Continuous monitoring of particulate matter, black carbon, wind speed, and wind direction began at the Sunshine Canyon Landfill (Landfill Site) and at Van Gogh Elementary School (Community Site) in Granada Hills in fall 2007. These data are used to characterize ambient air pollution concentrations on a neighborhood scale, in the context of the Los Angeles basin and to evaluate the impact of landfill operations on air quality in the community.

**Particulate Matter (PM\(_{10}\))**

PM\(_{10}\) is particulate matter less than 10 microns in diameter. A human hair is about 100 micrometers in diameter so roughly 10 PM\(_{10}\) particles could be placed on the width of a human hair. PM\(_{10}\) is present in dust, smoke, soot, and dirt. It can be inhaled and drawn into the lungs, causing health problems for some people.

**Black Carbon (BC)**

Black carbon is a sooty black material emitted from gas and diesel engines, coal-fired power plants, and other sources that burn fossil fuel. Many BC particles are too small to be visible. BC emissions can cause adverse health and climate effects.

**Wind**

Wind Speed and Wind Direction are measured because they can significantly affect when and how far airborne pollutants travel from their sources.

Air pollution from the surrounding region appears to be the main driver of high PM$_{10}$ at the Community Site.

High pollution levels at the Landfill Site did not occur at the same times as high pollution levels at the Community Site. Typically, when regional pollution levels were relatively low and Landfill levels were high, Community levels were not significantly high.

### Landfill Site

The Landfill Site’s PM$_{10}$ Federal and State exceedances are accompanied by high wind speeds, with wind direction falling within a narrow sector that encompasses the active portion of the landfill.

State exceedance days at the Landfill Site are also accompanied by low-speed winds from the Los Angeles basin (south and southeast), suggesting that the addition of elevated concentrations within the basin can push the Landfill Site’s PM$_{10}$ concentrations over the State threshold.

### Community Site

On days when PM$_{10}$ concentrations exceed the State standard at the Community Site, wind speeds are relatively low and wind direction is predominantly from the Los Angeles basin (southeast). This suggests that regional contributions are the main driver of exceedances of the State PM$_{10}$ standard at the Community.

### Monthly Average PM$_{10}$

Concentrations of PM$_{10}$ are trending up at the Landfill Site, while trending down at the Community Site.

Community Site measurements closely align with regional measurements.
