the intersection (see Corner 1 in Figure C-1). The pedestrian could easily tell which of the two loudspeakers at the corner was active because each loudspeaker was close to the position of the pedestrian waiting to cross at the associated crosswalk. Note that this was true despite the fact that both signals on the corner had the same sound. Other arrangements of loudspeakers resulted in somewhat worse performance. Accuracy at Corner 3 was poor, with participants answering correctly on only 25%

AR0072132

of trials in the simultaneous presentation condition and 80% of trials in the alternating presentation condition.

There was no evidence that response time differed across the four corners—that is, for different speaker arrangements. This suggests that the inaccurate judgments made from Corner 3 about which crosswalk had the "Walk" signal did not reflect uncertainty, but rather were mistakes of which the participants were largely unaware.

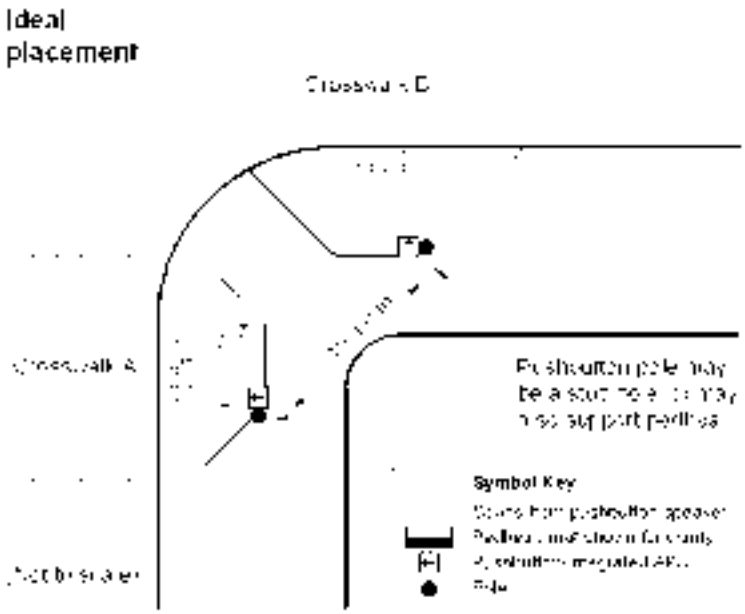

Figure C-2. Optimal location of pushbutton-integrated APS.

Figure C-2 illustrates the recommended placement of APS devices in relation to the crosswalk provided in the APS synthesis in 2003. This arrangement was based on the NEI research described above. However, the panel for the NCHRP Project 3-62 asked for additional research to determine if use of two poles at each corner was necessary, or if installation of two devices on one pole could result in accurate and fast identification of which crosswalk had the "Walk" indication.

Both the location of pushbutton-integrated APS and various associated signals were investigated under NCHRP Project 3-62 in an intersection in Portland, Oregon. (See Figure C-3 for the location of APSs on each corner and the sounds associated with each.) Ninety participants who were blind, who had low vision, or who had cognitive disabilities made all eight

AR0072133

approaches to a four-way intersection, were asked to push the button for to cross the street in front of them, and then to indicate when the "Walk" signal came on for the street in front of them. Participants did not cross the street except as they were guided from one corner to the next. (See NCHRP 3-62 Final Report and Scott, Myers, Barlow, and Bentzen, 2006.)

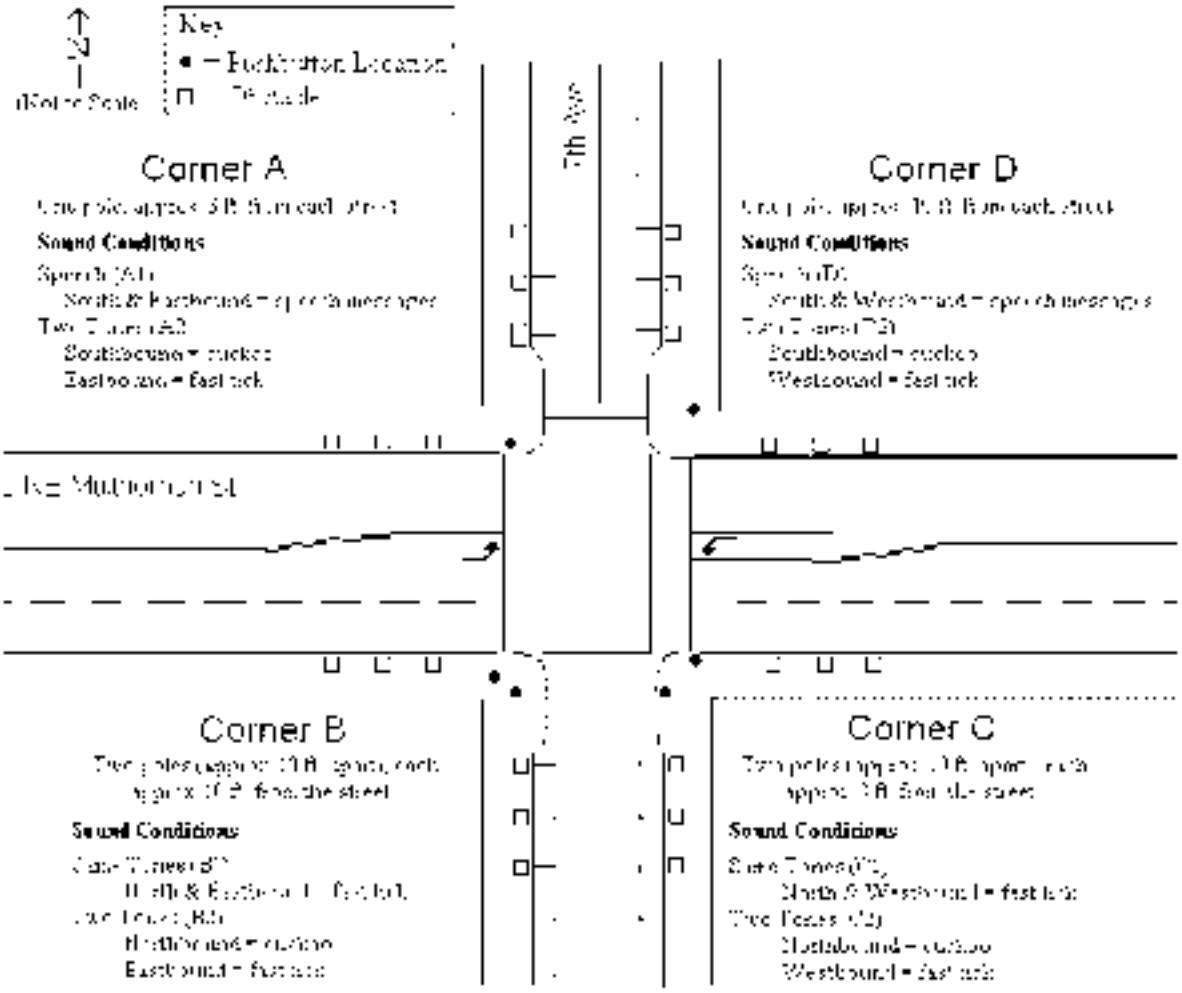

Figure C-3. Locations of pushbutton-integrated APS and associated "Walk" signals in NCHRP 3-62 research.

Results indicated that when pushbutton integrated APSs were mounted on separate poles, near the crosswalk line furthest from the center of the intersection, approximately 3 ft from the curb line, and approximately 10 ft apart, accuracy in judging when the correct crosswalk had the "Walk" signal was significantly better than when APSs were located according to other criteria (see Corner C, Figure C-3). On Corner C, participants in the totally blind and legally blind

AR0072134

subgroups indicated that the street in front of them had the "Walk" signal, when in fact the "Walk" signal was to cross the street beside them, in only 7.55% of trials. For all other tested arrangements, the same participants made this type of error in at least 26.9% of trials. Responses to the onset of the correct "Walk" signal were also significantly faster at Corner C.

For the two subgroups with the least vision, use of two different tones, when APS speakers were located on the same pole, resulted in errors in determining which street had the "Walk" interval on 50% of trials. Even when APSs were located on two separated poles, accuracy in identifying the onset of the correct "Walk" signal was significantly greater when both APSs on the same corner used the same tone (rapid tick) than when the two APSs used two different tones (cuckoo and rapid tick).

Speech "Walk" messages, when two APSs were located on the same pole, were also evaluated in this research. Speech messages resulted in a much lower error rate than two tones (19% versus 50%); however, locating the APSs on two separate poles and using the same tone on each for the "Walk" indication resulted in an error rate of less than 4%. Locating the APS speakers close to the crosswalk being signaled resulted in much better accuracy in identifying which street had the walk interval than variation in "Walk" indications.

The research recommended use of the rapid tick "Walk" indication because it produced the fastest and most accurate responses regarding which crosswalk has the "Walk" indication. This recommendation was in conjunction with recommendations for specific locations for the APS.

Participants who had enough vision to see the pedestrian signal (identified in the study as persons with low vision or cognitively impaired) reported that they used the visual signal. However, the results for these groups are in the same direction as the results for the two subgroups with the least vision. It thus appears that the participants who could see the visual pedestrian signals might nonetheless have been influenced by the APS pole arrangement and signal sound.

In research comparing devices having various features, conducted in Tucson and Charlotte under NCHRP Project 3-62, (see NCHRP 3-62 Final Report: Barlow et al., 2005; Bentzen et al., 2006), there were three types of "Walk" indications used in the devices—speech messages, birdcalls (cuckoo/cheep), and the rapidly repeating tone indication (rapid tick). Once pedestrians understood the crossing signal, the rapid tick provided the best cue in terms of starting to cross quickly in both cities. The faster response to the rapid tick signal confirms results of previous

AR0072135

research on pushbutton location and nature of "Walk" signal, in which responses were faster to the rich than to two different tones or to speech messages.

Research on Source of "Walk" Signal

Introduction

Signals typically installed in the United States have provided a loud beaconing "Walk" indication simultaneously from both ends of the crosswalk, and usually from two parallel crosswalks at the same time. As shown in the ACB and AER surveys, pedestrians who are blind often have difficulty if they try to use the APS to indicate the direction of travel on the associated crosswalk. Research has taken place in Canada, Japan, and the United States on the effect of source of the "Walk" signal on accuracy of aligning to cross and of making actual crossings.

Results of Research

Presentation Mode—Simultaneous, Alternating, and Far Side

Stevens (1993) and Barlow, Sawai, Takano, Yoshimura and Takeuchi (1998) tackled the problem of improving localization of "Walk" signals (beacons) by varying the source of the sound. They found that blind pedestrians could cross more quickly and with less veering when the "Walk" signal alternated back and forth from one end of the crosswalk to the other.

Barlow et al. (2000) confirmed the superiority and subjective preference for an alternating signal for beaconing at a simulated intersection, but found no advantage of the alternating signal when data were collected at an intersection with steady traffic on both streets. This was true for all tones tested (chirp, cuckoo, low cuckoo, and melody). It may have been that blind participants had good directional information from vehicular sound at the intersection or it may have been related to the shorter duration of the APS sound when installed at the intersection. In the previous testing at a simulated intersection (in quiet), the "Walk" signal continued for 36 s, more than the time required for participants to complete the curve crossing. Testing at the simulated intersection was also in a quiet environment.

Poulsen (1982) reported more accurate walking in a simulated crossing setting with a far end signal, than when a signal came simultaneously from both ends, and that far end signal was regarded favorably by a group of blind pedestrians in a field test at a real intersection.

AR0072136

Iiuchi, Takumi, Suzuki, Kai, Takakura, and Fujiura (2000) examined the effects of alternating "Walk" signals in which the sounds from both ends of a 60-ft-long crosswalk at the top of a T-intersection with alternating "Walk" signals were different. Participants were better aligned and maintained alignment better with the APS with different tones at the end of the crosswalk than with the APS having the same tone at the end of the crosswalk.

Wall et al. (2004) compared the usefulness of auditory signals in guiding crossing behavior in three signal presentation modes—simultaneous, alternating, and far side only. In several experiments, blind adults and blindfolded sighted adults crossed a simulated crossing with recorded traffic noise approximating street sounds. Audible signals were presented simultaneously from both ends of the crosswalk, alternating from one end to the other, or from the far end of the crosswalk only. The signals continued only for the typical U.S. "Walk" interval of 7 s, stopping when participants were approximately halfway across the simulated street.

The principal findings were the same for blind and sighted participants and applied across a range of specific signals (e.g., chirps, clicks, voices). Crossing was more accurate when audible signals came only from the far end of the crossing, rather than the typical practice of presenting signals simultaneously from both ends. Alternating the signal between ends of the crossing was not helpful. However, providing a locator tone at the end of the crossing during the pedestrian clearance interval improved crossing accuracy. These findings offer less promise for the usefulness of the alternating signal mode, especially when the findings for single versus dual crosswalks are considered. In previous studies, only one crosswalk was signaled, but this research compared signaling a single crosswalk versus two parallel crosswalks in two experiments. Errors were fewer in the alternating mode than the simultaneous mode, but only when a single crossing was signaled. The customary practice of signaling two parallel crossings at the same time seemed to draw participants somewhat toward the center of the intersection.

Research on Other APS Features

Previously described research has also looked at other specific features of APSs, including the pushbutton locator tone. The following sources are referred to: NCHRP Project 3-62 research; Barlow et al. 2005; Bentzen et al., 2006; Poulsen, 1982; San Diego research; and Williams et al., 2005.

AR0072137

Pushbutton Locator Tones

Pushbutton locator tones are a standard feature of almost all pushbutton-integrated APSs in use worldwide. In the United States, they are standardized to repeat once per second, and are to be audible only 6 to 12 ft from the pushbutton unless there is special actuation to raise the volume during the following pedestrian phase (Manual on Uniform Traffic Control Devices 2003 4E.09; Guidelines for Accessible Public Rights-of-Way, revised 2005). Pushbutton locator tones inform blind pedestrians that they need to push a button to actuate a "Walk" signal and/or pedestrian timing. Because the sound comes from the pushbutton, it indicates the location of the pushbutton.

Bentzen, Barlow, and Gabbert (2000) compared the speed of blind pedestrians on locating and working to an APS with a pushbutton locator tone (880 Hz square wave, with multiple harmonics, 3 ms attack time, 15 ms sustained tone at three repetition rates and three loudness levels relative to traffic sound along an eight-lane artery in Los Angeles. Best performance was with a repetition rate of once per second and loudness of 2 to 5 dBA above ambient sound measured at 1 m from the locator tone speaker.

Tactile Arrow

Tactile arrows aligned in the direction of travel on the associated crosswalk are features of all known pushbutton integrated APSs in use worldwide. Arrows vary in size and location on the APS. Some are on the pushbutton, some are on the vertical face of the housing, and some are on the top (horizontal) surface. The length of the arrow varies from approximately 1.5 in. to 2.5 in.; stroke thickness varies from approximately 0.09 in. to 0.25 in.; height above the surface varies from approximately 0.16 in. to 0.25 in.

The only research on usefulness of the tactile arrow for establishing crossing alignment was done in Denmark by Poulsen (1982). The "arrow" tested was a rod on top of the APS that was approximately 2.5 in. in length, 0.25 in. in width, and 0.25 in. high, with a bump indicating the far side of the crossing and additional bumps indicating the presence of islands or medians, if any. Alignment was equal with or without use of the arrow. The size and graspability of this unique arrow, as well as its location on the top of the APS, are thought to make it a better indicator of direction than smaller, nongraspable arrows and those mounted on the vertical face

AR0072138

of the APS. The failure to find any positive effect on alignment indicates that such an arrow for probably any arrow) should not be considered a primary cue for alignment.

Nonetheless, tactile arrows do serve the important purpose of indicating the crosswalk with which a particular APS is associated. Research under NCHRP 3-62 (See Final Report and Bentzen et al., 2006) found that increased familiarity with tactile arrows in Tucson and Charlotte resulted in an increase in use of tactile arrows, with arrows actually on the pushbutton being used more frequently than arrows that were not on the pushbutton itself. While participants looked at the incorrect (not desired crossing) arrows at 28 trials in Tucson, after extensive familiarization, they then found and pushed the correct pushbutton on all of these trials. In Charlotte, while there was a decrease in use of the wrong pushbutton following extensive familiarization, use of the wrong pushbutton on some trials remained. Under the same research, subjective responses indicating preference for various features indicated strong support for use of a tactile arrow to identify the correct pushbutton.

Vibrotactile Indications

Most pushbutton integrated APSs worldwide have vibrating tactile arrows or other surfaces that vibrate during the "Walk" interval. The vibration is required by pedestrians who are deaf-blind to inform them that the "Walk" signal is on. It is also used by some pedestrians without hearing loss to confirm which crosswalk has the "Walk" signal, especially in very noisy conditions.

Because it is necessary for pedestrians who are deaf-blind, as well as helpful for blind pedestrians in some situations, a vibrotactile "Walk" indication is required along with an audible "Walk" indication in the Draft Guidelines for Accessible Public Rights-of-Way. A signal having vibrotactile indication only is not permitted. An APS that is vibratory only gives no indication of whether there is a pushbutton, or where the pushbutton is located, and it gives no audible directional guidance.

Gallagher and Montesdeoca (Oct. 1998) surveyed blind pedestrians who were familiar with vibrotactile signals that did not have audible "Walk" indications and on which a vibrating arrow was located on a horizontal surface above the pushbutton. They found the vibrotactile signal to be well liked. In field research, they also found that use of the vibrotactile indication resulted in accurate crossing timing.

AR0072139

Tactile Map of the Crosswalk

Maps of the crosswalk are standard features of pushbutton-integrated APSs in Sweden, are in wide use in countries where Swedish devices are used, and are required in Austria for all APSs regardless of the equipment manufacturer (see Chapter 4 for photos and more information). There does not appear to be any research on the legibility or effectiveness of these maps of the crosswalk, but they do have the potential to enable users who are unfamiliar with a particular crosswalk to anticipate such characteristics as the number of vehicular lanes in each direction, and the presence of islands or medians, rail tracks, and bicycle lanes.

In NCHRP 3-62 research (see final report and Bentzen et al., 2006), one of four devices compared had a tactile map of the crosswalks. Mean ratings of participant agreement in Tucson and Charlotte with the statement "The crossing map was useful and easy to understand" were 4.00 and 4.17, respectively, on a 5-point scale (5 = strongly agree). However, even when they were thoroughly familiar with the map, only 9 of 49 participants used it across the two cities.

Pushbutton Information Message

On some pushbutton-integrated APSs, an optional feature is a speech message that comes from the pushbutton either whenever the button is pushed, or whenever the button is pushed and held for an extended time (see extended button press, above). This message always begins with the word "Wait," as it comes on only during the flashing and steady "Don't Walk" intervals. The next information identifies the intersection and the street to be crossed. The recommended format for this message is "Wait, to cross Howard at Grand." Additional information may be provided regarding unusual signalization (e.g., split phasing) or geometry (e.g., narrow median in the roadway).

In research conducted under NCHRP 3-62 (NCHRP 3-62 Final Report, Chapter 3, Bentzen et al., 2006), three of four devices used in field research in Tucson and Charlotte had pushbutton information messages. On all three devices, the pushbutton had to be depressed for at least 3 s to activate the full pushbutton information message. One device did not have the standard pushbutton information message when used in Tucson. The objective measure most closely related to the pushbutton information message was only whether participants used the extended button press, which activated the pushbutton information message; it was not possible to observe whether participants actually understood or used the information provided by the pushbutton

AR0072140

information message. However, when asked to rate the extent of their agreement with the statement "The pushbutton information message was easy to understand," the mean ratings for each city were above 4.0 on a 5-point scale (5 = strongly agree), indicating that the message was usually understood.

Extended Button Press

Additional features on pushbutton integrated APSs may be activated by an extended button press. These features include a pushbutton information message, a louder (beaconing) signal, and extended crossing time.

Noyce and Bentzen (2005) found that it was unusual for pedestrians to push pushbuttons for as long as 2 s. Therefore an extended button press of only 2 s is being standardized to activate any optional features that are available at an APS.

In NCHRP 3-62 research (NCHRP 3-62, Final Report, Chapter 3; Bentzen et al, 2006) the extended button press feature was installed on three or four types of APSs. The extended button press was little used except following familiarization with each device. The extended button press was used on 65% to 85% of crossings in Tucson and Charlotte following familiarization to device features. This may indicate that specific information and training are necessary for pedestrians who are blind, if use of the extended button press is expected. Desirability of a pushbutton information message, as well as beaconing, both of which were activated by an extended button press, was supported by subjective data.

Audible Beaconing

An optional feature on some currently available APSs is audible beaconing, which is usually activated only by an extended button press. Beaconing is provided by a louder signal during the next pedestrian phase. The beacon is intended to aid initial alignment and crossing within the crosswalk.

In NCHRP 3-62 research (NCHRP 3-62 Final Report, Chapter 3; Bentzen et al. 2006), one of four devices tested had the audible beaconing feature. On this device, the "Walk" signal and subsequent locator tone increased in volume for the next pedestrian phase following a button press of at least 3 s. No objective measure of the use of audible beaconing could be made. The only measure possible was use of the extended button press feature that also activated a pushbutton information message. However, when asked to rate the extent of their agreement with

AR0072141

the statement "The louder signal was helpful," the mean responses for Tucson and Charlotte were 3.86 and 4.00, respectively, on a 5-point scale (5 = strongly agree), indicating that this feature is desirable.

Additional research on the usefulness of APS for alignment and crossing within the crosswalk is provided in the section on effect of APS on specific crossing tasks (results of research orientation).

Other Concerns and Needs

Engineering Concerns

Noyce & Barlow (2003a) investigated problems reported with the interface between APS devices and signal controllers to determine whether there were systematic problems with the APS/controller interface. Most problems were found to be installation errors or wiring problems that had already been corrected by the manufacturer by the time research was conducted.

While the adjustment of the volume of the APS is critical for neighborhood acceptance and for usability by pedestrians who are blind, it continues to be an issue in many jurisdictions. In NCHRP 3-62 research on effect of device features (NCHRP 3-62 Final Report) researchers found that it was not possible to adjust all devices to have the same perceived loudness, despite extensive efforts and adjustments and involvement by manufacturers' representatives. Perceived loudness is not amenable to objective measurement and is influenced by conditions such as wind, humidity, precipitation, and nearby reflective surfaces.

APS devices, as with much new technology, have continued to generate maintenance and engineering concerns. As part of NCHRP 3-62 research, devices that were installed for human factors testing were monitored for a year by signal maintenance staff (see NCHRP 3-62 Final Report, Chapter 7). Concerns were expressed about more failures than expected, particularly of the vibratory feature of the devices. Manufacturers were said to be responsive to concerns and were continuously modifying devices to provide better durability.

Case studies of devices installed in cold weather areas were also developed as part of Project 3-62 (see NCHRP 3-62 Final Report, Chapter 6).

AR0072142

Training Needs

In NCHRP 3-62 research in Tucson and Charlotte, experimenters observed that some participants did not have adequate information or techniques for using pushbuttons and APS devices in crossing streets and many did not have good information and understanding about the complexity of intersection signalization. Of concern to researchers were comments from some participants (prior to any explanation or training in the use of APS) who seemed to be trying to use the fact that the locator tone was sometimes louder in response to ambient sound as a "Walk" indication. These participants generally did not look for or push the pushbutton, but heard the audible locator tone and, without knowledge of locator tones and their functions, made an assumption that it was some kind of "Walk" indication. This misunderstanding of ambient sound adjustment and the locator tone could lead to dangerous crossings. Where APSs with locator tones are installed, it may be necessary to make a concerted effort to provide information about the devices to individuals in the community.

The major reason for the tactile arrow is to enable users to identify which street the pushbutton controls. Many participants in NCHRP 3-62 research and in NEI research needed to be shown the arrows on the devices to understand which way the arrow pointed. Use of the tactile arrow and the incorrect pushbutton presented a very different picture in Charlotte than in Tucson. In Tucson, participants who looked at the arrow on the incorrect pushbutton always correctly rejected the incorrect pushbutton. However, in Charlotte, even after familiarization, participants looked at the arrow on the incorrect pushbutton and varied in rejection in 20% of trials. This confusion in using the correct pushbutton seemed to be related to participants' lack of strategies to maintain their orientation; some would completely turn to face the street parallel to their travel path while examining the arrow on the device, then push the button and line up to cross the parallel street. Strategies for looking for pushbuttons and aligning to cross need to be taught.

Need for Additional Research

At a meeting in September 2005, the project panel for NCHRP 3-62 developed the following list of issues for additional research:

- Guidance on the need for pushbutton APS on side streets.
- Wayfinding/beaconing (NEI project may address this need).

AR0072143

- Location/size/color of tactile arrow.
- Speech message clarity (consistency, programming and downloading messages, standardized library).
- Tactile map (consistency, availability, info on median refuge, guidelines).
- Cold weather issues (future follow-up on case studies, comparison study).
- Tone types (acceptability to nearby residences, which are appealing).
- APS effect on general pedestrian population (perhaps tie-in to tone acceptability study).
- Sound volume (best response to ambient sound, range and speed of response, range of decibel levels).
- Beaconing (volume, duration after press).
- Combining speech message and tones.
- Audible message during flashing "Don't Walk" (tone versus speech, countdown).
- Design of curb ramps (use in orientation/wayfinding, integration with signal design, effects on pole location).

Purpose of the Prioritization Tool

Municipalities responsible for the installation and operation of traffic signals are often required to make decisions about the use of accessible pedestrian signals. In many cases, there is a need to prioritize existing signalized intersections for APS installations. Two such cases include:

- where the number of requests exceeds the funding available in a given fiscal year, and
- where transition plans for making intersections accessible are being completed and decisions must be made about the order of installations.

This prioritization tool provides practitioners with the means to take observable characteristics of a pedestrian crosswalk and produce a score that reflects the relative crossing difficulty for pedestrians who are blind or visually impaired. This scoring system enables a prioritization of APS installations within a jurisdiction.

The information regarding prioritizing intersections for installation of APS is **not intended** for application to new or reconstructed intersections. In new construction or reconstruction projects, it is appropriate to consider the Draft PROWAG as the best guidance available at this time. This guidance states that in new construction, APSs should be installed whenever pedestrian signals are installed.

Understanding How Blind Pedestrians Cross at Signalized Intersections

Before discussing how intersection and crosswalk characteristics affect the travel of blind pedestrians, it is important to understand how blind and low vision pedestrians travel. This section gives an overview of this issue.

At any given time, people who are blind or visually impaired use travel and cross streets using a human guide, a long, white cane to identify and avoid obstacles, using a guide dog guide; special optical or electronic aids, or no additional aid. Whatever aid is used, street crossing is composed of a number of tasks.

1) Locating the Street —First, pedestrians who are blind must determine when they reach a street. This is typically accomplished using a combination of cues, including the curb or slope of the ramp, traffic sounds, and detectable warnings.

AR0072151

2) Street Recognition —Next, blind pedestrians recognize or determine which street they have come to. This information is only occasionally provided in any accessible format, so pedestrians who are visually impaired develop a mental map and keep track of where they are within that map, usually by counting blocks and street crossings. Assistance may be sought from other pedestrians.

3) Intersection Assessment — Next, pedestrians who are blind obtain critical information about intersection geometry, including the location of the crosswalk, the direction of the opposite corner, the number of intersecting streets, the width of the street to be crossed, and whether there are any islands or medians in the crosswalk. Vehicular sounds, where there is a stream of traffic on each street at the intersection, are used to infer intersection geometry.

Pedestrians with visual impairments also need to identify the type of traffic control system at an intersection. This may be determined by listening to traffic patterns through several light cycles and searching the sidewalk area for poles with pushbuttons. However, it has become difficult or impossible to determine the type of traffic control at many intersections by listening. The inability to determine whether a crosswalk is pedestrian actuated may result in failure to use pedestrian pushbuttons and in crossing at times other than the pedestrian phase.

4) Cross the Roadway —After determining the geometry of the intersection, aligning to face towards the destination curb, determining that the intersection is signalized, and having pushed a button (where necessary), pedestrians who are blind must recognize the onset of the walk interval. In the most common technique utilized for crossing at signalized intersections, pedestrians who are blind begin to cross the street when there is a surge of through traffic on the closest side of the street parallel to their direction of travel. Once pedestrians who are blind have begun to cross the street, they must maintain a heading toward the opposite corner. Turning traffic can make it difficult to establish a correct initial heading, and in the absence of traffic on the parallel street, pedestrians who are blind may veer toward or away from the intersection.

Optimal crossing conditions occur when crossing right angle signalized intersections with a moderate but steady flow of traffic through the intersection on each leg with a minimum of turning movements.

Pedestrian detection requires blind pedestrians to locate and push a pushbutton and then cross on the next pedestrian phase to be assured of having enough time to cross. Blind pedestrians have three types of problems at these locations:

AR0072152

- They cannot wait through a light cycle to assess and refine their heading by listening to vehicular trajectories before crossing at the next pedestrian phase, because they have to locate and push the button again (and reestablish their heading).
- At a location with little vehicular traffic, even if pedestrians who are blind know there is a pushbutton and use it, they may not be able to detect the onset of the walk interval if there is no through traffic on the street parallel to their crossing.
- Blind pedestrians may not be aware that there is a pushbutton and/or they may be unable to locate the pushbutton. In addition, some locations do not include a pedestrian phase, and at times when vehicular volume is low, there may not be enough time to cross the street.

In the past 20 years, significant changes in intersection geometry, signalization, driver behavior, and automotive technology have affected the ability of blind travelers in the United States to obtain the information they need to cross streets independently and safely. Traffic clearing the intersection also commonly overlaps the pedestrian phase by as many seconds as the duration of the walk interval. In such cases, blind pedestrians will first perceive the pedestrian phase, and then initiate crossing after the onset of the pedestrian change interval. These changes have increased the requests for APSs by blind pedestrians. Municipalities and states need a documented procedure to respond to such requests as required by the program access requirements of the Americans with Disabilities Act.

Overview of Prioritization Tool Worksheets

The prioritization tool includes three separate worksheets that should be used for rating each intersection. Blank forms included are included later in this appendix. The first worksheet is the *intersection worksheet* and is used for describing characteristics of the intersection as a whole, including space for a sketch of the intersection. The second worksheet is the *crosswalk worksheet* and is used for describing the features associated with each crosswalk at the intersection. A separate crosswalk worksheet should be completed for each crosswalk at the intersection. Each of these forms includes variables that either provide an assessment of level of difficulty that may be present for pedestrians who are blind or provide an indicator of the level of pedestrian activity in the vicinity of the intersection. The variables are further defined in the later sections of this document. Each form also includes space for additional comments to be

AR0072153

provided. Finally, a *supplemental form* is provided for those locations where more drawings or additional notes may be required.

Scoring System

The APS prioritization tool provides a score for an individual crosswalk. Higher scores indicate a greater priority for APS installation. Lower scores indicate a lower priority for APS. There is no particular score that indicates whether APS should be installed or not. The scores are intended to provide a *relative prioritization scheme* among a group of crosswalks.

The system of scoring is based on the premise that it is the individual crosswalk that is critical, as opposed to the intersection as a whole. Therefore, priorities for installation should be established on the basis of individual crosswalks, rather than complete intersections. Jurisdictions may choose to install APS at all crosswalks of an intersection when installing them at one crosswalk. However, the intent is to rank and consider each crosswalk separately. If a scoring system were used that is based on the combined score of all crosswalks at an intersection, a very difficult crosswalk for blind pedestrians combined with three crosswalks that are relatively easy could result in low ranking for the intersection as a whole. Such an intersection-based system could result in critical crosswalks being missed on a priority list.

The total score for a crosswalk is calculated as the sum of the individual crosswalk score and the intersection score. The intersection worksheet includes the intersection worksheet score in the bottom right corner. The total crosswalk scores are found in the bottom right corner of each of the crosswalk worksheets. Each crosswalk worksheet includes the crosswalk worksheet score and the intersection worksheet score (transferred from the intersection worksheet), which are added together to get the resulting total crosswalk score. The total crosswalk scores can be listed on the cover sheet for quick reference.

Intersection Worksheet Sketch

The intersection worksheet includes space for a simple sketch of the intersection being rated. At a minimum, the sketch should capture the following:

- Crosswalk location and orientation, including skew and any change in direction (each one should be labeled—e.g., A, B, C, and D) for correct reference to the crosswalk worksheets.
- Location of pushbuttons and other signal features.
- Geometrics, such as islands and lane configuration.

AR0072154

Additional sketches and notes, as required, should be recorded on the supplemental worksheet.

Intersection Worksheet Variables

Configuration

Pedestrians who are blind or visually impaired use the sound of traffic moving beside them as an alignment cue and as a cue for determining when the traffic signal changes. Therefore, the number of approaches to an intersection and the geometric configuration affects the difficulty of crossing. A standard four-leg intersection with perpendicular approaches is the easiest configuration. If those approaches are offset while still controlled by the same signal, the crossing becomes more difficult as it becomes harder to recognize the parallel traffic flow from the minor street. T intersections are more difficult for similar reasons. Crossing the top of a T intersection can be problematic due to the fact that the simultaneous traffic flow is from the stem of the T and is either turning right or left. Intersections with more than four legs can also result in ambiguous traffic flow cues for pedestrians with visual impairments.

Mid-block signalized locations are most difficult for blind pedestrians because there is no traffic stream parallel to the crosswalk to provide an audible cue. Given this, signalized mid-block crosswalks receive the highest point value in the configuration category (14 points). Since completing the remainder of the worksheets for a mid-block crossing may prove confusing, the categories that apply to a mid-block crossing have been listed in Table 1.

AR0072155

Table 1. Applicable Variables for Mid-Block Crossings

Intersection Worksheet Variable	**Applies to Mid-Block Crossing?**
Configuration	Yes
Signalization	Yes, Actuated
Transit Facilities	Yes
Distance to Facilities for Visually Impaired	Yes
Distance to Major Ped Attraction	Yes
Crosswalk Worksheet Variable	**Applies to Mid-Block Crossing?**
Crosswalk width	Yes
Posted Speed Limit	Yes
Curb radius > 25 feet	No
Islands or medians	Yes
Transverse slope	No
Apex curb ramp	No
Channelized right turn island	No
Skewed crosswalk	No
Pushbutton actuation required	Yes
Non-concurrent WALK interval	No
Leading Pedestrian Interval	No
Timed for crossing to median island	Yes
RTOR permitted	No
Leading protected left turn	No
Protected right turn overlap	No
Channelized right turn under signal	No
Off-Peak Traffic Presence	Yes
Pushbutton location	Yes
Requests for APS	Yes

AR0072156

Signalization

The sequence of phases at a signalized intersection and other features of the signal operation, such as interval lengths and actuation-only phases, affects the ability of a blind pedestrian to determine when it is appropriate to cross. This information is captured in two places. The *signalization* variable captures information about the general signal operation that may affect the difficulty of crossing any or all streets. The *crosswalk signalization* variable on the crosswalk worksheet captures details about the signal operation that impact a particular crosswalk.

The following signalization options are given on the form. The user should select the option that has the highest point value AND applies to the intersection of interest. For example, if an actuated intersection has an exclusive pedestrian phase, then the user should select only "exclusive pedestrian phase", since that option has a higher point value than actuation.

Pretimed —Pretimed signalized intersections are the easiest for a blind pedestrian to understand, since the phase sequence and intervals remain the same every cycle.

Actuated — Actuated signals are more difficult for blind pedestrians since the interval timing may change or phases may be skipped on each cycle. In addition, some actuated signals require the pedestrian to find and push a pushbutton to obtain a "Walk" interval. *Note: This intersection signalization variable is intended to capture actuation associated with vehicular traffic. Pedestrian actuation is captured within the crosswalk signalization variable on the crosswalk worksheet.*

Split phasing (on either street) —The auditory cues of split phasing can provide confusing information. Split phasing on the street parallel to the crosswalk can lead a blind pedestrian to believe they have the "Walk" interval because the cross-street traffic is stopped and they hear a surge on the parallel street, not knowing that left turning vehicles may be present.

In the image on the left in Figure D-1, a pedestrian going north on the east crosswalk (bottom right corner) will have the "Walk" indication. A pedestrian going north on the west crosswalk (bottom left corner) will have "Don't Walk" since the northbound left turning traffic has a protected turn. Without APS, if a blind pedestrian on the bottom left corner hears the northbound through traffic, they might assume that they have the "Walk" indication and cross the street — presenting a potentially dangerous conflict with northbound left-turning traffic which has a protected turn.

AR0072157

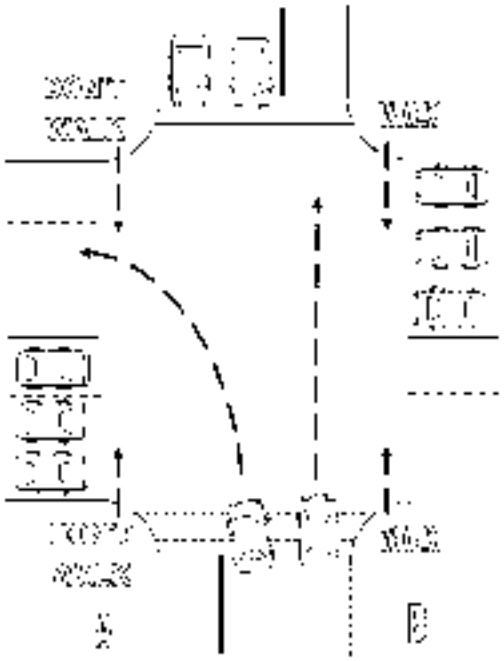

Figure D-1. Split phase illustration.

Split phasing on the street to be crossed can also be confusing in that the left-turning traffic onto the parallel street may be mistaken for the parallel street traffic surge. This variable does not include leading protected left turns, that signal feature is covered as a crosswalk-level variable.

Exclusive pedestrian phase – An exclusive pedestrian phase locks all vehicular traffic at an intersection to stop. It is much more difficult for a blind pedestrian to determine the onset of a walk interval when there is no vehicular movement and thus no surge of traffic. A lull in traffic flow may be perceived as the onset of the "Walk." However, a lull in traffic may also be perceived as gaps in traffic or changes between phases, rather than the onset of an exclusive pedestrian phase.

Where RTOR is permitted in combination with exclusive pedestrian phasing, an intersection may never be quiet enough for pedestrians who are blind to be sure that the pedestrian interval has begun. If they cross at such intersections independently, they are likely to begin crossing well into the pedestrian clearance interval. Additional points should be added for RTOR (separate variable described below) when present.

AR0072158

Transit Facilities Within a Block (~ 0.12 mi) of Intersection—Any Leg

The availability of transit facilities within close proximity to an intersection will increase the likelihood of blind pedestrians, as well as sighted pedestrians, crossing at that intersection. The probability increases as the number of stops and routes increases, with the greatest probability occurring when there is a major transfer facility present, such as a transit mall or rail station. The levels on the prioritization tool account for transit activity by recording the number of routes that have stops within a block of the intersection. A single route will most likely be on the major street of an intersection. Multiple routes may include multiple major street routes or a combination of major- and minor-street routes.

Distance to Facility Providing Services to the Blind or Visually Impaired

The closer a facility for persons who are visually impaired is to an intersection, the more likely it is that pedestrians who are blind or visually impaired will need to cross at that intersection. Facilities that fall into this category include an adult rehabilitation center, library for the blind, residential school for the blind, offices of rehabilitation counselors, and other centers providing services for people who are blind or visually impaired.

Knowing the locations of these facilities will be difficult for any transportation department without good communication with the blind community. It is the responsibility of the department and the blind community to maintain a working relationship with each other. Organizations such as regional associations for the blind would be able to inform the department of any new schools or facilities that provide services to persons who are blind or visually impaired.

Distance to Major Pedestrian Attractions

The intent of this variable is to serve as a surrogate measure for pedestrian usage at the intersection without having to make pedestrian counts. *Most agencies simply do not have such counts or the resources to acquire such.* Major pedestrian attractions include, but are not limited to, major shopping areas, major cultural venues, educational campuses, recreational areas and medical facilities. The designation of "major attraction" will depend on the characteristics of the municipality. The idea behind this variable is that higher pedestrian activity will increase the chance of blind or visually impaired pedestrians crossing at the intersection, which would increase the need for APS.

AR0072159

Crosswalk Worksheet Variables

Crosswalk Width

Crosswalk width is defined as the curb to curb measurement taken at the midpoint of the crosswalk. A longer crosswalk increases the potential that pedestrians who are blind will veer out of the crosswalk, as well as making it more critical for the blind pedestrian to start as quickly as possible after the onset of the walk interval. In the case of a channelized right turn island, the crosswalk length should be measured from curb to island (Figure D-2). Widths less than 40 ft receive no points.

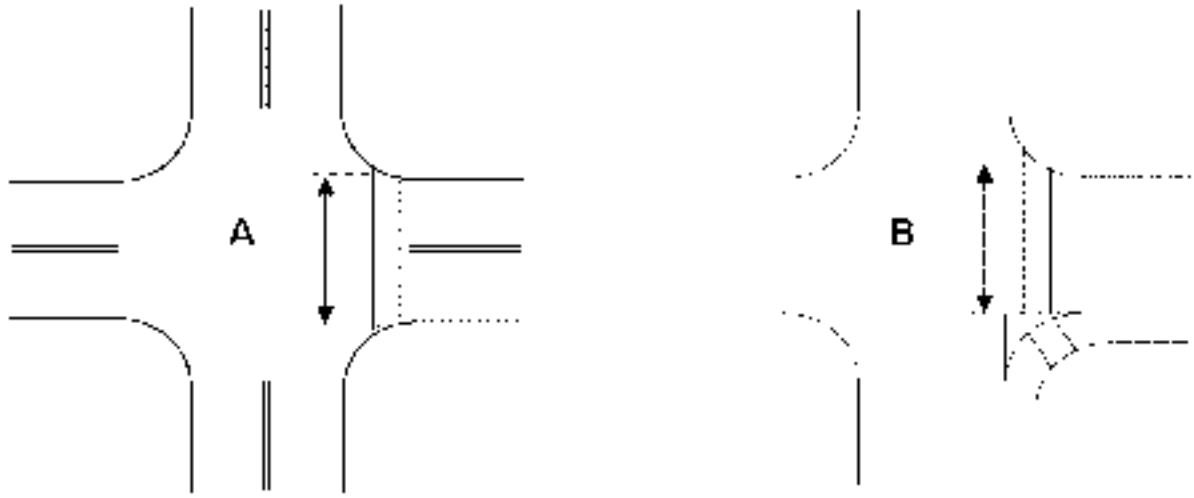

Figure D-2. Diagram A demonstrates the crosswalk width measurement of a standard crosswalk. Diagram B demonstrates crosswalk width measurement of a crosswalk at a channelized right turn lane.

Speed Limit (Street Being Crossed)

The higher the speed of the vehicles on the street being crossed, the lower the probability of avoiding an incident should a visually impaired pedestrian mistakenly step into the street, and the higher the probability of injury should a crash occur. Since operating speeds are not always available, the posted speed limit can be used as a surrogate measure. Speed limits of 20 mph and lower receive no points.

AR0072160

Approach/Crosswalk Geometrics

There are several geometric factors at a crosswalk that can negatively impact upon the ability of a blind pedestrian to safely cross the street. Each of the factors on the form under this heading is defined below.

Curb Radius > 25 ft (Either Corner)

It is more difficult to establish an "ideal" corner heading where curb radii are wide. Incorrect headings can result in pedestrians who are blind walking toward the center of the intersection.

Islands or Medians

Raised or painted crossing islands and medians can confuse blind pedestrians during their crossing, slow or delay their crossing, affect crossing alignment, and generally make the crossing more difficult. Points should be added for any median or island, painted, raised, or cut-through, that crosses the crosswalk, particularly where the crosswalk changes direction at the island. **Islands that are present for channelized right turns are taken into account in the "channelized right turn island" factor.**

Transverse Slope on Crosswalk (Cross Slope)

Crosswalks with a severe cross slope (> 5 %) can lead to veering toward the downhill side by a blind pedestrian during the crossing. Depending on the direction of the cross slope, they could either veer into the intersection or into the approach leg. A beaconing APS may counter this tendency to veer.

Apex (Diagonal) Curb Ramp (Either Corner)

Where the slope of the curb ramp is not aligned with the direction of travel on the crosswalk, blind pedestrians may misalign for the crossing and walk into the flow of parallel traffic. This misalignment most commonly occurs with "apex" curb ramp configurations (Figure D-3). This apex configuration occurs when the corner only has one ramp that points toward the center of the intersection, usually for the purpose of serving two perpendicular crosswalks. If the corner has two ramps that each serves one crosswalk, the corner has a perpendicular ramp configuration (Figure D-4).

AR0072161

Figure D-3. Photo and sketch of an apex ramp configuration.

Figure D-4. Photo and sketch of a perpendicular ramp configuration.

Channelized Right-Turn Lane Island

Crossings at a channelized right-turn lane normally require the pedestrian to cross to the island in one direction, reorient themselves, and then complete the crossing in a different direction (see Figure D-5). This direction change is potentially confusing to blind pedestrians. Most of the right-turn lanes where such islands are present are unsignalized. Therefore, an APS will not be installed for the right-turn lane crossing unless a traffic signal is being added. The APS installation that should be considered at these locations is on island for the crosswalks that

AR0072162

cross the through travel lanes. The locator tones, as well as the "Walk" interval tones and speech messages, on an APS device under these conditions may assist the visually-impaired pedestrian with the reorientation that is required to find the correct crosswalk.

Note: Islands and medians separating traffic lanes in the middle of the road are taken into account by the "islands or medians" variable. If the right-turn lane is signalized, refer to the "channelized right turn lane under signal control" variable.

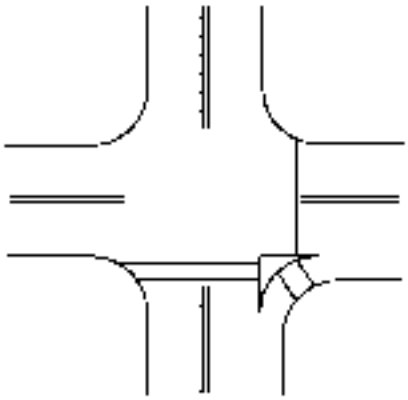

Figure D-5. Crosswalks at a channelized turn island.

Skewed crosswalk

If the direction of travel on a crosswalk is different from the direction of travel on the approaching sidewalk (is skewed), the consequence of failure to establish a heading toward the opposite corner is often that blind pedestrians will walk toward the center of the intersection and into the path of parallel traffic.

The degree of skew can vary from crosswalk to crosswalk. *Skew, in this case, is not defined by the angle at which the streets intersect.* If a blind pedestrian walking a straight line from the approaching sidewalk is headed toward parallel traffic lanes, the crosswalk is skewed (see crosswalk A in Figure D-6). If the blind pedestrian would end up deviating from the crosswalk but would still arrive at the opposite corner, the crosswalk is not defined as skewed for this rating tool (see crosswalk B in Figure D-6).

AR0072163

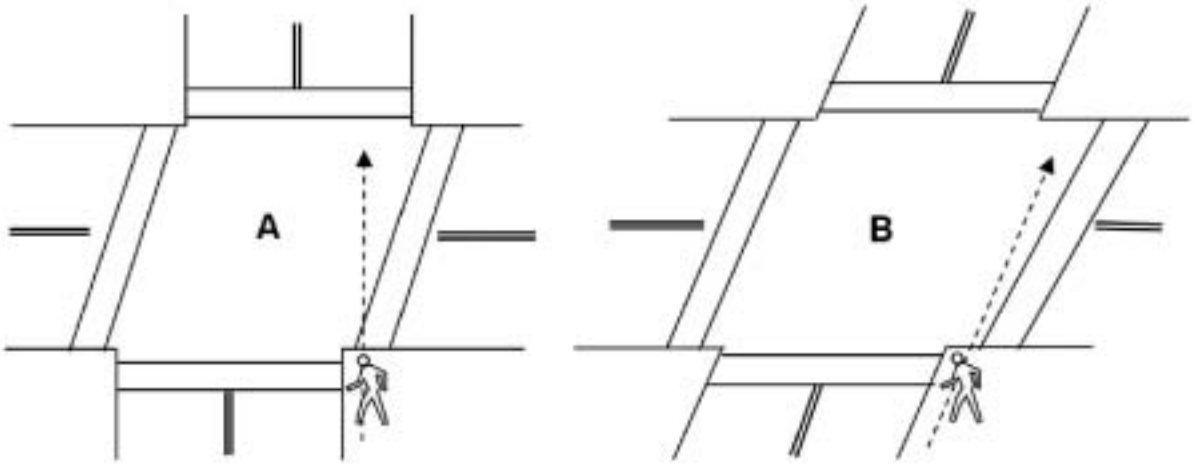

Figure D-6. Crosswalk A is defined as skewed because a pedestrian following the sidewalk line is headed toward the parallel traffic Crosswalk B is not skewed because a pedestrian following the sidewalk line is headed toward the opposite corner.

Skewing can also occur at crosswalks where the pedestrian walk signal only gives enough time for the pedestrian to reach a median. In this case, the blind pedestrian must be able to find the median to wait for the next signal cycle. A skewed or bent crosswalk may cause the pedestrian to miss the median. In this situation, the crosswalk is defined as skewed (Figure D-7).

Figure D-7. This crosswalk is defined as skewed because it is timed for median crossing (two-stage), and a blind pedestrian might miss the median due to the bent crosswalk.

AR0072164

Determination of skew should not consider the island of a channelized right turn (Figure D-5). Although crossing from curb to curb may involve a crooked path due to a direction change at the island, this disadvantage is already accounted for in the fields relating to channelized turn islands.

Pedestrian Signal Control

The ability of a pedestrian who is visually impaired to safely cross at a crosswalk can be impacted by the walk interval timing and other pedestrian signal control features. Each of these factors is defined below.

Pedestrian Actuation Required for "Walk"

At unfamiliar intersections, pedestrians who are blind have no way to know pedestrian actuation is required unless there is an APS with a locator tone. Therefore, pedestrians who are blind are unlikely to use pushbuttons at unfamiliar intersections and are more likely to cross relying only on the use of traffic surge, whether or not it corresponds to the onset of the walk interval. Even if the parallel traffic surge is interpreted correctly, the green phase timing may not be sufficient to allow a pedestrian to safely cross the street. The problem is compounded when the pushbutton is not right beside the probable location of a pedestrian who is wanting to cross; this may require pedestrians who are blind or visually impaired to repeatedly leave their chosen starting location and heading and push the button again, and then return to their chosen starting location and reestablish their heading.

Nonconcurrent Walk Interval

Some signal timing plans at multi-leg intersections display the pedestrian "Walk" signal at a different time than the green phase for adjacent parallel traffic (
Figure D-8). Pedestrians who are blind or visually impaired will typically assume that the walk interval will begin with the onset of through traffic on the parallel street. Without an APS, they will not know the appropriate time to cross at such locations.

AR0072165

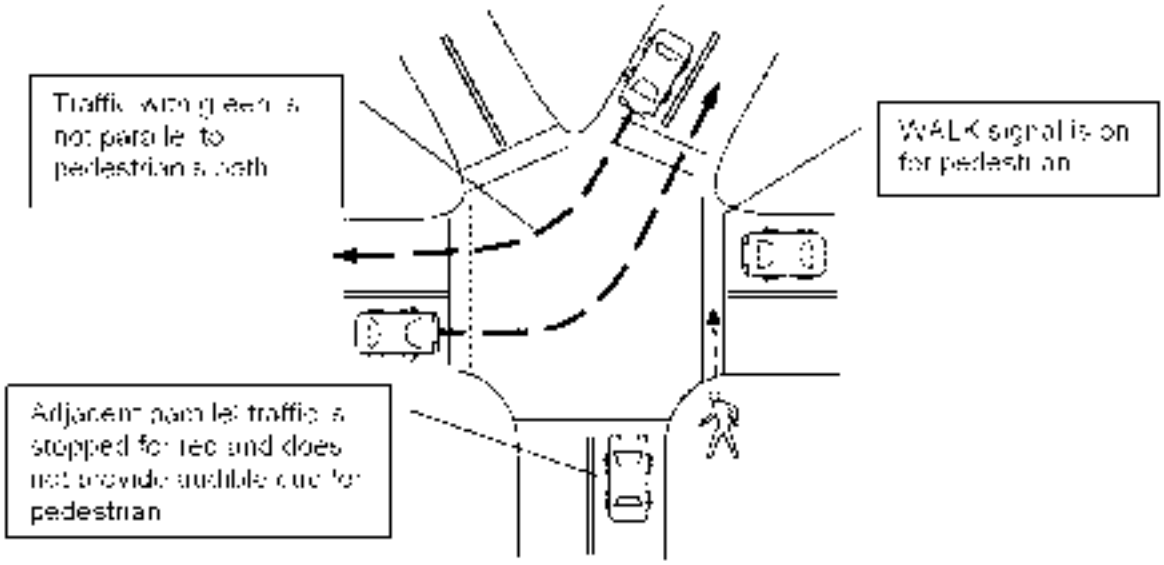

Figure D-8. Pedestrian crosswalk with nonconcurrent "Walk" interval.

Leading Pedestrian Interval – LPI (with Parallel Street Green)

The LPI permits pedestrians parallel to a traffic stream to move prior to the vehicles receiving a green signal, with a goal of allowing pedestrians to "claim" the crosswalk space prior to vehicles that may be turning right (Figure D-9). Unfortunately, this treatment creates a scenario in which blind pedestrians are unable to detect the beginning of the walk interval if there is no audible indication. Subsequently, they may begin crossing only when the parallel traffic starts, which may be too late in the pedestrian phase and at a time when drivers are not expecting them.

AR0072166

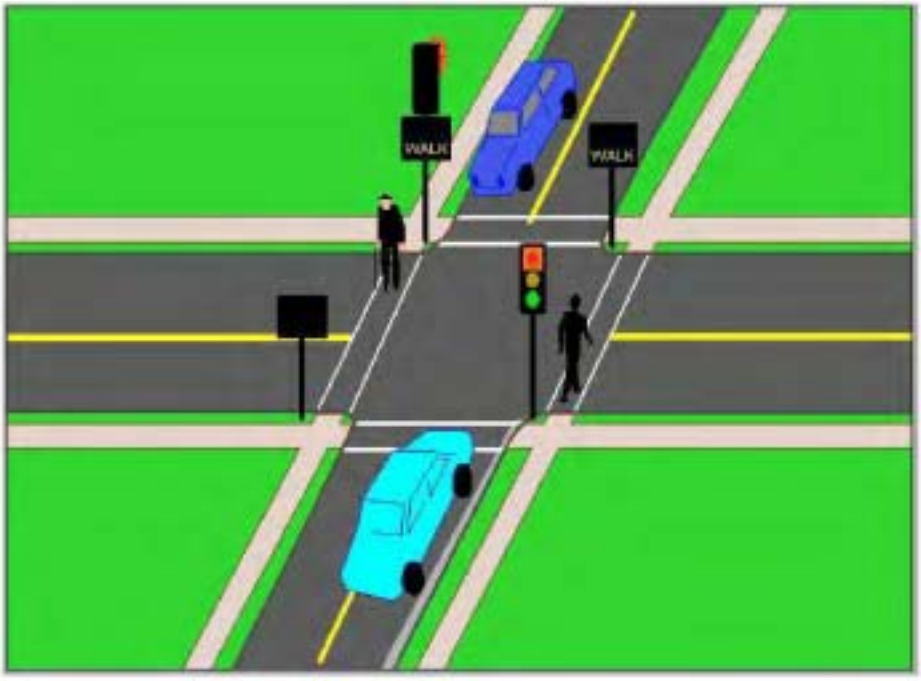

Figure D-9. Leading Pedestrian Interval (source: Insurance Institute for Highway Safety).

Timed for Crossing to Median Island

On wide streets with medians or crossing islands, blind pedestrians cannot easily determine whether the "Walk" signal is intended to allow them to cross the entire street or only to the mid-point. Without an APS providing an audible cue at the median, blind pedestrians are unable to recognize that they must stop there, which may place them in a high-risk situation. The MUTCD states: *"Where the pedestrian clearance time is sufficient only for crossing from the curb or shoulder to a median of sufficient width for pedestrians to wait, additional measures should be considered, such as median-mounted pedestrian signals or additional signing."* (MUTCD 2003)

Vehicle Signal Control

The types of signal phases available for vehicle traffic can greatly impact upon the ability of the pedestrian who is visually impaired to understand the audible cues from the traffic surges of various movements and make correct decisions about when it is appropriate to cross the street. Each type of signal phasing that may lead to this ambiguity is defined below.

AR0072167

Right-Turn-On-Red (RTOR) Permitted on Parallel Street)

The allowance of RTOR on the parallel street may create a false audible cue for the blind pedestrian

(

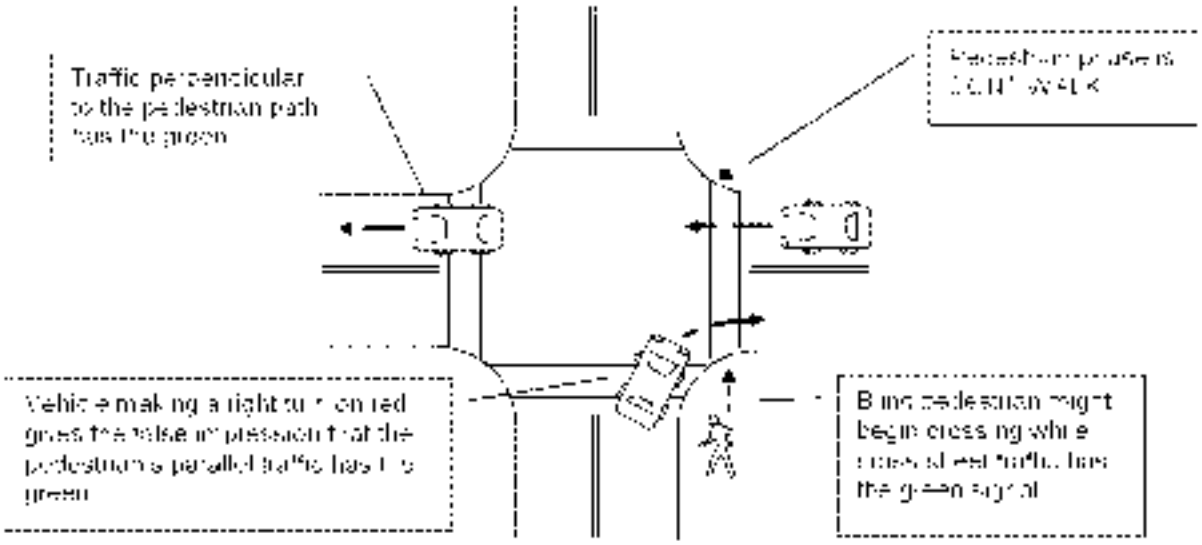

Figure D-10. Vehicles turning right after stopping may be interpreted as indicating the onset of the parallel green phase, and pedestrians who are blind or visually impaired may begin to cross the street at the wrong time. RTOR vehicles also make it harder to audibly recognize the onset of the parallel traffic movement

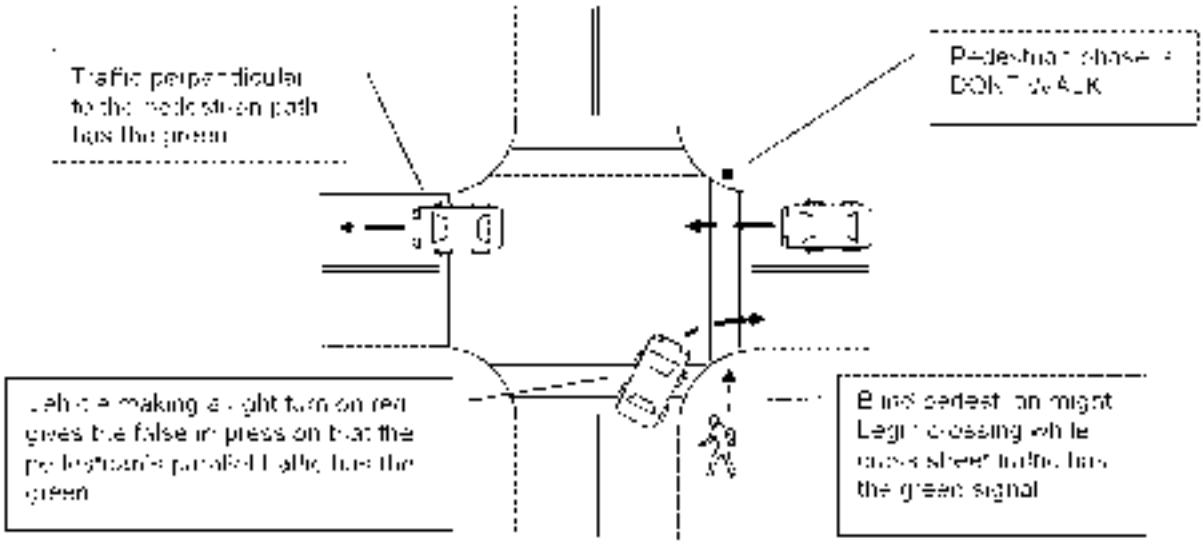

AR0072168

Figure D-10. Right turns on red can mislead blind pedestrians.

The allowance of RTOR during an exclusive pedestrian phase also sends mixed signals. If vehicles are turning, blind pedestrians may not be aware that they have a walk interval. If they do recognize it, there may be a delayed initiation of crossing which means they may not begin crossing on the walk interval and may still be in the street during the "Don't Walk" interval.

Leading Protected Left-Turn Phase (on Parallel Street)

It can be difficult for a blind pedestrian to audibly distinguish between the surge of traffic at the beginning of a protected left-turn phase and the beginning of the through traffic phase

(

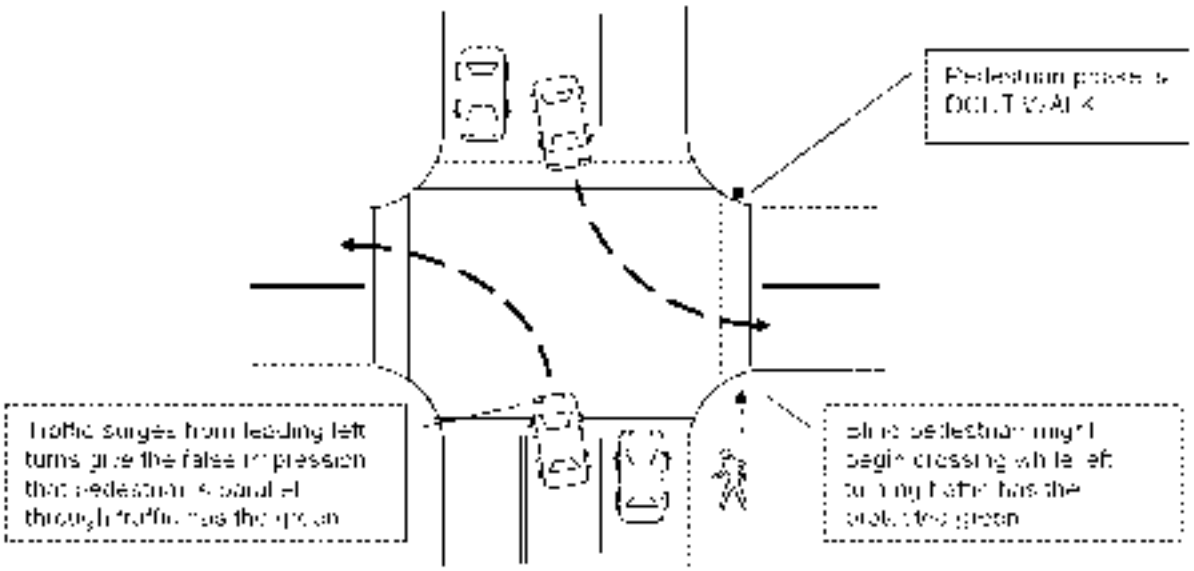

Figure D-11). The moving cars of the leading left-turn phase may also mask the sounds of the parallel through traffic beginning to move, particularly if the protected left-turn interval is followed by a permissive left-turn interval.

Note: Permits are not given for lagging left-turn phases, which are much better for a blind pedestrian. With a lagging left turn interval, the through traffic on the parallel street is the first vehicular maneuver after traffic stops on the cross street. The onset of the walk interval usually occurs at the same time and allows all pedestrians, including blind pedestrians to initiate the crossing. The pedestrians are then typically clear of the intersection by the time the lagging left-turn interval begins.

AR0072169

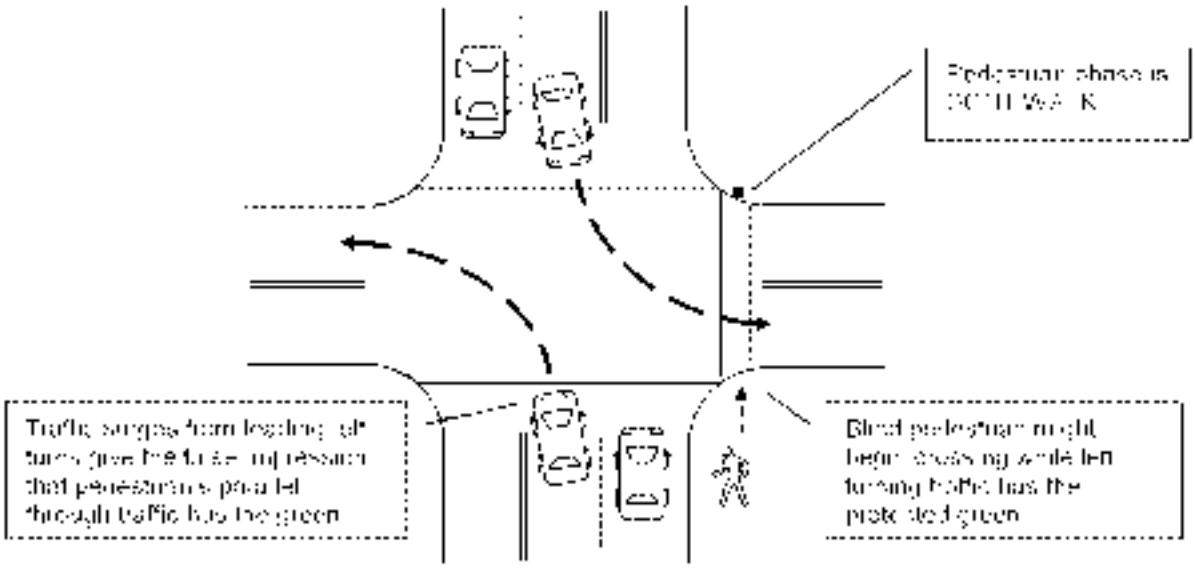

Figure D-11. Leading protected left turns can mislead blind pedestrians.

Protected Right-Turn Only Phase on Parallel Street

The surge of traffic by right-turning vehicles using a protected right-turn phase may be incorrectly interpreted as the beginning of the parallel through traffic surge and the simultaneous onset of the walk interval (figure D-12).

AR0072170

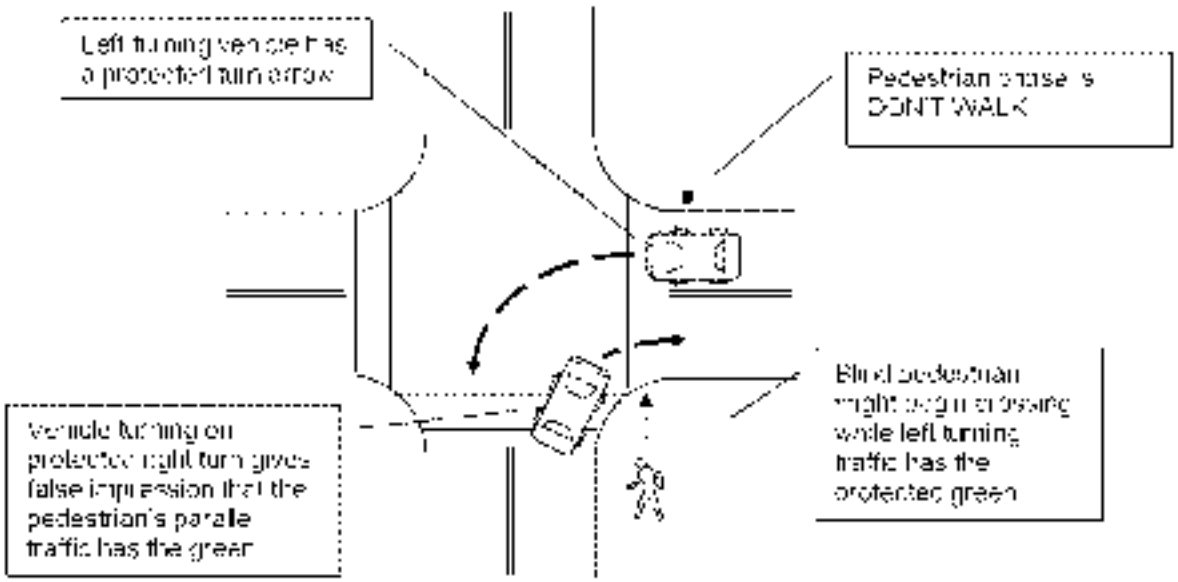

Figure D-12. Protected right turn phase can mislead blind pedestrians.

Channelized Right-Turn Lane under Signal Control

Turning vehicles at channelized turns are typically under yield control. They must stop only if there is traffic approaching intersection the cross street or if a pedestrian is in the crosswalk. However, at some channelized right-turn lanes, vehicles are controlled by a signal that prohibits turns if the signal is red (figure D-13). Without an audible indication, a blind pedestrian will not know that traffic at the channelized turn lane is under signal control and may attempt to cross when the traffic has a green signal. This confusion of priorities may lead to an unsafe crossing.

AR0072171

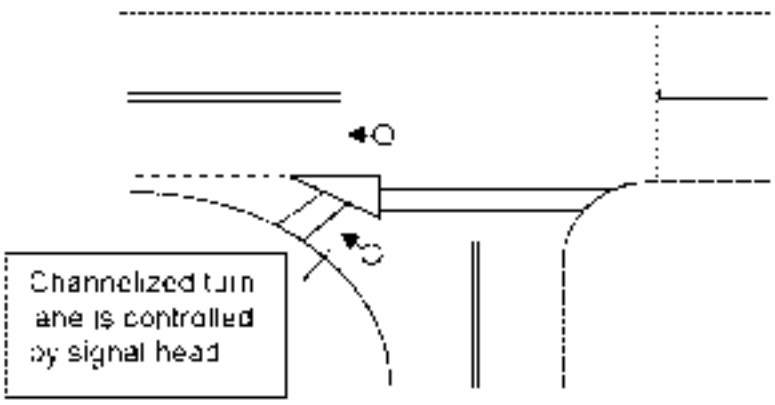

Figure D-13. Channelized turn lane under signal control.

Note: The point values for this factor are for the "signalization" component only. A channelized right-turn lane that is signalized will also receive points under "Channelized right turn island".

Off-Peak Traffic Presence

Traffic volume may impede or assist visually impaired pedestrians. Traffic flow that is very light or erratic (which most often occurs in off-peak periods) makes it difficult to use traffic sound to recognize signal changes. In such cases, audible signals can help to determine the onset of the walk interval. While many municipalities may have turning movement counts or average daily traffic counts, it is not a simple or uniform process to translate these numbers into a meaningful measure for assessing off-peak traffic presence. Instead, this variable is scored on the basis of the proportion of time that at least two vehicles are present at the beginning of a green phase in through lanes that are parallel to the path of the pedestrian.

Note that traffic presence in this category refers to traffic that is parallel to the crosswalk and passes straight through the intersection. If there is no through traffic at the intersection (no lanes continuing straight), there is no reliable traffic available for the blind pedestrian to use as a cue that the walk interval has begun, and the crosswalk would get a rating of "None" and receive the maximum number of points. An example of such a configuration is a T intersection (Figure D-14).

AR0072172

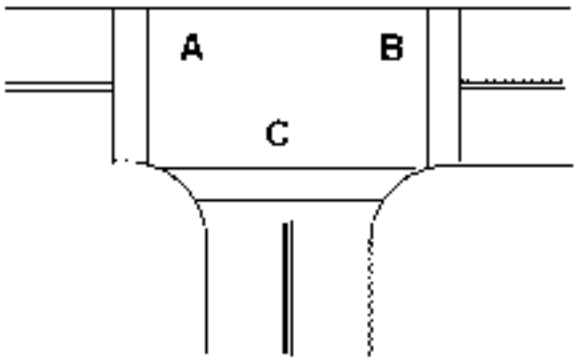

Figure D-14. Crosswalks A and B, across top of the T, at a T-intersection, have no parallel through traffic. In contrast, Crosswalk C has parallel through traffic.

Noting the number of signal cycles with two or more through vehicles over 5 to 10 cycles during the off peak should be sufficient for determining the percentage for scoring this variable. The levels provided on the worksheet reflect the results that may be acquired in such an exercise.

Distance to Alternative APS Crossing

If there is another signalized crosswalk with APS in close proximity to the intersection being rated, the intersection should receive a lower score (lower priority for APS) than a similar intersection where there is no nearby crossing alternative.

If an alternative accessible crossing is present and scored as such, care must be taken to ensure that the alternative crossing meets the need of the blind traveler by getting them to/from the destination. Just because a crossing is close, it may not always be in a location that helps get the person to their destination. A local orientation and mobility specialist or a pedestrian who has requested an APS can assist with making this determination.

Pedestrian Pushbutton Location (Either Corner)

Section 4E.09 of the MUTCD provides guidance on where pedestrian pushbuttons with APS should be located, as follows:

A. Adjacent to a level all-weather surface to provide access from a wheelchair, and where there is an all-weather surface, wheelchair accessible route to the ramp;
B. Within 1.5 m (5 ft) of the crosswalk extended;
C. Within 3 m (10 ft) of the edge of the curb, shoulder, or pavement; and

AR0072173

D. Parallel to the crosswalk to be used. (MUTCD 2003)

The crosswalk worksheet provides for points to be added if the location of pedestrian pushbuttons on either side of a crosswalk does not meet either B or C above. In essence, this variable will give an intersection with poorly located pushbuttons a higher priority for the installation of APS over an intersection with properly located pushbuttons (assuming all other characteristics of the two intersections are the same). Poorly located pushbuttons create much greater difficulty for blind pedestrians in terms of being easily accessible, being positioned in a manner to provide alignment cues, and being located close enough to the curb to be pushed and then cross on the same cycle.

Requests for an APS

Requests for an APS may come from a pedestrian who is visually impaired or from an orientation and mobility professional. These requests are usually very specific—the individual needs to travel from their home to their workplace and needs to cross this street using this crosswalk. Such requests should increase the priority for APS.

AR0072174

Blank Prioritization Tool Worksheets

On the following pages are blank forms that may be reproduced for use in the field when evaluating intersections and crosswalks. There are three separate forms to be used at all intersections – an *intersection worksheet*, a *crosswalk worksheet*, and *supplemental form* – as well as a cover sheet for easy reference of the crosswalk scores.

Supplemental Notes:

Figure D-18. Supplemental worksheet of APS prioritization tool

AR0072179

Examples of Completed Prioritization Tool Worksheets

The following two examples show how the prioritization tool would be used to rate two crosswalks. The first example is a crosswalk that would be relatively easier for pedestrians who are blind or visually impaired. The second example is a crosswalk that would be relatively difficult.

Example Crosswalk 1

This example uses the APS prioritization tool to rate a crosswalk at an intersection in a dense urban area. Both streets of the intersection are fairly narrow and have 35 mph speed limits. The signal is pretimed. Figure 5-1 shows an overhead view of the intersection, with the crosswalk of interest outlined.

Figure D-19. Overhead view of Crosswalk 1 (© Google Earth 2005).

The first worksheet deals with the intersection characteristics (Figure D-20). The total intersection score was zero, since the intersection was a simple four-legged configuration with a pretimed signal and was not located near transit facilities, facilities for the visually impaired, or major pedestrian attractions.

AR0072180

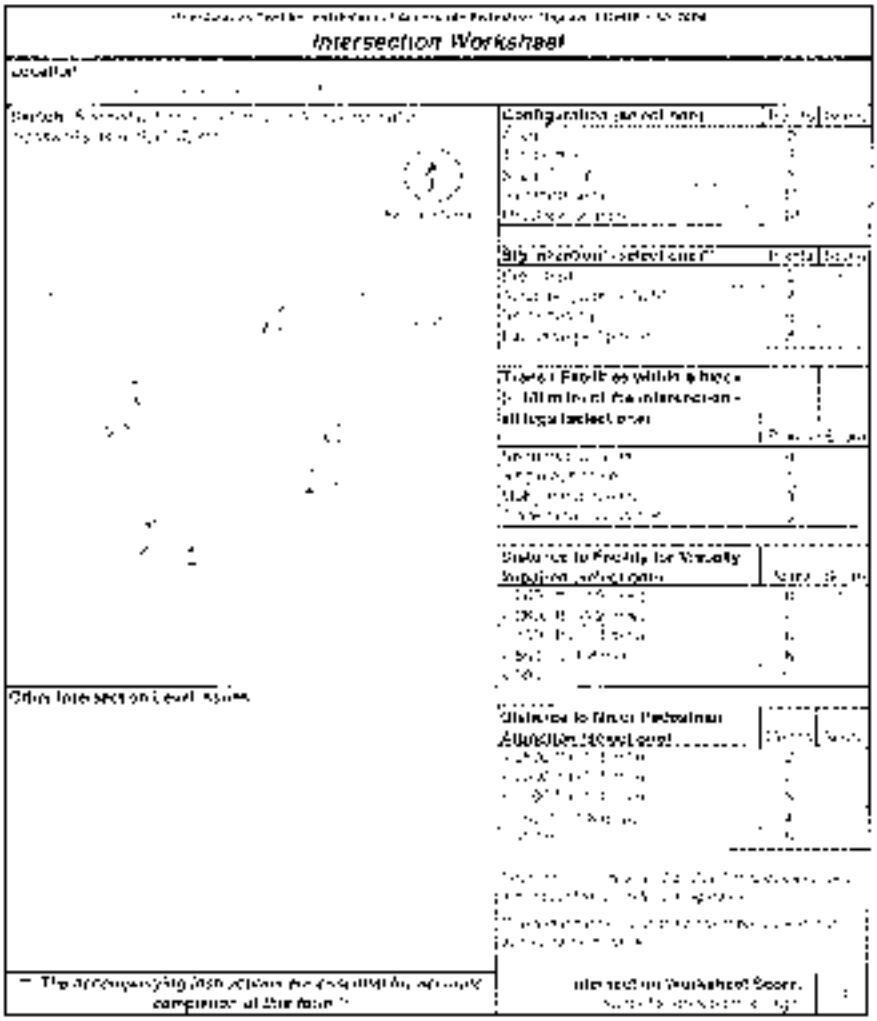

Figure D-20. Intersection worksheet for Crosswalk 1.

The second worksheet deals with the crosswalk (Figure D-21). Points were given for the following reasons:

- The crosswalk width is 50 ft. The worksheet range of 40–59 ft earns one point.
- The posted speed limit on Prospect (the street being crossed) is 35 mph. This earns three points.
- The traffic on Broadway (the parallel street) is constant, thereby giving constant audible cues for the pedestrian. This variable earns only one point.
- There is another APS-equipped crosswalk within 0.25 mi. Thus, the crosswalk being rated earns two points in this category.

AR0072181

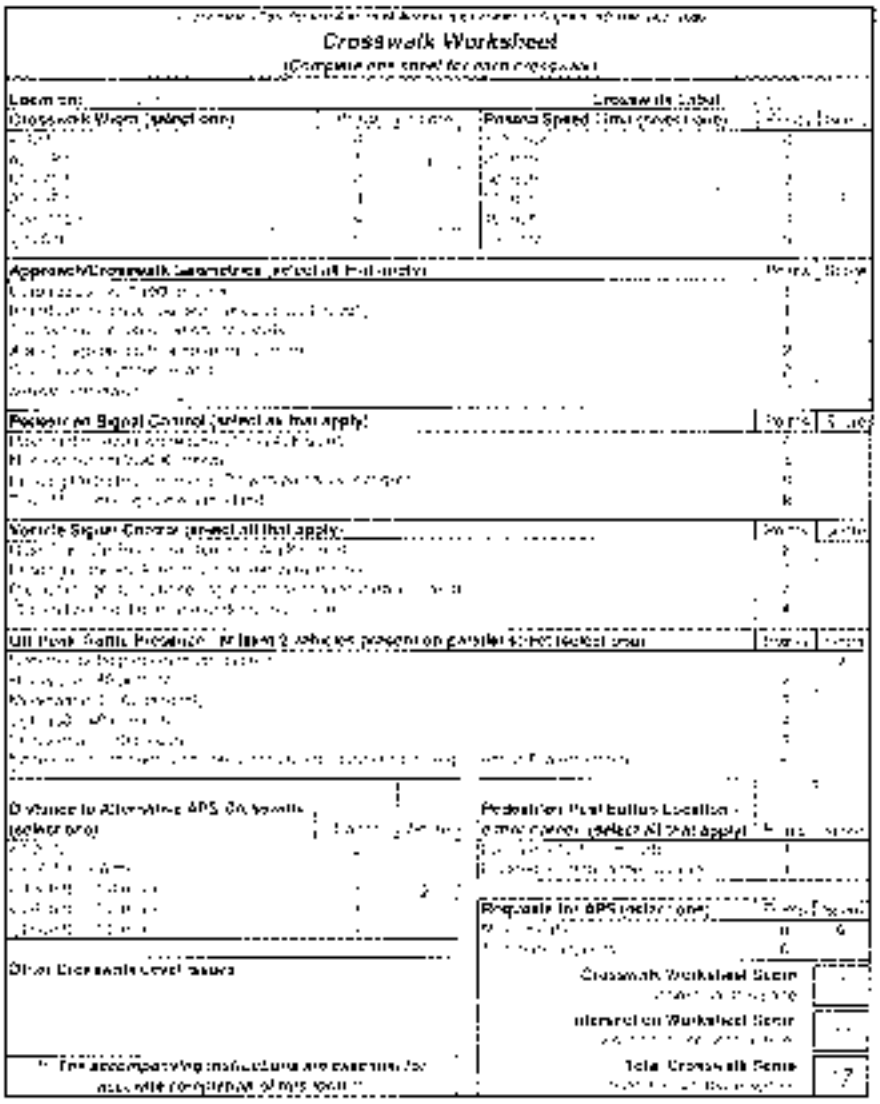

Figure D-21. Crosswalk worksheet for Crosswalk 1.

There are no characteristics of this crosswalk that would qualify under the sections for "Approach/Crosswalk Geometries," "Pedestrian Signal Control," or "Vehicle Signal Control." In addition, the pushbutton poles are located close to the curb and within the crosswalk lines extended and there have been no requests for an APS at this crosswalk; both receive zero points on the prioritization worksheet.

The crosswalk worksheet score is seven points. When added to the intersection score of zero points, this yields a total crosswalk score of seven points. In practice, this score of seven points would be compared to other crosswalks under consideration for APS installations. Those crosswalks with the highest scores would have the highest priority for APS.

AR0072182

Example Crosswalk 2

This example rates a crosswalk at a large intersection of a major arterial and a minor side street. The crosswalk of interest is on the east leg (highlighted in Figure D-22; shown at street level in Figure D-23).

Figure D-22. Overhead view of Crosswalk 2 (©Google Earth 2005).

Figure D-23. Street view of Crosswalk 2.

The first worksheet deals with the intersection characteristics (Figure D-24). Points were given for the following reasons:

- The signal is actuated but also uses split phasing, which is a higher point value than actuation, so the intersection gets the six points for split phasing. Split phasing is a less commonly used signal design, and the typically heavy turning movements make it harder to

AR0072183

effectively use the traffic movement cue to determine signal changes. APS would provide a definitive cue to the onset of the walk interval for pedestrians who are unable to see the pedestrian signal.

- There is a single bus route on the main street, which earns another point. The presence of public transit increases the likelihood that visually impaired pedestrians will travel at this intersection, thereby increasing the priority for APS.

There are no facilities specifically providing services for individuals who are visually impaired or major pedestrian attractors within 0.5 mi, so no points are given for those categories. The total intersection score is seven points.

AR0072184

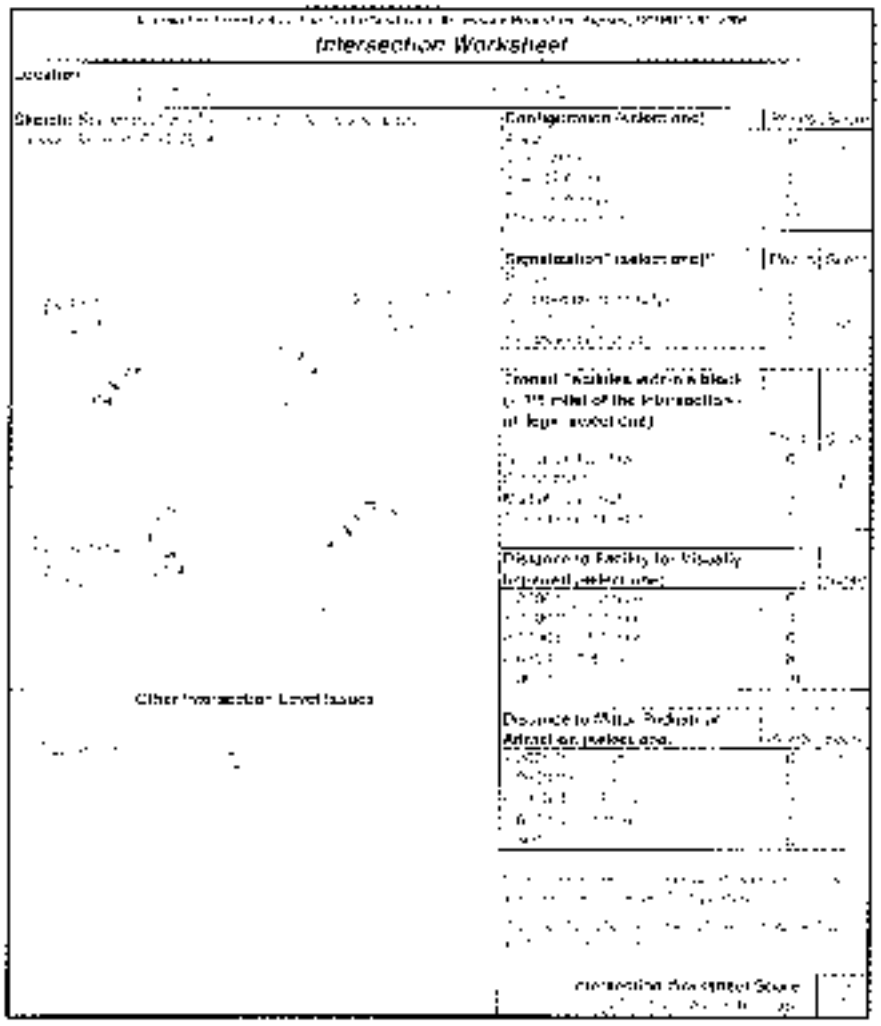

Figure D-24. Intersection worksheet for Crosswalk 2.

The second worksheet deals with the crosswalk (figure D-25). Points were given for the following reasons:

- The crosswalk width of 120 ft and speed limit of 45 mph on the main street earn the crosswalk four and five points, respectively. Wider crosswalks and faster traffic increase the crossing difficulty and risk to visually impaired pedestrians, and an APS may help expedite their crossing.
- The curb radius on one of the corners bordering the crosswalk is greater than 25 ft, so one point is given in the geometrics category. Larger curb radii create orientation problems for visually impaired pedestrians that may be decreased with the use of an APS.

AR0072185

- The signal requires pushbutton actuation for the pedestrian "Walk" signal, so four points are given for the pedestrian signalization category. An APS locator tone would help a pedestrian who is visually impaired recognize that there is a pushbutton at that crosswalk and help in locating the pushbutton.
- Right-turn-on-red (RTOR) is permitted at the crosswalk, so two points are given in the vehicle signal control category. RTOR may produce crossing traffic cues, and an APS would provide a definitive cue of the appropriate time to cross.
- During off-peak hours, there was enough parallel traffic to provide audible cues (two or more vehicles per cycle) about 75% of the time. This earns two points.
- There is not an alternative APS crosswalk within 0.5 mi, so four points are given towards the prioritization of an APS installation at this crosswalk.
- The pedestrian pushbutton at one end of the crosswalk is located more than 10 ft from the curb, which is contrary to the recommendations in Section 4E.09 of the MUTCD. Three points are given for this drawback, since a correctly installed APS would position the push button closer to the curb which facilitates orientation alignment for blind and visually impaired pedestrians.

The crosswalk worksheet score is 25 points. When added to the intersection score of seven points, this yields a total crosswalk score of 32 points. In practice, this score of 32 points would be compared with scores for other crosswalks under consideration for APS installations. Those crosswalks with the highest scores would have the highest priority for APS.

AR0072188

Appendix E - Glossary

In the following list, *MUTCD* refers to definitions taken from Section 4A.02 Definitions Relating to Highway Traffic Signals of the *Manual on Uniform Traffic Control Devices*

Accessible pedestrian signal (APS) A device that communicates information about pedestrian timing in nonvisual format such as audible tones, verbal messages, and/or vibrating surfaces. (*MUTCD*)

Actuated operation. A type of traffic control signal operation in which some or all signal phases are operated on the basis of actuation. (*MUTCD*)

Actuation. Initiation of a change in or extension of a traffic signal phase through the operation of any type of detector. (*MUTCD*)

Actuation indicator. Either a light, a tone, a voice message, or both audible and visual indicators that indicate to pedestrians that the button press has been accepted.

Alert tone at onset of WALK interval. A very brief burst of high frequency sound, rapidly decaying to a 500 Hz WALK tone, to alert pedestrians to the exact onset of the WALK interval.

APS. See *Accessible pedestrian signal.*

Audible beacon. Use of a sound source to provide directional orientation and alignment information.

Automatic volume adjustment. An APS volume control that is automatically responsive to ambient (background) sound; automatic gain control.

Braille street name. Provision of the name of the associated street in Braille above the APS pushbutton.

Button actuated timer (BAT). See *Extended button press.*

Clearance interval indicator Tones sounding during the pedestrian clearance interval that are differentiated from the WALK interval indicator (tones).

Controller unit. That part of a controller assembly that is devoted to the selection and timing of the display of signal indications. (*MUTCD*)

Crosswalk. (a) that part of a roadway at an intersection included within the connections of the lateral lines of the sidewalks on opposite sides of the highway measured from the curbs or in the absence of curbs, from the edges of the traversable roadway, and in the absence of a sidewalk on one side of the roadway, the part of a roadway included within the extension of the lateral lines of the sidewalk at right angles to the centerline; (b) any portion of a roadway at an intersection or elsewhere distinctly indicated for pedestrian crossing by lines or other markings on the surface. (*MUTCD*)

Crosswalk map. See *Tactile map.*

Cycle Length. The time required for one complete sequence of signal indications. (*MUTCD*)

Detectable warning. A standardized surface feature built in or applied to walking surfaces or other elements to warn visually impaired people of hazards on a circulation path.

Detector A sensing device used for determining the presence or passage of vehicles or pedestrians. (*MUTCD*)

Extended button press. On APS, holding the ped button down between 1-3 sec. may activate special features, including audible beaconing and

AR0072189

extended pedestrian clearance interval.

Fixed time operation. See *Pretimed operation.*

Flashing (flashing mode). A mode of operation in which a traffic signal indication is turned on and off repetitively. (*MUTCD*)

Full-actuated operation. A type of traffic control signal operation in which all signal phases function on the basis of actuation. (*MUTCD*)

Intersection. (a) the area embraced within the prolongation or connection of the lateral curb lines, or if none, the lateral boundary lines of the roadways of two highways that join one another at, or approximately at, right angles, or the area within which vehicles traveling on different highways that join at any other angle may come into conflict; (b) the junction of an alley or driveway with a roadway or highway shall not constitute an intersection. (*MUTCD*)

Interval. The part of a signal cycle during which signal indications do not change. (*MUTCD*)

Interval sequence. The order of appearance of signal indications during successive intervals of a signal cycle. (*MUTCD*)

Locator signal. See *Pushbutton locator tone*

Long button press. See *Extended button press.*

Long cane. A cane individually prescribed to provide safety and orientation information to persons who are blind or visually impaired; typically much longer than a support cane and not intended for support, typically has a white, reflective surface.

Major street. The street normally carrying the higher volume of vehicular traffic. (*MUTCD*)

Minor street. The street normally carrying the lower volume of vehicular traffic. (*MUTCD*)

Passive pedestrian detection. A feature that uses sensors (piezo-electric, infrared, microwave, or video camera serving remote sensor software) to trigger, cancel, or lengthen pedestrian timing, or to trigger the pushbutton locator tone when the pedestrian enters the detection zone.

Pedestrian. People who travel on foot or who use assistive devices, such as wheelchairs, for mobility.

Pedestrian change interval. An interval during which the flashing UPRAISED HAND (symbolizing DON'T WALK) signal indication is displayed. When a verbal message is provided at an accessible pedestrian signal, the verbal message is "wait." (*MUTCD*)

Pedestrian clearance time. The time provided for a pedestrian crossing in a crosswalk, after leaving the curb or shoulder, to travel to the center of the farthest traveled lane or to a median. (*MUTCD*)

Pedestrian phase (or ped phase). The cycle of pedestrian timing consisting of three parts: (1) the WALK interval (WALK sign); (2) the pedestrian clearance interval (flashing DON'T WALK); and the pedestrian change interval (steady DON'T WALK).

Pedestrian signal head. A signal head, which contains the symbols WALKING PERSON (symbolizing WALK) and UPRAISED HAND (symbolizing DON'T WALK), that is installed to direct pedestrian traffic at a traffic control signal. (*MUTCD*).

Pedhead. See *Pedestrian signal head.*

Permissive mode. A mode of traffic control signal operation in which, when a CIRCULAR GREEN signal indication

AR0072190

is displayed, left or right turns may be made after yielding to pedestrians and/or oncoming traffic. (*MUTCD*)

Preemption control. The transfer of normal operation of a traffic control signal to a special control mode of operation. (*MUTCD*)

Pretimed operation. A type of traffic control signal operation in which none of the signal phases function on the basis of actuation. (*MUTCD*)

Priority control. A means by which the assignment of right-of-way is obtained or modified. (*MUTCD*)

PROWAAC Public Rights of Way Access Advisory Committee of the U.S. Access Board, that includes advocates, engineers, architects, and public works officials

Protected mode. A mode of traffic control signal operation in which left or right turns may be made when a left or right GREEN ARROW signal indication is displayed. (*MUTCD*)

Pushbutton. A button to activate pedestrian timing. (*MUTCD*)

Pushbutton locator tone A repeating sound that informs approaching pedestrians that they are required to push a button to actuate pedestrian timing and that enables pedestrians who have visual disabilities to locate the pushbutton. (*MUTCD*)

Pushbutton message. A speech message that provides additional information when the APS pedestrian pushbutton is pushed.

Remote activation. A handheld pushbutton device allowing a pedestrian to send a message over a short distance to call the ped phase.

Semiactuated operation A type of traffic control signal operation in which at least one, but not all, signal phases function on the basis of actuation. (*MUTCD*)

Signal head. An assembly of one or more signal faces together with the associated signal housings. (*MUTCD*)

Signal Indication. The illumination of a signal lens or equivalent device. (*MUTCD*)

Signal phase The right-of-way, yellow change, and red clearance intervals in a cycle that are assigned to an independent traffic movement or combination of movements. (*MUTCD*)

Signal section. The assembly of a signal housing, signal lens, and light source with necessary components to be used for providing one signal indication. (*MUTCD*)

Signal timing. The amount of time allocated for the display of a signal indication. (*MUTCD*)

Signal warrant. A threshold condition that, if found to be satisfied as part of an engineering study, shall result in analysis of other traffic conditions or factors to determine whether a traffic control signal or other improvement is justified. (*MUTCD*)

Steady (steady mode). The continuous illumination of a signal indication for the duration of an interval, signal phase, or consecutive signal phases. (*MUTCD*)

Tactile. An object that can be perceived using the sense of touch.

Tactile arrow (aligned in direction of travel). A raised (tactile) arrow in an APS pushbutton that helps users know which crosswalk is actuated by the pushbutton.

Tactile map. A raised schematic map (located on an APS pushbutton housing) that shows what will be encountered as the pedestrian negotiates the crosswalk controlled by that push button.

AR0072191

Traffic control signal (traffic signal). Any highway traffic signal by which traffic is alternately directed to stop and permitted to proceed. (*MUTCD*)

Vibrotactile pedestrian device. A device that communicates, by touch, information about pedestrian timing using a vibrating surface. (*MUTCD*)

WALK interval. An interval during which the WALKING PERSON (symbolizing WALK) signal indication is displayed. When a verbal message is provided at an accessible pedestrian signal, the verbal message is "WALK sign." (*MUTCD*)

Cooperative Research Programs (CRP) grants permission to reproduce material in this publication for classroom and not-for-profit purposes. Permission is given with the understanding that none of the material will be used to imply TRB, AASHTO, FAA, FHWA, FMCSA, FTA, Transit Development Corporation, or AOC endorsement of a particular product, method, or practice. It is expected that those reproducing the material in this document for educational and not-for-profit uses will give appropriate acknowledgment of the source of any reprinted or reproduced material. For other uses of the material, request permission from CRP.

DISCLAIMER

The opinions and conclusions expressed or implied in the report are those of the research agencies. They are not necessarily those of the TRB, the National Research Council, AASHTO, or the U.S. Government.

This report has not been edited by TRB.

Note: The Transportation Research Board, the National Research Council, the Federal Highway Administration, the American Association of State Highway and Transportation Officials, and the individual states participating in the National Cooperative Highway Research Program do not endorse products or manufacturers. Trade or manufacturers names appear herein solely because they are considered essential to the clarity and completeness of the project reporting.

THE NATIONAL ACADEMIES

Advisers to the Nation on Science, Engineering, and Medicine

The **National Academy of Sciences** is a private, nonprofit, self-perpetuating society of distinguished scholars engaged in scientific and engineering research, dedicated to the furtherance of science and technology and to their use for the general welfare. On the authority of the charter granted to it by the Congress in 1863, the Academy has a mandate that requires it to advise the federal government on scientific and technical matters. Dr. Ralph J. Cicerone is president of the National Academy of Sciences.

The **National Academy of Engineering** was established in 1964, under the charter of the National Academy of Sciences, as a parallel organization of outstanding engineers. It is autonomous in its administration and in the selection of its members, sharing with the National Academy of Sciences the responsibility for advising the federal government. The National Academy of Engineering also sponsors engineering programs aimed at meeting national needs, encourages education and research, and recognizes the superior achievements of engineers. Dr. Charles M. Vest is president of the National Academy of Engineering.

The **Institute of Medicine** was established in 1970 by the National Academy of Sciences to secure the services of eminent members of appropriate professions in the examination of policy matters pertaining to the health of the public. The Institute acts under the responsibility given to the National Academy of Sciences by its congressional charter to be an adviser to the federal government and, on its own initiative, to identify issues of medical care, research, and education. Dr. Harvey V. Fineberg is president of the Institute of Medicine.

The **National Research Council** was organized by the National Academy of Sciences in 1916 to associate the broad community of science and technology with the Academy's purposes of furthering knowledge and advising the federal government. Functioning in accordance with general policies determined by the Academy, the Council has become the principal operating agency of both the National Academy of Sciences and the National Academy of Engineering in providing services to the government, the public, and the scientific and engineering communities. The Council is administered jointly by both the Academies and the Institute of Medicine. Dr. Ralph J. Cicerone and Dr. Charles M. Vest are chair and vice chair, respectively, of the National Research Council.

The **Transportation Research Board** is one of six major divisions of the National Research Council. The mission of the Transportation Research Board is to provide leadership in transportation innovation and progress through research and information exchange, conducted within a setting that is objective, interdisciplinary, and multimodal. The Board's varied activities annually engage about 7,000 engineers, scientists, and other transportation researchers and practitioners from the public and private sectors and academia, all of whom contribute their expertise in the public interest. The program is supported by state transportation departments, federal agencies including the component administrations of the U.S. Department of Transportation, and other organizations and individuals interested in the development of transportation. **www.TRB.org**

Author Acknowledgments

The research reported herein was performed under NCHRP Project 3-62. The University of North Carolina Highway Safety Research Center (HSRC) was the contractor for this study. Accessible Design for the Blind (ADB) was a subcontractor. Primary authors of this report are David Harkey (Director, HSRC), Daniel Carter (Research Engineer, HSRC), Janet Barlow (Principal, ADB), Billie L. Bentzen (Director of Research, ADB), Linda Myers (Research Associate, ADB), and Alan Scott (Graduate Student, Boston College). Mr. Harkey served as the Principal Investigator for this effort.

The authors wish to acknowledge the assistance and support of others who made this project a success. Several manufacturers of Accessible Pedestrian Signals (APS) provided invaluable donations of equipment, installation assistance, and technical expertise to this project.

- Campbell Company (Phil Tatel)
- Novax Industries (Doug Gibbe)
- Polara Engineering (John McGraffey), and
- Prisma Teknik (Jan Lund and Fredrik Dahlberg)

The field data collection efforts were conducted in Tucson, Arizona, Charlotte, North Carolina, and Portland, Oregon. The authors wish to acknowledge the following city transportation departments and individuals for their support of the project and their tireless efforts to install and maintain the APS equipment through the duration of the project.

- City of Tucson, Arizona Traffic Engineering Department, particularly John Swanson, Bob Hunt, Ray Svec and Richard Nassi
- City of Charlotte, North Carolina Transportation Department, particularly Tammy Drozd, Scott Dumont, Ken Bostick, Art Stegall, Justin Carroll, and Bill Dillard
- City of Portland, Oregon Department of Transportation, particularly Bill Kloos, Jason McRobbie and Dave Gilley

The authors also wish to acknowledge those individuals and organizations that provided assistance in recruiting and interviewing research participants, scheduling data collection and providing hospitality to participants.

- Tucson, Arizona – Arizona Department of Rehabilitation Services, Southern Arizona Association for the Visually Impaired, Glen Culp and Ian Stewart
- Charlotte, NC – Metrolina Association for the Blind, Laura Park-Leach and Eric Sticken
- Portland, OR – ARC of Multnomah County, Michael Yamada, Ben Horner, Rebecca Mock, and Bill West

Their able assistance facilitated a smooth and enjoyable research experience for both researchers and participants.

AR0072199

Summary

In 2000, two sections on APS were added to the *Manual on Uniform Traffic Control Devices (MUTCD)*, which became the first set of national standards for APS in the U.S. The *MUTCD* defines an APS as "...a device that communicates information about pedestrian timing in nonvisual format such as audible tones, verbal messages, and/or vibrating surfaces" (1). The rest of the *MUTCD* language provides standards, guidance and options, but does not specify walk messages or address many possible device features. In 2002, the U.S. Architectural and Transportation Barriers Compliance Board (Access Board) published draft recommendations and requirements for APS installation in *Draft Guidelines for Accessible Public Rights of Way* (2). The *Draft Guidelines* call for the use of pushbutton-integrated signals that provide audible **and** vibrotactile indications of the walk interval.

The objective of this research was to develop guidelines and training materials for implementation of accessible pedestrian signals (APS). The guidelines explain how APS provide optimal information through media such as tones and tactile or verbal indicators, and under what circumstances their installation is recommended. The training materials are intended to facilitate application of the guidelines and installation and operation of APS. This training is oriented toward technical issues and public education.

Two separate research experiments were undertaken in this project to develop the recommended guidelines for APS features and APS installation. The purpose of first study was to determine the effect of APS features, which are commonly found on most of the APS equipment marketed in the U.S., on the ability of pedestrians who are blind to locate and use pushbuttons, determine time to cross, determine appropriate heading for crossing, and maintain alignment while crossing. The second study was conducted to evaluate the effects of pole location, number of poles used in relation to number of APS devices, and type of WALK indication on the ability of pedestrians with visual or cognitive impairments to determine which crosswalk at a corner had the WALK signal. In addition to these two research studies, additional information about APS performance was gleaned from an engineering evaluation of the equipment installed during this research study, as well as from a series of cold weather case studies.

This research was the basis for more precise and well-supported standards and guidance on APS for inclusion in the *MUTCD* and the U.S. Access Board *Guidelines*. The research results have been forwarded to the Signals Technical Committee of the NCUTCD and to the Federal Highway Administration (FHWA) as background and support for changes in Part 4 of the *MUTCD* as well as to the U.S. Access Board.

The training materials consist of a set of PowerPoint presentations that comprise a one-day training course and a companion resource document, *Accessible Pedestrian Signals: A Guide to Best Practices*. These materials are available at www.walkinginfo.org/aps and provide guidance on where and how APS should be installed. The training is directed at three main audiences – traffic engineers, orientation and mobility (O&M) instructors, and signal technicians.

One of the first questions that must be answered by local engineers and others responsible for the installation of APS devices is when and where is it appropriate to

AR0072200

install such devices in other than new construction and alteration/reconstruction. In many cases, there is a need to prioritize intersections for APS installations. The *MUTCD* currently provides some guidance on this matter, but a more definitive approach is needed by practitioners. As part of this research effort, an intersection prioritization tool was developed, applied by practitioners, and then validated by comparing the objective ratings achieved with the tool to the subjective ratings of pedestrians with visual impairments and O&M specialists. The tool itself, which includes a set of instructions for application, is also available on the web at www.walkinginfo.org/aps.

The results of this research have produced a set of recommended guidelines for APS installation and operation that will make it easier and safer for pedestrians with visual impairments to cross streets at signalized intersections. In time, the results will make their way into the *MUTCD* and other guides, which will lead to greater uniformity in the field.

AR0072201

CHAPTER 1
INTRODUCTION

SUMMARY OF THE PROBLEM

All pedestrians, including those with visual impairments, must accomplish five primary tasks to safely cross a street at a signalized intersection:

1) Locate the street and the crosswalk.
2) Determine the form of signal actuation for the walk interval (and locate the pushbutton if required).
3) Establish the appropriate heading (alignment) for initiating the crossing.
4) Identify the time at which it is legal and safe to begin crossing, and
5) Maintain the appropriate heading during the crossing.

In the technique most often utilized for crossing at signalized intersections, pedestrians who are blind or visually impaired begin to cross when they hear a surge of traffic parallel to their direction of travel. While many intersections pose little difficulty, some intersection geometries and traffic conditions make it very difficult for persons with visual impairments to cross safely and independently. To assist visually impaired pedestrians and make street crossings a task that can indeed be done independently and safely, pushbuttons and audible signals have been used in this country with varying degrees of success. In fact, the Transportation Equity Act for the 21st Century (TEA-21) modified 23 USC 217(g) by directing that pedestrian safety considerations be incorporated for all transportation plans and projects, including installation of audible traffic signals and signs at street crossings where appropriate. However, research indicates that some of the current audible signals, widely used in some parts of the United States, have a number of problems, including the following:

a) Users did not know whether a pushbutton was present.
b) Users found it difficult to locate the pushbutton.
c) Users could not tell which signal (crosswalk) was actuated by the button.
d) Users could not push the button and return to the point of crossing before the Walk interval began due to the long distance between the button and the intersection corner.
e) The signal was too quiet or too loud.
f) Users could not localize the sound and use it for guidance across the street.
g) Where the "chirp" or "cuckoo" sounds were used, users crossed against the signal when they "heard a bird rather than the signal, and
h) Users failed to cross with the signal due to thinking it was an actual bird.

The research undertaken in this project, in coordination with research on accessible pedestrian signals (APS) that was conducted under concurrent related projects, discovered or developed solutions to most of the user-oriented problems identified above. In addition, guidance for design and installation of APS that provide information for pedestrians who are deaf-blind was developed. The research under this project also obtained engineering data and knowledge

AR0072202

required for addressing issues such as general installation requirements, and physical installation, operation, and maintenance requirements.

This research was the basis for more precise and well supported standards, guidance and support on APS for inclusion in the *Manual on Uniform Traffic Control Devices (MUTCD)* and in the *Guidelines for Accessible Public Rights of Way*, the Access Board was providing minimum design guidelines implementing the ADA in public rights of way (*U.S.*). The research results were forwarded to the Signals Technical Committee of the National Committee on Uniform Traffic Control Devices (NCUTCD) and to the Federal Highway Administration (FHWA) as background and support for changes in Part 4 of the *MUTCD*, as well as to the U.S. Architectural and Transportation Barriers Compliance Board (Access Board). The NCUTCD approved revisions to Part 4E of the *MUTCD*, which would implement the recommendations of this report at their June 2000 meeting, and sent them to FHWA for their consideration for the next *MUTCD* edition.

The results and products of this research may be used to increase the safety and mobility of pedestrians at signalized intersections, including those persons who are blind or visually impaired as well as those persons who are both visually and hearing impaired, by providing them with standardized information functionally equivalent to that provided to other pedestrians.

OBJECTIVE

The objective of this research was to develop guidelines and training materials for implementation of accessible pedestrian signals (APS). The guidelines explain how APSs provide optimal information through media such as tones and tactile or verbal indicators, and under what circumstances their installation is recommended. The training materials are intended to facilitate application of the guidelines and installation and operation of APS. This training is oriented toward technical issues and public education.

ORGANIZATION OF REPORT

This report provides a summary of prior research on APS, documents the results of all human subject experiments and other evaluations conducted, and provides recommended guidelines for APS installation and operation. The components of this report are as follows:

- Chapter 2 – Research Synthesis – includes a summary of research on APS that was used in designing the trials in this project and developing the recommendations.
- Chapter 3 – Experimental Trials on Accessible Pedestrian Signal Features – includes the trials conducted in Tucson and Charlotte, which included an evaluation of multiple pushbutton-integrated APS devices and their effects on crossing behaviors by pedestrians with visual impairments.
- Chapter 4 – Experimental Trials on Pushbutton Location and WALK Indicator – includes the trials conducted in Portland to specifically evaluate the effect of number of poles and pole placement, as well as type of WALK indication, on crossing behaviors by both visually impaired and cognitively impaired pedestrians.

AR0072203

- Chapter 5 – Cold Weather Case Studies – includes a summary of the case studies prepared as related to the installation, operation, and maintenance of APS in cold weather environments.
- Chapter 6 – Engineering Evaluation – includes the results of the engineering evaluation that has been completed to date.
- Chapter 7 – Recommended Guidelines – provides a discussion of the guidance recommended on the basis of the experimental results.
- Chapter 8 – Intersection Prioritization Tool – includes a discussion of the effort to develop a tool for assessing and prioritizing intersections with respect to crossing difficulty by pedestrians with visual impairments.
- Chapter 9 – Training and Resources – provides a discussion of the plans for the development of the training materials in the next phase of the study and includes an outline for the materials.
- Chapter 10 – Conclusions – includes a summary of the study objectives, project findings, and recommended guidelines.

ADDITIONAL RESOURCES

- *Accessible Pedestrian Signals: A Guide to Best Practice* – This companion document (referred to hereafter as the *Guide*) provides training information for engineers, orientation and mobility specialists, and signal technicians on when, where, and how to install APSs. See more information on the *Guide* in Chapter 9.
- PowerPoint Presentations – these presentations are the materials for a one-day training course that covers the most critical information in the *Guide*. The presentation files include scripts to ensure that they can be read and understood outside of the course. See more information on the presentations in Chapter 9.
- Web site (www.walkinginfo.org/aps) – This site includes all of the materials produced as part of this project, including this report, the *Guide*, the PowerPoint presentations for training, and the Intersection Prioritization Tool to assist practitioners in prioritizing locations for APS installation.

AR0072204

AR0072205

CHAPTER 2

Research Synthesis

Provided in this chapter is a summary of the APS research that is related to the research undertaken in this effort. A more comprehensive synthesis of this research can be found in Appendix C of the *Guide*.

INTRODUCTION

Although APSs have been widely used in Japan and Sweden since the 1960s, the early development of APS in these countries was not, as far as these authors have been able to ascertain, based on research. The first substantial research on APS appears to have been done in 1976 by Frank Hulscher, an electrical engineer with the Department of Motor Transport, New South Wales, Australia. Hulscher's research was the basis for the well developed, fully standardized, and highly successful pushbutton-integrated APS system in use in Australia today.

Substantial research on APS in the U.S. began with a project undertaken by the San Diego Association of Governments in 1988 to investigate the "bird call signals" widely used in Japan, and being imported into the U.S. at that time. The results of this project were the basis for a policy of implementing standard signals at intersections in San Diego where a city access committee recommended them, following a systematic evaluation including use of a rating scale.

Since 1996, there has been a concerted research effort related to APS. Several research studies and surveys have documented problems of pedestrians who are blind or who have low vision at signalized intersections without APS (*3, 4, 5, 6, 7, 8*). Several studies in the U.S. have compared travel by blind pedestrians with and without APS (*9, 10, 11, 12, 13, 14, 15*). In these studies, some of the APSs have been signals mounted on the pedestrian signal head, while others have been receiver based systems, and others been pushbutton integrated devices. Methods of these studies are described below; results and conclusions are cited topically.

San Diego Association of Governments surveyed 71 national, regional, and local organizations representing and/or serving elderly persons and persons who were visually impaired to determine their involvement in installation of audible signals and the level of support for audible signals; 36 responses were received (*8, 16, 17, 18*, hereafter referred to collectively as San Diego research). A separate survey was also sent to members of California Association of Orientation and Mobility Specialists to gather information about their experience with audible signals. Surveys were mailed to 67 members, and 27 responses were received.

In 1998, the American Council of the Blind (ACB) and the Association for Education and Rehabilitation of the Blind and Visually Impaired (AER) conducted similar surveys to determine problems experienced by blind pedestrians during street crossings. Problems with audible signals currently installed were also identified by the surveys.

- ACB survey – surveys administered orally, in groups, to 158 pedestrians who are visually impaired (*6*, hereafter referred to as ACB survey).
- AER survey – mailed to 1000 orientation and mobility specialists. 549 surveys returned (*5*, hereafter referred to as AER survey).

AR0072206

Murakami et al. conducted a survey of 50 blind pedestrians in Japan (7). Ishaque et al. compared crossings by 27 legally blind pedestrians at three intersections in Huntington Beach, California, having "bird call" signals and one control intersection without APS (14).

In research by The Smith-Kettlewell Eye Research Institute, 20 blind participants made a total of 80 crossings at 4 fixed-time signalized intersections in downtown San Francisco, both with and without Talking Signs® (10, 11, 12, hereafter referred to collectively as SKERI research). Talking Signs is a receiver-based APS. Intersection signal phases were pretimed, and pushbutton use was not required. There were nine measures, including measures of crossing timing, safety, orientation (precision), and independence.

Marston and Golledge compared crossings by blind participants with and without APS, using the receiver-based APS system, Talking Signs, in a study investigating the use of Talking Signs remote infrared audible signs for a number of transit tasks (13).

The effects of a pushbutton-integrated APS, a receiver-based APS manufactured by Relume, and typical visual pedestrian signals without APS on the street crossing behavior of 24 totally blind participants were compared by Williams, Van Houten, Ferraro, and Blasch (15).

As part of a project on blind pedestrians at complex intersections, funded by the National Eye Institute, National Institutes of Health, a series of studies on crossings by blind pedestrians with and without APS is in progress in four cities, Portland, Oregon; Charlotte; Tucson; and Cambridge, Massachusetts. Objective data on measures of street crossing performance by sixteen participants who were blind was obtained at two complex, signalized intersections in each city. Measures were similar to those used in the SKERI research, including nine broad measures of crossing timing, orientation, and independence. Results from all four cities are not yet analyzed, but slightly different analyses have been reported in several articles. Results from pre-installation testing in two cities, Portland and Charlotte, are reported in Bentzen et al. (4, hereafter referred to as NEI-2 cities) and Barlow et al. (3, hereafter referred to as NEI-3 cities); reports on three cities, Portland, Charlotte, and Cambridge (Barlow et al. (9, hereafter referred to as NEI Portland pre-post) compares results of testing with and without APS in one of these cities, Portland, Oregon.

PROBLEMS WITH SPECIFIC TASKS AT SIGNALIZED INTERSECTIONS BY PEDESTRIANS WHO ARE BLIND OR WHO HAVE LOW VISION

Locating the Crosswalk

In SKERI research and NEI research-3 cities, research participants requested assistance in locating the crosswalk on about 17% of street crossings. On approximately 29% of crossings in both studies, subjects who located the crosswalk independently began crossing from outside the crosswalk.

Establishing and Maintaining the Correct Heading

In the AER survey, 97% of O&M specialists who responded indicated that their students had difficulty aligning to cross the street, while 66% indicated that their students sometimes had difficulty knowing where the destination corner was.

In SKERI research, participants started crossing from an aligned position on 48% of crossings without use of APS, and completed their crossings within the crosswalk on 58% of

AR0072207

crossings. In the NLI-3 cities research (without APS), participants started from an aligned position on 73.4% of crossings. Participants requested assistance or required intervention for safety while aligning to cross on 10% of crossings. Of participants who aligned independently, 58.4% completed their crossings within the crosswalk.

The broadcast sound from speakers mounted on the pedestrian signal head has not seemed to provide usable directional information. ACB and AER surveys indicated that pedestrians who are blind are sometimes not able to localize the sound of an APS in order to use it for guidance across the street. ACB – 67%, AER – 39% – 85% of ACB respondents indicated that they were sometimes confused by unexpected features such as medians or islands, while 64% of O&M respondents indicated that their students had difficulty with medians or islands.

Finding and Using Pushbuttons

In the ACB and AER surveys, many respondents indicated that they or their students had difficulty with pushbuttons (ACB – 90%; AER – 94%). Reasons were: 1) they couldn't tell whether they needed to push a button; 2) they had difficulty locating the button; 3) they couldn't tell which crosswalk was actuated by the button; or 4) the pushbutton was so far from the crosswalk that they couldn't push the button and then return to the crosswalk and establish a heading before the WALK interval began.

Uslan et al. also found that the major problems 27 legally blind participants had with "bird call" type APSs were in locating the pole and the pushbutton and determining which pushbutton was for which crosswalk (74). Participants traveling with guide dogs experienced the most difficulty locating the pole. Sometimes participants first located the incorrect button and subsequently located and pushed the correct button after waiting and listening through one or more cycles.

This replicated the findings of San Diego's research (76). Gallagher and Montes de Oca also noted this problem in research on vibrotactile-only APSs (79).

In the NLI-2 cities results, at crossings where pushbutton-actuation was required, participants looked for, found, and pushed the button on only 16.3% of these crossings in Portland, and none (0%) of the crossings in Charlotte.

Identifying the Onset of the WALK Signal

In the surveys conducted by ACB and AER, many respondents indicated that they or their students sometimes had difficulty knowing when to begin crossing (ACB – 91%; AER – 98%). Reasons were: 1) the surge of traffic was masked by right-turning traffic; 2) traffic flow was intermittent; 3) the intersection was too noisy; and 4) the surge of traffic was too far away. In the AER survey, 79% of respondents indicated that blind students sometimes had difficulty determining the onset of the WALK interval at intersections having exclusive pedestrian phasing.

On 24% of trials at SKERI research, blind pedestrians requested assistance in knowing when to start crossing at crosswalks where they did not use APS. On 34% of trials on which they independently initiated crossings, they began crossing during the flashing or steady DON'T WALK.

In the Japanese survey, 46% of respondents stated that "To take a moment to start" was difficult without APS, and Uslan found that, at the control intersection without APS, which was

AR0072208

commenced the earliest to cross without APS. 4 out of 15 participants began crossing during DON'T WALK.

The NEI 3 cities research found that pedestrians who were blind independently began crossing during the walk interval on only 48.6% of crossings and completed crossings after the onset of perpendicular traffic on 26.9% of crossings. The need for push-button activation of the walk interval affected the likelihood that participants would begin crossing during the walk interval. On the pedestrian-actuated crossings, participants began crossing during the walk interval on only 19.5% of the crossings compared to 71.7% of crossings where the pedestrian phase was on recall (the pedestrian phase was indicated in every cycle). Mean latency in beginning crossing (the time between onset of the WALK signal or near-side parallel traffic and the participant beginning to cross) was 6.41 seconds without APS.

Common Problems with APS in the United States

ACB and AER surveys reported the experience of pedestrians with visual impairments in using APS that had "bird call" signals, bells, and buzzers. There were problems both with APS being considered too quiet and too loud. Ushai et al. found that at one intersection with split phase timing, where the bird call signals for parallel crosswalks had separate timing, three of 15 blind participants initiated their crossings with the signal for the parallel crosswalk, walking into the path of left-turning vehicles (14).

These surveys also looked at data from blind pedestrians and O&M specialists from California, whose experience with APS is almost exclusively with "bird call" signals that are intended to provide unambiguous information regarding which street has the WALK interval. Many respondents indicated that they or their students sometimes did not know which crosswalk had the WALK interval (ACB = 68%; AER = 72%). Reasons were: 1) users forgot which signal was associated with which crossing direction; 2) users didn't know which direction they were traveling; and 3) the intersection was not aligned with primary compass directions.

Ushai et al. found that on many trials blind participants failed in their attempts to cross streets because of indecision regarding the pole or button, even though all participants were fully familiar with the "bird call" signal, they knew what to listen for at each intersection, and they could listen through as many cycles as they desired (14). Sometimes participants located the incorrect button and then pushed the correct button after waiting and listening through one or more cycles.

AER and ACB surveys confirmed that blind pedestrians rarely do confuse the sounds of birds with APS sounds. These surveys also indicated that many blind pedestrians are sometimes unable to localize the sound of an APS and use it for guidance across the street. Furthermore, when APSs are too loud, and are at intersections that are close together, the APS for one intersection may be heard from another, leading some pedestrians to incorrectly think they have the WALK interval.

Respondents to the Japanese survey indicated that "direction taking at the starting position" and "keeping direction while walking in the crosswalk" were a problem, even with APS.

AR0072209

EFFECT OF APS ON STREET CROSSINGS BY BLIND PEDESTRIANS

Since it is known that pedestrians with visual impairments have difficulty with many of the tasks that, taken together, comprise street crossing, it would be convenient to assume that APS would improve all measures of crossing at signalized intersections. To determine the extent to which this is true, a number of research projects have obtained objective data comparing street crossings with and without APS on one or more of the following measures:

- Locating the crosswalk.
- Aligning to cross and maintaining alignment while crossing.
- Use of pushbuttons.
- Identifying the walk interval.
- Delay before beginning to cross.
- Independence in any or all crossings tasks.

Projects that have already been mentioned are: SKERI research, NEI Portland pre-post; Uslan et al. (14); Marston and Golledge (15); and Williams et al. (17). There are several additional studies that shed light on this topic. Hulscher reported an estimate by Leith (personal communication) comparing starting delay pre- and post-APS installation (20). Wilson conducted a pre- and post-APS installation study of behavior of adult, non-disabled pedestrians at one intersection (21). As part of NEI research, in three different experiments Wall, Ashmead, Bentzen and Barlow, blind and blindfolded sighted participants made crossings at a simulated intersection, in the presence of recorded traffic sound to determine the effect on crossing accuracy with signals comprised of bird calls, percussive "ticks," a click train, or a female voice (22). The signals, all of which were mounted at a height of eight feet, came either simultaneously from both ends of a crosswalk (typical practice), alternated from one end to the other, or came from the far end of the crosswalk only. These researchers also compared crossing accuracy when signals came from two parallel crosswalks (typical practice), or from a single crosswalk. A further comparison was between Walk signals with a typical 7 sec. duration versus a 7 sec. Walk signal followed by a locator tone.

Locating the Crosswalk

SKERI research found that starting crossing from within the crosswalk increased from 70% to 93% with use of the APS.

NEI Portland pre-post research found significant increases in participants' ability to begin crossings from within the crosswalk at locations where pushbutton use was required, and pushbutton locator tones were installed. Pre-installation, 77% of crossings began from within the crosswalk; post-installation, 97% of crossings began within the crosswalk, indicating that locating the crosswalk was significantly improved by the presence of pushbutton-integrated APS. (9)

Orientation (Aligning to cross and maintaining alignment while crossing)

On 48% of crossings in SKERI research, where APS information was not available, blind pedestrians were not facing directly toward the opposite corner when they started their crossing;

AR0072210

they were facing somewhat toward or away from the center of the intersection. With the use of receiver-based APSs, participants were well aligned when beginning 80% of crossings.

However, in NEI Portland pre-post research, alignment showed only a very small trend toward improvement, with 70% of independent crossings starting from an aligned position pre-installation and 84% post-installation. NEI research in a simulated crossing found the presence of a locator tone during the second half of the crossing had a positive effect on alignment (22).

Using Pushbuttons

Data reported in NEI pre-APS installation testing indicated that blind pedestrians typically didn't search for and use pedestrian pushbuttons at unfamiliar intersections without APS (3, 4). However, the addition of pushbutton locator tones and the knowledge that an APS might be installed resulted in participants looking for the pushbuttons on over 98% of crossings, although looking for the pushbutton did not always result in finding and using the correct pushbutton. Participants independently looked for and used the pushbuttons on 93% of crossings after pushbutton integrated signals with locator tones were installed (9).

Initiating the Crossing

Delay in beginning to cross

Hulscher cites a personal communication from Lamb in which Lamb estimated that, following APS installation, delay in beginning crossings was reduced an average of 2.3 seconds for all pedestrians (20).

Wilson, in a pre- and post-APS installation study of adult non-disabled pedestrian behavior at one intersection, found the following results (21):

- For pedestrians using the pushbutton, delay in beginning crossings was reduced by 20%, from 2.7 sec to 2.1 sec.
- The time taken to cross by persons who started during the walk interval decreased by about 5%; crossing time for other pedestrians was unchanged.
- For pedestrians who arrived at the crossing during the flashing or steady Don't Walk and who waited to cross until the onset of the walk interval, the proportion who failed to complete their crossings before the onset of opposing traffic was reduced by one half, from 22% to 11%.

Williams et al. found that mean latency in beginning crossing without APS was more than 5 seconds, which was reduced to 2.2 seconds with a receiver-based APS device with a tone WALK indication and 3.8 seconds with a pushbutton integrated APS using speech messages (15). Williams also assessed participants on total number of signal cycles missed before crossing. Without APS, mean wait time was almost 2 full cycles, while with either type of APS the mean wait time was just over a half a cycle.

In NEI Portland pre- post research, in 144 crossings pre- and post-APS installation at two intersections in Portland, Oregon, the weighted mean starting delay for blind pedestrians without APS was 5.1 seconds, and after APS installation, the delay was only 2.9 seconds. Ustan et al. also found significant differences between speed of crossing at a control intersection and intersections where APS were installed; crossings at locations with APS were completed faster (14).

AR0072211

Starting during WALK and completing crossing before the onset of perpendicular traffic

In SKERI research, participants began crossing during the walk interval on only 66% of crossings without APS, but on 99% of crossings with APS.

In NEI Portland pre-post installation, pre-installation, the pedestrian actuated crossings were highly problematic for pedestrians who are blind. Pre-installation, participants began crossing during WALK on only 25% of crossings. Post-installation, there was dramatic improvement in participants correctly determining the appropriate time to start crossing, with 84% of crossings initiated during WALK. Similarly, participants completed crossing after the onset of perpendicular green on 50% of crossings pre-installation, with a significant decrease post-installation to 12% of crossings completed after the onset of perpendicular green.

Furthermore, only 77% of decisions about when to start crossing were made independently pre-installation as opposed to 95% post-installation. Pre-installation, the total number of crossings where the individual independently determined a start time and actually began crossing during the walk interval was less than a quarter of crossings. Post-installation, with the addition of the APS, there was a significant increase both in independence and in beginning to cross at the appropriate interval.

For crosswalks where the pedestrian phase was on recall, the APS sounded at the beginning of the walk interval, regardless of whether the pushbutton was used or not. However, the WALK indication only sounded for the first seven seconds of the walk interval, unless the pushbutton was pushed again. Pre-installation, 70% of independent crossings began during the walk interval; post-installation, this increased to 100%.

Marston and Golledge found that at crossings without APS, almost half (48%) of the participants attempted to cross during the steady don't walk interval, a time recorded as unsafe by the researcher (*13*). With access to the pedestrian signal information provided by APS, no participant started crossing at an unsafe time.

Effect of APS on Independence and Confidence

Both the NEI research and the earlier SKERI research on which the method was based measured independence on three street crossing tasks both with and without APS: locating the crosswalk, starting to cross within the walk interval, and completing the crossing. The NEI research also measured independence on aligning to cross. The percentage of crossings on which participants were independent on each task is as follows:

Task	Without APS		With APS	
	SKERI	NEI	SKERI	NEI
Locating crosswalk	81%	82%	99%	95%
Aligning to cross	NA	94.5	NA	97%
Starting to cross during WALK	76%	79%	100%	92%
Completing the crossing	81%	86%	97%	96%

Table A-1. **Percentage** of crossing tasks on which participants were independent.

Marston and Golledge measured confidence in street crossing with and without APS (*13*). The range of responses for the no APS condition, by street crossing task, was 4.7–5.5 (5 pt. scale).

AR0072212

1=no confidence, 5=very confident), while the range of responses by task for the APS condition was 4.8-5.0.

Detectability of WALK Signal

Holscher found that, because of the masking of high frequency signals by predominantly low frequency traffic noise, and because a majority of blind pedestrians have some upper frequency hearing loss, the optimal "fundamental" frequency of the WALK tone should be between 300 Hz and 1000 Hz, and the tone should be comprised of multiple short bursts of sound to aid localization (20)

Stuffeldt, in research cited by Holscher, conducted extensive testing of APS at crossings where they were mounted on the pedestrian signal head, and found that an 880 Hz signal was most detectable in a background of traffic noise (20)

Holscher's recommendation and Stuffeldt's result was supported by Poulsen, who compared the noise spectrum of traffic as attenuated by windows to arrive at a recommended signal frequency (880 Hz) that would not be largely masked by traffic noise, but would also not transmit through windows and become a public annoyance (23)

At San Diego research laboratory measurements of "birdcall" signals from Nagoya Electric Works of Japan found that neither signal was highly directional, however, the cheep was more detectable than the cuckoo. The cheep was produced by a continuous frequency variation with a fundamental frequency base of 2800 Hz, and the cuckoo consisted of two frequencies with a combined frequency base of 1100 Hz. (Currently available "cuckoo/cheep" signals may vary from this manufacturer's standard.)

Hall, Rabelle, and Zabilsky worked with audiologists to develop a signal that provided the most localizable melody for an accessible signal, and recommended a melody that was composed of fundamental frequencies between 300 Hz and 1000 Hz, but including harmonics extending to 7000 Hz (24)

At NBI research (unpublished data), Wall, Ashmead, Barlow, and Bentzen carried out a series of experiments on detectability of WALK signal alternations in a laboratory setting (25) Experiment 1 evaluated the detectability of signals in white noise, Experiment 2 evaluated the detectability in traffic noise, and Experiment 3 evaluated detectability in traffic noise for subjects with age-related hearing loss. Signals evaluated were an 880 Hz square wave, a bird chirp, a cuckoo, two click trains, two percussive signals ("blink" and "tick"), a four-tone melody, and female and male voice signals. Results indicated that audible signals of a more percussive nature with predominantly lower frequencies were best heard in background traffic noise. In addition to one of the percussive signals, participants with age-related hearing loss were better able to detect male voice signals. Signals with a simple percussive nature tended to need less gain to be heard in noise, relative to the levels necessary to be heard in quiet. In other words, percussive signals were more detectable at lower volumes. When asked their preference, most participants liked voice signals best, but all of the voice signals needed more gain to be heard. Note that the measurements in these studies was the point at which the signal was detected, not the point at which the message was easily understandable. Intelligibility of voice messages was not evaluated or assessed by participants. The cuckoo and chirp, most commonly used in the U.S. as an audible signal at the time of the study, required the most gain to be detectable amid background noise.

AR0072213

Localizability of WALK Signal

An additional factor, if audible pedestrian signals are to be used as beacons to guide pedestrians with visual impairments across a street, is how well signals can provide directional information. Laroche, Giguère, and Poirier compared localization of cuckoo and cheep signals to localization of 4 four-note melodies varying in fundamental frequencies, harmonics, note duration, and temporal separation between notes (26). In combined objective and subjective testing, the cheep and a melody with minimal harmonics were found to be less localizable than the cuckoo and the other three melodies. In a follow-up study, Laroche, Giguère, and Lemoyne compared the typical cuckoo-cheep sounds used in Canada with a cuckoo having a lower fundamental frequency, and the melody that was recommended as a result of their 1999 research (27). In both studies, the signal was 56 seconds long (much longer than typical U.S. WALK indications) and the measurements were in a simulated pedestrian corridor in a quiet environment. In situations with actual traffic sounds, the cheep was found to result in significantly greater veering and longer crossing time than any of the other signals, which did not differ from each other.

At NEI research, Wall Ashmead, Bentzen, and Barlow found no significant differences in localizability among several disparate signals, including cuckoo, chirp, "tok" and voice messages, when tested in research that involved multiple crossings of a simulated street, in the presence of recorded vehicular sound (22). The five signals used were representative of signals in wide use or that showed promise for directional beaconing. None of the analyses indicated any systematic differences between the five signals. Further experiments focused on presentation mode and signal location, rather than signal sound characteristics.

Speech WALK Indications

Listeners with normal hearing require that speech be 15 dB louder than background noise for intelligibility to reach 90% (28). This means that, in order to be intelligible, speech messages should be louder than tone indications. The effect of that louder sound level on the ability of blind pedestrians to hear other sounds in the intersection, or on our near neighbors, may limit the acceptability of speech messages.

Bentzen, Barlow and Franck conducted research to obtain information from stakeholders regarding the structure and content of speech messages for APS WALK messages and for "pushbutton messages" that are only available during the flashing and steady DON'T WALK intervals (29). WALK messages convey that the WALK signal is on and provide the name of the street being crossed. Pushbutton messages provide intersection and crosswalk identification information, and they may also provide information about unusual intersection signalization and geometry. The research utilized an expert panel of stakeholders, who prepared a survey comprised of sample messages (verbal and forms to determine respondent understanding of messages. The survey was administered to people who are visually impaired, O&M specialists, transportation engineers, and APS manufacturers. The resultant recommended model messages are contained in the *Guide*.

Van Houten, Malenfant, Van Houten, and Retting found that redundant information conveyed by audible pedestrian signals increases the attention of all pedestrians to turning traffic and may contribute to a reduction in pedestrian vehicular conflicts and crashes at signalized intersections (30). This signal also gave participants who were blind precise information about the onset of the walk interval and which street had the walk interval.

AR0072214

Accuracy and Speed in Identifying WALK Indication for a Given Crossing

In NEI research, Ashmead, Wall, Bentzen, and Barlow investigated how location of APS speakers in different positions relative to the crosswalk affected the accuracy and speed of identifying the correct crosswalk (see Figure 2-1 below for APS positioning used in research, using typical placements seen in the U.S. (Ref.)). All loudspeakers emitted the same WALK indication.

Note: The question to the pedestrians always was, "Which has the WALK signal, the crosswalk straight in front of you or the one to your right?"

Corner 1: loudspeakers near curb, on outside of crosswalk line.
Corner 2: loudspeakers near back edge of sidewalk, on outside of crosswalk line.
Corner 3: loudspeakers near curb but facing across pedestrian's position.
Corner 4: loudspeakers near back edge of sidewalk mounted on the same pole.

Under the most typical signal mode, simultaneous presentation from both ends of the crosswalk, the most accurate performance occurred when signals were placed close to the curb line, near the side of the crosswalk that was furthest from the corner of the intersection (see corner 1 in Figure 2-1). The pedestrian could easily tell which of the two loudspeakers at the corner was nearer because each loudspeaker was close to the position of the pedestrian waiting to cross at the associated crosswalk. Note that this was true despite the fact that both signals on the corner had the same sound. Other arrangements of loudspeakers resulted in somewhat worse performance. Accuracy at corner 3 was poor, with participants answering correctly on only 25% of trials in the simultaneous presentation condition and 50% of trials in the alternating presentation condition.

There was no evidence that response time differed across the four corners, that is, for different speaker arrangements. This suggests that the inaccurate judgments made from corner 3 about which crosswalk had the walk signal did not reflect uncertainty, but rather were mistakes of which the participants were largely unaware.

Figure 2-2 illustrates the recommended placement of APS devices in relation to the crosswalk provided in the APS Synthesis in 2003. This arrangement was based on the NEI research described above. The NEI research was the basis for additional research on

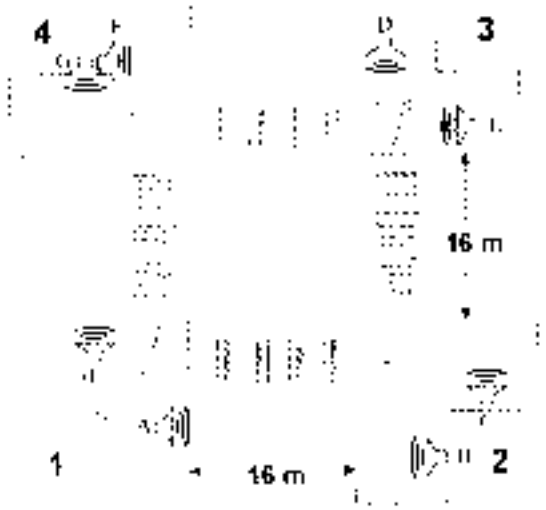

Figure 2-1. Positions and headings of loudspeakers and pedestrians at each corner in NEI research. (Figure from Ashmead, et al., 2004a). The figure is not drawn to scale.

AR0072215

pushbutton location within the current project.

Research on Source of WALK Signal

A number of investigators have tackled the problem of improving localization of WALK signals by varying the source of the sound. All investigators used some measure of the straightness of the path of travel from one end of the crosswalk to the other; some also measured mental loading.

Stevens (*41*) and Tauchi, Sawai, Takato, Yoshinuma, and Takeuchi (*42*) found that alternating acoustic signals result in performance superior to that of simultaneous signals, as did Lovelock et al. (*27*). However, when Lovelock et al. compared simultaneous and alternating signals at a real intersection, there was no significant difference. Tauchi, Takano, Suzuki, Kai, Takahara, and Jojima found better performance when the alternating signals at each end of the crosswalk were different (e.g. "chirp" vs. "cheep, chirp") than when they were the same (e.g. "chirp" and "chirp") (*43*).

Poulsen compared simultaneous acoustic WALK signals with signals at the far end of the crosswalk and found superior performance with signals at the far end (*24*). Wall et al. compared simultaneous, alternating (same sounds), and far-end signals, and found the far-end signals resulted in significantly better performance than either simultaneous or alternating signals, which were equal (*22*).

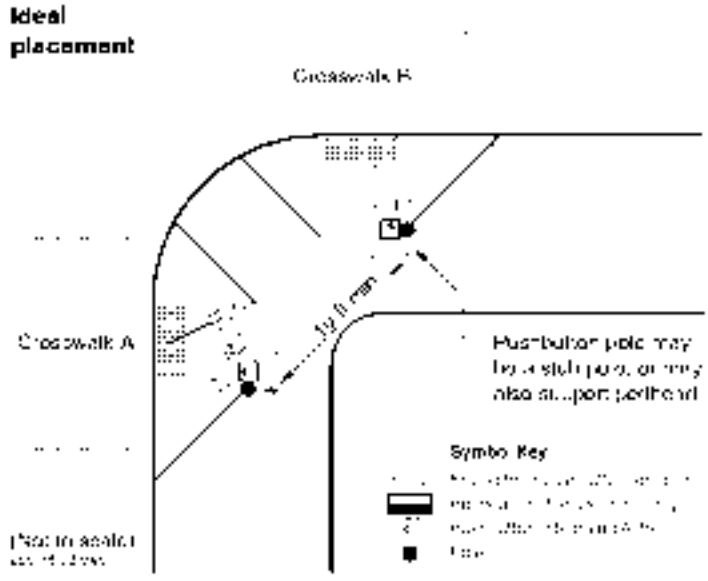

Figure 2-2. Optimal location of pushbutton integrated APS.

AR0072216

AR0072217

CHAPTER 3

Experimental Trials on Accessible Pedestrian Signal Features

INTRODUCTION

The most commonly used accessible pedestrian signals (APSs) in the U.S. have been pedhead-mounted devices, where speakers are attached to the visual pedestrian signals. These APSs can make a variety of sounds, but commonly use birdcalls (cuckoo and cheep). A different type of APS, known as a pushbutton-integrated APS, has been used in much of Europe and in Australia and is now becoming more common in the U.S. On pushbutton-integrated APSs, the speaker is located in the pushbutton housing, and the device typically provides a pushbutton locator tone in addition to an audible WALK indication. The pushbutton locator tone repeats constantly, at one-second intervals to tell pedestrians that there is a pushbutton and to help them locate and use the pushbutton. Tactile arrows are also a standard feature to help blind pedestrians determine which street the device serves (*see Figure 3-1*). The arrow vibrates during the walk interval to communicate walk signal information to pedestrians who cannot hear or who want to tactually confirm audible signal information. Various other features are currently available on some devices.

Until 2000, when two sections on APS were added to the *MUTCD*, there were no national standards for APS in the U.S. The *MUTCD* now defines an APS as "…a device that communicates information about pedestrian timing in nonvisual format such as audible tones, verbal messages, and/or vibrating surfaces" (*1*) The rest of the *MUTCD* language provides standards, guidance and options, but does not specify walk messages or address many possible device features. In 2002, the U.S. Access Board published draft recommendations and requirements for APS installation in *Draft Guidelines for Accessible Public Rights-of-Way*, which were further updated in November 2005 (*2*). The *Draft Guidelines* call for the use of pushbutton-integrated signals that provide audible **and** vibrotactile indications of the walk interval.

Figure 3-1. Pushbutton-integrated APS with tactile arrow.

Research was needed to expand upon or modify the APS guidance now available to ensure that the information being provided to pedestrians who are blind or who have low vision (including those with hearing loss) is consistent among

AR0072218

intersections and will allow users to safely, efficiently, and independently cross at signalized intersections. The purpose of the study documented in this chapter was to determine the effect of APS features, which are available on devices of the type recommended in the Access Board's *Draft Guidelines*, on the ability of pedestrians who are blind to locate and use pushbuttons, determine time to cross, determine appropriate heading for crossing, and maintain alignment while crossing.

In this experiment, four pushbutton-integrated APSs were evaluated in comparison to each other. APSs from each of four manufacturers were installed at all crosswalks at one of four intersections in each of two cities. Psychophysical data on street crossings by approximately 20 blind pedestrians were obtained for each manufacturer's APS installed with their "standard features" in each city. These technologies differed from one another in interface designs and features, such as the pushbutton locator tone, pushbutton size and shape, design, and location of tactile arrow, type of actuation indicator/confirmation tone/speech, tick, burst, type of walk indication (speech message, rapid tick, bird call tones), and availability of additional features such as tactile map of the crosswalk, additional information about the intersection or audible beaconing. APS features are described in detail in the *Guide*. The following descriptions of features are condensed from that report.

- Pushbutton locator tone: "A repeating sound that informs approaching pedestrians that they are required to push a button to actuate pedestrian timing and that enables pedestrians who have visual disabilities to locate the pushbutton." (*MUTCD 2000*, 4E.08; 17). Pushbutton locator tones sound during the flashing and steady DON'T WALK intervals. The locator tone informs pedestrians of the need to push a button, provides an audible cue to the location of the pushbutton, and may provide a clue as to the destination corner when approaching on the crosswalk. In available products, the pushbutton locator tone varies from a click sound to a beep type tone. *MUTCD* standard requires that "... the tone shall repeat at 1 second intervals and shall have a duration of 0.15 seconds or less" (17). The pushbutton locator tone typically has automatic volume control that adjusts the volume according to changes in ambient sound level.
- Pushbutton size and shape: Pushbuttons are required by the *Draft Guidelines* to be at least 2 inches in diameter and to require less than 5 lbs force to push (2).
- Tactile arrow: A raised (tactile) arrow is incorporated into the device to help users know which crosswalk is actuated by the pushbutton. The arrow may be part of the pushbutton, above the pushbutton, or on top of the device. This arrow also vibrates during the WALK interval.
- Actuation indicator: A tone or voice message indicates to pedestrians that the button has been pushed and a WALK signal requested.
- Additional intersection information (pushbutton information message): A pushbutton information message is a speech message that provides additional information when the pedestrian pushbutton is pushed during the flashing or steady DON'T WALK intervals. When used, this message identifies the intersection, provides the name of the street that the pushbutton controls, and may provide other intersection geometry or signalization information. The message is intended to be audible when standing at the pushbutton location. Pedestrians may be required to press the pushbutton for approximately three seconds (see extended button press) to call up this additional speech message. Recent

AR0072219

research indicates that pressing the button for one second or longer is optimal timing [24].

- Walk indication: The walk indication provides an audible and vibrotactile indication of the WALK interval. The audible indication can be provided by tones or speech messages and generally repeats for the entire WALK interval. Different manufacturers currently provide different walk indications, but any of the devices could provide any of the sounds used. In this research, one manufacturer provided bird calls (cuckoo chirp), one provided a rapidly repeating tone, and two provided speech messages. The *MUTCD* and *Draft Guidelines* recommend that the walk indication be the same volume as the locator tone, and no more than 5 dB above ambient sound levels, unless there is special activation of audible beaconing. The vibrotactile indication of the WALK interval is typically provided by a tactile arrow on the pushbutton device that vibrates during this interval.
- Audible beaconing: Beaconing is the use of an audible signal in such a way that blind pedestrians can home in on the signal from the opposite corner as they cross the street. This is intended to provide directional orientation. APS currently provide audible beaconing in one of two ways: from pedhead-mounted speakers aimed in the center of the crosswalk approximately one third of the way across the street, and by using pushbutton integrated speakers that elevate the volume of the walk indication and the subsequent locator tone for one pedestrian phase, which is called by an extended button press.
- Crosswalk map: One manufacturer's signal incorporates a raised schematic map showing what will be encountered as the pedestrian negotiates the crosswalk controlled by that pushbutton. The map shows just the crosswalk controlled by that signal, not the entire intersection, and includes: number of lanes to be crossed; whether these are vehicular or bicycle lanes or tracks for rail vehicles; which direction traffic will be coming from in each lane; and whether there is a median.

METHOD

Overview

Data were collected in two cities (Tucson, Arizona, and Charlotte, North Carolina) for 40 visually impaired participants (20 in each city) crossing at four intersections. Each intersection was equipped with pushbutton integrated APS devices from a different manufacturer. The full range of features currently in use on pushbutton-integrated devices in the U.S. was represented across these four manufacturers. In each city, participants crossed at the same intersections two or three times under two or three information conditions designed to represent typical experiences of pedestrians who are blind.

One information scenario, defined as the "no information" condition, represented the situation in which pedestrians who are blind know that there will be an APS at the intersection, but do not have any information about the APS features and probably have not had previous experience with pushbutton integrated APS. This condition was only used in Tucson. The "general information" condition represented the situation in which the participants had heard a general description of the devices. They knew there would be a new type of APS at the intersection and had been told about possible features of APS devices, similar to someone who has heard or read about new types of APSs, but has had no experience with them (Tucson and Charlotte). A third information condition, defined as the "specific information" scenario,

AR0072220

represented the situation in which a blind pedestrian knows the intersection will have an APS and knows from prior experience and instruction with the APS device how it will function and what features it will have (Tucson and Charlotte). During the break between the general information and specific information conditions, participants were shown a working demonstration unit of each device and given the opportunity to manipulate it and to experience all the types of information that it provided. Immediately before beginning each crossing in the specific information condition, participants were told which of the devices would be present at that crossing, and the features of the device were reviewed.

In Tucson, each participant crossed at each intersection 3 times, once for each condition, for a total of 12 crossings. In Charlotte, the no information condition was dropped due to the amount of time required to travel between intersections, so each participant made eight crossings, two at each intersection. Although participants returned to each intersection two or three times, several procedures minimized the possibility of learning about specific intersections or about the APS at specific intersections. Participants were not told that they would be returning to the same intersections; order of intersections was different in each block of crossings; each approach to the intersection was different; and parking locations were usually different. Few participants indicated that they recognized that they were returning to the same intersections.

Measures recorded included speed and accuracy in locating and pushing the correct pushbutton, speed and accuracy in beginning crossing during the WALK interval, crossing alignment, and crossing path. Data on the traffic sound levels and movement were also collected. After each crossing, a series of questions was asked to learn what information participants used to make the crossing and to obtain their perceptions about the APS at that crossing.

Participants

Twenty participants who are blind were tested in each city. All had insufficient vision to see crosswalk lines, pushbutton poles, or pedestrian signals. All participants were accustomed to crossing independently at signalized intersections using a long cane or guide dog and none were familiar with the intersections being used for testing. Ages were similar across cities, ranging from 24 to 70, with a mean age of 44. There were 24 male and 16 female participants. The majority of participants used a long cane as their travel aid, with only four in each city using a guide dog. Thirty-nine of the participants rated themselves as good to excellent travelers; one participant rated his travel ability as fair. Thirty-two (16 in each city) of the participants stated that they traveled independently more than 5 times a week.

An attempt was made to recruit up to five participants in each city who met the criteria for vision loss and independent street crossing, and who also had moderate to severe hearing loss. Recruiters were unable to obtain this number of deaf-blind persons in each city who cross streets independently. In Tucson, two participants were identified with mild hearing loss and one other had moderate to severe hearing loss, with bilateral hearing aids. Only one participant in Charlotte reported mild hearing loss, three others may have had some hearing loss, based on researcher observations and notes, but such loss was not diagnosed or self reported in participant interviews.

AR0072221

Location

Cities and Intersections

Several cities were considered to participate in this study, including: Boston, MA; Cambridge, MA; Charlotte, NC; Milwaukee, WI; Minneapolis/St. Paul, MN; Portland, OR; San Diego, CA; and Tucson, AZ. Charlotte and Tucson were selected for participation as field sites on the basis of meeting the following criteria:

- Availability of appropriate intersections (see criteria for intersections below).
- Willingness to temporarily install APSs at four intersections.
- Ability to provide necessary technical support for data collection during human factors testing.
- Ability to provide engineering evaluation of the different technologies.
- Willingness to provide information on installation and maintenance of the equipment.
- Population that enabled the recruitment of 20 blind or deaf-blind participants.
- Availability of a local orientation and mobility specialist who is capable, willing and able to participate in subject recruitment, scheduling, and data collection.

Four intersections were selected for APS installation in each city. The criteria originally established for these locations included:

- Semi-actuated or fully actuated, with pedestrian push buttons for each crossing direction.
- Concurrent pedestrian signal phasing.
- Four-way intersection of a busy arterial and a minor street with little traffic.
- Arterial with four travel lanes and minor street with two travel lanes.
- Similar geometric and operational characteristics.
- Similar pedestrian signal head and push button configurations (each pole and pushbutton controls the signal for one crosswalk).
- Within easy walking distance of each other (i.e., walking the circuit can be completed within 1 hour).

Upon visiting the various cities and examining sites, it was determined that the last criterion could not be met. In order to obtain locations with enough similarities, it was necessary to use intersections that were not within walking proximity. Thus the subjects were transported between sites by vehicle. The other criterion that was adjusted was the number of lanes and traffic volume on the minor street. Information on the number of lanes and traffic volumes is provided below, in the descriptions of intersections in each city. Controllers and wiring also had to be capable of accommodating the pushbutton-integrated APS equipment.

AR0072222

Tucson

Intersections used in Tucson were quite wide and relatively busy. Major street volumes were between 30,000 and 40,000 vehicles per day. Traffic counts were not available on the minor streets at each intersection. Each intersection had two phase signalization, fully actuated, with a 7 second WALK signal. The major street crossings required the traversal of four through lanes and a left turn lane; total crossing widths varied from approximately 60 ft to 78 ft. The minor street configuration required crossing one through lane and a left turn lane; total crossing widths ranged from approximately 41 ft to 58 ft. Curb ramps were diagonal and pedestrian pushbutton poles were fairly consistently located near the outside line of each crosswalk. Location in relation to the sidewalk (back of sidewalk or on street side) varied. An illustration of one of the Tucson intersections is shown in Figure 3-2.

One site had a right-turn-only lane (northbound to eastbound) from the minor onto the major crossings in both the general and specific information conditions were made on the west crosswalk of the major street to keep all crossings as comparable as possible and to avoid possible conflicts and auditory confusion. At this crosswalk, one crossing was made in one direction, and one was made in the other direction, which minimized learning about the specific crosswalk or corners.

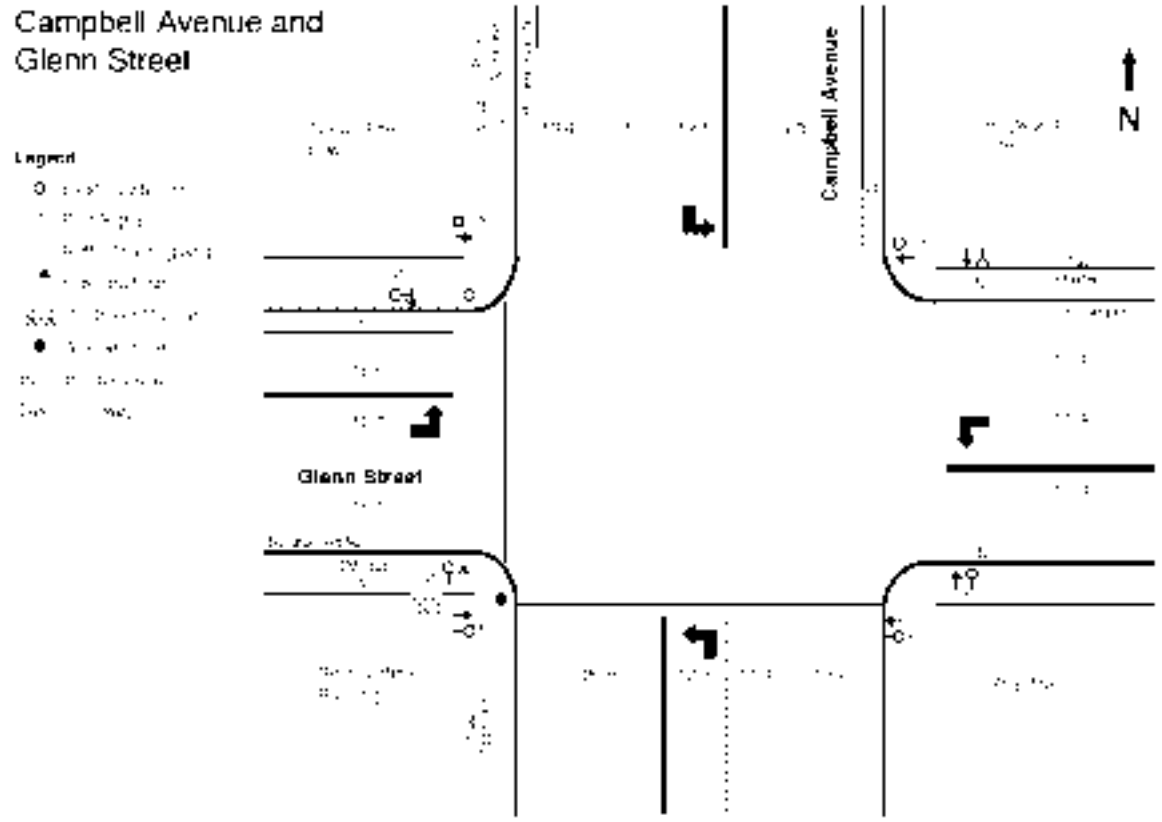

Figure 3-2. Intersection of Campbell Avenue (major street) and Glenn Street (minor street) in Tucson, AZ where APS devices were installed for the experiments.

AR0072223

Charlotte

Intersections selected in Charlotte were, on average, somewhat narrower than the Tucson intersections. Major street crossings at three sites required traversal of four through lanes and ranged in width from 49 feet to 83 feet. The fourth intersection (with approach widths of 79 and 83 ft) had parking lanes on each side of the street and an exclusive left-turn lane on both approaches. Minor street crossings were 34 to 55 ft in width. Traffic volumes on the major roads ranged from 20,000 to 25,000 vehicles per day, while minor street volumes ranged from 3,000 to 6,000 vehicles per day. Most curb ramps were in line with the crossing. Originally, pushbuttons were provided only for the major street crossing or two pushbuttons were located on the same pole. Additional stub poles were installed in order to provide separation of the APS. An illustration of one of the Charlotte intersections is shown in Figure 3.3. At two intersections, sidewalk location or street geometry made it impossible to install separate poles on one of the intersection corners. That corner of each intersection was used as a destination corner only during the experimental trials.

APS Device Features

Four manufacturers (Campbell Company, Novax Industries Corporation, Polara Engineering, Inc., and Prisma Teknik) of pushbutton integrated APS were asked to provide

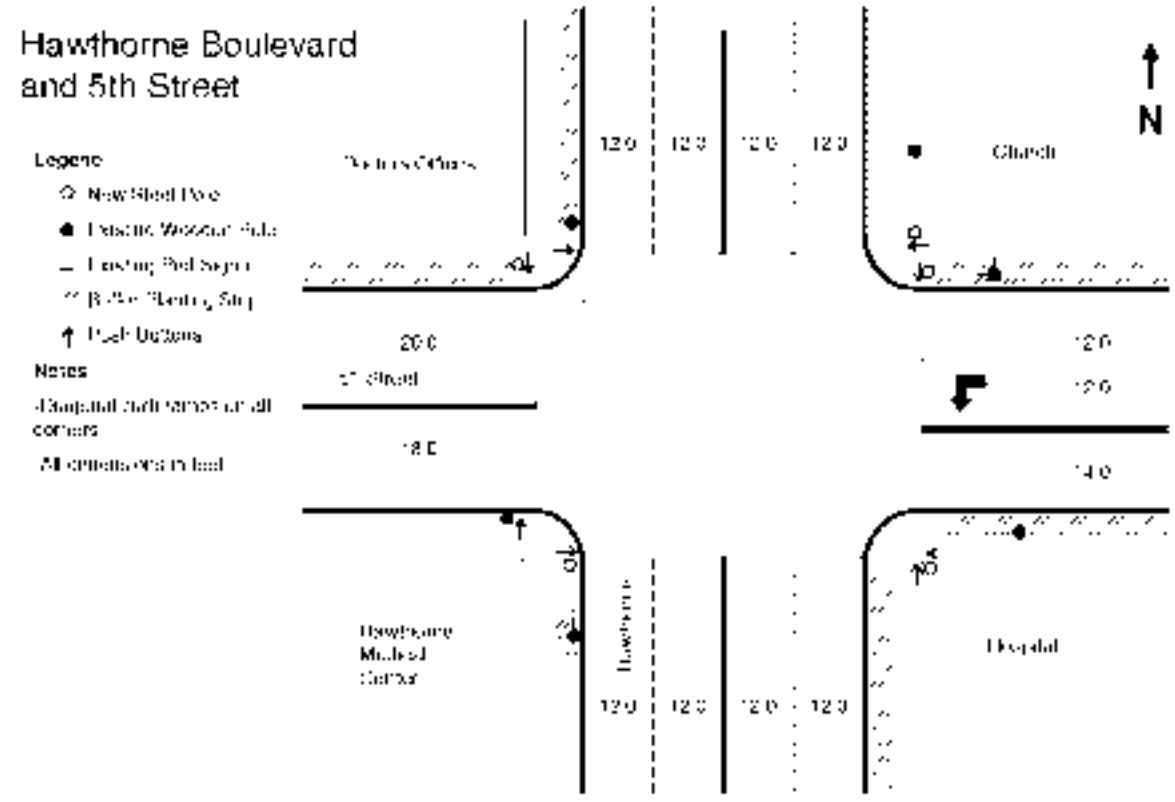

Figure 3-3. Intersection of Hawthorne Boulevard (major street) and 5th Street (minor street) in Charlotte, NC where APS devices were installed for the experiments.

AR0072224

devices with their 'standard features' for the project. The devices provided and tested are shown in Figure 3-4. These four APSs represented all that were being actively marketed in the U.S. at the onset of this research. While all pushbutton-integrated APS devices are capable of providing most of the features evaluated in this project, some manufacturers provide certain features as standard and others as optional. All APS had a pushbutton locator tone, an audible actuation indicator, an audible walk indication, a tactile arrow that vibrated during the walk interval and automatic volume adjustment. Because more than a year elapsed between data collection in Tucson and Charlotte, the manufacturers of devices B and C had developed new models, so the devices used in the two cities were not identical.

In the analysis that follows, the results are presented in terms of APS A, B, C and D. The purpose of the project was NOT to assess each product, but rather to determine the effectiveness of the specific features (e.g., pushbutton style, locator tone, etc.) on the ability of a pedestrian with visual impairments to safely cross the street. The recommended guidelines developed as a result of the research discuss the required features, which may be provided by multiple manufacturers.

Figure 3-4. Pushbutton-integrated APS units from four manufacturers were deployed for the experiments.

AR0072225

APS A

The locator tone was a bright beep (same tone as APS C) from a speaker at the pushbutton. The APS pushbutton unit was a rectangular box approximately 4 in wide x 7.1 in high x 2.5 in deep, with a 2-inch diameter rounded plastic pushbutton, a speaker below the pushbutton, and an arrow above the pushbutton. Apertures for the sound were located on the front and the side of the pushbutton speaker unit. There was an additional speaker attached to the pedestrian signal head. The tactile arrow was on a panel above the pushbutton, inside a raised circle. A relatively loud pushbutton actuation tone sounded when the button was pushed. The WALK indication was a cheep or a chirp that came from an overhead speaker installed on the pedestrian signal head. The arrow also vibrated during the WALK signal.

APS B

This APS had an electronic sounding locator tone. In Tucson, this unit had a 2-inch diameter, rounded metal pushbutton which protruded out at the bottom of the device below a rectangular sign (pedestrian symbol and print arrow); the tactile arrow was on the sign above the pushbutton. In Charlotte, the pushbutton was still rounded and at the bottom of the device, but it was plastic and the arrow was part of the pushbutton itself. A speech message, stating "Wait," sounded in response to pushing the button as a pushbutton actuation tone. If the pushbutton was held for three seconds or longer, additional information about the crossing was provided by a speech message "Wait to cross [street name] at [street name]." When the WALK signal was illuminated, a speech message "[Street name]. Walk sign is on to cross [street name]," which was repeated approximately three times. The arrow vibrated during the WALK interval in both cities, but had a noticeable clicking sound in Charlotte.

APS C

APS C had a beeping locator tone (very similar or identical to tone of APS A). The APS was a combination pushbutton and pedestrian sign, available with either a print pedestrian symbol and arrow or an informational plaque. It was basically rectangular with a rounded bottom and measured 14 in high x 6 in wide x 2 in deep. The pushbutton was in the middle of a flat tactile circle near the bottom of the device, and there was a raised tactile arrow on the pushbutton. A quiet click tone indicated to users that they had successfully pushed the button; the button was electromagnetic and did not seem to move or push. If the pushbutton was pressed for three or more seconds, it provided additional information about the crossing following the same model as APS B. The WALK signal was a speech message following the same model as used in APS B. The arrow on the pushbutton vibrated when the walk signal came on. Also, in response to an extended button press, the WALK signal and subsequent locator tone increased in volume for that pedestrian phase to provide beaconing. The housing of the device was slightly different in Charlotte than the Tucson devices.

APS D

APS D had a clicking locator tone. The entire flat smooth front panel of the rectangular box-like device was the electronic pushbutton. The tactile arrow was on top of the pushbutton device. There was a short beep to indicate that the button had been pushed to request a WALK signal. When the pushbutton was held in for three or more seconds, a pushbutton information message was heard. In Tucson, the pushbutton information message did not use the same format as the others. The message was "We want to help you cross the street." In Charlotte, the

AR0072226

information message followed the format described in description of APS B. The WALK signal was a rapid ticking sound and the arrow on top of the device vibrated during the WALK. There was a tactile crosswalk map made up of raised symbols on the side panel of the device, on the side away from the street.

APS Installation and Sound Adjustment

General Description

Although an attempt was made to find four intersections in each city with comparable features, it was impossible to find four that were truly identical, even within one city. Because APS were being installed at existing intersections, there were slight differences in location in relation to the crosswalk, curb ramps and sidewalk configuration at each intersection. APSs were installed on poles that were present at the intersection where possible. In general, Tucson uses mast arms for signal installation, while Charlotte typically uses span wire installations. This results in differences in pole and APS location. Tucson already had two pushbuttons on each corner, mounted on poles separated by at least 10 feet, usually beyond the outside crosswalk lines. Most poles were behind the sidewalk, although some were on the curb side of the sidewalk. In Charlotte, 15 additional poles were installed to locate the APS so the pushbuttons (and APS speakers) were separated by at least 10 feet on all corners on which participants began their crossings (two target corners had two APS on some poles). This separation was created in order to follow the Guidance in *MUTCD* 4E.09 *G1*. Most APSs were in line with the crosswalk lines and between one foot and 10 feet from the curb face.

Signal technicians were not familiar with all the devices to be installed. There was a learning curve in understanding the installation specifications and other requirements. Adjustments were also made after researchers arrived in each city to ensure all devices were installed and operating as designed. Particular attention was paid to alignment of arrows and speakers and adjustment of volume of the WALK messages and locator tones.

Sound Levels

There are two criteria for sound level. One addresses the distance from which sounds should be audible, and the other addresses the difference in sound between ambient sound and signals. *MUTCD* 4E.06 Guidance reads "The accessible walk signal tone should be no louder than the locator tone, except when there is optional activation to provide a louder signal tone for a single pedestrian phase." *MUTCD* 4E.09 Guidance reads "Pushbutton locator tones should be intensity responsive to ambient sound, and be audible 1.8 to 3.7 m [6 to 12 ft] from the pushbutton, or to the building line, whichever is less. Pushbutton locator tones should be no more than 5 dBA louder than ambient sound" [1]. There are several problems with implementation of this guidance, although, in practice, when attended to, it works fairly well.

The distance at which a signal is audible cannot be objectively measured. This is always a subjective measure, so the distance at which signals are heard is always subject to individual differences in perception by the individual who installs or adjusts the volume on any APS. Furthermore, audible distance is influenced by humidity, atmospheric pressure, and reflective surfaces such as buildings or controller boxes nearby. Therefore, it is never a constant even for the same individual. A locator tone that can be heard no more than 6 feet away by one person on a still day, may be heard more than 20 feet away by the same individual on a windy day.

AR0072227

Humidity, reflective surfaces nearby, and obstacles between the APS and the pedestrian can also affect the ability to hear the locator tone or signal from particular positions.

Another difficulty is that the automatic volume adjustment response is not very precise and varies among the devices because manufacturers use different algorithms. The rate of response to changes in ambient sound can greatly affect differences in perceived loudness. For example, if a loud truck passes by and there is a slight delay in the response to this loud ambient sound, the signal will still be heard as loud after the truck is well away from the intersection and the ambient sound level is lower.

In addition, the amount by which ambient sound and signal volume differ is not capable of easy measurement in the field because the individual bursts of signal sound are too short to be accurately measured by normal sound level meters. Optimal volume adjustment has not yet been adequately researched. An informal survey of jurisdictions having experience installing APS, as well as of APS manufacturers, indicates that in practice, technicians typically adjust the volume by listening to it in the relevant environment (35).

An APS may need to be carefully adjusted before the volume is perceived as loud enough by most users who are blind or who have low vision, but not too loud to be tolerated within the neighborhood. After installation of devices, researchers went to each intersection with the traffic signal technicians to check and adjust the volume on all devices. In general the volume was adjusted downward in an attempt to meet the recommendations of the *MUTCD*. Standing at each crosswalk departure location, researchers listened to each device while the signal technician adjusted the volume and consensus was reached on the volume level. APS A and APS B required adjustments at the pedestrian signal head; at times the volume would seem to change after the pedestrian signal head was reassembled. APS C and APS D are adjusted with handheld PDA type devices from the ground.

Manufacturers were available during the installation and final adjustments and provided invaluable assistance in getting devices adequately adjusted. In Tucson, all were in contact by phone or e-mail. In Charlotte, three manufacturers sent representatives to work with the signal technicians and researchers on final adjustments. Despite every effort, there were differences in perceived loudness between devices, between intersections, and between cities.

Device Functioning

Tucson

APS A did not seem to respond well to ambient sound, although the manufacturer's representative suggested that their adjustments were so little that it was imperceptible to individuals listening to the signal.

The adjustment for ambient sound also did not seem satisfactory in APS B. The locator tones seemed quite loud at all times, audible as much as 50 feet away from the devices, despite a great deal of time spent attempting to adjust the devices.

There were some variations in the functioning of APS C, which were not completely diagnosed and were inconsistent. The devices installed in Tucson were prototypes of the new model and that may have caused some problems. Automatic volume adjustment seemed to work well. However, at times, the locator tone seemed to shut off at one of the devices. There was also a slight delay in the beginning of the speech walk message after the visual WALK signal was

AR0072228

displayed. The WALK and green ball for vehicles would be displayed for approximately a second before the speech walk message began, the reason for this could not be determined although a controller or wiring issue was suspected. Near the end of the experimental trials, it was determined that the beaconing function was not working because the devices were not wired correctly for it to function.

It was necessary to change some of the settings of APS D so the locator tone would sound during flashing DONT WALK. Some devices were not functioning properly, but the experimental trials could be conducted with the devices available. The automatic volume adjustment seemed to work well.

Charlotte

Even after numerous adjustments with the manufacturer's representative, APS A didn't seem to respond to ambient sound but was quite loud all the time. The locator tone could be heard from 50 feet away.

APS B was really adjusted to be too quiet due to complaints from an office/residence on one corner. Baffles were installed to block sound traveling back toward the residential neighborhood. It was very hard to hear the locator tone when approaching the intersection along the sidewalk, although it could be heard when standing at the street waiting to cross. The APS did adjust to ambient sound within a narrow range (low maximum volume).

The locator tone of APS C seemed somewhat louder than other devices. It did vary with ambient sound but could be heard from 50 feet away as the intersection was approached. There was a building on one corner and controller on same corner that reflected the sound.

APS D needed some changes in the settings but seemed to respond well to ambient sound.

Procedure

Participants were tested in individual sessions lasting approximately four hours. Much of the time was used in traveling between intersections in an air conditioned vehicle, so the session was not excessively strenuous or stressful. Each block of trials consisted of the following:

- Participant and three researchers traveled by passenger car to the first intersection.
- After parking about ½ block from the intersection, participant and researchers walked to the starting point for each crossing (a randomized distance of 50-100 feet from the corner), where instructions were given to the participant.
- Participant made one street crossing with O&M specialist monitoring for safety, using typical O&M procedures.
- Participant and O&M specialist returned across the street.
- All returned to the car and proceeded to the second intersection.
- While riding to the next intersection, O&M specialist obtained subjective data about the participant's experience with the previous crossing.
- The same process was repeated at each of the four intersections.

AR0072229

A minimum of a half-hour refreshment break was taken between the general information and the specific information conditions. During the break, participants were familiarized with demonstration units of each type of APS.

At each intersection, participants made one crossing of the major street in a counterclockwise direction (with the street and parallel traffic on the left), and one crossing of the major street in a clockwise direction. In the no information condition, participants in Tucson made one crossing of the minor street in a counter-clockwise direction. (The no information condition crossing was always a minor street crossing.) Order of intersections and approach (clockwise or counterclockwise) were counterbalanced so each participant made two clockwise and two counterclockwise crossings in each block of trials, and crossed the major street clockwise and counterclockwise with each type of APS. No two crossings were identical.

Before beginning the experimental trials, after review of the consent form, the following information was provided to participants:

> *We're going to be traveling to different intersections. At each intersection, you will make one street crossing; then we'll go on to another intersection.*

This was followed by the following instructions, according to the information condition. For the no information condition, participants were given the following instructions before each crossing:

> *There is a street in front of you. When you come to the street, cross it the way that you usually do. If you think you don't have enough information to make the crossing please ask me for assistance. You may request assistance for any part of the street crossing task. For instance you might like to have help locating the crosswalk, aligning to cross, or knowing when the walk interval begins, or you may request to be guided for the entire task. If you think you'd ask another pedestrian for assistance, just ask me. I will intervene only if necessary for your safety.*
>
> *Researchers (names of those on site provided) will be recording information about the traffic at the intersection, your use of the pushbutton, where you began crossing from, when you began your crossing and where you end your crossing. We will ask you about what information you used to cross the street after you complete the crossing.*

Before the general information condition, a description of the features of the pushbutton integrated APS used in the study was read. The script for this description was as follows:

> *At each of these intersections, new types of Accessible Pedestrian Signals or APS are installed. These APS have some features that you might not have experienced before.*
>
> *First, all of them have what is called a locator tone. Locator tones are intended to notify you that there is a pushbutton at the intersection and to help you in finding the pushbutton. Some individuals have found that they are able to hear the locator tone while crossing, as they approach the other side of the street, and use it for directional assistance. The locator tones on these APS are different tones, but have one quality that is standardized: they repeat at a repetition rate of once per second.*

AR0072230

The WALK indication on these APS may be provided by a speech message, or a rapidly repeating tone that is just a faster version of the locator tone, or a cuckoo or chirp. Both the walk indication and the locator tone may get louder or softer, depending on the sound of traffic. Each device also has an arrow that points toward the crosswalk it controls and in the direction of travel on the crosswalk. That arrow vibrates when that crossing has the WALK signal. That may be useful when you are having trouble hearing the WALK indication.

There are some other features that these APS may have; not all of them have all of these. They may provide a tone or a speech message to let you know that the button has been pushed. There may be a tactile map of the crosswalk on the side of the device.

They may have a feature called extended button press that calls additional features when the button is pressed for three seconds or more. If you hold the button in, you may get a louder signal and/or a speech message that provides additional information about the crossing.

The whole description, or any part of it, was read again if participants had questions, or requested a review.

Before each crossing in the general information condition, the following instructions were provided to each participant:

There is a street in front of you. At all of these crossings, it is necessary to push the pedestrian pushbutton to get the walk signal. There is an accessible pedestrian signal for the crosswalk. Do your best to figure it out and use its information to help you make your crossing.

If you think you don't have enough information to make the crossing, please ask me for assistance. You may request assistance for any part of the street crossing task. For instance, you might like help locating the crosswalk, aligning to cross, or knowing when the walk interval begins, or you may request to be guided for the entire task. If you think you'd ask another pedestrian for assistance, just ask me. I won't tell you how to use the Accessible Pedestrian Signal, but will help you with other aspects of the crossing if you ask. I will intervene only if necessary for your safety.

Researchers (Barlow and Huang or Barlow and Carter) will be recording information about the traffic at the intersection, your use of the pushbutton, where you begin crossing from, when you begin your crossing and where you end your crossing. We will ask you about what you used to cross the street after you complete the crossing and ask questions about your perception of the APS or this intersection.

Before beginning the crossings in the specific information condition, participants and researchers took a break in a quiet room with refreshments. During this time, each participant was familiarized with functioning demonstration units of each APS installed for the research. A description of the pushbutton, rather than device labels or manufacturers' names, was used in discussing the devices. APS A was referred to as the one with the round plastic pushbutton; APS B was the one with the round metal pushbutton in Tucson and one with the plastic pushbutton

AR0072231

with the arrow on it in Charlotte. APS C was the one with the flat metal pushbutton with the arrow on it and APS D was the one with the flat panel pushbutton. Participants were allowed to examine each device, and they were shown the pushbutton, the tactile arrow, and the tactile map of the crosswalk if available. They could hear the actuation indicator tone or message, the pushbutton locator tone, the walk indicator, and the pushbutton information message if available. The ambient sound response of the devices was explained and demonstrated. The researcher also confirmed participants' understanding of the tactile arrow, by asking each person to point in the direction the arrow was pointing. Those who were incorrect were shown the correct orientation of the arrow and demonstrated their understanding. They were encouraged to ask questions about the devices and their features.

Before each crossing in the specific information condition, each participant was told which type of APS was installed at that crossing, and the features of that type of APS were reviewed.

> *There is a street in front of you. There is an Accessible Pedestrian Signal for the crosswalk. You've now been introduced to the various signals and I'll just review briefly some of the features of this one. As at previous crossings, if you need assistance with any part of the task, just ask me. I will intervene only if necessary for your safety. We will ask you about what you used to cross the street after you complete the crossing and ask questions about your perception of the APS at this intersection. I'll briefly review the features of the device installed here, followed by appropriate description from a script.*

Each description was different to fit the device installed at that intersection. For example,

- *This is the one with the flat panel pushbutton.*
- *It has a tapping or clicking locator tone.*
- *The entire flat front panel is the pushbutton. The raised part at the bottom is a light that lights up when the button has been pushed. You will hear a short beep to indicate that you have pushed the button.*
- *There is an arrow on top of the pushbutton device that indicates the direction of the street that it controls and vibrates during the walk phase.*
- *There is a tactile crosswalk map on the side panel of the device, on the side away from the street.*
- *If you hold the pushbutton in for more than three seconds, you will hear a speech pushbutton information message.*
- *When the walk signal comes on, you will hear a rapid ticking sound.*

Following completion of all crossings, participants were asked to use a Likert scale to rate the extent of their agreement with four questions. These subjective data allowed for comparing the four APS types in terms of interface issues, special features, and beaconing.

In Tucson, in the no information condition, all crossings were of the minor street. Traffic on the major street was relatively steady even in off peak hour conditions. In Charlotte, it became clear during piloting that the distance and travel time between intersections was too great

AR0072232

to complete crossings in all three conditions in less than five hours. The no information condition was dropped due to these time constraints.

RESULTS AND DISCUSSION

Results have been organized according to: 1) use of the pushbutton, 2) results most closely associated with crossing timing, 3) results most closely associated with wayfinding, and 4) subjective results. Within the first three sections, results are also broken down by information condition and city, and by device and city.

As previously discussed, there were differences between Tucson and Charlotte in intersection characteristics such as the volume of traffic, width of streets, location of pedestrian pushbuttons, as well as minor differences in some of the devices installed in the two cities. There were also differences in the procedure followed. Therefore, data were analyzed separately for each city, and not combined. Any statistical comparison between cities would be confounded by these differences; therefore no inferential analyses of differences between cities were conducted.

Inferential analysis of all measures at all levels of all factors was made difficult by a large amount of systematically missing data. For example, if 16 of 20 participants searched for the pushbutton at a given intersection, and 10 found it, there were data on use of the pushbutton features for the 10 participants who found the pushbutton. If 4 participants asked for assistance in finding the pushbutton (i.e., did not find it independently), there was information on the use of the tactile arrow and use of the extended button press for 14 participants, thus, 4 in addition to the 10 participants who found the pushbutton independently. For the 2 who searched and did not find a pushbutton or request assistance finding one, and for the other 4 participants who did not search for the pushbutton, there is no pushbutton-related data available.

The data were analyzed in three primary ways. For those variables that provided interval level data (e.g., latencies), median replacement was used to replace missing data. Appropriate inclusion criteria were then determined for investigating each question of interest. For example, in order to ask which of the various devices allowed for more rapid onsets of crossing following the audible signal, it was statistically appropriate to include only those participants who had used all of the pushbuttons in a given information condition and thus had available WALK information to use at each intersection in that information condition. Listwise deletion was used to eliminate those individuals from the analysis who did not meet the inclusion criteria, and paired-samples t-tests or repeated-measures ANOVAs were conducted.

A second method was used to analyze data pertaining to information condition (ignoring device differences) or device differences (ignoring information condition). In order to determine whether observed differences were statistically significant, it was necessary first to transform the data into interval level. The following is an example of how this was done. In order to investigate whether or not participants were more likely to use the tactile arrow feature on one device than another, a new variable was calculated for each device type. Imagine that for a given device type a participant did not use the feature in the 'no information condition,' but did in the 'general' and 'specific information' conditions. This individual thus used the feature two-thirds (67%) of the time for this device. Percentages were calculated in this way for each device and for each participant. The data could thus be treated as interval level, and either a repeated-measures ANOVA or a paired samples t-test could be used to look for differences between the devices.

AR0072233

Finally, basic descriptive statistics are provided for many of the categorical level variables. Once again inclusion criteria were established for each category (e.g., only those participants who searched for the pushbutton) and then percentages were calculated for the number of these participants who used a certain feature or performed in a given way.

Interpretation of data across information conditions is always confounded somewhat by the possibility of learning about the particular intersections. The no information, general information and specific information trials could logically only take place in that order; that is, order could not be randomized or counterbalanced. However, procedures were used that minimized the likelihood that participants learned specific crosswalk or intersection characteristics, or the locations of APS at particular corners. Therefore significant differences across information conditions are most likely due to the effect of the level of information with APS devices unless otherwise noted. In the general information condition, these participants (most of them who used the APS at most of the crossings) gained some 'hands on' familiarity with the APS. In the specific information condition, this was supplemented by participants' use of demonstration devices of each APS, as well as by knowing which APS would be present at each crossing, as they prepared to make that crossing. The additional information was consistent with the intent of that condition, which was to represent the common situation in which pedestrians who are blind or visually impaired know what kind of an APS they will find at a crossing, and know its features. While many pedestrians who are blind or who have low vision travel novel routes at least occasionally, most travel by these pedestrians, like travel of pedestrians who have unimpaired vision, is on familiar routes. Also, many jurisdictions prefer to work with certain manufacturers and may have installed a number of devices with similar or 'standard' features in their jurisdiction, so it is not unusual for pedestrians who are blind to have had experience with the type or types of devices installed in their area.

Use of the Pushbutton

Finding and Using Pushbutton

Data were collected on searching for the pushbutton, time to find and use the pushbutton, using the wrong pushbutton, correctly rejecting or incorrectly using the wrong pushbutton, use of the tactile arrow, use of the tactile map, use of the extended button press feature, and listening to the intersection information message resulting from the extended button press. Results are reported for only the most informative measures, including searching for the pushbutton, finding the pushbutton, using the wrong pushbutton, use of the tactile arrow, use of the extended button press feature and use of the tactile map.

In Tucson, at many intersections throughout the city, signals are installed on mast arms and each corner has two pushbuttons on poles that are separated, and located near the end of each crosswalk. Use of a pushbutton is required to actuate the WALK signal for both the major and minor streets at most signalized intersections. Thus, participants should have had prior experience crossing at intersections where pushbuttons were installed in predictable locations. However, participants were asked, at the end of all trials, whether they usually use pushbuttons when they are present. Nine of 20 said they usually do not use pushbuttons, while six said that they usually do, and the other five said they use pushbuttons only when they know that the pushbuttons are there or it is a particularly difficult intersection.

In Charlotte, which has many curving streets resulting in skewed intersections, it is very common to have two pushbuttons on the same pole, or to require pushbutton actuation for only

AR0072234

the major street at an intersection. Two pushbuttons on one corner are occasionally mounted on two separate poles, one at the end of each crosswalk, but that is not common. Therefore participants may not have had experience with consistent pushbutton placement, and may have been familiar with situations where pushbutton actuation was not necessary for all crossings. Because no data was collected in the no-information condition in Charlotte, we have no data indicating use of pushbuttons. However, following all experimental trials, participants were asked whether they typically used pushbuttons when crossing streets. Seven out of 20 said they usually do not use pushbuttons, six said that they usually do, and the other seven said they do only when they know that the pushbuttons are there. Also, in related research in Charlotte, UNC sixteen blind participants crossing at complex, unfamiliar signalized crossings, without APS, did not look for pushbuttons on any of the 64 crossings at which pushbutton actuation was necessary.

Information Condition

Tucson – Based upon participants' reports of their typical pushbutton use, it is not surprising that in the no-information condition in Tucson, only five participants looked for the pushbutton on every crossing, and at each of three intersections, one additional person (different people) looked for the pushbutton. Of the 28.8% of 80 trials on which participants looked for the pushbutton, the correct pushbutton was found and used on 83% of trials, while the incorrect pushbutton was used on 13% of trials (*see Table 3-1*). A few participants requested assistance in finding the pushbutton, and then pushed it. So the button was pushed on more trials than it was found independently.

Information condition appears to have had a significant effect on participants' choosing to search for the pushbuttons. In trials following general information, participants searched on 97.5% of trials, and participants searched on 100% of trials following specific information. The overall analysis is significant ($F(2,38) = 51.37$, $p<.001$), as is the comparison between no information and general information conditions ($F(1,19) = 49.76$, $p<.001$).

There are several likely explanations for the large increase in looking for pushbuttons between the no information and general information conditions. First, a possible cause of the low incidence of looking for the pushbutton in the no information condition may have been that all crossings in this condition were across the minor street. Because pedestrian timing was concurrent, and because there was always adequate traffic on the parallel street, there was sufficient information from vehicular flow for participants to cross without using the pushbutton.

TABLE 3-1 Pushbutton measures by information condition – Tucson

AR0072235

Second, prior to the general information trials, participants were told that pushbuttons were needed to activate the WALK signal and its associated timing at every crossing. Finally, prior to the general information trials, participants were told that all pushbuttons would have a locator tone coming from the pushbutton, so they knew they could use the sound of the locator tone to help them find the pushbutton. Therefore, the increase in looking for the pushbutton (as well as in use of the pushbutton—see below) was likely attributable to several factors, most of which are amenable to increased training in the function of signalized intersections, with emphasis on the use of a pushbutton, which is often required to actuate a pedestrian timing of adequate length. The presence of a locator tone to inform pedestrians of the presence of a pushbutton and its location may also influence the use of pushbuttons, since five participants in Tucson and seven in Charlotte said they only used pushbuttons if they knew they were there and where to find them.

The looking for the pushbutton variable was used as an inclusion variable for analysis of the use of the wrong pushbutton, and the interaction with the pushbutton variable (i.e., those who found the pushbutton with or without assistance) was used as an inclusion variable for the analyses of specific pushbutton features (i.e., use of arrow, extended push). Where these criteria were applied across all three levels of information, the result was too few participants to provide sufficient power. This is the result of having so few participants look for the pushbutton in the no information condition. Using the same inclusion criteria but restricting the analysis to the general information and specific information conditions where the number of participants who searched for the pushbuttons is much higher, there was no significant difference in participants' looking for the pushbutton, finding the pushbutton, using the wrong pushbutton, or using the tactile arrow. However, the increase in use of the extended button press, from 38.8% to 77.8%, was significant ($\chi^2(1) = 2.750$, $p \leq .05$).

Although there was no significant difference between the general and specific information conditions with regard to the number of participants who pushed the wrong pushbutton, it is nonetheless interesting to consider the implication of the use of the wrong pushbutton. The primary reason for inclusion of the tactile arrow on APS is to enable pedestrians who are blind or who have low vision to accurately determine which pushbutton controls which crosswalk. In Tucson, across the general and specific information conditions, participants looked at the arrow on the incorrect pushbutton on 25 trials. However, on 100% of these trials they correctly rejected the incorrect pushbutton (*see Table 3-2*).

Charlotte – In Charlotte, where no data was collected in the no-information condition, increasing familiarity from general information to specific information condition had no effect on participants' looking for the pushbutton. With one exception, every participant searched for the pushbutton on every trial. This was similar to the result from Tucson. However, increasing information between the general information and specific information conditions did lead to participants finding the pushbutton on a greater percentage of trials, which was not the case in

TABLE 3-2 Percentage and proportion of trials on which participants correctly rejected the incorrect pushbutton (i.e., checked the tactile arrow on the incorrect pushbutton, and then chose not to push that button), by information condition

City	General Information	Specific Information
Tucson	100% (12/12)	100% (16/16)
Charlotte	52% (17/33)	80% (24/30)

AR0072236

Tucson. As shown in Table 2-3, 19 participants searched for the pushbutton on every trial, and participants found the button on average 67.1% of the time following general information, while the same participants found the button on average 84.2% of the time following specific information ($t(18) = 2.233$, $p<.05$).

There was a trend towards increasing information leading to lower use of the incorrect pushbutton. Following general description, participants used the wrong pushbutton on average 25% of the time. Following specific information, participants used the wrong pushbutton only 10.3% of the time. This difference approaches significance ($t(16) = 1.975$, $p = .066$).

Use of the incorrect pushbutton presented a very different picture in Charlotte than in Tucson (see Table 3-3). In Tucson, participants looked at the arrow on the incorrect pushbutton on 28 trials, but they always correctly rejected the incorrect pushbutton. However, in Charlotte, participants looked at the arrow on the incorrect pushbutton on 63 trials, and correctly rejected it on only 41 trials (65%). While the improvement in overall use of the wrong pushbutton from the general to the specific information condition approached significance, participants still failed to reject the incorrect pushbutton on 30% of trials (6/20) following specific information. To observers, participants in Charlotte seemed less skilled, particularly in orientation, which may have related to the generally curving and hilly streets of the area as contrasted to Tucson's square flat grid pattern. The confusion of pushbuttons seemed to be related to the participants' lack of strategies to maintain their orientation; some would completely turn to face the street parallel to their travel path, while examining the arrow on the device, and then push the button and "line up" to cross the parallel street.

The increased information also led to significantly greater use of the tactile arrows from 86.7% of trials following general information, to 100% of trials following specific familiarization ($t(14) = 2.48$, $p<.05$). Increased information also resulted in a significant increase in use of the extended button press feature (from 17.7% to 71.1%; $t(14) = 6.804$, $p<.001$).

Devices

Tucson – When considering APS devices with regard to locating and using pushbuttons, and when collapsing across information conditions, there is a slight trend such that the percentages of participants finding the correct pushbutton was higher for APS A and B than for

TABLE 3-3 Pushbutton measures by information condition – Charlotte

Example: On average, each participant used the arrow on 86.7% of crossings in the general information condition.

AR0072237

APS C and D. This difference did not appear following the specific information condition (see *Table 3-4*). Additionally, a slight trend in Charlotte was in a different direction.

APS D resulted in the highest rates of using the wrong pushbutton in the specific information condition; however there were not large differences in this regard, and there were no trials on which participants failed to reject the incorrect pushbutton after checking the arrow, so the arrow was apparently well understood. These results may suggest that it was more difficult to locate the arrow on APS D than on the other APS, but not more difficult to "read" the arrow. The arrow was on top of the APS, while it was on the front surface of all the other APS. The high rate of using the wrong pushbutton, attributable entirely to participants who did not reference the arrow, may also reflect the location of the APS D device in Tucson, for the parallel (uncrossed) street, which was on a pole that was within the approach sidewalk rather than at the back of the sidewalk as most others were.

A fairly clear trend emerges when examining the data for use of the tactile arrow on the correct device. In the general information condition, participants used the tactile arrow 76% and 89% of the time on APS A and APS C, respectively. On APS B and APS D, the equivalent rates were 61% and 56%, respectively. In the specific information condition, this trend continued. APS A and C both resulted in 89% using the tactile arrow, while APS B and D resulted in 68% and 56% using the tactile arrow. This trend does not appear in the Charlotte data, suggesting that arrow use is therefore unlikely to be due to differences in device characteristics. However, the arrow position on APS B was different between the two cities and may help explain the much higher rates of use in Charlotte. Furthermore, although arrow use for APS D was higher in Charlotte than in Tucson, it remained the lowest between devices within Charlotte.

It was possible to use the data on use of the tactile arrow to compute inferential statistics regarding device differences by collapsing across the general and specific information conditions, as described near the beginning of the results section. This required using only those participants who interacted with all four pushbuttons in both conditions, providing a sample of 12 participants. The resulting analysis is significant ($F(3, 33) = 4.64$, $p<.01$). The average percentages match the frequency analysis from above quite well, APS A 85.4%, APS C 87.5%, APS B 66.7%, and APS D 50.0%. A comparison of the two devices with the greatest difference, APS C and APS D, is significant ($F(1, 11) = 9.00$, $p<.05$). APS C was only marginally better than APS B ($F(1, 11) = 4.66$, $p = .054$). However, it is unclear if there is a meaningful difference between device characteristics, as an identical pattern of results did not appear in the Charlotte data.

There is no clear picture with regard to the use of the extended pushbutton features of the three devices in which they were present.

On the whole, the Tucson data associating devices with use of the pushbutton does not present a very clear picture. There were not large differences in the numbers of participants finding the various APS devices under the general or specific information conditions. The one clear conclusion is that the tactile arrow was more likely to be used on the APS C devices than on APS B, and the trend suggests more so on both APS C and A devices than on APS B and D.

**** Missing data

NA Feature not available on device

AR0072239

The arrow on APS C was on the pushbutton and the arrow on A was large and the main feature on the front of the device.

Charlotte – In Charlotte, it is also difficult to say anything about differences in rates of finding the pushbutton attributable to device (*see Table 3-5*). By the time participants were familiarized with the devices, the rates were fairly similar. In the general information condition, APS C led to the highest rates of finding the pushbutton (79%), while APS A resulted in the lowest (53%). These differences may be attributable to the large numbers of participants who found and used the incorrect pushbutton at APS A and quit looking for a pushbutton, even when they checked the arrow and it pointed the wrong way. In the specific information condition, all devices resulted in rates of finding the correct pushbutton between 80% and 90%. There were unavoidable differences in volume setting between devices in Charlotte. The locator tones of APS A and C were louder than the others, and several participants complained about the sound of APS C echoing off of a nearby building.

In the general information condition, about 20% of participants used the wrong pushbutton when at intersections with APS D, B and C, and 43% of the time when using APS A. The intersection with APS A was also the one with the lowest rates of use of the correct pushbutton. This may have been due to an idiosyncrasy in locations of APS A devices at this intersection: one was close to the crosswalk, making the sound echo, and the other was behind the sidewalk.

However, by the time the participants had received specific information, no more than two participants used the wrong pushbutton at any given intersection. The most noteworthy thing that appears from the data following the specific information is that some participants who checked the tactile arrow nonetheless pushed the incorrect button. The fundamental problem here may be a lack of understanding of arrows, even with the demonstration of arrows that was provided. It could also be because the demonstration was at a corner, not on a barrier, and no information was provided regarding the usual geometric relationships between corner, crosswalk, and pushbutton. Some participants seemed to decide that the correct pushbutton was always on the right, or always on the left, when, in fact, the side of the pedestrian on which the pushbutton was located was determined by whether the parallel street was to participants' left or right and varied depending on whether the pedestrian was making a clockwise or counterclockwise crossing (part of the counterbalancing scheme).

Possibly of more interest is the difference in occurrence of situations in which participants checked the wrong pushbutton and then decided it was incorrect (correct rejection). Following general information, the APS D devices led to an 80% correct rejection rate, APS B a 57% rate, and the APS C and A devices around 50%. Following specific information, the results did not closely match those following general information. Although APS C had the lowest rate of correct rejection, there were only 3 participants who ever checked the wrong pushbutton and thus this is not a stable measure. For the other three devices, the rates were at or above 75%, with APS A leading the category with 90% correct rejections.

It should be noted, in examining these results and comparing to Tucson, that APS B had been significantly redesigned and the arrow was actually on the pushbutton rather than above the pushbutton in Charlotte. This seems to have affected the use of the tactile arrow on the device. With regard to tactile arrow use following general description, APS A, B, and C resulted in 88% or higher rates of use. Only 65% of participants used the feature on APS D. Following specific

***** Missing data—2 participants

NA Feature not available on device

familiarization, the rate on APS D was up to 95% and all other devices reached 100% usage rates. This may indicate that when pedestrians who are blind or visually impaired know what kind of arrow they will encounter, they are quite likely to use it at unfamiliar crossings, or it may simply be that following specific information, they understood arrows better and were more inclined to check them out. The rate of arrow usage in Charlotte appears to be somewhat higher than that for Tucson, but pushbutton location was fairly consistent in Tucson. In Tucson, some participants may have decided that they could be sure which crosswalk was controlled by the pushbutton solely on the basis of location of the pushbutton. However, even with the higher rate

AR0072241

of arrow usage in Charlotte, participants pushed the wrong button, after using the arrow, on more trials in Charlotte than in Tucson (*see Table 3-5 above*).

The rates of use for the extended pushbutton feature look similar to those for the tactile arrow. In the general information condition, 6% of participants (1 participant) used the extended press feature on APS D, while .22% and .36% used the feature on APS B and C, respectively. Following specific information, the rates of use were equivalent for APS B and D (.65% ea.), but were used slightly more on APS C (.80% ea.

Latency to Find and Use Correct Pushbutton (Pushbutton Latency)

Tucson

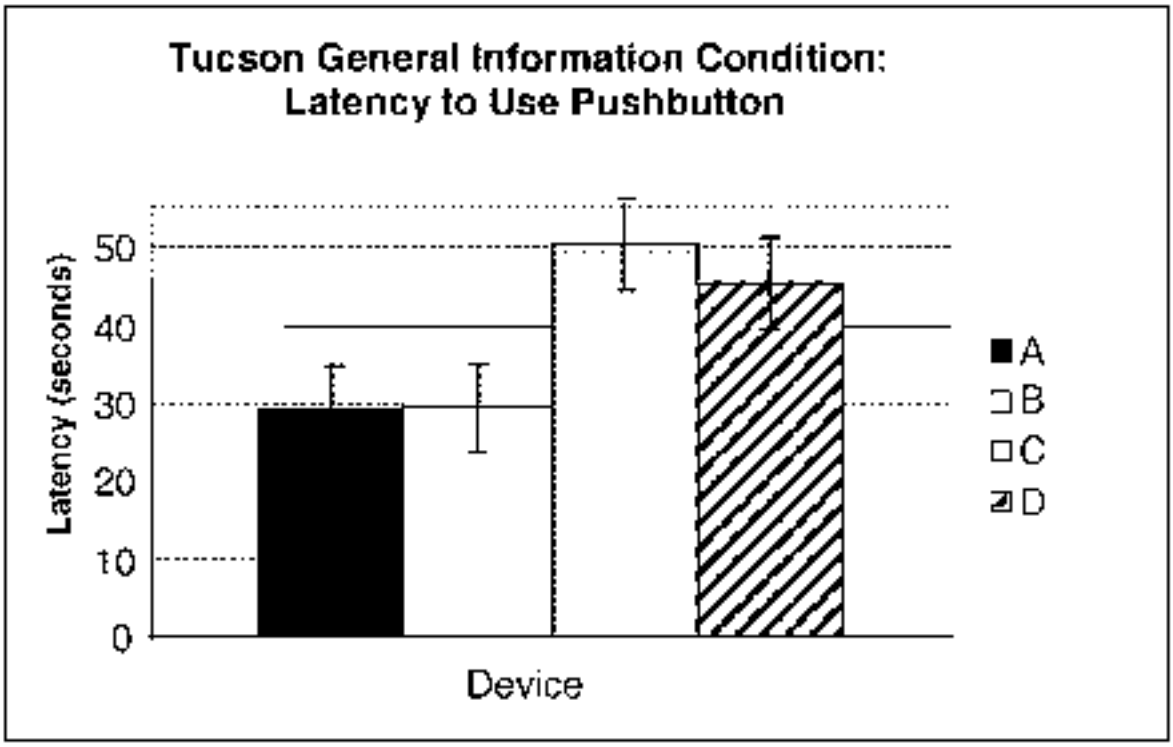
With regard to time to locate the pushbutton in Tucson, there were so few participants who looked for and found the pushbutton in the no information condition, that no statistical tests could be done for either information condition or device.

In the general information condition, median replacement resulted in the replacement of four to six data points for each device. (Since all analyses were conducted using paired-samples or repeated measures methods, the estimates of error used in the t-tests and ANOVAs are not a matter of variability around the mean but rather a measure of covariability across conditions. Therefore, this method of data replacement does not artificially inflate power.) The subsequent ANOVA revealed significant differences attributable to device. The mean amount of time to locate and use the correct pushbutton varied between 29 and 50 seconds, with the times for APS A and B being similar (28.95 and 29.55 seconds, and those for APS C and D being longer, 50.30 and 45.50 seconds. The overall analysis was significant ($F(3,57) = 3.56$, $p<.05$). A comparison between the averaged latencies on APS A and B devices, and the averaged latencies on APS C and D revealed a significant difference, ($F(1,19) = 11.12$, $p<.01$). Finally, no statistically significant difference was found between APS C and APS D (*see Figure 3-5*). The difference between these two pairs of devices, in time to locate and push the correct pushbutton, may be that APS A and APS B had very typical, rounded, pushbuttons, while the pushbuttons of APS C and APS D were unique. Although it is impossible to differentiate, it is possible that participants found all devices in approximately equal amounts of time, but it then took longer to find the actual button for APS C and D.

In the specific information condition, the use of median replacement resulted in the replacement of between three and six data points per device, and the ANOVA revealed no significant differences between latencies ($F(3,57) = 2.706$, $p>.05$). The lack of significance clearly differs from the analysis in the general information condition, and furthermore, a closer look at the means reveals a different pattern than was present in the general information condition as well. With specific information, the means for the APS A, B, and C are very similar, and APS D had a trend towards faster latencies (*see Figure 3-6*).

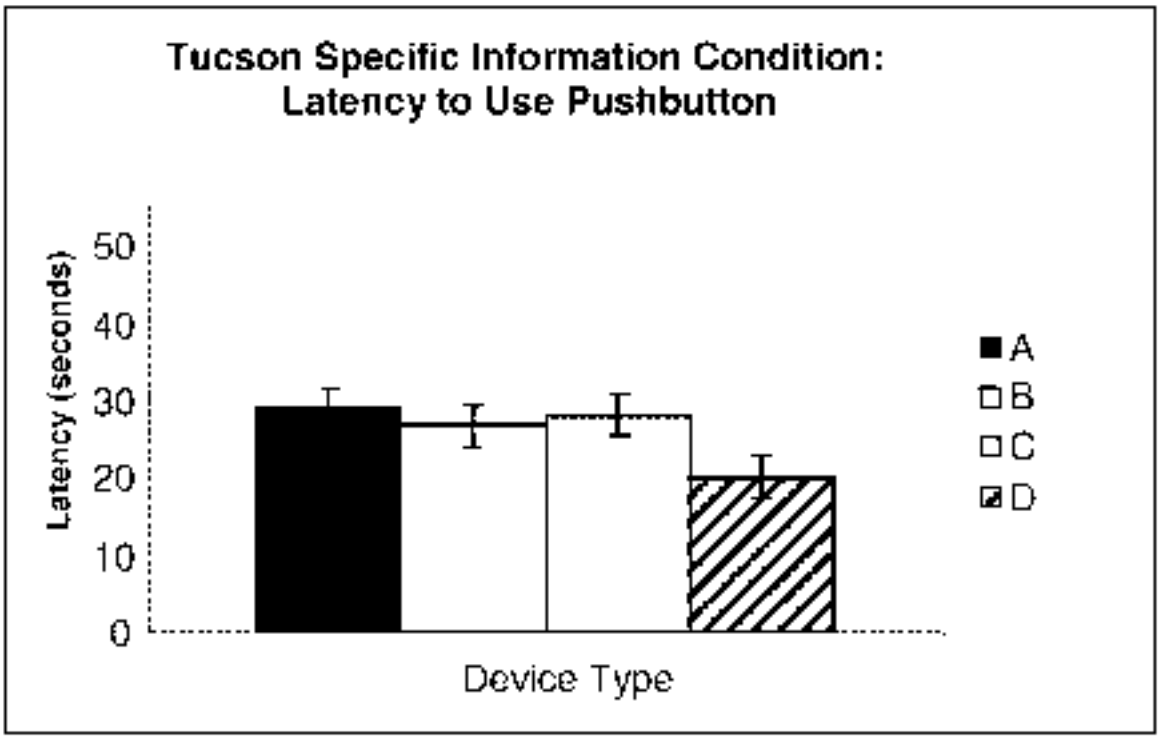
Looking from one Tucson figure to the other, it appears that there is a considerable improvement for the APS C and D buttons between the general information and specific information conditions. For the APS C and D, this does represent a significant improvement ($t(19) = 2.32$, $p<.05$, and $t(19) = 4.85$, $p<.001$, respectively). Furthermore, it appears that the average latency to find the pushbutton has decreased between the general information and specific information blocks. This is statistically confirmed ($t(19) = 4.147$, $p<.001$) and reveals

AR0072242



F(3,57) = 3.560, p≤.05, N=20

Figure 2-5. Latency to use the pushbutton: general information condition – Tucson.



F(3,57) = 2.106, p≤.05, N=20

Figure 2-6. Latency to use pushbutton: specific information condition – Tucson.

AR0072243

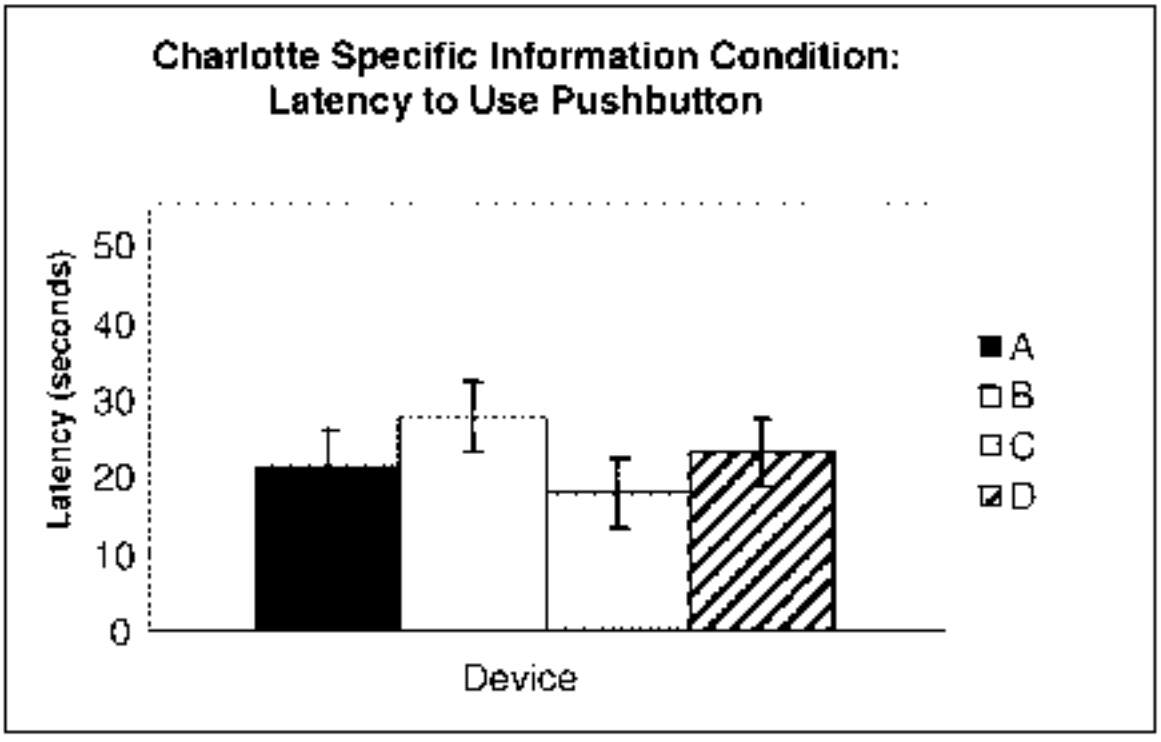
that the average amount of time to use the pushbutton in the specific information condition (25.70 sec) is faster than that in the general information condition (38.58 sec).

The measure of latency to find and push the correct pushbuttons includes any time taken to use the tactile arrow on the incorrect APS and to reorient it and to find and push the pushbutton on the device. Therefore the improvement in latency for APS C and D may not indicate a decrease in latency for finding the pushbutton pole and the device, but a decrease in time taken to actually locate and push the button on the device. APS C and D both had unique pushbuttons, so until participants had specific hands-on familiarization, and knew what sort of pushbutton they would encounter at each intersection, they took some time in deciding what part of the device to actually push. This was particularly evident to researchers in the case of the flat panel pushbutton of APS D.

Charlotte

With regard to time to locate the pushbutton in Charlotte, although more than 80% of participants found each pushbutton individually, only five participants found all four pushbuttons. Thus, the limited amount of latency data available in the general information condition makes running any within subjects statistical tests inappropriate.

Analysis of data from the specific information condition required median replacement of up to four missing values per device and revealed no significant differences attributable to device ($F(3,57) < 1.00$). (see *Figure 3-7*). The average amount of time to use the pushbutton following



F(3,57) < 1.00, N=20

Figure 3-7. Latency to use pushbutton: specific information condition – Charlotte.

AR0072244

the specific information was similar between the two cities (22.4 seconds in Charlotte and 25.7 seconds in Tucson).

In comparing the specific information results across the two cities, both analyses are non significant, and the trends are not the same, but the average amount of time to find the pushbuttons is rather similar. One reason for the difference in trend may be that pushbutton-integrated APS were more familiar to the Charlotte participants; there are a number of pushbutton-integrated APS in Charlotte, and none in Tucson.

Crossing Timing

Measures associated with crossing timing included time to begin crossing (Starting Latency), interval during which participants began crossing (Start Interval), interval during which participants finished crossing (Finish Interval), and whether participants finished crossing before the onset of perpendicular traffic (Finish Before Perpendicular). The longer participants delayed starting to cross, the greater was the likelihood that they would still be in the crosswalk when perpendicular traffic received a green signal.

Information Condition

Tucson – There was only one participant who began each crossing without assistance and who had the audible WALK signal for all 12 crossings. Furthermore, there were only four participants who had the audible WALK and crossed independently at each of the eight crossings in the general and specific information blocks. Therefore, analyses of starting latency were undertaken with all 20 participants while keeping in mind the potential confounds. There are differences in measures of crossing timing across information conditions; these significant differences are exclusively between the no information condition and both the general information and specific information conditions, which did not differ from one another on any of these measures.

The overall analysis of differences in starting latency across information conditions, using 19 participants to the instance of missing data), is significant ($F(2,38) = 11.580$, $p<.001$). No information differs from both general information ($F(1,19) = 9.699$, $p<.01$), and specific information ($F(1,19) = 16.307$, $p<.001$), which are not significantly different from one another (*see Table 3-6*).

TABLE 3-6 Measures of crossing timing by information condition – Tucson (N = 19)

* Significant at $p < 0.001$

[1] Latency in seconds measured from the onset of WALK

[2] Each value represents the average percentage of trials within the given block in which each participant performed accordingly.

AR0072245

There are no significant differences on measures of crossing timing between the general and specific information conditions, and the improvement in all measures of crossing timing between the no information and the general and specific information conditions is likely attributable to increasing use of the pushbutton and thus presence of the audible WALK signal. In the no information condition, in 80 possible trials, participants used the pushbutton on only 16 trials. By the general information condition this had increased to 66 of 80 trials. However, in the no information condition, participants were always crossing a minor street and had good traffic cues indicating the onset of vehicular green, which was concurrent with the WALK signal if it had been present. In the absence of the WALK signal, the length of the parallel vehicular green nonetheless allowed ample time for most participants to complete their crossings before the onset of perpendicular green. The picture might have been different if participants were crossing a major street instead of a minor street on crossings in the no information condition. Note, however, that latency in the no information condition was more than five seconds, even though participants were crossing the minor street in the presence of good vehicular cues. If greater use of the pushbutton, and consequent presence of the WALK signal, accounts for increased starting during the WALK interval, starting during the WALK interval may be increased by participants knowing there is a pushbutton and being able to find the pushbutton and the same training as suggested under Use of the Pushbutton.

Of concern to the researchers in the no information condition were comments of some participants who seemed to be trying to use the locator tone changes in volume (in response to ambient sound) as a walk indication. These participants generally did not look for or push the button, but heard the audible pushbutton locator tone, and without knowledge of locator tones and their function, made an assumption that it was some kind of walk indication. This misunderstanding of the ambient sound adjustment and of the locator tone could lead to dangerous crossings. Where pushbutton integrated devices with locator tones are installed, a concerted effort should be made to provide information about the devices to pedestrians in the community.

Charlotte – In Charlotte, there were nine participants who crossed independently and had audible WALK signals at every crossing. Analysis of crossing timing measures with these nine individuals revealed no significant differences attributable to level of information (see *Table 3-7*).

TABLE 3-7 Measures of crossing timing by information condition – Charlotte (N=9)

	General information	Specific information	t(8)
Starting Latency in sec. **	3.19	2.82	1.214
Started during WALK *	86.21%	94.44%	1.355
Completed during WALK or FDW *	68.89%	77.78%	1.170
Completed before perpendicular Green *	91.67%	97.22%	1.512

* Significant at $p < 0.05$

** Latency in seconds measured from the onset of WALK.

* Each value represents the average percentage of trials within the given information condition in which each participant performed accordingly

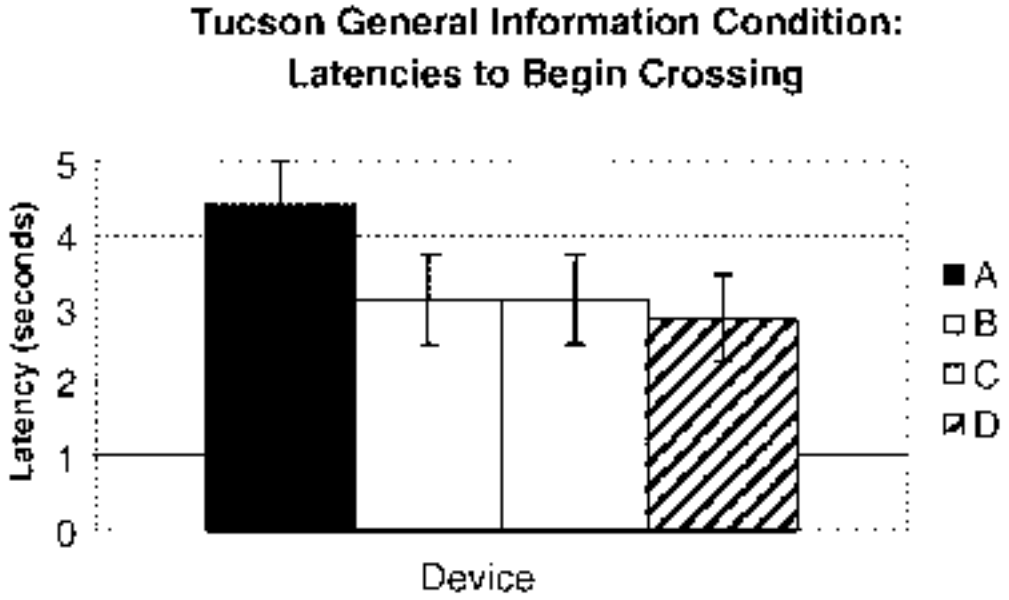
AR0072246

When analyzing measures of crossing timing, including all 20 participants, as was done with the Tucson data, keeping in mind the possible confounds, all measures showed significant differences (results not presented here). This lends support to the hypothesis that significant differences present in the Tucson analysis were the result of participants' increasing use of the pushbuttons and thus higher rates of audible WALK signals, rather than increasing understanding of the APS features.

Device

Tucson Data were not analyzed by device for the no information condition, as there was little use of APS. However, data for the general information condition was analyzed using the presence of audible WALK information at each intersection as the inclusion criterion, which resulted in only seven participants. The overall analysis failed to achieve significance ($F(3,18) = 1.390$, $p>.05$) – (*see Figure 3-8*).

In order for comparisons between devices to be meaningful, it is important that the conditions be as similar as possible in every other respect. Therefore, participants who were included in the analyses of measures of crossing timing entered all four streets independent of assistance in determining crossing timing and had the audible WALK signal from each of the four devices during the given information condition. This resulted in an analysis of data from 7 participants in the general information condition and 17 participants in the specific information



$F(3,18) = 1.390$, $p>.05$, $N = 7$

Figure 3-8. Latency to begin crossing by device: general information condition – Tucson.

AR0072247

condition. Occasionally, one of these individuals would be missing a piece of data, and descriptive statistics were calculated from the remaining individuals (see *Table 3-8*).

The numbers above represent those who had APS at all four intersections and entered all four without assistance. But consider for a moment if we just look at the assistance with crossing timing variable (one of two inclusion criterion variables). In the general information block the number of participants who began crossings without assistance for APS A, B, C, and D were 18, 20, 18, and 13 respectively. In the specific information block, they were 20, 20, 20, and 19. When we consider the numbers of participants who had the APS and entered independently, they are 14, 18, 16, and 10 in the general information condition, and 19, 19, 18, and 18 in the specific information condition. The fewer number of participants included in the above calculations (7 and 17) is a result of the specific effects of the listwise deletion procedure necessary for meaningful comparisons.

Although most participants did perform the majority of their crossings independently and with audible WALK information, the relatively low number of participants who did so at the intersection with APS D in the general information condition (n=10) greatly limited the number of participants included in the full analysis. Participants had a great deal of difficulty locating and pushing the pushbutton on APS D in the general information condition and some were observed to be quite frustrated and requested assistance with starting crossing. In addition, some seemed confused on hearing the rapid tick walk indication and asked for confirmation from the orientation and mobility specialist (which was recorded as a request for assistance on the crossing). Interestingly considering the trouble discussed here, starting latencies were faster for APS D than for the other three APS in both information conditions (statistically confirmed in the specific information condition only, see below).

Following specific familiarization, the majority of participants were using the APS devices and thus the sample size for the analysis of latency following listwise deletion is 17. In this case, the analysis of latency to begin crossing by device is significant ($F(3,48) = 3.466$, $p < .05$). The means look rather similar between APS A, B and C: 3.35, 3.59, and 3.71 seconds, respectively. The mean amount of time to begin crossing with the APS D was 2.24 seconds. A

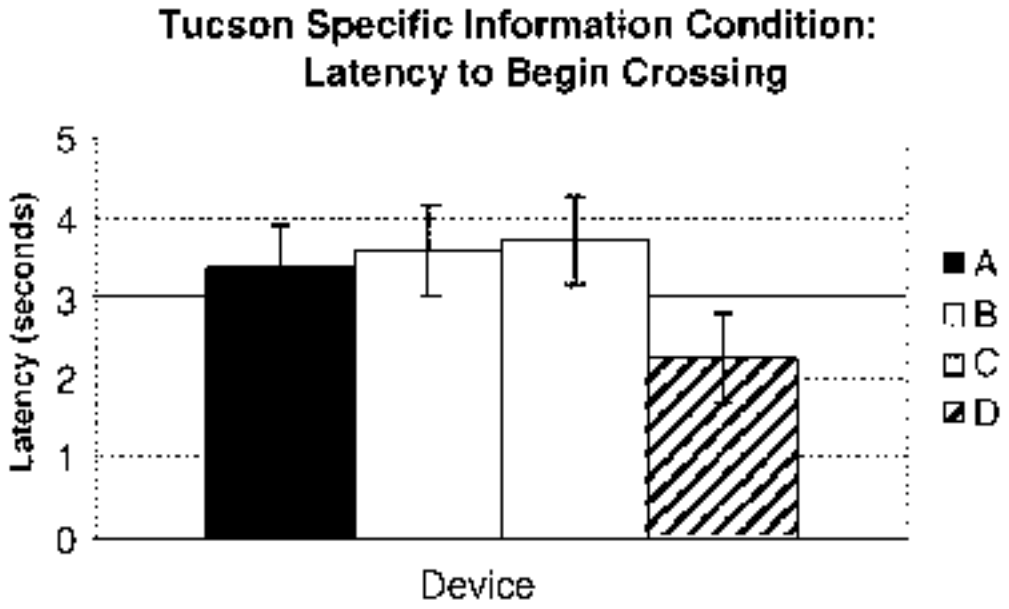
AR0072248

comparison between the averaged latencies for APS A, B and C and APS D, shows that the average amount of time to begin crossing for these three APS was significantly slower than for APS D ($F(1,16) = 41.86$, $p < .001$), and the various devices each produced slower responses than APS D when compared directly (*see Figure 3-9*), confirming the results of our previous research finding the most rapid response to the correct WALK signal was when it consisted of rapid ticks.(5,6)

Looking back at general information (*see Figure 3-8*), there was a similar trend amongst the means even though there were not significant differences. APS D resulted in the fastest latencies (but keep in mind the large amount of missing data), APS C and B had identical latencies (to a hundredth of a second). The exception was that APS A resulted in the slowest latencies following general information. APS A was the device with pedhead-mounted walk indications and participants may have been momentarily confused by the fact that the WALK signal was coming from a different place than the locator tone. On the other hand, participants in Tucson were somewhat more familiar with cuckoo/chirp pedhead-mounted APS than they were with the other types, since APS having cuckoo/chirp WALK signals are commonly installed there.

It should be expected that the faster starts in response to the APS D devices will result in other positive consequences related to the crossings. An analysis of the frequencies for a number of other measures of crossing timing following specific information supports this notion. Participants at the intersection with APS D devices were equivalently or more likely to begin



$F(3,48) = 5.466$, $p < 0.05$, $N = 17$

Figure 3-9. Latency to begin crossing by devices: specific information condition – Tucson.

AR0072249

crossing during the WALK signal than at other intersections. These individuals finished their crossings during the WALK or flashing DON'T WALK 75% of the time versus 53% for APS A, 47% for APS B, and 29% for APS C. There was very little variability between devices in the number of participants failing to complete crossings before the onset of perpendicular traffic, with no more than 2 participants remaining in the crosswalk at the end of the WALK phase for any device. APS A also faired well in this analysis, with 88% of participants entering during the WALK signal, and 53% completing during the WALK or flashing DON'T WALK. There was no one left in the crossing when opposing traffic began to flow at intersections where APS A were installed. APS C resulted in the worst scores on all measures, however the poor performance may have been caused by irregularities in the functioning of APS C that were observed by the researchers in Tucson (see discussion of devices in Method). Following specific familiarization, participants were slowest to respond to APS B and C, the two devices with speech walk messages. Participants were fastest with the walk signal of APS D. Furthermore, this analysis matches up well with the frequency analysis such that the faster responses lead to more starting during walk interval, and higher rates of crossing completion before the end of the flashing don't walk interval.

Charlotte – Conducting analysis of starting latency by device, following general information was based on a sample size of only 10 participants who were presented with WALK signals for each device, and who independently initiated a total four crossings. The overall analysis failed to achieve significance, $F < 1.00$ (*see Figure 3-10 and Table 3-9*).

Following specific information, the majority of participants were using the APS and thus the sample size improved to 18. However, the analysis of latency to begin crossing was once again non-significant (*see Figure 3-11*).

In addition to having mean latencies in each information condition which were not significantly different from one another, the relative orders from fastest to slowest between the two information conditions was not the same. For example, following general information, the slowest mean response latency was at the intersection with the APS D (3.70 seconds), but in the

AR0072251

specific information condition, this intersection had the fastest mean latency (2.28 seconds). In the general information conditions, participants in Charlotte were observed to hesitate more on first hearing the rapid tick WALK signal at APS D, possibly to decide if what they were hearing was really the WALK signal. However, in the specific information condition, the pattern in Charlotte is very similar to that in Tucson; that is, the fastest responses were for APS D while responses to the other APS were similar to one another.

There was very little variability in the percentage of individuals who began crossing during the WALK signal (80-90% – general information, and 89-94% – specific information), or the percentage of participants who completed their crossings before the onset of perpendicular green (80-100% – general information, and 94-100% – specific information). There was slightly more variability in the percentage of individuals who finished during the WALK or flashing DON'T WALK (50-70% – general information, and 59-88% – specific information).

In comparing performance on latency to cross in the general information condition, the patterns between Tucson and Charlotte are not the same. In Tucson, the speech messages and rapid tick signal all produced equally fast starts (~5 seconds), while in Charlotte the rapid tick resulted in the slowest mean start, and the two speech messages provided the most rapid starts. Recall that within each city, these were not significant differences and no statistical tests were computed between the cities.

WAYFINDING

Measures associated with wayfinding were whether participants 1) were within the width of the crosswalk when they began crossing (Began Within), 2) were correctly aligned so that they were facing directly parallel to the crosswalk when they began crossing (Correctly Aligned), 3) traveled within the crosswalk lines at all points in the crossing between the beginning and ending (Crossed Within), and 4) ended the crossing within the crosswalk lines (Ended Within).

Information Condition

Tucson

Table 3-10 shows the percentages of all participants who performed in the given way on each measure, divided out by both device type and information condition, without concern for whether or how each participant used each device. There is no systematic difference attributable to information condition that is apparent in the data. Between general and specific conditions, performance for some devices improved slightly for one or two measures, but declined for other measures. Inferential analysis was conducted to reveal any significant differences attributable to device or an interaction between device and information condition (see below under Device).

Charlotte

Again, there are no systematic differences attributable to information condition that are apparent from the data. Between general and specific conditions, performance for some devices improved for one or two measures, but declined for another measure or two (*see Table 3-11*).

AR0072252

Because of observations in Tucson, it was noted in Charlotte if participants were standing immediately beside the pushbutton to begin their crossing, this sometimes resulted in their being outside the crosswalk lines when beginning. Therefore this table includes percent of participants who either began within the crosswalk or at the pushbutton. When that is considered, almost all participants began at one of these locations. This behavior has some implications for placement of pushbuttons closer to or within the extension of the crosswalk lines.

AR0072253

Device

The measures of wayfinding are all categorical. To enable statistical analysis with regard to device, the categorical level variables were transformed into interval level variables (percentages) collapsing across familiarization level, using the method outlined near the beginning of the results section.

Tucson

Table 3-12 shows the average percentage of trials on which each participant performed accordingly for a given APS in Tucson.

Collapsing across information conditions, it doesn't appear that any APS reliably provided more useful information than any other with respect to wayfinding. Furthermore, no specific type of interaction (general interaction, use of tactile arrow, or use of extended message; not presented in these tables) shows reliable improvement or impoverishment of ability to find and align to the crossing. One can also look at a given APS following general information and compare it with the same APS following specific information to see if type of information has specific effects on measures of wayfinding. There are no significant differences here, either.

One-way ANOVAs were computed in order to investigate whether the various devices produced differences in the percentage of trials participants began within the crosswalk, collapsing across information conditions, and no significant differences were found ($F(3,57) < 1.00$), correctly aligned with the crosswalk ($F(3,57) = 1.58$, $p > 0.05$), traveled within the crosswalk ($F(3,57) = 1.86$, $p > 0.05$), or ended within the crosswalk ($F(3,57) = 1.67$, $p > 0.05$).

Charlotte

Table 3-13 shows the average percentage of trials on which each participant performed accordingly for a given APS in Charlotte.

Device did not result in differences between the percentage of trials in which participants began their crossing within the crosswalk ($F(3,57) < 1.00$). Some participants lined up at the pushbutton, with their hand on the tactile arrow as shown in Table 11, probably to use the vibration to confirm the WALK. In many cases, because of the location of the pushbuttons, this meant participants were not within the crosswalk when starting to cross.

An analysis of alignment by device was significant ($F(3,57) = 2.79$, $p < 0.05$). Participants aligned themselves correctly more often at the intersection with APS D than those with APS C ($F(1,19) = 5.63$, $p < 0.05$) and APS A ($F(1,19) = 7.107$, $p < 0.05$). Better alignment at the intersection with APS D is probably attributable to the sidewalk and ramp configuration at

TABLE 3-12 Participant performance by device – Tucson

Measure	APS A	APS B	APS C	APS D	F(3,57)
Began within	86.65%	79.10%	77.55%	81.70%	< 1.00
Correctly aligned	83.40%	69.20%	81.75%	76.00%	1.58
Crossed within	61.65%	56.70%	70.10%	71.75%	1.86
Ended within	68.35%	81.40%	61.85%	63.30%	1.67

$p < 0.05$

AR0072254

that intersection, rather than to a specific device feature since APS D had the lowest use of the tactile arrow (*see page 26*). At that intersection, the approach to the crosswalk was straight, and confined by landscape strips, and pushbuttons were near the street.

The analysis for travel within the crosswalk in Charlotte was also significant ($F(3,57) = 5.19$, $p < 0.01$). Comparisons revealed that the percentage of trials the participants traveled within the crosswalk at APS D intersection was significantly lower than that for APS C ($F(1,19) = 7.027$, $p < 0.05$), and APS B, ($F(1,19) = 12.67$, $p < 0.01$). This may seem surprising, given that alignment was very good at the intersection having APS D. However, that intersection had the widest crossing. Furthermore, the percentage of the trials that participants traveled within the crosswalk for APS A was significantly lower than that for APS B ($F(1,19) = 5.65$, $p < 0.05$). The clockwise crossing at APS A had one diagonal curb ramp rather than two perpendicular ramps, which may have affected maintaining alignment as participants stepped off the curb.

The analysis of percentage of crossings in which participants ended their crossing within the crosswalk was also significant, ($F(3,57) = 3.95$, $p < 0.05$). For crossings having APS D, participants ended their crossing within the crosswalk on 57.7% of trials, but in this case it was only significantly lower than crossings at APS B (85.0%, $F(1,19) = 10.50$, $p < 0.01$). A very small deviation, especially one occurring early in a crossing, can easily take the traveler outside the crosswalk at a wide crossing, for participants who had traveled within the crosswalk for most of the crossing and felt they should have completed their crossing (who thought the road was narrower than it was) might correct by turning away from their parallel street looking for the curb and thus veer out of the crosswalk. The crossings at APS D were the widest (79 ft and 83 ft) and one of the crossings at APS B was the narrowest in Charlotte (49 ft). The other crossing at APS B was in the middle (58 ft).

The results regarding wayfinding in Charlotte are quite different from those in Tucson, where there were no significant differences attributable to device. It should be noted that almost all traffic in Charlotte turned right or left at the intersections, so there were few traffic cues for alignment or for correcting crossing alignment during crossing, while straight-through traffic was more plentiful in Tucson. Because of these differences in vehicular flow across cities, it is difficult to argue that specific information was being used to guide participants across the street. In Tucson, analyses of where participants traveled and where they ended their crossings were both non-significant, and the lowest percentages were both recorded at the intersection with the APS B. However, that intersection had the steadiest traffic on the minor roadway. These analyses seem to tell us little more than which intersections were particularly difficult with respect to

TABLE 3-13 Participant performance by device – Charlotte

AR0072255

crossing within the crosswalk, and do not directly address the usefulness of the signals for guidance across the street.

It was the observation of the orientation and mobility specialists involved in data collection that most participants did not use any type of consistent strategy to maintain their alignment when having to orient with a pushbutton, then realign to cross. Most deviated on their approach to the street to detect any pushbutton and locator tone they heard, and some became completely disoriented and lined up to cross the wrong street. The most common techniques taught for aligning to cross streets involve maintaining initial approach alignment and utilizing traffic traveling through the intersection to align. Where pushbuttons are used, the individual often must turn off the approach path to push the button, and the crossing must be made on the next through traffic phase without waiting through a cycle to align, which prevents the use of those techniques.

SUBJECTIVE RESULTS

Likert Ratings

In both cities and following each street crossing in all information conditions, participants were asked to rate their level of agreement with four statements using a 5-point Likert scale (1=strongly disagree; 5=strongly agree). Also in both cities, responses to an additional 11 statements were recorded following completion of all crossings in the specific information condition only.

Questions Asked after Every Trial in Every Condition

The four statements rated after all crossings in both cities were the following:

1. It was easy to find the pushbutton.
2. I was sure I pushed the button for the street I wanted to cross.
3. I was certain the signal was for the crosswalk I wanted.
4. I used the signal to help me find the opposite corner.

Questions 1 and 2 were not asked if participants had not used the pushbutton. Question 3 was not asked if there was no WALK signal. Question 4 was asked after all crossings since the participant could possibly have used the pushbutton locator tone to find the opposite corner, even when there was no audible walk signal.

In the no information condition in Tucson (not conducted in Charlotte), so few participants interacted with the pushbutton that results are not informative. In the general and specific information conditions, results by device and by city are quite similar, while across information conditions they vary (*see Table 3-14 and Figure 3-11*). For all but one statement, ratings were as favorable or more favorable following specific information than following general information. In both information conditions in Tucson, 78% of participants replied agree or strongly agree in response to the statement, "It was easy to find the pushbutton."

AR0072256

Although there was little improvement in objective measures between the general and specific information conditions, participants rated statements regarding their ability to use the APS more positively following specific information. Thus, even though participants were not familiar with a specific intersection, having specific information and experience with the APS at that intersection, and knowing which APS they would encounter, increased participants' perception of ease and confidence in interacting with the APS.

Following specific information, more than three fourths of participants generally felt that finding pushbuttons was easy, and most of the participants (approx. 90%) were confident that they pushed the correct button and started crossing with the correct WALK signal. Not nearly as many agreed that they used the signal to help them find the opposite corner. The lack of reported use of the signal to find the opposite corner is likely attributable to a number of factors. Participants who used dog guides (4 in each city) reported that they just followed their dog's guidance in the street. Others stated that they were using vehicles for their alignment cues or that they couldn't hear the locator tone of the APS until they were within a step or two of the opposite curb, so they didn't really use it.

Two devices, APS C and A, were specifically designed to provide beaconing to the opposite corner. Beaconing by the APS C consisted of a louder WALK, followed by a louder

TABLE 3-14 Range of mean response ratings for the various APS by question, collapsed across devices

Questions	Tucson Range of Mean Response Ratings	Charlotte Range of Mean Response Ratings

locator tone for the duration of the pedestrian phase, a strategy that was expected to be beneficial based on the laboratory findings in related research (*36*). The beaconing feature on the APS C was available only after an extended button press. This feature was not working correctly on APS C in Tucson, due to some wiring problems that were not discovered until the end of data collection, however, it was functioning in Charlotte. APS A provided beaconing from overhead speakers aimed at the center of the crosswalk during the WALK signal only. Other research had not found this system to be very useful for the alignment task (*22, 5*). For most trials in which participants reported that they used APS signals to help them find the opposite corner, the signal available would have been the relatively quiet locator tone.

The most interesting finding here is that, for each city and each information condition, the numbers of participants who reported using the APS to help them find the opposite corner are very similar for all devices. That is, even though the locator tone from only one device (APS C) became louder when the user used the extended button press (80% of participants used this feature in the specific information condition), there is no clear pattern that participants reported using the beaconing of APS C more than other devices. Researchers observed some participants altering their path to travel straight toward the pushbutton (and louder locator tone) of APS C in Charlotte, but participants did not seem to realize that they had done so.

AR0072258

In the general information condition, with regard to these first four measures, participants in Charlotte did not rate their experience using APS as highly as participants in Tucson for three of the four devices. This could have been attributable to having less experience with the experimental task than participants in Tucson, who had already had one block (no information condition) of testing (*see Figure 3-12*).

The poorer ratings for the APS B in Charlotte, following general information, were probably because the volume of both the locator tone and the speech walk message were lower than those for any other device, with baffles preventing sound traveling back down the sidewalk. These volume restrictions were in response to a neighbor's objection. Nonetheless, following specific information and despite the low volume, its ratings increased to essentially equal the ratings in Tucson. With the exception of APS B, ratings following specific information were higher in Charlotte than in Tucson.

The poor ratings for APS D in the general information condition in Charlotte may have been because the crossings at the intersection in Charlotte where APS D were installed were wider than those in Tucson, and there was initial confusion for some participants about whether the WALK indication was really the WALK indication. Following specific information, ratings for the APS D, like those for the APS B, increased markedly, to be even higher than comparable ratings in Tucson.

Questions Asked During the Specific Information Condition Only

After each crossing in the specific information condition only, participants were asked to state the extent to which they agreed with an additional nine statements (statements 5 – 13) using a 5-point Likert scale (1=strongly disagree; 5=strongly agree).

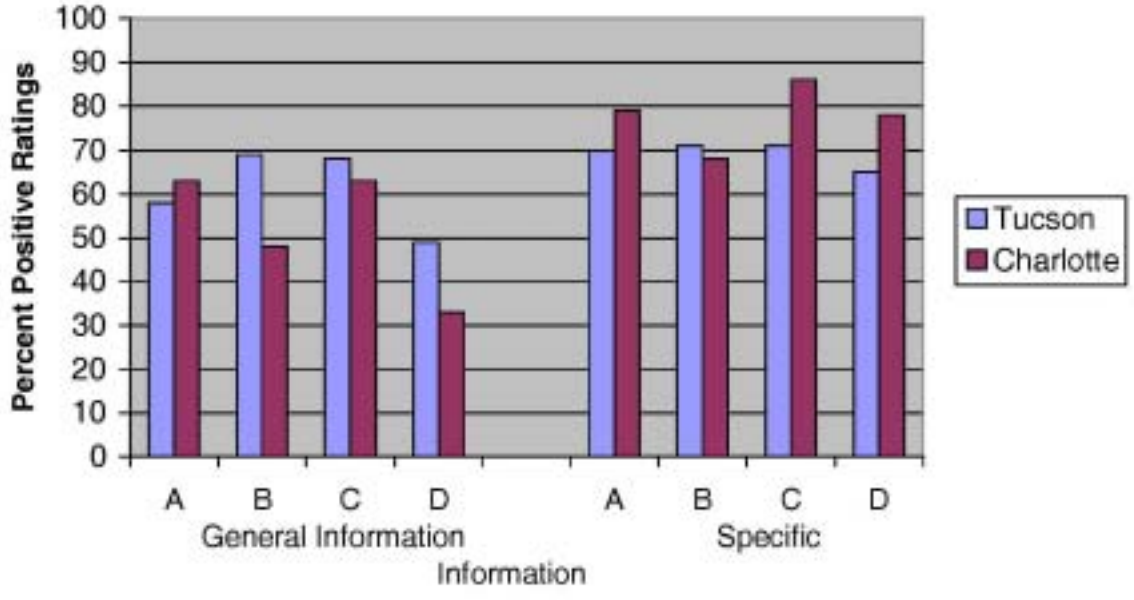

Figure 3-12. Percentage of positive ratings (agree or strongly agree with statements) by information condition and device.

AR0072259

In order to be included in repeated-measures ANOVA testing for significant differences between devices within a given city, each participant had to have a valid response on the question of interest for each device. Questions were not asked if they were not applicable (i.e., a participant who did not use the tactile arrow would not be asked if the tactile arrow was helpful in aligning to cross). Thus, for analysis of subjective evaluations of device differences in the usefulness of the tactile arrows for aligning to cross, only those participants who used the tactile arrow on each of the four devices were included. Similar inclusion criteria were used for each of the questions, thus resulting in varying sample sizes for the analyses of responses to statements 5 – 13. Overall, there were few significant differences between the various APS for any question in either city (see *Table 3-14*).

Regarding helpfulness of the locator tone for finding the pushbutton (Question 5), there was a significant difference only in Charlotte ($F(3,54)=4.88$, $p<0.01$). The mean rating for APS B (3.05) was significantly worse than for APS C (4.37; $F(1,18)=7.58$, $p<0.05$) and for APS A (4.32; $F(1,18)=13.75$, $p<0.01$). This was undoubtedly because of the low volume setting of APS B in Charlotte, which was also rated as having the volume too low (see question 14 below). The range of all other mean ratings across both cities was 3.21 to 3.79, indicating a generally positive view of the information provided by a locator tone.

Participants in Charlotte may have had greater exposure to locator tones due to a fair number of APS C devices installed elsewhere around the city, and the most positive ratings were obtained for APS C in Charlotte. When asked, 11 participants reported having used locator tones before, however other ratings of the usefulness of the locator tone for finding the pushbutton were fairly equivalent between the two cities. After completing crossings in which the participants located the pushbutton independently, participants were asked how they knew where to find the pushbutton. Collapsing across all device types and information conditions, participants in Tucson reported using the locator tone 95% of the time, while the rate was at 83% in Charlotte. The lower percentage in Charlotte is largely the result of low rates of locator tone use on APS B. As discussed below, there were some considerable volume concerns for the locator tone on APS B which may have been the primary cause of diminished reliance on the feature in Charlotte.

Regarding helpfulness of the vibratory walk signal (Question 6), across both cities, only 2 participants used the feature at each of the four intersections, and thus no statistical analysis could be computed. Overall, the feature was used 11 times in Tucson and resulted in a mean response rating of 4.36, and it was used 27 times in Charlotte with a mean response rating of 4.37. Use of the vibratory feature may have been by participants who wanted to be sure they knew which APS was providing the WALK signal or some participants may have been just trying out the vibratory feature.

The mean rating for whether the tactile arrow was useful for knowing the pushbutton was for the street to be crossed (Question 7), collapsing across devices in both cities, was 4.34. There were no significant differences between the devices for either city. The high mean rating, however, indicates that participants regarded the tactile arrow as being very useful in determining which pushbutton was for which street.

The mean rating for whether the tactile arrow was useful for crossing alignment (Question 8), also showed no significant differences between devices within each city, but the

AR0072260

mean ratings were all on the positive side of the scale in Charlotte and on the negative side of the scale in Tucson.

With regard to the helpfulness of the activation tone or message (Question 9), mean ratings for each city were strongly positive. There were no significant differences between devices in Charlotte, but in Tucson, differences were significant ($F(3,54)=2.90$, $p<0.05$). APS C was rated significantly worse (3.58) than both APS B (4.58, $F(1,18)=6.33$, $p<0.05$) and APS D (4.26, $F(1,18)=6.61$, $p<0.05$) devices. However, APS C, which had the lowest mean in Tucson, had the highest mean in Charlotte (4.61), perhaps because some participants in Charlotte had prior experience with APS C. The most important conclusion that can be taken from ratings on this question is, therefore, that a good activation tone or message was very important to participants.

The speech walk message was available only on APS B and APS C (Question 10). The mean ratings, by city, indicate that participants found the speech messages quite understandable in both cities. In Tucson, there was no significant difference between devices, but in Charlotte, APS C (4.68) was rated significantly higher than the APS B (4.00; $t(18)=2.25$, $p<0.05$).

The pushbutton information message was available on APS B, C and D (Question 11). There was no significant difference between devices in either city, but mean ratings for each device at each city were all at or above 4.00, demonstrating participants' agreement that "The pushbutton information message was easy to understand."

The tactile map was used by only 9 participants across both cities. The mean rating for the statement "The crossing map was useful and easy to understand." (Question 12) was 4.00 in Tucson and 4.17 in Charlotte, with all participants rating it 3.00 or above. There was insufficient data for further analysis. Researchers observed that many participants seemed to like the tactile map feature during the indoor demonstration, but most did not use it during experimental trials.

Regarding the helpfulness of the locator (beaconing) signal feature (Question 13), this feature was available only on APS C and only in response to an extended button press. Collapsing across both cities, 31 participants used the feature, giving it a mean response of 3.94 across cities, with only 4 participants rating it on the negative side of the scale.

Additionally, participants were asked to rate the volume of both the locator tone and the walk signal (items 14 & 15) on a 5-point scale (1=too quiet; 5=too loud). The means for the locator tone and WALK signal volumes in both cities were less than, but close to, 3.00, halfway between too quiet and too loud (*see Table 3-15*). The two most extreme mean ratings regarding the volume of the locator tone were APS A (2.20—Tucson) and APS B (1.80—Charlotte). APS A did not seem to respond well to ambient sound, which might have contributed to the lower rating in Tucson, where traffic was quite noisy much of the time. In addition, one APS A device was installed several feet behind the stop line, so it was somewhat further away from the approach sidewalk. The volume of the locator tone of APS B was very quiet in Charlotte with baffles installed on the approach side of the device due to neighbor complaints, so most of its sound was directed at the curb area and into the street, which was not very helpful in hearing the locator tone when approaching on the sidewalk. The most extreme rating regarding the volume of the WALK signal was also on APS B (Charlotte), probably for the same reason. The speech message was very difficult to hear. On the whole, participants were comfortable with APS volumes, although they would have liked them slightly louder.

AR0072261

TABLE 3-15 Mean rating of satisfaction with the volume levels of devices by locator tone and WALK signal within each city – N = 20 (1=too quiet; 3=just right; 5=too loud)

	APS A	APS B	APS C	APS D	F(3,57)
14. Level of locator tone					
Tucson	2.20	3.05	2.75	3.00	4.23*
Charlotte	2.75	1.80	2.75	2.25	13.08***
15. Level of WALK signal					
Tucson	2.80	2.50	2.70	3.05	2.89*
Charlotte	2.70	2.20	2.95	2.90	5.89**

* p≤0.05
** p≤0.01
*** p≤0.001

Despite the relative similarity in ratings, there were nonetheless significant differences by device for the locator tone and the WALK signal volume in both cities. In Tucson, the analysis of locator tone volume was significant (F(3,57)=4.23, p≤0.01), with participants indicating that the volume was too quiet on APS A when compared to the nearly perfect ratings obtained on APS B (3.05; F(1,19)=8.99, p≤0.01) and APS D (3.00; F(1,19)=8.94, p≤0.01). The analysis of ratings for the WALK signal volume were also significant (F(3,57)=2.89, p≤0.05). The mean rating for the APS D (3.05) indicated that it was considered about right, while APS B (2.50) was considered somewhat quiet in comparison (F(1,19)=8.88, p≤0.01).

In Charlotte, mean ratings for both the locator tone and WALK signal indicate that participants considered them somewhat too quiet. The analysis of responses to the level of the locator tone was significant (F(3,57)=13.08, p≤0.001). The mean rating for APS B (1.80) was significantly worse than for all others: APS D (2.25; F(1,19)=5.15, p≤0.05); APS C (2.75; F(1,19)=31.32, p≤0.001); APS A (2.75; F(1,19)=26.48, p≤0.001). This was to be expected considering APS B was set to a lower volume. Furthermore, the rating on APS D was significantly worse than that on the APS C (F(1,19)=7.31, p≤0.05), and that on APS A (F(1,19)=10.56, p≤0.01). The analysis of responses to the level of the WALK signal was also significant (F(3,57)=5.89, p≤0.01). The mean rating for APS B is significantly worse than all others: APS A, F(1,19)=4.52, p≤0.05; APS D F(1,19)=13.11, p≤0.01; APS C F(1,19)=12.04, p≤0.01. Once more, this was to be expected and no other significant differences emerged.

Although there are significant differences in the ratings for locator tone and for WALK signal volumes in each city, the fact that the differences in rank order change order across cities and across locator tones vs. WALK signals, makes it difficult to draw any firm conclusion about volume. This variation probably is indicative of the difficulty of regulating the signals to have equivalent perceived loudness between each other, within each city, and of the fluctuation of volume of both locator tones and WALK signals according to ambient sound. Although the accommodation to ambient sound is intended to make locator tones and WALK signals detectable and understandable in an easy moment with changing sound, response time and delay

AR0072262

both vary somewhat across devices. In addition, all devices were subject to a maximum permitted volume of 89dB. Perceived loudness is affected by several other factors in addition to volume setting of devices and their response to ambient sound. These include the comparative spectrum of the signal to the ambient sound at any time, wind, humidity, and reflective surfaces.

Subjective Responses

After completing each crossing in the final block of trials, and after responding to all of the above discussed statements, participants were asked what they liked most and liked least about the devices at the intersection they had just crossed. Participants were not limited in the number of features that they could list in either of these two categories.

In an attempt to quantify these responses, positive and negative comments for each device were categorized. By the time these questions were asked, most participants had had experience with pushbutton locator tones, the pushbuttons, the activation tones/messages, the tactile arrow, and the WALK signals. The vibrating arrow was present on all devices, but used by few participants, so it had few comments. Features such as the crossing map, the extended button press, and the louder (beaconing) signal feature were not present on every device and were not used by all participants even when present, so these features drew few comments.

Categories of positive comments were the following.

- Location and Type of Button
- Location and Type of Arrow
- Walk Signal Type (Speech vs. Other)
- Walk Signal Information Distinguishing Streets
- Locator Tone
- Pushbutton Activation Tone
- Vibrating Arrow
- Pushbutton Information Message (after extended push)
- Volume Increase Feature (beaconing)
- Tactile Map
- Responsiveness to Ambient Noise

Categories of negative comments included the following. Note that there is some overlap between positive and negative comments. Some features some participants liked, other participants disliked.

- Location and Type of Button
- Location and Type of Arrow
- Walk signal type (speech vs. other)
- Walk Signal is Confusing
- Lack of Info. Distinguishing Streets
- Difficulty Understanding the Walk Signal
- Pushbutton Activation Tone or Volume
- Locator Tone

AR0072263

- General Volume Complaints (Locator or Walk Signal)
- Lack of Features (Info Message or Volume Increase)
- Crossing Map Difficult to Read

With one exception, in each city, all devices had more positive comments than negative comments. In Charlotte, the APS D had more negative responses. The number of total positive comments, by device, in Tucson was between 31 and 48, while in Charlotte, it was between 22 and 29. The number of total negative responses, by device, in Tucson was between 18 and 37, while in Charlotte, it was between 14 and 20. APS B and C had more positive comments in both cities than APS A and D.

Across both cities, APS A and B had the location and type of pushbutton that garnered the most positive comments. Both of these devices have large, rounded pushbuttons, more closely resembling typical pushbuttons than those of APS C and D. Also across both cities, the pushbutton of APS D had the most negative comments. It was a flat panel electronic pushbutton on the face of the device. During experimental trials, researchers observed considerable exploration of APS D before the button was actually pushed. In fact, in the general information condition, researchers observed a number of incidents when the button was pushed by accident while participants were exploring the device and trying to figure out where the pushbutton was located. The lack of anything that felt like a pushbutton was clearly confusing to many participants and they pushed on the light, map symbols, or the arrow while exploring the device, and often were not aware of what they pushed to get the confirmation tone.

In Tucson, APS D also received the most negative comments regarding the type of arrow. The arrow was only 1.5 inches long, with a stroke width of 3/4 inch, while the next smallest arrow was that of the APS C device, at 2 inches long, with a stroke width of 1 inch. Also, the arrow of APS D was the only one located on the top (horizontal) surface of the device. In the objective data, in the general information condition, the pushbutton and arrow of APS D appeared to be more problematic than the pushbuttons and arrows of the other devices. Following specific familiarization, this difference had largely disappeared, however. In Tucson, the location and type of arrow of APS C received more favorable comments than those of any other device. That arrow was the only one that was located on the pushbutton for the Tucson experiments in Charlotte. APS B also had the arrow on the pushbutton.

There were many comments regarding the type of WALK signal (speech—APS B and C vs. bird calls—APS A vs. rapid tick—APS D). In Tucson, there were between 9 and 13 positive responses to the WALK signals of all devices, and no negative responses. The higher numbers of responses were for APS B (13) and APS C (11), which both had speech messages, although the difference in numbers may not be meaningful. However there were 7 (negative) comments categorized as "Walk signal is confusing," for both APS A and APS D, the two devices having tone signals. There was a similar pattern in Charlotte, for both positive and negative responses, although the number of responses was less. Therefore, the general trend is that participants preferred the speech messages to either type of tone signal. It should be recalled, however, that in objective measures of latency in starting to cross, there was some advantage to the rapid tick signals. This pattern, in which subjective preference favors speech signals, but objective performance favors tone signals, was also found in research on pushbutton location and WALK signal conducted as part of this project (*see Chapter 4* (1,37)).

AR0072264

There was a notable preference for devices providing speech information to distinguish between streets having the WALK signal, that is, APS B and C, and a smaller number of negative comments regarding the lack of this information from APS A and D. There were comments that the speech messages of APS B were difficult to understand, but no such comments for APS C.

Something as simple as having a clear and audible tone to indicate that the pushbutton had been activated appears to be particularly appreciated by pedestrians who are blind, as this feature was mentioned positively by many participants. Both APS A and D received positive comments in both cities, and APS B also received positive comments in Charlotte. Those who commented positively regarding APS B specifically commented that they liked the "Wait" message (the pushbutton actuation indicator) that they heard immediately when they pushed the button during the flashing or steady don't walk intervals. There were a few negative comments on the sound of the activation indicator, mentioning APS C and A. Overall, the actuation tone of APS A received the highest number of positive comments across both cities (12), and APS D next (7).

Regarding location tones, all devices across both cities received an approximately equal number of positive and negative comments.

There were scattered positive comments about the pushbutton information message and beaconing that could be activated by an extended button press, the vibrating button or arrow, the tactile map, and the responsiveness to ambient sound. Negative comments regarding these features were all with regard to APS A, which lacked the pushbutton information message and the tactile map. In Tucson and Charlotte, APS A also did not seem to respond to ambient sound, although it has that capability. There were five positive comments about the tactile map, but three comments that it was hard to read.

In addition to reporting which features they liked most and liked least for each device immediately following use of the device in the specific information condition, participants were also asked a series of questions after completing all crossings. These questions were:

1. Which location tone did you like best?
2. Which location tone was easiest to home in on?
3. Which pushbutton was easiest to find? (after finding the device)
4. Which walk signal gave you the best info for which street had the walk signal?
5. Which walk signal was easiest to hear?

AR0072265

Participants were not limited to one device in answering the questions and could also respond with a "none" response (see *Table 3-16*).

It appears that preference for locator tones was fairly well distributed, with a slight preference for the locator tone on APS C followed by APS D. Interestingly, APS A and C have use the same locator tone, which some participants noted. Ease of finding the pushbutton was not related to reports of usefulness of the locator tone, as participants reported APS A to be the easiest to find, followed by APS B. This seems related to the rounded shape of the pushbuttons on those devices, about which many participants commented favorably. The clearest picture emerges in reports of which WALK signal gave the best information. Participants believed that those devices with speech messages (APS B and APS C) provided the least ambiguous information regarding the WALK signal. Finally, participants showed no clear preference for which walk signal was easiest to hear. APS A (bird calls) received the most votes across both cities, while APS C (speech) received nearly as many.

Attempting to amass all of this subjective information, the most desirable APS would have the following features:

- A locator tone (any)
- A rounded pushbutton
- A clear pushbutton activation tone
- Responsiveness to ambient sound
- A tactile arrow that is incorporated into the pushbutton itself
- A speech walk signal that indicates the name of the street to be crossed

TABLE 3-16 Frequencies of responses to questions on preference questionnaire

	None	APS A	APS B	APS C	APS D
Which locator tone did you like the best?

- A pushbutton information message

SUMMARY AND CONCLUSIONS

This research evaluated what features of pushbutton-integrated APS were useful to pedestrians who are blind and how much information or training was needed in order to enable them to make use of those features. The results do not present a focused picture of one device and set of features that will provide unambiguous information to pedestrians who are blind or who have low vision at a range of intersections. So many factors are involved in the street crossing tasks that it is difficult to determine what features affected performance. Among the devices, some features seemed more useful or to be used more frequently, but even this information seemed to vary between the two cities. The results seem to support that when pedestrians who are blind have used a device and know what kind of APS they will use at an intersection, device characteristics or features, such as the physical design of the pushbutton or tactile arrow, do not make much difference.

A fact that became clear in this research was that pedestrians who are blind do not have adequate information about using pushbuttons and APS devices in crossing streets and many did not have good information about the complexity of modern intersection signalization. When participants had some general information about new types of APS, they performed better at locations with APS installed than they did when no information was given to them about the APS. Although there was little improvement in objective measures between the general and specific information conditions, participants' ratings regarding their ability to use the APS were more positive following after receiving specific information. Thus, even though participants were not familiar with a specific intersection, having specific information and experience with the APS at that intersection, and knowing which APS they would encounter, increased participants' perceptions of ease and confidence at interacting with the APS.

Device Adjustments and Volume

Despite all efforts by cities and researchers involved in this project, it was difficult to install devices within the existing infrastructure in locations that were truly comparable. Both cities made every effort to install the devices for this project in optimal locations, but slight differences in pole locations, such as distance from the curb or sidewalk, or position in relation to the curb ramp, made some pushbuttons more difficult to find than others. Even when everyone was enthusiastic to get installations, it was impossible to locate all devices in accordance with current *MUTCD* guidance and the *Draft Guidelines* (1, 2). On one corner this was due to the curb radius and a fire hydrant. On another, the sidewalk and curb ramp would have had to be completely rebuilt to locate a second pushbutton pole. Many poles, and consequently pushbuttons, in Tucson were more than 5 feet outside the extension of the crosswalk lines, which may have contributed to some participants crossing outside the crosswalk, or to crossing alignment problems. These locations are examples of the real-world conditions that will be faced by engineers at most intersections. Unless the intersection is new or being completely rebuilt, it will often be difficult to achieve the optimum placement of APS.

AR0072267

The adjustment of the volume of the APS is critical for neighborhood acceptance and for usability by pedestrians who are blind. Even with ambient sound response, this is a difficult balance to strike. While most blind pedestrians felt the volumes were slightly too quiet, researchers thought some of them were too loud for neighborhood acceptance, particularly if they had been in residential locations. At one intersection in this research, volume of devices was turned down and severely baffled in response to a neighbor's complaints. Part of the problem may have been that the device had been installed and left over the weekend with the locator tone volume much too loud, due to a misunderstanding of the volume adjustment. Community objections to APS and locator tones are likely to affect the installation of APS, so proper volume adjustment is critical. In this research, the sound levels and ambient sound response of APS C and D were adjustable with handheld PDA-type devices and they seemed to be much easier to install and adjust.

Development in placement of APS and refinements in techniques used by pedestrians who are blind may also change their expectations about the volume of locator tones. If pedestrians who are blind continue to the edge of the street, then listen for the locator tones, it may be easier to adjust the sounds to be heard in the street vicinity and not on the approach sidewalk. And location of pushbuttons closer to the street and crosswalk location allows the volume of the locator tone and walk indication to be lower.

Use of Pushbutton

The results regarding the use of pedestrian pushbuttons by pedestrians who are blind indicates that typically, pedestrians who are blind do not use pedestrian pushbuttons. In Charlotte, where it is common to require pushbutton actuation for only the major street crossing at an intersection, 7 out of 20 participants said they usually do not use pushbuttons, 6 said that they usually do, and the other 7 said they do only when they know that the pushbuttons are there. In related research in Charlotte, 16 blind participants crossing at complex, unfamiliar signalized crossings, without APS, did not look for pushbuttons on any of the 64 crossings at which pushbutton actuation was necessary (*26*). Even in Tucson, where use of a pushbutton is required to actuate the WALK signal for both the major and minor street crossings at most signalized intersections, 9 of 20 participants said they usually do not use pushbuttons, 6 said that they usually do, and the other 5 said they do only when they know that the pushbuttons are there or the intersection is particularly difficult. In the Tucson experimental trials under the no information condition, only five participants looked for the pushbutton on every crossing, and at each of these intersections, one additional person (different people) looked for the pushbutton.

Learning Pole/Device

In the general and specific information conditions in both cities, most participants (98%) searched for the pedestrian pushbuttons, probably because they had been told that the pushbutton had to be used to actuate the APS, and the locator tone had been explained. In the no information condition, some were observed to wonder out loud about the locator tones that they heard, but few had actually investigated the pushbuttons or tried to determine where the tones were coming from.

Two types of subjective data support the usefulness of locator tones. First, participants were asked, following each crossing for which they used the pushbutton, how they located the pushbutton. This was an open-ended question, permitting multiple responses. Participants said they used the locator tone on most trials, regardless of device (Tucson 95%, Charlotte 83%). The

AR0072268

lower percentage in Charlotte is largely the result of low rates of locator tone use on one device, where the volume was too quiet. Furthermore, when asked following each trial on which they had specific familiarization and experience with the four APS devices, to rate their agreement with the statement "The locator tone helped me find the pushbutton," mean responses for each device at each city were all in the positive direction. All APS across both cities received an approximately equal number of positive and negative comments, and no particular APS locator tone resulted in a higher percentage of participants finding the pushbutton.

The presence of a locator tone to inform pedestrians of the presence of a pushbutton and its location may also influence the use of pushbuttons, since five participants in Tucson and seven participants in Charlotte said they used pushbuttons if they knew they were there and where to find them.

However, the presence of a locator tone does not guarantee that pedestrians who are blind will find the pushbutton, even with specific information about the type of APS. In the specific information condition when participants looked for the pushbutton on 100% of trials, they failed to find the correct pushbutton on 21% of trials in Tucson and 16% of trials in Charlotte. Possible reasons for this failure are that participants were not experienced at the task of looking for a pushbutton and maintaining orientation, so some found and used the wrong pushbutton (recorded as did not find pushbutton) or participants may have had difficulty locating the pushbutton and requested assistance (also recorded as did not find pushbutton). When data are examined for finding both correct and incorrect pushbutton for a crossing, participants found a pushbutton on over 90% of trials in both the general and specific information conditions. In the specific information condition, participants found a pushbutton on 95% of trials in Tucson and 99% of trials in Charlotte. However, some still found and used the incorrect pushbutton while others found the incorrect pushbutton and identified it as such without activating it, but then did not proceed to find the correct pushbutton. This may indicate the need for additional training and techniques for locating pushbuttons and recognizing the correct pushbutton, along with the provision of APS with longer tones.

Of concern to the researchers in the no information condition were comments of some participants who seemed to be trying to use changes in the locator tone volume (in response to ambient sound) as a walk indication. These participants generally did not look for or push the button, but heard the audible locator tone, and without knowledge of locator tones and their function, made an assumption that it was some kind of walk indication. This misunderstanding of the audible sound adjustment and of the locator tone could lead to dangerous crossings. Where pushbutton-integrated devices with locator tones are installed, it may be necessary to make a concerted effort to provide information about the devices to individuals in the community.

Pushbutton Design and Features

Pushbutton Style

Indirect evidence for difficulty in finding the two pushbuttons that were atypical, the flat-panel pushbutton, and the flat recessed circular pushbutton, was found in the latency to find and push the correct pushbutton. The time included both the time to find the pole and the device, and the time to locate and use the button on the device. In the condition in which participants only had a general description of APS features, the two unusual pushbuttons took significantly longer to locate and push than the two buttons that were typical. When participants had specific

AR0072269

information about and experience with the various pushbuttons, all differences in latency disappeared.

Style of pushbutton was frequently mentioned when participants were asked what they like most and least regarding each APS. The two APS having two inch diameter rounded pushbuttons "that pushed" drew a number of positive comments to the open-ended question.

On the basis of the objective latency results and the subjective preferences, it is recommended that the APS have a clearly defined pushbutton that is actually identifiable. While protruding buttons did receive positive comments from participants, there was not enough evidence to warrant such a recommendation. It is also important to remember that any pushbutton needs to be designed to deter vandalism. The greatest design in the world is useless if the button has become inoperable as a result of vandals.

Tactile Arrow

In Tucson, increased information did not significantly affect use of tactile arrows. Almost 69% of participants used the arrow in the general information condition and 73% used it in the specific information condition. However, in Charlotte, increased information also led to significantly greater use of the tactile arrows, from 87% of trials following general information to 100% of trials following specific familiarization.

In Tucson, the tactile arrow was more likely to be used on the APS C devices than on others. The tactile arrow was on the pushbutton of APS C. It was also on the pushbutton of APS B in Charlotte and may have contributed to more use of the arrow on APS B there. However, the increased usage of the arrow on the pushbutton was not enough evidence to support a recommendation along these lines. While the arrow may have been "identified" more often when located on the pushbutton, there was no evidence that it was used more often for wayfinding when compared to arrows located at other places on various APS.

One of the purposes of the tactile arrow is to identify which street the pushbutton controls. Use of the tactile arrow and the incorrect pushbutton presented a very different picture in Charlotte than in Tucson. In Tucson, while participants looked at the arrow on the incorrect pushbutton on 28 trials, they always correctly rejected the incorrect pushbutton. However, in Charlotte, participants found the arrow on the incorrect pushbutton on 63 trials, and correctly rejected it on only 41 trials (65%). While there was a decrease in overall use of the wrong pushbutton from the general to the specific information condition, participants still failed to reject the incorrect pushbutton on 20% of trials (6/30) following specific information. To observers, participants in Charlotte seemed less skilled, particularly in orientation. The confusion of pushbuttons seemed to be related to the participants' lack of strategies to maintain their orientation. Some would completely turn to face the street parallel to their travel path, while examining the arrow on the device and then push the button and line up to cross the parallel street. See additional comments on this subject under wayfinding.

Extended Button Press

Additional optional features on pushbutton-integrated APS are activated by an extended button press. These features included street name information provided in the pushbutton information message and a louder signaling (beaconing) feature. Where speech messages are used for this information, it may be necessary for pedestrians to know the street names in order to recognize which street is being signaled. This is particularly true at corners where two

AR0072270

pushbuttons are mounted on the same pole, although that situation was not included in this research. In both cities, the increase in use of the extended button press following specific information was significant, from 38.8% to 77.8% in Tucson, from 17.7% to 71.1% in Charlotte. This may indicate that more specific information and training is necessary if use of the extended button press is expected.

Pushbutton Information Message

The pushbutton information message provided additional intersection information (street names) in response to an extended button press during the flashing or steady don't walk intervals. As mentioned above, in the general information condition, few participants used the extended button press that was required to actuate the message. However, following hands-on familiarization with each of the three APS having this feature, participants chose to use the feature on more than 70% of crossings in both cities. When asked to mention features they liked most or least on each APS, there were a number of positive comments regarding the pushbutton information message, and there were no negative comments. Mean ratings for the statement "The pushbutton information message was easy to understand" were all at or above 4.0 (=Agree).

Crossing Timing

WALK Signals

There was significant improvement in all measures of crossing timing between the no information and the general and specific information conditions in Tucson. The measures were latency (time to start crossing), starting during the walk interval, completing crossing during the flashing DON'T WALK, completing crossing during the steady DON'T WALK, and completing crossing before the onset of perpendicular green. This is likely attributable to increasing use of the pushbutton and thus presence of the audible WALK signal. If greater use of the pushbutton, and consequent presence of the WALK signal, accounts for increased starting during WALK, then starting during the walk interval may be increased by education and training of individuals who are blind about the use of pushbuttons and their effect on signal timing. In Tucson and Charlotte, there were no significant differences on measures of crossing timing between the general and specific information conditions.

There were three types of WALK indications used in the devices installed in this research – speech messages, bird calls (cuckoo-cheep) and the rapidly repeating tone indication (rapid tick). In Tucson, in the specific information condition, starting to cross was significantly faster at APS D (rapid tick) than at any of the other devices. The pattern was similar in Charlotte, but did not reach significance. It appears that once pedestrians understood the crossing signal, the rapid tick crossing signal provided the best cue in terms of starting to cross quickly in both cities. The bird call tones and speech messages work all quite similar in both cities. The faster response to the rapid tick signal is supported by results of research on pushbutton location and nature of WALK signal, conducted under this same project, in which responses were quicker to the rapid tick than to cuckoo/chirp tones or to speech messages (see *Chapter 4*) (37).

Beaconing/Locator Signal

One APS provided beaconing with a locator signal that was re-activated by the same extended button push that actuated the pushbutton information message when it was present. Therefore data on use of the extended button press does not clearly indicate whether the extended press was used to actuate the pushbutton information message, the locator signal, or

AR0072271

both. When asked to rate the extent of their agreement with the sentence, "The louder signal feature was helpful," the mean rating was positive (3.94), with only four participants giving it a negative rating, possibly because they did not think the signal got loud enough.

Another APS provided a pedhead-mounted speaker that was aimed toward the middle of the street and possibly provided beaconing during the WALK interval. However, for all signals, collapsing across cities and information conditions, less than 35% agreed that they used the signal to help them find the opposite corner. The most interesting finding here is that, for each city and each information condition, the numbers of participants who reported using the APS to help them find the opposite corner are very similar for all devices. That is, even though APS C and A had beaconing features, there is no clear pattern that participants reported using those signals more than other devices to find the opposite corner. Researchers observed some participants altering their path to travel straight toward the pushbutton (and louder locator tone) of APS C in Charlotte, but participants did not seem to realize that they had done so.

The lack of reported use of the signal to guide the pedestrian to the opposite corner is likely attributable to a number of factors. Participants who used dog guides (4 in each city) reported that they just followed their dog's guidance in the street. Others stated that they were using vehicles for their alignment cues, or that they could not hear the locator tone of the APS until they were within a step or two of the opposite curb, so they did not really use it. Ongoing research in another project is investigating additional beaconing options and may provide more insight in this area (76).

Wayfinding

Collapsing across information conditions, it does not appear that any APS reliably provided more useful information than any other with respect to wayfinding. Furthermore, no specific type of interaction (general interaction, use of tactile arrow, or use of extended message) shows reliable improvement or impoverishment of ability to find and align to the crossing. Because of observations in Tucson, data were collected in Charlotte on whether participants were standing immediately beside the pushbutton to begin their crossing. This sometimes resulted in them being outside the crosswalk lines when beginning their crossing. Almost all (97%) were either at the pushbutton or within the crosswalk when beginning their crossing. This behavior indicates that APS pushbuttons should be placed close to, or within, the extension of the crosswalk lines.

It was the observation of the orientation and mobility specialists involved in data collection that most participants did not use any type of consistent strategy to maintain their alignment or to realign when having to interact with a pushbutton. Most deviated on their approach to the street to check any pushbutton and locator tone they heard, and some became completely disoriented and "lined up to cross the wrong street. The most common techniques taught for aligning to cross streets involve maintaining initial approach alignment and utilizing traffic traveling through the intersection to align. Where pushbuttons are used, the individual often must depart from the approach path to push the button, and the crossing must be made on the next through traffic phase without waiting through a cycle to align, which prevents the use of those techniques. Additional techniques and strategies are needed by blind pedestrians where pushbuttons are used.

AR0072272

Recommended Features of Pushbutton-integrated APS

As noted at the beginning of this summary, the results do not present a completely focused picture of one device and set of features that will provide unambiguous information. However, they do provide insight into use of various features and the information needed by pedestrians who are blind to use the APS and their features efficiently. Based on the objective data recorded for the 40 participants who made crossings, as well as subjective information obtained from these individuals, the APS should have the following features at all installations:

- Pushbutton locator tone (any)
- Clearly defined pushbutton that is tactually identifiable
- Tactile arrow (exact location on APS unit is not defined)
- Audible WALK indication (see discussion below on speech vs. tones)
- Vibrotactile WALK indication
- Responsive to ambient sound

Subjective preference for speech WALK signals was much greater than for tones. However, it is impossible to make speech WALK signals understandable to all users, including the large population having age-related upper frequency hearing loss in addition to visual impairment, under all ambient sound conditions. Furthermore, other research conducted in this study and described in the next chapter showed that understanding of which crosswalk has the WALK indication is significantly more accurate with rapid tick walk indicators located close to the crosswalk than with speech signals or two different tone signals. Finally, response to the correct WALK indication was faster with the rapid tick signal, leading to less delay in starting to cross the street, and increasing the likelihood that crossings would be completed during the flashing DON'T WALK interval. So despite the subjective preference, rapid tick is recommended for the WALK signal. Nonetheless, where two pushbuttons must be installed on the same pole, speech message WALK indications are needed to resolve ambiguity in which crossing has the WALK interval (see Chapter 5).

Under certain circumstances, the following secondary APS features are also desirable:

- Pushbutton information message
- Louder signal (audible beaconing)
- Tactile map of crosswalk

The recommended guidelines in Chapter 7 provide more guidance on when these secondary features may be desired.

AR0072273

CHAPTER 4

Experimental Trials on Pushbutton Location and WALK Indicator

INTRODUCTION

It is critical that any APS system provide clear information as to which crosswalk has the walk interval. Presently, APSs in the United States are not located at intersections in any consistent pattern, nor do APSs use consistent sounds to convey the WALK indication. Pedestrian pushbutton location is also not standardized in the United States, which makes it difficult to provide unambiguous audible WALK indications when an APS is added to an existing pedestrian signal.

Many cities in the U.S install pedestrian pushbuttons for crosswalks in both directions on a corner on a single pole. There are various reasons for this practice:

- Many installations use a single pole on a corner for span wires or mast arms to support traffic signals; money is saved by placing both pushbutton units on the same pole rather than installing additional poles with associated wiring and conduit.
- Poles are sometimes installed at various locations on the corner due to limited right of way or infrastructure constraints (e.g., underground utilities).
- AASHTO design guidelines discourage poles near the curb for vehicular safety reasons and to prevent turning trucks from damaging poles.

The *Manual on Uniform Traffic Control Devices* (*MUTCD*) 4E.08 reads "Pedestrian pushbutton detectors should be capable of easy activation and conveniently located near each end of the crosswalks" (1). However, poles where pushbuttons are located vary greatly in distance from the crosswalk. *MUTCD* 4E.09 provides that "At corners of signalized locations with accessible pedestrian signals where two pedestrian pushbuttons are provided, the pushbuttons should be separated by a distance of at least 3 m (10 ft)", and pushbuttons for APS should be located "adjacent to a level all-weather surface to provide access from a wheelchair, and where there is an all-weather surface, wheelchair accessible route to the ramps within 1.5 m (5 ft) of the crosswalks extended, within 3 m (10 ft) of the edge of the curb, shoulder, or pavement and parallel to the crosswalk to be used" (1). The U.S. Access Board's *Draft Guidelines for Accessible Public Rights-of-Way*, applicable to new construction and alterations, would also require that accessible pedestrian signals (APSs) be separated by at least 10 ft (2).

This set of experiments was undertaken to build on the knowledge base of why APSs are needed and to understand the importance of appropriate installation techniques. The primary purpose of this study was to determine the effect of three factors on the ability of pedestrians with visual or cognitive impairments to determine which crosswalk at a corner had the WALK signal. The factors under investigation were as follows:

1) Whether there were significant advantages to installing two poles on a corner, each with its own pushbutton-integrated APS, over installing two pushbutton-integrated APSs on a single pole.

AR0072274

2) whether proximity of these poles to the curb influenced the ability of participants who had visual or cognitive impairments to push the correct pushbutton and to know when the WALK signal came on for the street in front of them.

3) Whether there were significant advantages to using the same sound, versus two different sounds, versus two speech messages to indicate the walk interval.

METHOD

Participants

Participants for this effort were selected with the goal of comprising groups that included persons with a wide age-range, balanced as closely as practical to frequency of independent travel and frequency of crossing at unfamiliar intersections. Altogether, there were 90 adults who were visually or cognitively impaired and who, by self-report, independently traveled outdoors on at least one route and crossed signalized intersections. Half of the participants had some degree of visual impairment, and half of the participants were cognitively impaired.

Local recruiters having extensive knowledge of, and contacts within, agencies or organizations relevant to each group of participants were hired, and the participants were recruited by word of mouth, flyers, and distributed e-mails. Many participants were associated with one of the following agencies: the Oregon Commission for the Blind, the ARC (formerly Association for Retarded Citizens) of Multnomah and Clackamas Counties, Independent Living Resources, the Brain Injury Association of Oregon, Traumatic Brain Injury Club, Legacy Good Samaritan Hospital, and Medical Center Young Adult Support Group.

The following information was gathered during personal interviews with persons with visual impairments who had expressed an interest in participating: date of birth, highest level of education, amount of vision (including ability to see walk/don't walk signs, poles, and crosswalk lines), etiology, date of onset of disability, additional disabilities, type of travel aid used, self rating of travel ability, frequency of independent travel, and frequency of crossing at unfamiliar intersections. Interviews with participants who were cognitively impaired gathered similar information: date of birth, highest level of education, amount of vision, date of onset of disability, additional disabilities including seizures, living situation, street crossing practices, frequency of independent travel, and frequency of crossing at unfamiliar intersections.

Forty-five participants with visual impairments were divided into three subgroups, of 15 participants each, based on their ability to see pedestrian signals, crosswalk lines, and poles. The group that had the least vision (referred to as totally blind) reported that they were totally blind or had only light perception and could not see pedestrian signals, crosswalk lines, or poles. This group ranged in age from 21 to 78, with a mean age of 47.6 years. Another group (referred to as legally blind) reported they were legally blind, some of them could occasionally see pedestrian signals and either occasionally or usually could see crosswalk lines and poles. This group ranged in age from 22 to 85, with a mean age of 51.6 years. A third group (referred to as low visual acuity) had visual impairments, but they were not necessarily legally blind and could usually see pedestrian signals, crosswalk lines, and poles. This group ranged in age from 19 to 74, with a mean age of 48.6 years. Participants who normally used a long cane as a travel aid in all the subgroups used a long cane during the research. No participant used a guide dog as a travel aid.

AR0072275

Forty-five adults with cognitive disabilities were also divided into three subgroups of 15 participants. One group was composed of people who had had head injuries. This group ranged in age from 22 to 57, with a mean age of 45.9 years. Another group was composed of people who had had strokes and whose vision and hearing might have been affected, but who were not legally blind. This group ranged in age from 35 to 78, with a mean age of 52.5 years. A third group was composed of people who were developmentally delayed. This group ranged in age from 19 to 85, with a mean age of 49.1 years. All participants were cognitively capable of personally consenting to participation, and all said they independently crossed streets at signalized intersections.

Location and APS Equipment

The intersection of NE 7th Avenue and NE Multnomah Street in Portland, Oregon was equipped with eight pushbutton-integrated APS units that were mounted on temporary poles, with pushbuttons located 42 inches from the ground. In pushbutton-integrated APS, audible signals come from the pushbutton housing, unlike pedhead-mounted APS, in which the audible signals come from a speaker mounted in or on the pedhead. The pushbutton-integrated APS units used in this study included a pushbutton locator tone, automatic volume adjustment in response to ambient noise level, a tactile arrow that vibrated during walk interval (aligned in the direction of travel on the associated crosswalk), an audible "click" sound and red LED to confirm that the button had been pressed, and an audible WALK indication that varied during the experimental conditions.

The pushbutton locator tone is intended to aid approaching pedestrians with locating the pushbutton and to inform them that they need to push a button to receive a pedestrian signal and the extended green time needed to cross the street. The tone repeated once per second and was adjusted to be audible only six to twelve feet from the pushbutton. The audible WALK indications varied during the experimental conditions and were changed by the researchers with the use of a handheld programming unit supplied by the manufacturer (Polara Engineering).

Two APSs mounted on a single pole were used on two corners, and APSs mounted on two separated poles were used on the other two corners. On corners A and D (the northwest and northeast corners), the two APSs for crossing both streets at each corner were mounted on a single pole; on corners B and C (the southwest and southeast corners), the two APSs on each corner were mounted on two poles separated by at least 10 feet (*see Figures 4-1 and 4-2*), meeting the guidelines of the *MUTCD* as previously described.

Distance of the poles from the street was also varied. On corner A, the pole was installed approximately 3 feet from each street, and on corner D, the pole was installed approximately 10 feet from each street. The same was true for the corners with two pushbutton poles: on corner C, each pole was installed approximately 3 feet from the street, and on corner B, each pole was installed approximately 10 feet from the street.

The choice of tones and speech messages used in the experiment was based on current practice and on recent laboratory research (*58, 59*). The single tone used was a rapid tick, as this tone has been found to be more highly detectable than other tones in use or proposed for APS. When two tones were used, they were the rapid tick and cuckoo. The cuckoo sound was selected over the chirp sound (both are often used together at an intersection) because it is not the same as any birdcall in the U.S., it is not mimicked by any birds common to the U.S., and it is more

AR0072276

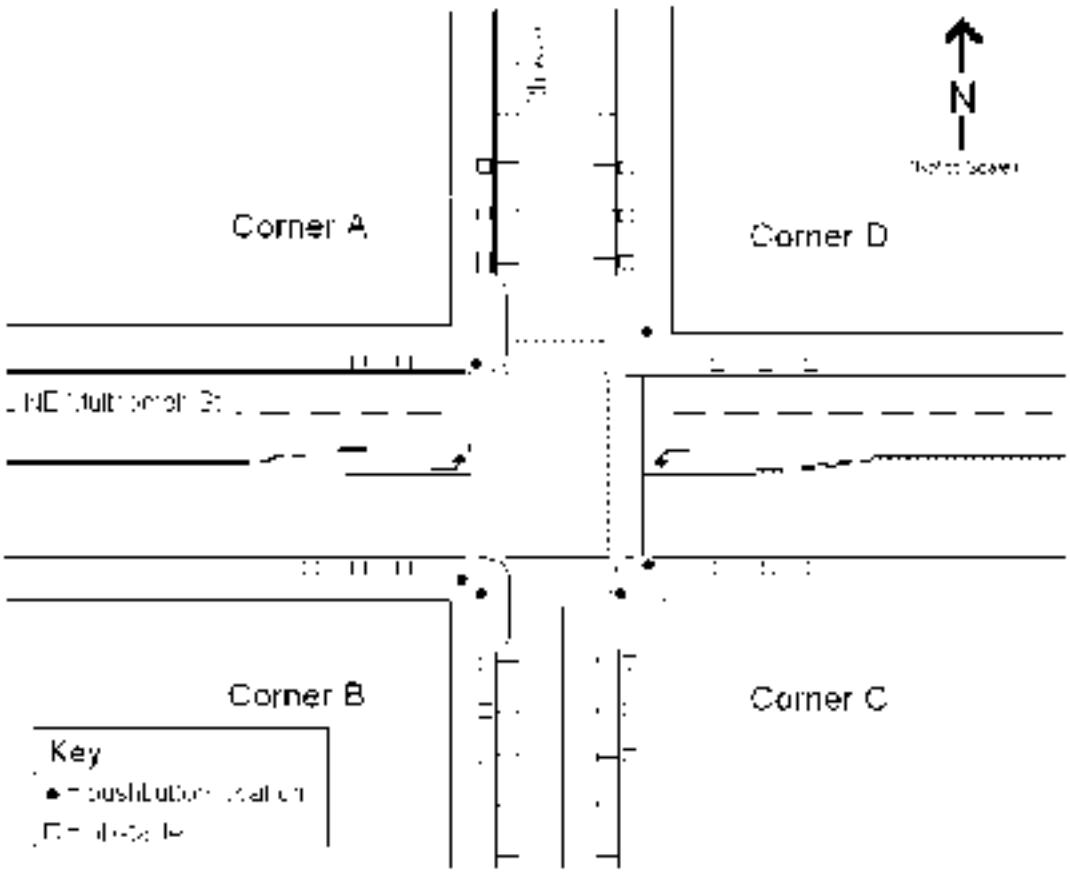

Figure 4-1. Intersection diagram for NE Multnomah Street and NE Seventh Avenue in Portland, OR.

detectable than the clamp sound. However, the cuckoo sound is not as detectable and localizable as the rapid tick.

There were two possible sound conditions on each corner. The audible WALK indication was set by the researchers for either: two different tones (cuckoo and rapid tick) or two same tones (rapid tick) on the corners having two poles. On the corners with just one pole (see *Table 4-1*), the audible WALK indication was either two different tones (cuckoo and rapid tick) or two speech messages ("7th, walk sign is on to cross 7th" or "Multnomah, walk sign is on to cross Multnomah."

The total duration of all audible and visual WALK indications was seven seconds. There was a 0.5 second pause between repetitions for all sound conditions. Each speech message repeated twice during each WALK interval, and the cuckoo and rapid tick messages repeated three times during each WALK interval. This variability was due to the length of the messages. Each speech message was approximately 3 seconds, and each repetition of the cuckoo or rapid tick was approximately 2 seconds.

AR0072277

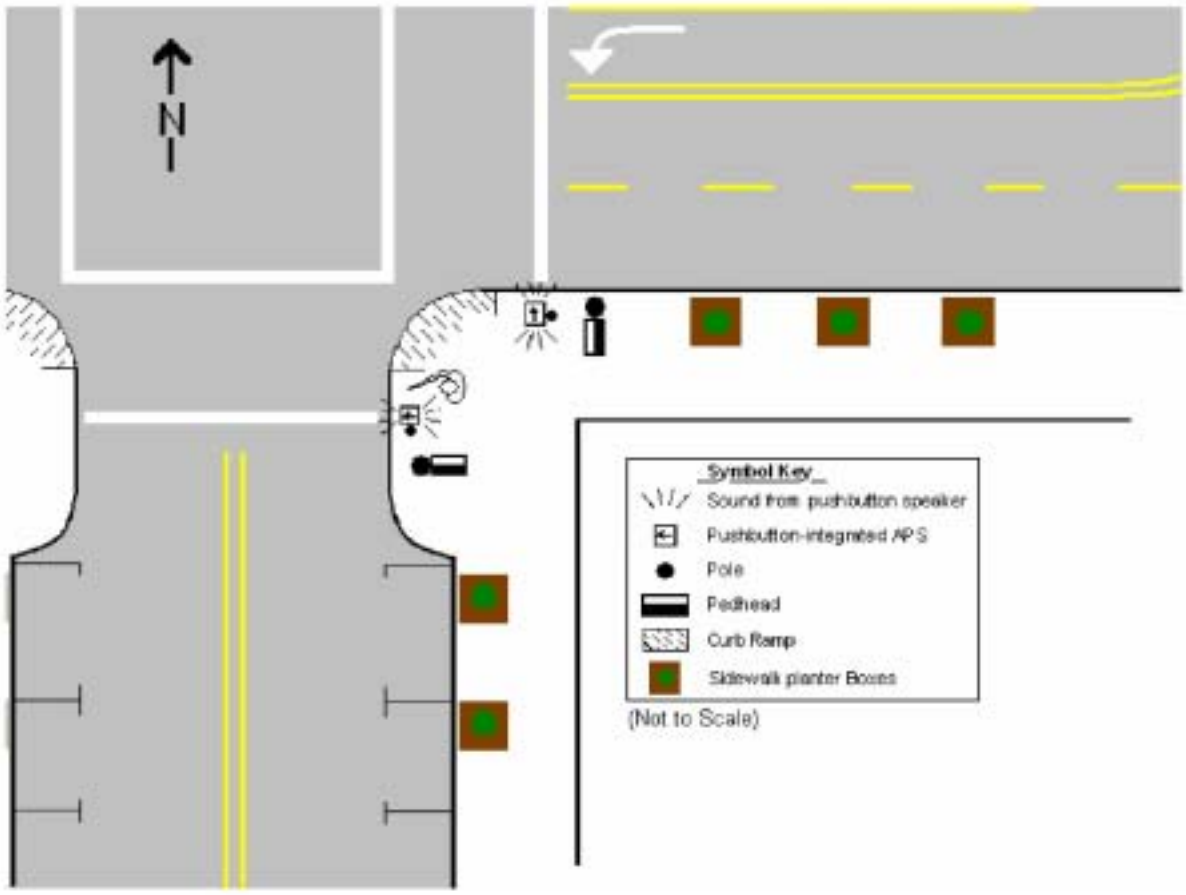

Figure 4-2. Diagram of Corner C (southeast corner of NE Multnomah Street and NE Seventh Avenue in Portland, OR).

To reiterate, two sound conditions (two tones or two speech messages) were assigned to corners having a single pole (corners A and D), and two sound conditions (two different tones or same tone) were assigned to corners having two poles (corners B and C). Testing every sound condition at every corner would have resulted in an experiment that required two sessions. Additionally, testing the same tone from each APS at corners having a single pole would have been noninformative. If both APSs have the same tone coming from the same location, there is no cue to indicate which crosswalk is being signaled. However, on corners having two pushbutton poles separated by at least 10 feet, it may be possible to hear which pushbutton is sounding. Researchers recognized that either two different tones or speech messages could have been used in APSs at corners having two poles; both would have provided information that was redundant to the cue that was provided by the location of the APS. A decision was made to use the most commonly used strategy in the U.S., which is the use of two different tones.

Procedure

All 90 participants were individually tested in approximately one-hour sessions. First the participants were familiarized with a nonfunctioning demonstration unit of the APS that included the tactile arrow indicating the direction of the associated crosswalk. Participants then listened to

AR0072278

a tape recording of the various sounds that would come from the APS. The sounds included a locator tone and the three possible WALK indications. The participants were told that they were to identify the walk interval on the street in front of them by raising their hand. Participants were told that they could use the visual WALK signal if they could see it, the pushbutton sounds or messages, or the traffic. They were encouraged to use any information that they would normally use to determine when the WALK signal comes on. Then the participants were guided to the starting location for the first trial.

Before the participant arrived at the corner, the APS devices were configured to one set of the possible WALK indication sound conditions. The APS devices on corners having two poles were randomly set to either the same tone condition (rapid tick – condition 1) or two tones condition (cuckoo and rapid tick – condition 2). While the starting settings were determined randomly, the two corners with two poles were always set up for the same condition (#1 or #2) for each block of trials. The two APS units on each corner having a single pole were randomly set to either the two-tones condition or the speech message condition. Both APSs on the single pole corners were always set for the same condition within a block of trials. (*See Table 4-1.*)

Each participant completed 16 trials, which were conducted in two blocks of 8 trials with a short rest period (usually five to ten minutes) in between. For an intersection such as was used in this experiment, a pedestrian can approach each of the four corners from two different directions. Therefore, as shown in the Table 4-1, there are eight possible unique approaches/crossings at the intersection. Each participant completed all eight approaches in a randomly determined order both prior to and after the rest period. During the rest period, the

TABLE 4-1 Sound conditions and crossing direction

Corner A – one pole close to the curb	Sound condition A1: speech messages	Sound condition A2: two tones
APS for crossing southbound	Multnomah. walk sign is on to cross Multnomah	Cuckoo
APS for crossing eastbound	Seventh. Walk sign is on to cross seventh	Rapid tick
Corner B – two poles 10 feet from the curb	Sound condition B1: same tone	Sound condition B2: two tones
APS for crossing northbound	Rapid tick	Cuckoo
APS for crossing eastbound	Rapid tick	Rapid tick
Corner C – two poles close to the curb	Sound condition C1: same tones	Sound condition C2: two tones
APS for crossing northbound	Rapid tick	Cuckoo
APS for crossing westbound	Rapid tick	Rapid tick
Corner D – one pole 10 feet from the curb	Sound condition D1: speech messages	Sound condition D2: two tones
APS for crossing westbound	Seventh. WALK sign is on to cross Seventh	Rapid tick
APS for Crossing southbound	Multnomah. WALK sign is on to cross Multnomah	Cuckoo

AR0072279

APS devices at each corner were reconfigured to use the alternate sound condition.

For all trials, participants were positioned to start 30 feet from the pushbutton. For each trial, participants were instructed as follows:

> *"When I say Go, first, go push the button to cross the street in front of you. Then, stand where you would wait to cross the street. Raise your hand when the WALK comes on for the street in front of you, which is [street name]."*

When participants were 20 feet from the pushbutton, a stopwatch was started, it was stopped when participants pushed the correct pushbutton. If a participant pressed the incorrect pushbutton, but continued to search for the other APS, the time continued to run and was stopped it and when the participant pressed the correct pushbutton. On the other hand, when participants pressed the incorrect pushbutton and went and stood at the street demonstrating their belief that they had pressed the correct button, no time was recorded. In this instance, the experimenter would then press the correct pushbutton, and the remainder of the trial would be recorded. A stopwatch was also used to time the delay between the onset of the correct WALK signal and when participants raised a hand indicating their judgement that the WALK signal had come on for the street in front of them.

Once participants had pressed a pushbutton and taken up a position where they would normally wait to cross the street, one of the researchers always pressed the other pushbutton. By doing so, and in combination with beginning participants at certain times during the intersection phasing, the researchers attempted to ensure that on half of all trials, the first WALK signal to come on was that for the street in front of the participants while on the other half of the trials the first WALK signal was for the street beside participants. However, it was not entirely possible to achieve this balance given testing constraints.

For every trial, as soon as participants raised their hands to indicate their belief that the WALK signal for the street in front of them had come on, the trial ended, and the experimenter directed or guided them to the next starting point. A trial was also ended if, after pressing the pushbutton, a participant waited through four consecutive WALK intervals without responding.

Other information recorded on each trial included which pushbuttons the participants investigated and in which order, and which walk signal was the first to come on after the participants pressed the correct pushbutton. After the participants had completed all 16 trials, a short survey was administered to learn the attitudes and preferences of the participants towards the various pushbutton arrangements and sounds. The questionnaire addressed:

- which corner was the easiest and hardest,
- how easy it was to find and use the pushbuttons when the poles were near to or away from the curb and when the APS were on one pole or two poles,
- whether the participant used the arrow to determine which crosswalk the button controlled,
- which cues the participant used (i.e., visual signal, audible signal, or motion) to decide when the WALK had come on, and
- which walk indication was the participant's favorite and least favorite.

AR0072280

Also included was the researcher's observation of what cue the participant seemed to be using during the trials.

RESULTS

The vast majority of significant findings, both practically and statistically, were found in the data collected from the two sub-groups having the least vision, referred to as totally blind and legally blind. Most of the results presented here will therefore focus upon these 30 participants. Relevant findings from the low visual acuity subgroup and the cognitively impaired group follow. Mean substitution was used to deal with all missing WALK signal response delays and pushbutton location times. For example, if a given totally blind subject was missing pushbutton location data on corner A-southbound approach-speech condition, the mean for the totally blind subjects on corner A-southbound approach-speech condition was substituted.

Accuracy in Recognizing Correct Walk Signal

For the purposes of analysis and discussion, a correct response was one in which the hand raise occurred during one of the 7-second periods in which the visual pedestrian signal for the street in front of them was in WALK. It was possible for a correct response to occur following either a correct or an incorrect pushbutton activation. This resulted from the fact that an experimenter always pushed whichever pushbutton the participant had not. This allowed response data to be collected on trials in which an incorrect button push had occurred. An incorrect response was defined a bit more narrowly than a correct response. An incorrect response was recorded when the hand raise occurred during the first WALK interval for the side street. That is, after the participants pressed a pushbutton and took up a position to wait to cross the street, the visual and audible WALK signal to cross the street beside them came on first, and participants mistook this information to mean the WALK signal had come on for the street in front of them.

As explained in the procedure section, it was not possible to ensure that for each trial there would be an equal probability that the first WALK signal to come on would be for the street in front of the participant vs. the street beside the participant. Therefore, the number of trials in which an "error" was possible varies between corners and individual pushbutton position and sound conditions. The error rates presented in this section reflect the number of incorrect responses divided by the number of trials in which an error was possible (i.e., trials in which the first WALK signal after a pushbutton was pushed was for the street beside the participant). Error rates were calculated using a few different operational definitions of what constituted an error, and regardless of the method chosen the rank order of the corners remained the same. Therefore, this method for calculating error rates was chosen because the researchers felt that it best addressed the issue of whether or not the pole placements and sound conditions provided either ambiguous or unambiguous cues for the onset of the WALK signal.

One of the most striking findings of this study was the very low error rate at the two pole near the curb configuration of corner C (4.53, 7.55%); see *table 4-2*. No other pushbutton configuration resulted in less than a 26.9% error rate. Next, the other two pole configuration (corner B) resulted in a lower error rate than both of the single pole corners. However, due to a lack of independence of the measures (i.e., repeated measures design), no statistical test could confirm whether or not the two pole configurations resulted in overall lower error rates than the

AR0072281

TABLE 4-2 Error in recognizing correct WALK signal, by corner

Corner	# of incorrect responses/total possible instances	error rate
A	17/56	30.36%
D	19/52	36.54%
C	4/53	7.55%
B	14/52	26.92%

corners with a single pole. Nevertheless, the actual differences between error rates in most of the situations discussed here are quite substantial.

For the corners with two poles, there were two possible audible signal conditions, same tone (sound condition 1) or two different tones (sound condition 2). In the same tone condition, a rapid tick indicated the onset of the WALK signal for both street crossings, while in the two different tone condition, a cuckoo signaled the northbound or southbound crossing and the rapid tick signaled the eastbound or westbound crossing. For the corners with a single pole, there were also two possible audible signal conditions, two different tones (condition 2) or two speech messages (condition 1). The two tone sound condition produced higher error rates on each corner than the corresponding same tone condition or speech message condition. (*see Table 4-3*) Overall, the two different tone/sound conditions resulted in a 36.27% error rate (37/102). For the two pole APS arrangements at corners B and C, the two different tone sound condition resulted in 12 errors on 52 possible trials (23.08%), while the same tone sound condition resulted in half as many errors (6/53, 11.32%). On corner C (two pole near the curb configuration), the error rate was a mere 3.57% (1/28) for same tone condition. For the single pole APS arrangements at corners A and D, the two tone sound condition was especially troublesome, causing errors on 50% of the possible trials (25/50). The speech message condition resulted in much reduced error rate of 18.97% (11/58).

Walk Signal Response Delay

For pedestrians to safely cross at signalized intersections, they should begin crossing during a walk interval for the street they wish to cross. It is also important that they begin crossing as soon after the onset of the WALK signal as possible to allow themselves adequate time

TABLE 4-3 Error in recognizing correct WALK signal, by corner and sound condition

Corner/sound condition	# of incorrect responses/ total possible instances	Error Rate (%)
A1 / Speech	7/33	21.21
A2 / 2 Tones	10/23	43.48
D1 / Speech	4/25	16.00
D2 / 2 Tones	15/27	55.56
C1 / Same Tones	1/28	3.57

B1 / Same Tones	5/25	20.00
B2 / 2 Tones	9/27	33.33

AR0072282

to cross the street before the onset of perpendicular traffic.

WALK signal response delays measured from the onset of the corner WALK interval for totally blind and legally blind participants were both low and consistent for the two-pole, near the curb pushbutton arrangement at corner C. Regardless of the sound condition (same tone vs. two different tones) on approach direction, it took participants approximately 2.0 seconds to correctly respond to the onset of the WALK signal at corner C. Planned comparisons revealed significantly faster responses to the signals at corner C than those at corner A ($F(1,29)=8.598$, $p\leq0.011$, corner B ($F(1,29)=6.156$, $p\leq0.051$, and corner D ($F(1,29)=31.459$, $p\leq0.0001$), (see *Figure 4-3*).

It was discussed earlier that for corners with a single pole, the two speech messages condition resulted in a much reduced error rate compared to the two different tones conditions. The effect of the speech messages on the walk signal response delay is not as clearly defined or, in most instances, as positive. At corner A, the speech message WALK indication resulted in significantly faster responses than did the rapid tick WALK signal ($F(1,29)=8.533$, $p<0.011$), however, the mean response delay for the speech condition (2.5 sec) was slower

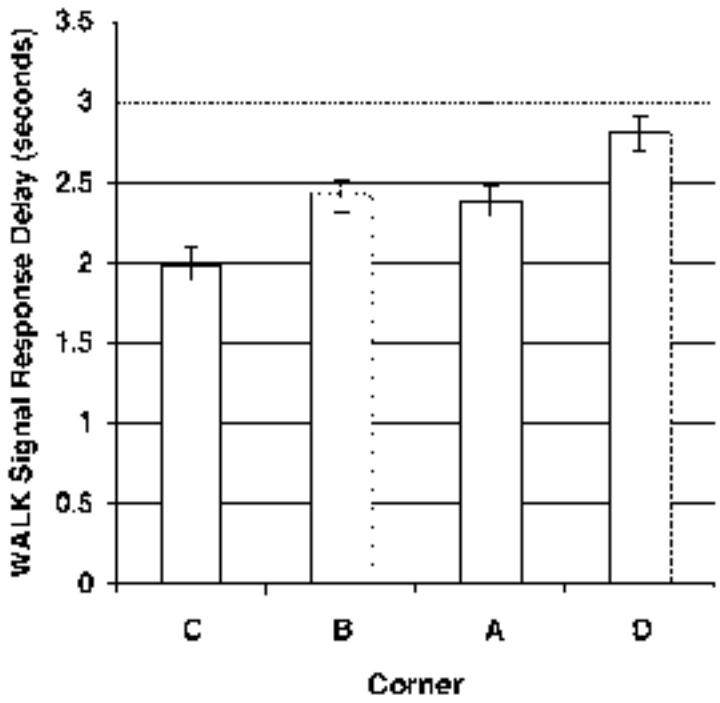

Figure 4-3. Mean WALK signal response delay by corner.

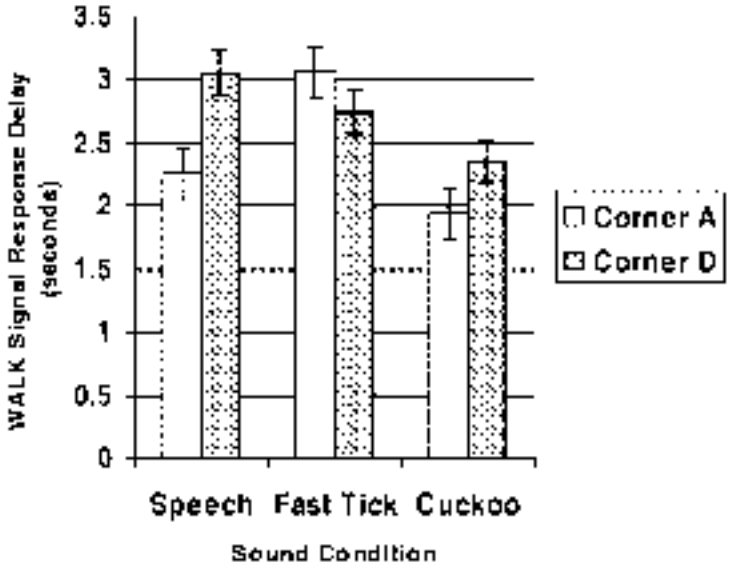

Figure 4-4. Effect of sound condition on WALK signal response delay at corners with two APS on one pole.

AR0072283

than that for the cuckoo WALK signal (1.9 sec; *see Figure 4-4*). This difference did not however achieve significance ($F(1,29)=1.604$, $p > 0.05$). At corner D, the mean response delay for the speech message WALK signal was quite high (3.1 sec) and was slower than the mean response delays for the rapid tick WALK signal (2.7 sec) and for the cuckoo WALK signal (2.4 sec). The speech message WALK signal resulted in significantly slower responses than the cuckoo ($F(1,29)=6.976$, $p < 0.05$), while the difference between response delays for the speech message and the rapid tick failed to reach significance ($F(1,29)=2.407$, $p > 0.05$).

Pushbutton Location Times

Another factor of particular interest is how quickly blind participants were able to locate and press the appropriate pushbutton given the different APS arrangements at the four corners of the intersection. The pushbutton location times were measured from the time the participant crossed a line that was 20 feet away from the appropriate pushbutton to the time that they pressed the correct pushbutton. Again, when participants were unable to find the correct pushbutton or pressed the incorrect pushbutton and stopped searching for the correct button, no pushbutton location time was recorded. On average, pushbutton location times were fastest at corners D (13.6 seconds) and A (14.95 seconds; *see Figure 4-5*). While the difference between mean pushbutton location time at corners D and A was not statistically significant ($F(1,29)=2.497$, $p>0.05$), the mean pushbutton location time at corner D was significantly faster than that at corners C ($F(1,29)=8.838$, $p<0.05$) and B ($F(1,29)=20.156$, $p<0.005$). The mean pushbutton location time at corner A was significantly faster than that at corner B ($F(1,29)=13.049$, $p< 0.1$), but was not significantly faster than that at corner C ($F(1,29)=1.395$, $p>0.05$).

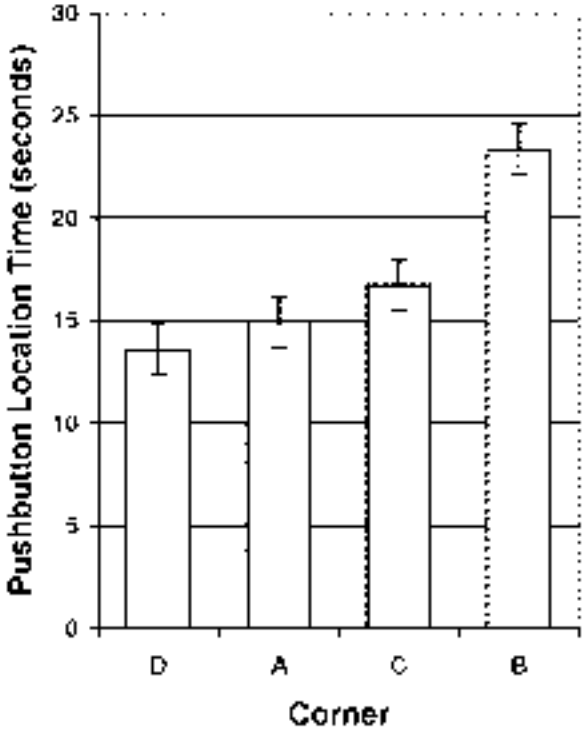

Figure 4-5. Pushbutton Location Time by Corner.

One result of interest was the very large discrepancy in pushbutton location times between northbound approaches to corner C (12.0 seconds), and westbound approaches to the same corner (21.6 seconds). Figure 4-6 clearly shows that the mean pushbutton location time for the northbound approaches to corner C was amongst the fastest across all approaches and corners. Also, the mean pushbutton location time for northbound approaches to corner C was significantly faster than the mean pushbutton location time for westbound approaches to the

AR0072284

same corner ($t_{(1,29)}=-81.968$, $p<0.001$). Possible reasons for this discrepancy will be addressed in the discussion.

Low Visual Acuity Subgroup

The analysis of the data collected from participants with low visual acuity (the subgroup with the most vision) demonstrated very few statistically significant differences; however, the majority of the trends in the data matched those for the totally blind and legally blind sub-groups. While the overall error rate for the low acuity group was only 5.36% (6/112), five of the six errors occurred on trials with the two different tone sound condition on corners A and D, the two most difficult conditions for the totally and legally blind participant sub groups. Also similar to the analysis described above, mean WALK signal response delay at corner C (1.1 sec) was faster than those at all of the other corners (corner D, 1.2 sec, corner B, 1.3 sec, and corner A, 1.4 sec). The differences were moderately significant between mean WALK signal response delays at corners C and A ($p=.066$) and those at corners C and B ($p=.077$). It is of particular interest that although most members of this group of participants could see the visual walk signal, the same pattern of results as those obtained from participants with less vision emerges. This point will be addressed further in the discussion.

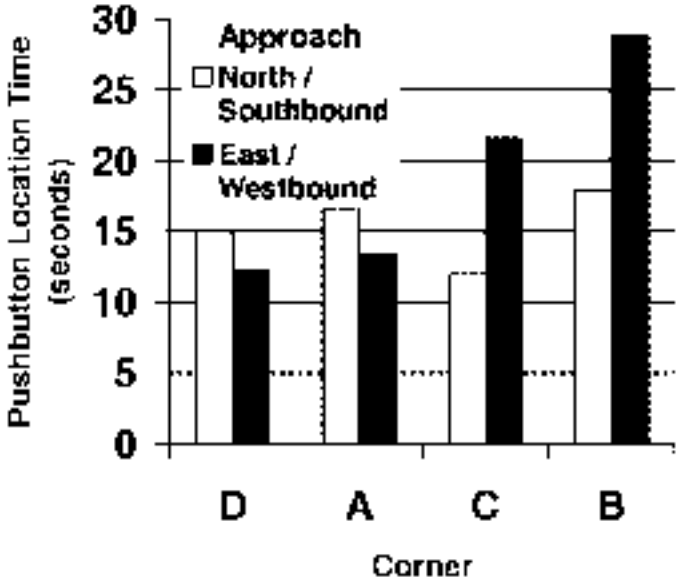

Figure 4-6. Pushbutton Location Time by Corner and Approach.

Although the speech command resulted in no errors with this subgroup, it did result in the slowest response times at both corners A and D. At corner A, the speech message resulted in significantly slower responses than did the cuckoo ($t_{(1,29)}=-6.230$, $p<0.01$), but the mean WALK signal response delay for the speech message (1.6 sec) was not significantly slower than that for the rapid tick (1.4 sec). At corner D, no comparisons reached significance; however the mean WALK signal response delay for the speech message (1.3 sec) was slower than the delays for the cuckoo (1.1 sec) and the rapid tick (1.2 sec).

One difference from the participants who are totally blind or legally blind is in the ability of the participants with low visual acuity to efficiently find the correct pushbutton. The low visual acuity participants had little difficulty finding the correct pushbutton for the westbound approach to corner C. As a result, the fastest pushbutton location times for this subgroup were obtained at corner C (0.6 sec), although all pairwise comparisons failed to reach significance. Mean pushbutton location times at corners A and D were again similar to one another (both were

AR0072285

7.2 seconds due to rounding), and the slowest pushbutton location times were again recorded at corner B (7.7 sec).

Cognitively Impaired Group

The analysis of the data collected from the 45 participants with cognitive impairments similarly has few statistically significant differences; however the majority of trends in the data again matched those of the 50 totally blind or legally blind participants. The participants with cognitive impairments made very few errors (10/3621) resulting in an overall error rate of 2.76%. The few errors committed did follow a pattern similar to those of the visually impaired participants. Only two of the ten errors occurred on corners with two poles (corners B and C), and more errors were committed in the two different tone conditions (6/10) than in the same tone or speech message conditions (4/10). Once again, the mean WALK signal response delay at corner C (0.9 sec) was faster than those at all of the other corners; however, there was no significant main effect for corner ($F < 1.0$) and all mean WALK signal response delays were less than 1.05 sec. Once more, all of these participants had sufficient vision to be able to see the visual walk signal, and yet the pattern of results is again similar to the visually impaired participants.

Mean pushbutton location times at corners D (6.19 sec) and C (6.22 sec) were both significantly faster than those at corners A (6.59 sec) and B (6.57 sec). The very small difference between the most extreme mean pushbutton location times (0.40 sec) does, however, qualify the importance of the significant differences. Once more, it is noted that for these participants the westbound approaches to corner C did not cause greater difficulty in finding the correct pushbutton than northbound approaches to the same corner.

Survey Results

The self-report questionnaire data is similar to the behavioral results in some ways and dissimilar in others. While corner C produced the most favorable behavioral results, the 45 participants with visual impairments gave the single vote close to the curb configuration (Corner A) the most votes as the overall easiest corner (27/45, 60.0%), while the two-poles-near-the-curb configuration (Corner C) received the second most votes (13/45, 28.9%). Corner B (the two-poles-further-from-the-curb configuration), which produced some of the worst pushbutton location times and walk signal response delays, received the most votes as the most difficult pushbutton arrangement (34/45, 75.6%). The survey questions that most conflicted with behavioral results assessed participants favorite and least favorite sounds. Even though the rapid tick resulted in the best response accuracies and consistently fast walk signal response delays, it only received 17.8% of the vote as the favorite sound (8/45), and received the most votes as the least favorite sound (25/45, 56.6%). The speech message was the most popular of the sound messages (29/45, 64.4%), and also received the least votes as the least favorite sound (6/45, 13.3%).

DISCUSSION

Safe and legal pedestrian crossings at signalized intersections require that pedestrians correctly identify which crosswalk has the WALK indication. Positive information is provided by visual pedestrian signals and by APS (audible and vibrotactile) where they are available. Where pedestrian phasing is concurrent with vehicular phasing, the onset of the WALK signal can also be inferred by a surge of vehicular traffic going parallel to the crosswalk, from the lanes closest to

AR0072286

the pedestrian. In the absence of APS, pedestrians who are unable to see visual pedestrian signals typically attempt to begin crossing with this vehicular surge.

At complex, unfamiliar, signalized intersections without APS, pedestrians who are blind often fail to begin crossing within the WALK interval for the desired crosswalk [36]. Even when APS are present, pedestrians who are blind sometimes find audible signal information ambiguous in terms of which crosswalk is being signaled [5]. It is critical that any APS system provide unambiguous information. The results indicate that pushbutton location affects the ambiguity of WALK signal information.

Accuracy in Recognizing Correct Walk Signal

On the corner having pushbutton-integrated APS on two poles near the street, participants in the totally blind and legally blind sub groups indicated that the street in front of them had the WALK signal, when, in fact, the WALK signal was to cross the street beside them, on only 7.55% of possible trials. This pole arrangement for APS devices corresponds to the arrangement that is required in some other countries, including Sweden, Denmark, and Australia [40]. For all other pushbutton-integrated APS arrangements tested in this study, participants in the totally blind and legally blind sub groups indicated that the street in front of them had the WALK signal, when it was actually the WALK signal to cross the street beside them, on at least 26.9% of trials. On these trials, if they had been crossing the street, they were likely to have started crossing at the onset of traffic on the street perpendicular to their direction of travel.

Use of the configuration with two pushbutton poles with APS near the curb, both having the same tone, resulted in excellent accuracy by participants who were unable to use visual pedestrian signals (totally and legally blind sub-groups). This pole configuration and use of same tone sound was also beneficial to participants having more vision (low visual acuity sub group and cognitively impaired groups) in determining which crosswalk had the WALK signal. This corresponds to the pushbutton pole arrangement plus WALK signal system that is common in countries using pushbutton-integrated APS [40].

Those participants who had vision sufficient to see visual pedestrian signals (i.e. the cognitively impaired participants and the low visual acuity participants) were recorded by experimenters as having typically used the visual pedestrian signals to determine the onset of the correct walk interval and they also typically reported reliance on the visual pedestrian signals. It is therefore of interest that their results are in the same direction as those for the two sub groups who were always or usually unable to see the visual pedestrian signals. It appears that, whether or not it was on a conscious level, or observable to experimenters, the participants who could see the visual pedestrian signal information were nonetheless influenced by both the pushbutton pole arrangement and the WALK signal sound. If they were not influenced by pole arrangement and the nature of the walk sound, accuracy would be expected to be the same under all pole arrangements and sounds.

Walk Signal Response Delay

Pedestrians who do not begin crossing promptly following the onset of the WALK interval may not complete their crossings before the onset of perpendicular traffic, at which time they are particularly at risk for crashes. Recent research on pedestrians who are blind making crossings at complex, unfamiliar, signalized intersections, found that on 51.4% of trials, crossings were not initiated during the WALK interval, and on 26.9% of trials, crossings were completed after the

AR0072287

onset of perpendicular traffic (36). Therefore, it was of interest to measure the delay in response to the onset of the WALK signal for the correct crosswalk.

In this study, for participants who were always or usually unable to see visual pedestrian signals (totally and legally blind sub-groups), responses to the onset of the WALK signal for the correct crosswalk were significantly fastest on the corner having two pushbutton poles with APS near the curb (corner C), and responses were uniformly fast at this corner regardless of sound condition. Although the overall mean walk signal response delay for this corner was approximately two seconds and well within the normal walk interval, delay would likely be longer if actually making crossings, as pedestrians who are blind typically require a little time to determine whether there are vehicles turning across the crosswalk. Mean WALK signal response delay for blind pedestrians crossing at complex, unfamiliar signalized intersections without APS has been found to be 6.4 seconds (36).

Responses to the correct WALK signal were also fastest at the corner having two pushbutton poles with APS near the curb for the participant groups who always or usually could see the visual pedestrian signal. Mean WALK signal response delays were lower for these groups than for the groups who were always or usually unable to see visual pedestrian signals.

It appears that, whether or not it was on a conscious level, or observable to experimenters, the response delay of participants who could see the visual pedestrian signal information was influenced by the pushbutton pole arrangement. Installing pushbuttons on two poles near the curb seems to promote fast reaction time to the onset of the WALK signal, and is thus likely to promote faster initiation of crossings for pedestrians with visual and cognitive disabilities.

Pushbutton Location

By comparing the time to press the correct pushbutton at corners having pushbuttons in different pole configurations, we are able to infer the participants' ability to easily locate the correct pushbutton. This task includes deciding which pushbutton controls the street they are preparing to cross. Nearly all participants were observed to visually or tactually use the tactile and/or visual arrows on APS to confirm which crosswalk was associated with the APS, and 82 of 90 participants (91%) reported that they used the arrows. The results of this research, therefore, would not necessarily be applicable to pushbuttons that did not have tactile and visual arrows that were carefully aligned with the direction of travel on the associated crosswalk.

For the participant sub-groups in this study who had the least amount of vision and who were rarely or never able to see visual pedestrian signals, time to press the correct pushbutton was marginally faster at the two corners having two pushbuttons on a single pole. The mean pushbutton location time for the corner having two pushbutton poles far from the curb was longest. However, any advantage in speed of pressing the correct push button is far outweighed in importance by the greater accuracy in identifying which crosswalk had the WALK signal. Errors in determining which crosswalk has the WALK signal may result in crashes, while delay in locating the correct pushbutton does not typically have negative consequences for life safety.

For the low visual acuity sub-group, unlike the sub-groups having even less vision, mean pushbutton location time was fastest for the corner having two pushbutton poles near the curb. However, as for the sub-groups having less vision, mean pushbutton location time was slowest for the corner having two pushbutton poles far from the curb. For the group having cognitive

AR0072288

impairments, the corner having two pushbuttons near the curb resulted in one of the two fastest times, which were not statistically different from one another.

Therefore, although the results for time needed to find and press the correct pushbutton are not as clear-cut or definitive as for speed and accuracy in identifying the crosswalk being signaled, having two pushbutton poles near the curb generally appeared to promote speed and, by inference, ease of locating the correct pushbutton.

Speed in locating the pushbutton appears to have been significantly influenced by the relationship between pushbutton location as designed to test the hypotheses of this experiment, and pushbutton location with relation to geometric idiosyncrasies at each corner. There may have been some difference attributable to slight differences in perceived loudness of each APS device as well. It was extremely difficult to make the perceived loudness of the APS signal the same from each device. Simply setting all devices the same for volume and ambient noise response is not sufficient because differences in the nature and distance of reflective surfaces at each corner also influence perceived loudness. At each corner, there was a significant difference in time to press the correct pushbutton depending on the direction from which the corner was approached.

For example, at the corner having two pushbutton poles near the curb, corner C (see *Figure 4-2*), mean time for pushing the correct pushbutton on westbound approaches was much longer than northbound approaches to the same corner. When approaching westbound, participants passed very close to the pushbutton to cross the street beside them (the parallel street) and the locator tone of that APS was usually very audible to participants. They may have been able to hear the locator tone for the pushbutton to cross the street in front of them (correct pushbutton) when they approached the incorrect pushbutton, but the loudness of the sound would have been much less. (Recall that locator tones are only intended to be heard 6 to 12 feet from the pushbutton, and the pushbuttons were approximately 10 feet apart.) Therefore it commonly occurred that participants would check the arrow for the APS for crossing the parallel street before finding and pressing the pushbutton for the street in front of them. When approaching the corner northbound, participants did not pass quite as close to the pushbutton for the parallel street because the pushbutton pole was on a bulb out in the curb line, so they did not delay to check the arrow for the parallel street before finding and pushing the correct button.

Sound Condition

The two different tone condition may have produced more errors than the same tone condition at all corners because some participants with visual impairments had previous experience with cuckoo signals at other locations in the city and may thus have been primed to respond to the cuckoo, regardless of whether it was the correct signal. This could also explain why the cuckoo resulted in the fastest response rates at the single pole corners. Nonetheless, when pushbuttons were on two poles near the curb, accuracy was equally good with two tone and same tone conditions.

The two different tone condition may have had particularly high error rates on the single-pole corners because there was no redundant APS location information to indicate which crosswalk was associated with which sound. The speech message condition resulted in lower error rates than the two tone condition, but mean WALK signal response delays for the speech message WALK condition were slower. This may reflect greater cognitive demand for processing the speech messages than the tones, or may reflect the different lengths of the sounds and

AR0072289

messages themselves. A single complete speech message lasted approximately three seconds, whereas a single cuckoo lasted somewhat over one second.

Comparison of Objective Measures and Subjective Judgments

Subjective judgments of participants, recorded on the survey, were variance with objective measures in three important ways. First, corner A was the pole close to the curb and the most preferred pole arrangement with corner C (two poles far from the curb) a somewhat distance second choice. This is in contrast to objective measures in which corner C produced the fastest and most accurate responses to the walk indications. Because accuracy in responding to the walk indication is essential to safe street crossing at signalized intersections, despite the subjective preferences, the arrangement at corner C is recommended.

Second, speech messages were used at the locations with two pushbuttons on a pole and resulted in better accuracy than two tones sound condition, but less accuracy than the rapid tick. Speech messages also resulted in slower response times than the rapid tick indication. When it is possible to separate the poles, the rapid tick WALK indication is recommended.

Third, the rapid tick was the least preferred WALK indicator, but it produced the fastest and most accurate responses to the walk indication. Because accuracy in responding to the WALK signal, that is, beginning the crossing when the wrong WALK signal comes on, has direct consequences for safety in crossing, the rapid tick is preferred over other WALK indications used in this research. Verbal messages may have been rated highly simply because participants were primarily native English speakers, because ambient sound was never excessively loud, and because it provided additional information, that is, the name of the street to be crossed. The cuckoo may have been rated more highly than the rapid tick simply because it was a more familiar walk indication to some participants. Therefore despite some dislike of the rapid tick WALK indication, it is the recommended sound because it results in fast and more accurate decisions regarding which crosswalk has the WALK.

RECOMMENDATIONS

The recommended location for two pushbutton integrated APS on a single corner is consistent with Guidance in *MUTCD* 4L.09.

- Place each APS device on a separate pole, located as close as possible to the curb line.
- Place each APS as close as possible to the line of the associated crosswalk that is furthest from the center of the intersection.
- Place the two APS at least 10 feet apart.

The recommended WALK indication for APS that are located according to these recommendations is a rapid tick, or percussive sound, at 10 repetitions per second. Both APS should have the same WALK indication. Where it is technically infeasible to install two pushbuttons on a corner on two separate poles, it is recommended that verbal WALK messages following the model "*Mulnomah. Walk sign is on to cross Multnomah*" be used. Two different tones to indicate which crosswalk has the WALK interval at an intersection where there are two pushbutton-integrated APS on a single pole provides ambiguous information and may result in pedestrians crossing with the wrong signal. Speech WALK indications should be used sparingly.

AR0072290

however, as it is not possible to make them understandable under all ambient sound conditions, and to all pedestrians. In this experiment, speech messages were evaluated in a situation where all participants were told the name of the street that they were approaching. If the pedestrian is not familiar with the area or is confused about the street names, the speech message, which begins with the street name, will not clarify which crossing has the WALK. If speech messages are used, additional features may be needed on the device to provide street name information to the pedestrian who is unfamiliar with the intersection. These features would include a high-contrast tactile arrow oriented parallel to the direction of travel on the associated crosswalk, and a pushbutton information message that provides the name of the street controlled by the pushbutton. Braille street name information on the APS is also desirable.

Jurisdictions desiring to standardize the WALK indication should also standardize the location of APS so that they will provide unambiguous information regarding which crosswalk has the WALK interval. Where APS are installed in a variety of locations, engineering judgment is required to determine, for each intersection, whether the rapid tick or a speech WALK indication will provide the most unambiguous information to pedestrians.

AR0072291

CHAPTER 5
COLD WEATHER CASE STUDIES

INTRODUCTION

Cold weather case studies were conducted in order to ensure that this research covered a wide variety of climates in the evaluation of APS devices. Cities in cold weather climates could potentially face unique issues due to cold temperatures, snow, ice, and removal methods such as snowplowing and salting. The goal of these case studies was to find out what effects these cold weather characteristics had on the installation, operation, and maintenance of the APS devices, as well as the interaction with pedestrians who are visually impaired. The information acquired from these case studies will be used to develop additional recommendations for practitioners and will be part of the training materials to be developed later in this study.
